Annex E

Report of the Standing Working Group on the Aboriginal Whaling Management Procedure (AWMP)

Members: Donovan (Convenor), Allison, Baulch, Bell, Betancourt, Bickham, Brandão, Brandon, Brownell, Butterworth, Castro, Chilvers, Cipriano, de Moor, Deimer-Schüette, Double, Dupont, Elvarsson, Feindt-Herr, Gallego, George, Givens, Gunnlaugsson, Hiruma, Ilyashenko, Iñíguez, Jackson, Jaramillo-Legorreta, Jérémie, Katsuyama, Kelly, Kim, Kitakado, Lang, Lauriano, Leslie, Mate, Moore, New, Palacios, Palka, Palsbøll, Panigada, Punt, Quakenbush, Reeves, Ritter, Robbins, Rodríguez-Fonseca, Roel, Rose, Sakamoto, Scheidat, Scordino, Simmonds, Skaug, Stimmelmayr, Suydam, Tajima, Thomas, Tiedemann, Wade, Walløe, Weller, Witting, Yamada, Yasokawa, Zeh.

1. INTRODUCTORY ITEMS

1.1 Convenor's opening remarks
Donovan welcomed the participants to Panama. He noted that the SWG had a considerable amount of work to do this year, including the completion of two *Implementation Reviews.*

1.2 Election of Chair
Donovan was elected Chair.

1.3 Appointment of rapporteurs
Butterworth, Givens and Punt acted as rapporteurs, with assistance from the Chair.

1.4 Adoption of agenda
The adopted agenda is given in Appendix 1.

1.5 Documents available
The new primary documents available to the SWG were SC/64/AWMP1-15, SC/64/BRG1, SC/64/BRG3, SC/64/BRG9 and SC/64/Rep3.

2. *IMPLEMENTATION REVIEW* OF GRAY WHALES WITH EMPHASIS ON THE PCFG

2.1 Summary of intersessional Workshop
Donovan briefly summarised the key conclusions of the intersessional Workshop held from 19-23 March 2012, kindly hosted by the Southwest Fisheries Science Center in La Jolla, California (SC/64/Rep3). With respect to gray whales, the Workshop focus was to build upon the work of the 2011 Annual Meeting to facilitate the completion of the *Implementation Review* with emphasis on the Pacific Coast Feeding Group (PCFG) at the 2012 Annual Meeting.

The Workshop was pleased to note that the code implementing the control programme and that producing summary statistics had been validated and it thanked Brandão and Punt for their hard work in this regard. A final set of *SLA* variants to be considered in the trials was agreed and these can be found in Appendix 2 of the present report. Considerable effort was put in after the 2011 Annual Meeting and at the Workshop to finalise the trial specifications and complete conditioning of the trials.

The Workshop undertook a thorough review of abundance estimates (Calambokidis *et al.*, 2012) and it agreed a final set of estimates based on the modified Jolly-Seber estimator developed at the 2011 Intersessional Workshop. These are given in Table 1 below. It was agreed that the 1998 estimate which was negatively biased to an appreciable extent for likely values of the detection probability for animals available to the surveys for the first time should be excluded. The Workshop also agreed that the operating model would be fitted to the abundance estimates for the NCA-NBC area (~41-52°N) while the *SLA*s would be based on the abundance estimates for the smaller OR-SVI area (Oregon to SVI ~42-49°N).

Table 1

JS1 abundance estimates (N) and standard errors in OR-SVI and NCA-NBC after exclusion of known calves from the year in which they were identified as calves.

Year	N	SE(N)
Region: OR-SVI		
1998	63	4.1
1999	78	8.4
2000	89	11.9
2001	117	8.9
2002	133	15
2003	151	13.7
2004	157	15.5
2005	162	15.7
2006	154	15.3
2007	152	14.5
2008	150	12.5
2009	146	14.9
2010	143	16.8
Region: NCA-NBC		
1998	101	6.2
1999	135	12
2000	141	13.2
2001	172	12.6
2002	189	9.2
2003	200	16.4
2004	206	14.9
2005	206	22.6
2006	190	18.8
2007	183	23.1
2008	191	16.1
2009	185	23.2
2010	186	18.7

The Workshop also welcomed the results of a simulation-based assessment of plausible levels of external recruitment into the PCFG stock (Lang and Martien, 2012). The generation of simulated datasets followed the steps outlined in TOSSM (IWC, 2007a). A number of suggestions were made for additional work and a revised paper for the 2012 Annual Meeting is discussed under Item 2.2 below. In addition, the Workshop strongly supported continued collection of genetic samples, particularly throughout the range of the northern stock.

In reviewing the intersessional results, a number of agreements were reached for modifications including:

(1) adult survival should be constrained to be <0.99 in future trials;
(2) the upper limit on maximum pregnancy rate of 0.6 should be retained;
(3) correction of an error in the previous trial specifications;
(4) incorporation of emigration as well as immigration in the trials; and
(5) incorporation of a revised value (0.3) of the proportion of whales classified as PCFG whales in the November-May period.

The Workshop also reviewed the requirements for graphical and tabular summaries to review results. These are not repeated here, but the agreed list can be seen in Appendix 2. The Workshop finalised the list of factors to be considered in the trials and these are given in Table 2.

The final set of *Evaluation* and *Robustness Trials* proposed by the Workshop can be found as Tables 3 and 4.

The Workshop agreed to a work plan for tasks to be undertaken prior to the 2012 Annual Meeting. The results of that work are detailed below.

In discussion, the SWG thanked the participants at the Workshop for their hard work and **endorsed** the report and its recommendations.

2.2 New information

2.2.1 Abundance

SC/64/AWMP10 provides an analysis of 13 years (1998-2010) of photo-id data for PCFG gray whales which were defined to be those whales present from 1 June to 30 November between 41°N to 52°N (northern California and northern British Columbia). Both closed and open population models were explored for abundance estimation. Closed models failed to accommodate transient behaviour of whales that were only seen in one year. Simulation showed that the standard Lincoln-Petersen (LP) estimator was biased high and even the trend was incorrect due to the transiency pattern. Instead of using LP, a limited LP estimator which removed transient whales by only using observations of whales in consecutive years that were also seen either before or after the consecutive years was used to construct the estimate. Various open Jolly-Seber type models were also fitted to the data. Those analyses demonstrated a relationship between minimum tenure (days between first and last sighting) and resighting probability in subsequent year and first-year apparent survival which includes permanent emigration. Post-first-year survival (excludes transients) for whales present in 1998 was 0.968 (SE=0.0093), but was only 0.881 (SE=0.0217) for whales first seen in 1999 or later which suggested some level of permanent emigration of whales that entered the PCFG during the 1999-2000 stranding event. The transients and minimum tenure preclude use of the standard Jolly-Seber abundance estimator. SC/64/AWMP10 considered two estimators (JS1 and JS2) that excluded the transients. JS1 assumed that all new whales in each year were seen and estimated the number of previously seen, and whales still in the population using the estimated resighting probability for each whale that was sighted. Simulation showed that it will underestimate the initial population size because all whales in the first year are 'new' but with the parameter values for these data, it provides the best current abundance estimate. The JS2 estimator was based on the resighting data after removing whales that were seen in only one year and is a parallel to the limited LP estimator. As expected, simulation showed that JS2 provides a better initial estimate of abundance but is biased low for the current abundance because any newly seen whales in the last year are excluded.

The SWG noted that bias identified in SC/64/AWMP10 is largest for 1998 and that this was a reason for excluding the estimate of abundance for 1998 when conditioning the trials.

2.2.2 Stock structure

SC/64/AWMP2 tested the assumption that individuals of the southern feeding group mate with the rest of population, and therefore that the eastern North Pacific gray whale represents one interbreeding population because this assumption is key to making appropriate management decisions given there is an interest by native groups in Washington and British Columbia to resume their traditional hunts. Such hunts could disproportionally affect whales of the PCFG, and

Table 2

Details of factors considered in trials.

Factors	Levels (reference levels shown bold and underlined)
$MSYR_{1+}$ (north)	**2%**, **4.5%**
$MSYR_{1+}$ (PCFG)	**1%**, **2%**, **4.5%**
Immigration rate (annual)	**0, 1, 2**, 4, 6
Pulse immigration (1999/2000)	**0**, 10, **20**, 30
Proportion of PCFG whales in PCFG area, ϕ_{fut}	0, **0.3**, 0.6, 1
Struck and lost rate (PCFG area)	0, **50%**, 75%
Northern need in final year (linear change from 150 in 2010)	**340**, 530
Historic survey bias	**None/Appendix 2, Table 6**, increasing between 1967 to 2002 from 0.5→1 (north only) 50% (PCFG only)
Future episodic events[1]	**None**, 3 events occur between yrs 1-75 (with at least 2 in yrs 1-50) in which 20% of the animals die. Events occur every 5 years in which 10% of the animals die[2]
Time dependence in K	**Constant**, halve linearly over 100yr; double linearly over 100yr
Time dependence in natural mortality, M *	**Constant**, double linearly over 100yr
Parameter correlations	Yes, **No**
Probability of mismatching north whales, p_2	0, **0.01**, 0.01-0.05
Probability of mismatching PCFG whales, p_1	**0**, 0.5
Frequency of PCFG surveys	**Annual**, 6-year
Incidental catch	**Reference**, double reference, half reference
Future sex ratio	**0.5:0.5**, 0.2:0.8 (M:F)
Episodic events with future pulse events[1]	**None**, 3 events occur between yrs 1-75 (with at least 2 in yrs 1-50) in which 20% of the north stock die and a pulse of 20 animals is added to the PCFG stock.

[1]The average value for adult survival needs to be adjusted to ensure the population is stable for these trials. [2]Selected to mimic the implications of stochasticity in the population dynamics.

Table 3

The *Evaluation Trials*. Values given in bold type show differences from the base case trial. The final three columns indicate which trials apply to which 'broad' hypotheses. For 'broad' hypotheses B and I, the number given is the plus in 1999/2000. Unless specified otherwise ϕ_{PCFG}=0.3, the struck and lost rate is 0.5, and there are no stochastic dynamics or episodic events.

Trial	Cond-ition	Description	$MSYR_{1+}$ North	$MSYR_{1+}$ PCFG	Final Need	Annual immigration	Survey freq.	Survey bias (north)	Hypothesis P	B	I

11B	Y	Halve incidental catches	4.5%	2%	10/1	20	Y
12A		Sex ratio = 0.2: 0.8	4.5%	4.5%	10/1	20	Y
12B		Sex ratio = 0.2: 0.8	4.5%	2%	10/1	20	Y
13A		Relative probability of harvesting a PCFG whale, ϕ_{PCFG} =1	4.5%	4.5%	10/1	20	Y
13B		Relative probability of harvesting a PCFG whale, ϕ_{PCFG} =1	4.5%	2%	10/1	20	Y

understanding how these whales are related to the rest of the population is necessary for properly managing such hunts. SC/64/AWMP2 analysed 15 nuclear microsatellite loci in 82 samples representing the PCFG and 51 samples from one of the calving lagoons – considered to be representative of the larger population – to test the hypothesis that the eastern North Pacific gray whale represents one interbreeding population. There was no indication of population substructuring based on the nuclear loci, suggesting that all sampled whales do indeed represent one interbreeding population. Combined with the results presented in Frasier *et al.* (2011), the mitochondrial and nuclear markers suggest one interbreeding population that is seasonally subdivided based on maternally-directed site fidelity to different feeding areas.

In discussion, the SWG questioned whether defining the larger population using samples from San Ignacio Bay, Mexico was appropriate because previous analyses had found differences between the Mexican lagoons using microsatellites (Alter *et al.*, 2009) and between animals inside lagoons and those sampled while feeding or migrating using mtDNA (Goerlitz *et al.*, 2003). It also noted that the sample sizes representing the larger eastern North Pacific population were very small, and the SWG was concerned about the reliability of genotyping given that gender could only be determined for 93 of the 133 samples. Finally, although the value for F_{ST} was low (0.0010), the uncertainty associated with this estimate may be large, implying that a wide range of migration rates may be comparable with the data. The SWG **recommended** that all estimates of F_{ST} be accompanied by confidence intervals.

Previous comparisons of the PCFG with whales feeding north of the Aleutians have revealed small but significant levels of mtDNA differentiation, which suggest that matrilineal fidelity is important in creating structure among feeding grounds. The relatively high levels of genetic diversity in the PCFG, however, suggest that some immigration into the group could also be occurring. In SC/64/AWMP4, a simulation-based approach was used to evaluate the plausible range of immigration into the PCFG. This work represents an update to the results presented in Lang and Martien (2012) and reflects modifications made in response to some of the recommendations from the intersessional Workshop (SC/64/Rep3, item 2.4.2.2). An individual-based population model was used to create simulated datasets that incorporate a post-whaling split of the PCFG from the larger ENP population. The scenarios simulated incorporated annual immigration ranging from 0 to 0.0008 (corresponding to between 0 and 16 immigrants/year when the larger ENP population reaches carrying capacity) both with and without additional pulse immigration. Comparison of mtDNA summary statistics (haplotype diversity, number of haplotypes, F_{ST} , and χ^2/df) generated from sampling of the simulated populations with those from empirical data suggest that immigration of less than two and more than eight animals per year (once the simulated larger ENP population has reached carrying capacity) are inconsistent with the empirical data, and that immigration of ~4 animals per year led to results that were most consistent with the empirical data. SC/64/AWMP4 also explored whether changes to the specifications of the model could result in a finding that no annual immigration into the PCFG is consistent with the empirical data. Most simulations were based on the PCFG splitting from the larger ENP in 1930 and on carrying capacity for the PCFG (K_{PCFG}) being set to 200 in accordance with recent abundance estimates. Additional simulations were performed that involved the PCFG splitting from the larger ENP population between 1940 and 1990. Results suggested that if the PCFG was colonised after 1950, and most plausibly between 1960 and 1980, a scenario with no annual immigration could lead to results similar to those found in the empirical data. In addition, simulations incorporating K_{PCFG} ranging from 500 to 5,000 were run; these simulations suggested that K_{PCFG} would need to be >500 and more plausibly between 2,000-3,000 animals for the simulations with no annual immigration to produce summary statistics consistent with those derived from the empirical data.

The SWG thanked Lang and Martien for providing this analysis which responded to several of the recommendations from the intersessional Workshop. Some discussion followed regarding how the mtDNA diversity in the simulated ENP population compared to measures based on the empirical data. As recommended at the intersessional Workshop, the mtDNA mutation rate parameter was tuned to produce simulated diversity values that more closely matched the observed data for the larger ENP population. After tuning, the median values of haplotype diversity and number of haplotypes were similar between the simulated and empirical data, but simulated values of nucleotide diversity were markedly higher than that found in the empirical data. The simulated datasets in SC/64/AWMP4 for the ENP stock yielded consistently higher nucleotide diversity estimates than observed. An alternative explanation could be that the simulated population size of the ENP stock is too high, as diversity scales with population size (at equilibrium). Tiedemann also noted that a higher-than-observed diversity in the simulated dataset will introduce a bias into the migration estimates towards a systematic underestimation.

Notwithstanding the difficulties, the SWG was pleased to see that the TOSSM framework was being used to address this complex issue. It **recommended** that future analyses consider a broader range of parameter choices to explore the robustness of the conclusions to uncertainty regarding these parameters.

Overall, SC/64/AWMP4 suggested that migration rates of greater than one or less than ten were most comparable with the genetics data. However, the SWG noted that fixing several parameters meant that the uncertainty associated with estimates of migration rates is higher than suggested by SC/64/AWMP4, and also that the population size trajectories for the PCFG in SC/64/AWMP4 are not comparable with the mark-recapture estimates of abundance for migration rates of roughly two and higher, and best for a zero migration rate. The *Implementation Trials* developed during the March 2012 intersessional Workshop cover migration rates from zero to six per year when the northern stock equals 20,000 animals. Given the assessment performed in SC/64/AWMP4, and the photo-identification work summarised by Calambokidis *et al.* (2012), Scordino considered that zero immigration should be allocated very low plausibility. The SWG **agreed** that the trials cover a plausible range of migration rates and that the information in SC/64/AWMP4 does not lead to a need to modify this range.

2.3 Progress with intersessional tasks

The SWG was pleased to note that the tasks identified in the work plan from the March 2012 intersessional Workshop had been completed and thanked those undertaking the work.

(1) The need to revise the scenarios regarding incidental catches was discussed by Punt, Scordino and Weller. However, these scenarios were not changed given that the magnitude of change with the updated incidental

take estimates was a fraction of a whale and not thought large enough to warrants changes to the structure of the operating models.

(2) All of the trials were reconditioned and provided to the Steering Group.
(3) Brandon, Punt and Scordino reviewed the results of the conditioning, and identified several trials for which the conditioning appears to have problems (see SC/64/AWMP11).
(4) Laake conducted further simulation analyses related to the plausibility of trials in which bias is varying (see Item 2.2).
(5) Lang and Martien conducted further TOSSM-based simulations to explore the plausibility of different levels of immigration into the PCFG (see Item 2.2).

Punt noted that all of the trials (see Tables 3 and 4 for a summary) had been run for the eleven *SLA*s (see Table 5 of Appendix 2). Software has been developed which produced the plots and tables identified by the March 2012 intersessional Workshop.

2.4 Finalise the specifications for the trials and presentation of results

The SWG **endorsed** the trial specifications, including the choice of *Evaluation* and *Robustness Trials*. The SWG selected a graphical format to summarise the results of the conditioning as well as those of projections based on different *SLA* variants, in addition to tables of the mandatory statistics (see Section F of Annex F of SC/64/Rep3 for details). The graphical summaries are based on those used previously to select the *Gray Whale SLA*, but with a focus on the PCFG. The full set of graphs and tables are available to members of the Scientific Committee through the Secretariat.

SC/64/AWMP11 presented an update on progress towards identifying a final set of trials for the ENP gray whale *Implementation Review*. Following the March 2012 intersessional Workshop, the proposed set of trials was conditioned and the authors of SC/64/AWMP11 evaluated the adequacy of this process for each trial. The primary factor assessed was the extent to which each trial was able to mimic the observed patterns in the time series of PCFG abundance estimates (all of the trials were able to mimic the abundance estimates for the northern stock). Only five of the 55 trials conditioned were identified as needing further scrutiny before being retained or dropped from the final set of trials. These trials (denoted by a first letter for the hypothesis, then the trial number and finally a last letter for the specifications for $MSYR_{1+}$ for each stock) were: B02C; IO2C; P05A; P14B, and P58B (robustness trial P08B).

Past practice in the SWG is only to drop trials from consideration if there is consensus to do so. Some members noted that trials P14B and P58B were sufficiently similar to the data to continue to be used for evaluating *SLA* variants. Consequently, only trials B02C, I02C, and P05A were dropped for further consideration given problems with conditioning.

2.5 Review results of trials

The SWG noted that its evaluation of *SLA*s was based on the objectives accepted by the Commission (IWC, 1983; 1995) which are to:

(a) ensure that the risks of extinction to individual stocks are not seriously increased by subsistence whaling;
(b) enable aboriginal people to harvest whales in perpetuity at levels appropriate to their cultural and nutritional requirements, subject to the other objectives; and
(c) maintain the status of stocks at or above the level giving the highest net recruitment and to ensure that stocks below that level are moved towards it, so far as the environment permits.

Highest priority is accorded to the objective of ensuring that the risk of extinction to individual stocks is not seriously increased by subsistence whaling.

2.5.1 Evaluation Trials

There were 75 *Evaluation Trials*, three of which were not considered further owing to problems conditioning them (see Item 2.4). The SWG adopted the following criteria (related to conservation performance) for identifying trials to examine in detail.

(1) The lower 5%ile of the final depletion distribution is lower than 0.6 (the MSYL level) and the lower 5%ile of the rescaled final depletion is lower than 0.6.
(2) The trial involved episodic events.
(3) The lower 5%ile of the trend in 1+ population size indicated a decline in population size of 5% or larger over the final 20 years of the 100-year projection period.

These criteria identified 16 trials (see Table 5). The SWG considered these trials in detail by reviewing the Zeh plots, the time-trajectories of 1+ population size for each *SLA* variant along with the median time-trajectory of 1+ population when there are no future catches and when there are only incidental catches (i.e. no aboriginal catches), and the median time-trajectories of 1+ population size for all *SLA* variants (see Appendix 3 for an example). Based on this review, the SWG identified the following features of the results.

- *SLA* variants 3, 6, 9, and 11 did not meet conservation objectives on trials with $MSYR_{1+}$ less than 4.5% and were not considered further.
- *SLA* variants 7 and 10 are most likely to lead to a declining trend in the lower 5%ile of 1+ population size.
- Most of the trials selected involve $MSYR_{1+}$=1% (trials P01C, B01C, I101C, P02C, P13C), episodic events, or no immigration from the north stock into the PCFG (trials P02B, B02B, I02B).
- All *SLA* variants lead to a declining trend in the lower 5%ile of 1+ population size for the trials based on $MSYR_{1+}$ = 1% when there is no immigration into the PCFG stock (trial P02C – this trial is the most challenging from a conservation viewpoint).
- *SLA* variant 5 leads to the best performance for the difficult trials. For example, only *SLA* variant 5 did not lead to a declining trend in the lower 5%ile of 1+ population size for trials B10B and P10B. However, this *SLA* variant also leads to the lowest landings and is hence 'inefficient' (lower landings without a correspondingly large increase in population size compared to some other *SLA* variants).
- The episodic events trials (e.g. P08B, P08B) show that episodic events can have a large impact on performance. The value for survival was adjusted for these trials so that the population persists, but this means that $MSYR_{1+}$ is effectively lower than 2% for these trials.
- The lower 5%ile of population size can drop below the initial levels in the trials with occasional large (20%) drops in abundance even though the overall trend in the lower 5%ile of 1+ population size is positive (e.g. B07B).

Table 5

Evaluation Trials which were considered in detail (see text).

Hypothesis		
P	B	I
01C	01C	01C
02B	02B	02B
02C	-	-
08B	08B	-
09B	09B	-
10A	10A	-
10B	10B	-
13C	-	-

2.5.2 Robustness Trials

The SWG applied the criteria used for the *Evaluation Trials* to select the following *Robustness Trials* for further consideration: P03A, P04A, P05A, P12A, P12B, P13A, P13B, B03A, B04B, B05B, B12B. Note that none of the *Robustness Trials* included episodic events. Based on the review of these trials, the SWG identified the following features of the results.

- Only *SLA* variants 1-3 reduce the strike limit for the trials in which abundance declines (e.g. *Robustness Trials* 05A and 05B).
- *SLA* variants 7 and 10 perform very poorly in terms of conservation performance for robustness test 13B compared to their performance for the other trials.
- The *SLA* variants perform adequately for the trials in which the sex ratio of future catches is female-biased (e.g. P12A). However, the sex ratio of the hunt should be monitored and considered in future *Implementation Reviews*.

The SWG thanked the small group which assembled the outputs (Brandon, Givens, Scordino); it would have been impossible to review the larger number of the trials without the ability to reduce the number of trials to a manageable number for full SWG review.

2.5.3 General comments and selection of SLAs

SC/64/Rep3, Annex D describes the hunting management plan proposed by the Makah Tribe. In order to minimise the risk of taking PCFG whales, the plan restricts the hunt both temporally (to the migratory season for gray whales, i.e. 1 December-31 May) and geographically (to the Pacific Ocean region). Some PCFG whales are present during the migratory season and thus the plan proposes an allowable PCFG limit (APL) during hunts that are targeting eastern North Pacific migrating whales, with the aim of ensuring that accidental takes of PCFG whales do not deplete the PCFG. The APL formula is provided in Appendix 2. The Tribe also recognises that whales struck in May might have a higher probability of being PCFG whales since they feed in this area in June. It thus proposes an additional requirement that all animals struck-and-lost in May are assumed to be PCFG whales (i.e. count against the APL), whereas whales struck between December and April are not.

Weather conditions and availability of whales makes it likely that most hunting will occur in May. However, there are insufficient data to assess the number of strikes by month. Consequently, it is not possible to reliably estimate the proportion of struck-and-lost whales that would count towards the APL. Given this uncertainty about how the plan would respond to failing to take into account struck-and-lost PCFG whales, the Tribe had proposed two *SLA* variants (1 and 2) that spanned the options as to when the hunt might occur.

SLA variant 1 proposes that struck-and-lost whales do not count towards the APL, i.e. there is no management response to PCFG whales struck but not landed. *SLA* variant 2 proposes that all struck-and-lost whales count towards the APL irrespective of hunting month, i.e. the number of whales counted towards the APL may exceed the actual number of PCFG whales struck. A number of other *SLA* variants were proposed by the Tribe to explore additional management options. However, none of the variants precisely mimicked the management plan proposed to the IWC.

The purpose of the trials is to provide information on those *SLA* variants that meet the Commission's objectives, with primary attention given to conservation performance.

After the initial examination of the trial results for each of the 11 *SLA* variants, the SWG **agreed**:

(1) *SLA* variants 1 and 2 were potentially satisfactory and performed well in nearly all 72 *Evaluation Trials* (see Appendix 4); and
(2) *SLA* variants 1 and 2 performed acceptably for all *Robustness Trials*.

Given this, the SWG focused on those few trials for which conservation performance required further consideration. It noted that the trials with 1% $MSYR_{1+}$ are the most challenging and that the conservation performance for some of these trials for both variants was not satisfactory (see Table 6). However, the SWG noted that given the available information for the eastern North Pacific population as a whole (the observed recovery rate from severe historical depletion, as well as the current recovery rate from the 1999/2000 mortality event), the most recent assessment (Punt and Wade, 2012) resulted in an estimated MSYR rate of 4.6% [90% posterior interval 2.2%, 6.4%]. Therefore, the $MSYR_{1+}$=1% trials were considered to be at the lower bounds of plausibility and that the conservation performance in these trials alone was not reason to preclude the conclusion that both variants have overall satisfactory conservation performance.

The SWG then focused on certain trials within the 2% $MSYR_{1+}$ set for which conservation performance might be considered questionable. Trial 08B (pulse and bias) involved 10% declines in abundance every five years as a proxy for random biological, environmental or anthropogenic events (e.g. disease or contamination). As noted above, these trials are in effect trials with lower $MSYR_{1+}$ than the nominal 2% of the trial. Given this, the SWG **agreed** that both variants 1 and 2 could be considered to have acceptable performance for these two trials.

Trial 10B (pulse and bias) involves an assumption that the relative probability of harvesting PCFG whales in the Makah U&A is double the observed ratio of PCFG whales to migrating whales observed in the available photo-identification studies. The conservation performance of *SLA* variant 2 was considered acceptable for this trial but that for variant 1 was considered marginal (Table 6). In discussing the results of this trial, the SWG noted that the ratio of PCFG whales to migrating whales could be monitored directly from data collected during the hunting period allowing this assumption to be evaluated.

In conclusion, the SWG **agreed**:

(1) *SLA* variant 2 performed acceptably and met the Commission's conservation objectives for conservation while allowing limited hunting; and
(2) *SLA* variant 1 performed acceptably for nearly all the trials and could be considered to meet the Commission's conservation objectives provided that it is accompanied

Table 6

Final depletion and rescaled final depletion statistics for *SLA*s 1 and 2 for the trials with $MSYR_{1+}$=1% and the trials with $MSYR_{1+}$=2% for which conservation performance might be considered to be questionable.

	SLA variant 1				*SLA* variant 2			
	Final depletion		Rescaled final depletion		Final depletion		Rescaled final depletion

by a photo-identification programme to monitor the relative probability of harvesting PCFG whales in the Makah U&A which is undertaken each year and the results presented to the Scientific Committee for evaluation.

The SWG **agreed** that the *Implementation Review* was completed.

Finally, the SWG noted that the *SLA* variants tested did not correspond exactly to the management plan proposed by the Makah to the US government. The SWG **agreed** to test such a variant intersessionally and present the results to the next Annual Meeting.

2.6 Other business

Spatial mixing between eastern and western North Pacific gray whale stocks along the Pacific coast of North America outside of the feeding season has been recently documented (IWC, 2012a). This raises issues about the population structure within the Sakhalin feeding area; see SC/64/BRG10 and IWC (2012a). The broad issue of stock structure of North Pacific gray whales is being addressed in the BRG sub-committee (Annex F) and through a basinwide research programme (IWC, 2012a). However, as noted last year, this finding raises concern about the possibility of whales feeding in the western North Pacific being subject to the proposed Makah Tribe hunt in northern Washington.

Last year (IWC, 2012a, p.15) the Committee had agreed that formally there was no need to modify the existing trials structure which had been designed to evaluate the *SLA*s for the northern and PCFG areas in the context of eastern gray whales. However, it had also noted that this structure does not incorporate conservation implications for western gray whales and the Committee had stressed three points.

(1) The new information on movements of gray whales highlighted the importance of further clarification of the stock structure of North Pacific gray whales. In particular, the matches of western gray whales with animals seen in the PCFG area and other areas along the west coast emphasised the need for efforts to estimate the probability of a western gray whale being taken in aboriginal hunts for Pacific gray whales (noting that this did not require incorporation of western gray whales into the *Implementation Review*).

(2) It had strongly endorsed the basinwide research programme, noting that the results of the research may require further trials for future *SLA* testing, but that this would certainly be a matter for consideration at the next *Implementation Review* if not before.

(3) The Committee will continue to monitor the situation and was willing to respond to any guidance or requests for further information from the Commission.

SC/64/BRG9 addressed point (1) above. It provided estimates for the probability of taking ≥1 western North Pacific whale during the hunt using five models from three model classes which vary depending on the type of data being used for estimation. Model set 1 makes use of abundance estimates for the western and eastern North Pacific populations. Model set 2 makes use of these abundance estimates, as well as sightings data from the proposed hunt area. Model set 3 makes use of the sightings data only. Within model sets 1 and 2, two models (A and B) differ depending on whether migrating eastern and western North Pacific whales are assumed to be equally available to the hunt per capita (A) or whether this assumption is relaxed somewhat (B). All models make the precautionary assumption that all western North Pacific whales migrate to the North American coast and are thus potentially available. The authors of SC/64/BRG9 considered Model 2B the most plausible because it made use of both available types of information and used a less restrictive assumption about the per capita strike probability on western relative to eastern North Pacific whales. Based on this model, the probability of taking one or more western gray whales in a single season ranged from 0.014 to 0.050, depending on whether the median or upper 97.5th percentile estimate was used and whether five or seven whales would be struck in a year (corresponding to two different types of strike limits in the Makah proposal; see SC/64/Rep3, Annex D). The probability of taking one or more western North Pacific whales once over five seasons, based on base case limits in the Makah plan (20 or 35), ranged from 0.056 to 0.225 across these same variables for Model 2B.

Moore stated that the estimates for the probability of taking one or more western gray whales based on the alternative scenario that total strikes *of non-PCFG whales* would equal three or four in a single year, and 15 or 20 over a 5-year period. The estimate of 3 non-PCFG strikes was informed by taking the average across all *Evaluation Trials* for *SLA* variant 1 (conditional on the bias hypothesis (B)), given the median estimated annual number of total strikes less the median estimated number of PCFG strikes; the estimate of four non-PCFG whales was calculated under the same scenarios, but taken as the average over the difference between the upper 95%ile of estimated annual total strikes and the lower 5%ile of such for PCFG strikes. The justification for considering these scenarios was that, given other management measures within the Makah Tribe's plan – most importantly the provision to cease the annual hunt if a certain number of PCFG whales are struck – it may be unlikely that the maximum strike limits of five or seven annually would be achieved. The additional estimates did not change the assessment presented in SC/64/BRG9, since, for the models considered most credible, the estimated parameters related to western gray whale strikes over the course of five years fell within the range of estimates presented in SC/64/BRG9.

The SWG welcomed this work. However, it **agreed** that the description of the methods was insufficient for a full review. It also noted that there are several categories of uncertainties that might need to be considered but that SC/64/BRG9 does not explain the choice of uncertainties addressed. The question was also raised that some of the results (such as the probability of encountering a western gray whale given a catch of five whales reported in the abstract) did not seem consistent with other information presented in SC/64/BRG9. The SWG also noted that additional sensitivity tests (e.g. to choices of priors) should be conducted, more information on convergence of the MCMC algorithm should be provided, and posteriors for model outputs should be presented.

The SWG **recommended** that a revised document be developed for further review at next year's meeting, noting its potential importance for the provision of management advice. It established an Advisory Group (Brandon, Givens, Punt, Scordino) to provide guidance to Moore and Weller.

3. *IMPLEMENTATION REVIEW* FOR BERING-CHUKCHI-BEAUFORT SEAS BOWHEAD WHALES

Donovan recalled the procedure and purpose of *Implementation Reviews* for aboriginal whaling *SLA*s, as summarised under Items 2.1 and 7. The SWG should assess whether there is any new information that would suggest that the range of trials used to evaluate the *Bowhead SLA* is no longer sufficient to ensure that it meets the Commission's conservation and user objectives.

3.1 Consideration of new information with a focus on whether this implies a need for new trials

SC/64/AWMP6 reviewed publications and information relevant to the Scientific Committee's 2012 *Implementation Review* of Bering-Chukchi-Beaufort Sea (B-C-B) bowhead whales and data that was provided under the Scientific Committee's Data Availability Agreement (DAA). Since the last *Implementation Review* in 2007, major studies ranging from molecular biology to broad-scale distribution/relative abundance have been conducted on B-C-B bowhead whales by the local, state, and federal government and the oil and gas industry in Alaska. Of particular relevance to the 2012 *Implementation Review* is the following: (i) the last abundance estimate accepted by the Scientific Committee is 12,631 with CV 0.2442 for the year 2004 (Koski *et al.*, 2010); (ii) subsistence harvest totals from recent years for US communities; and (iii) recent stock structure investigations. Also reviewed were selected publications relevant to the status of B-C-B bowhead whales (e.g. satellite telemetry, oil and gas, health status, etc.). The review did not identify any new information suggesting a concern with the current management scheme.

3.1.1 Stock structure

SC/64/BRG1 reported on a satellite telemetry study of 57 B-C-B bowhead whales tagged during 2006-11. The results elucidated the seasonal movements of bowheads in this stock throughout the entire annual cycle of migration. The paper was also considered by the Sub-Committee on Bowhead, Right and Gray Whales (Annex F) and so the presentation to the SWG focused on those results relevant to stock structure within the B-C-B stock. All tagged bowhead whales used the western Bering Sea during winter; the time period when mating occurs. All but one tagged whale migrated past Point Barrow in spring and went to Amundsen Gulf. The one exception migrated west along the Chukotka coast and summered in the Chukchi Sea. This whale was tagged near Barrow the previous August, but had not returned to Barrow before the tag stopped transmitting in August the following year. The movements of this whale indicate that individuals may not return to the same summer area in consecutive years. While most tagged whales summered within the Canadian Beaufort Sea, extensive summer movements included travel far to the north and northeast to overlap with at least one tagged bowhead whale from the eastern Canada stock. The two whales overlapped in space, but not in time, and each returned to its area of origin in the autumn. Other summer movements included complete transits from the Canadian Beaufort Sea to an area offshore of Barrow and back to the Canadian Beaufort Sea; and one whale travelled to the coast of Chukotka, Russia in July and spent the rest of the summer there. The autumn migration route across the Chukchi Sea was variable within and between years. The authors concluded that the movements and behaviour observed during this study support the hypothesis of a single stock of bowhead whales in the western Arctic. Further, they noted that satellite telemetry has proven to be a powerful new tool for determining the spatial and temporal distribution of B-C-B bowhead whales.

During discussion of these findings, it was noted that when conception occurs (usually March), all the tagged animals are consolidated in the northern Bering Sea. This is further evidence that B-C-B bowhead whales constitute one breeding population.

The SWG commended the authors of SC/64/BRG1 for providing useful and relevant data on bowhead migration patterns, and recognised the cooperation of native hunters who were closely involved in all aspects of this study, and deployed most of the tags. It **agreed** that the tracking information provided no evidence to suggest that the trials evaluated during the previous *Implementation Review* (IWC, 2008b) did not adequately address stock structure concerns. The SWG **recommended** that such tagging and telemetry efforts continue.

SC/64/AWMP3 compared the use of SNPs and microsatellites for studying population structure, assignment and demographic analyses of bowhead whale populations in the Sea of Okhotsk, Bering-Chukchi-Beaufort Seas, and eastern Canada. The authors found that datasets of 42 linked and unlinked SNPs and 22 microsatellites provided similar power to detect low levels of population differentiation, but neither marker performed well for Bayesian analysis of population structure when the level of population differentiation was low. Microsatellites provided greater precision than this set of SNPs for estimating N_e and applying assignment tests. Using the microsatellites, SC/64/AWMP3 found small differences between B-C-B individuals estimated to have been born before 1949 and those born after 1979. However all analyses indicated that the B-C-B stock of bowhead whales represents a single population. The SWG noted that this paper was discussed primarily in the Stock Definition sub-committee (Annex I) since it evaluated of merits of studying different genetic markers.

The SWG concurred with SC/64/AWMP3 that the SNPs results were consistent with previous results from microsatellite analysis, and also noted that the use of SNPs has the advantage that the SNPs can be reproduced between labs and can be obtained from non-optimal tissues. With respect to conclusions about stock structure, the SWG **agreed** that the results provided no evidence to suggest that the trials evaluated during the previous *Implementation Review* (IWC, 2008b) did not adequately address stock structure concerns.

SC/64/AWMP9 presented sequences from three mtDNA genes from 350 bowhead whales from the B-C-B, eastern Canadian Arctic and the Sea of Okhotsk stocks, and discussed methods to calculate gene and site specific mutation rates. SC/64/AWMP9 used the data to demonstrate the improved resolution in phylogenetic analysis provided by increasing amounts of DNA sequence and in resolving recurrent substitutions. The mutation rate for the control region for bowhead whales was estimated as 2.8% per million years which is about half as fast as gray, humpback and minke whales reported in the literature and the time to most recent common ancestor of the mtDNA was estimated as 1.16 million years. Estimates of F_{ST} among the three bowhead stocks showed the Sea of Okhotsk stock to be significantly different from both B-C-B and Canada but Canada and the B-C-B do not differ significantly. The F_{ST} estimated between the Okhotsk and B-C-B stocks based upon the three gene mtDNA dataset was greater than a previous estimate in the literature calculated from control region alone. Tests of neutrality differed in their results for the control region compared to the two protein coding genes, with the latter both showing evidence for a population expansion that was not recovered from the control region sequence.

The SWG **agreed** that the results in SC/64/AWMP9 did not support the need for any additional trials for the *Bowhead SLA*. Consideration of the methodological issues raised in this paper were discussed by the Stock Definition Sub-Committee (see Annex I).

SC/64/AWMP1 investigated the demographic history the B-C-B population of bowhead whales using a variety of analytical methods, including approximate Bayesian computation and extended Bayesian skyline analysis, in addition to many classical bottleneck and demographic tests. The results support a pre-depletion ancestral population size of 10,000 to 20,000 individuals. However, uncertainty over mutation rate limited the precision of these estimations. This is the first genetic-based estimate of the pre-whaling population size of bowhead whales. In addition, the signal for a historical population expansion having begun approximately 75,000 years before present was supported by multiple analyses. A subsequent, non-anthropogenically driven, population reduction, that ensued about 15,000 years ago, was also detected. No genetic signature for the recent population depletion caused by commercial whaling was recovered through any analysis incorporating realistic mutation assumptions. The authors concluded that while bowhead whales have a dynamic demographic history, the reduction in population size caused by commercial whaling was of insufficient magnitude to contribute to this genetic history. From a biological perspective the bottleneck was of short duration in relation to the long generation time of the bowhead whale, which served as a buffer to minimise erosion of variability through genetic drift.

The SWG **agreed** that the new information presented provided no evidence to suggest that the trials evaluated during the previous *Implementation Review* (IWC, 2008b) did not adequately address stock structure concerns.

3.1.2 Abundance and rate of increase

A new agreed abundance estimate is not required for completion of the B-C-B bowhead whale *Implementation Review*. When a new estimate becomes available it can be incorporated into the *Bowhead SLA* calculations to provide management advice.

In SC/64/AWMP5, it was noted that George *et al.* (2004) fitted an exponential growth model to the 1978-2001 ice-based survey data of Zeh and Punt (2005) via generalised least squares, obtaining an estimated annual rate of increase (ROI) for B-C-B bowhead whales of 3.4% with a 95% confidence interval (CI) of 1.7% to 5%. SC/64/AWMP5 adds the 1985 and 2004 abundance estimates obtained from aerial photography survey data by Koski *et al.* (2010) to the ice-based survey data to obtain an updated ROI for 1978-2004. The resulting ROI value is 3.5% with 95% CI 2.2% to 4.8% (Fig. 1). Thus, the point estimate is almost identical, but the two added estimates improved precision. Photographic surveys can be carried out even in years when ice-based surveys are unsuccessful because of weather and/or ice conditions. When large numbers of photos are obtained, as in 1984-86, the resulting photographic survey estimate can be more precise than many of the ice-based survey estimates.

The SWG **recommends** that the Committee adopt this estimate (3.5% with 95% CI 2.2%, 4.8%) as the best available estimate of annual rate of increase for the B-C-B bowhead population. It also **agreed** that the best estimate of current abundance is 12,631 (95% bootstrap percentile CI 7,900 -19,700; 5% lower limit 8,400) for 2004 (Koski *et al.*, 2010).

The SWG was pleased to receive information from recent ice-based surveys that count whales migrating past Barrow, Alaska (SC/64/AWMP7). Full discussion of these surveys will occur in conjunction with the presentation of new abundance estimates within the next two years.

The 2009 visual survey was nearly a complete failure due to closed leads through the latter half of the season and was not discussed further. In 2010 and 2011, a primary perch and a second independent observer (IO) perch were used. The 2010 survey began with an unusually early (31 March)

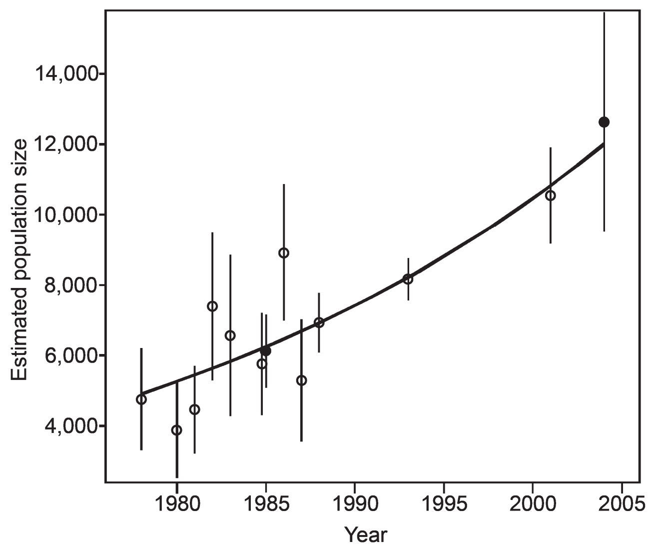

Fig.1. Estimated rate of increase for the B-C-B bowhead whales for the period 1978 to 2004 (from SC/64/AWMP5). The black dots indicate estimates based on photo mark-recapture techniques, the open dots are ice-based estimates.

pulse of bowheads that has not previously been documented (1978-present surveys). Field protocols were devised for operating the IO perches, and methods were developed for real-time and *post hoc* matching of whale sightings between perches. In 2010, a substantial portion (roughly 1/3) of the bowhead migration occurred during times when sightings were impossible due to closed near-shore leads while ice conditions rendered the acoustic data useless. Therefore, no abundance estimate was attempted for 2010, although the survey yielded a large amount of IO data from which estimates of detection probabilities were calculated.

By contrast, the 2011 survey conducted from 4 April to 5 June was extremely successful. Bowheads again arrived earlier than usual, with the first sightings on 9 April and a major pulse on 16 April; earlier sightings were made by whalers. Seven acoustic recorders were deployed of which six provided useful data. The survey resulted in one of the highest raw number of new whales seen. The same IO methods used in 2010 were applied in 2011, with the exception of the real-time matching. Total IO effort was about 180 hours in 2011. An aerial survey was conducted in spring 2011 near Point Barrow concurrent with the ice-based census. Some 4,594 photographs containing 6,801 bowhead whale images were obtained (not accounting for resightings). Thus, the 2011 season was exemplary in that full visual, acoustic and aerial photographic surveys were conducted in the same season. As a final note, first sighting data from 1978 to 2011 surveys were compiled which indicated an earlier arrival of bowheads at Barrow in recent years. This finding is consistent with observations of Barrow whale hunters who have independently reported earlier arrival of bowhead whales at Barrow.

In discussion, the earlier timing of the migration was emphasised and it was noted that there is age-structure within the northbound migration (Koski *et al.*, 2006). However, until the photographs have been analysed it is not known whether large whales were present in the 'early' animals. Rugh *et al.* (2004) found that the arrival times of well-marked whales varied among years, with some large whales (without calves) arriving early in the migration.

SC/64/BRG4 presented estimates of visual detection probabilities from the spring 2011 ice-based survey of bowhead whales migrating near Barrow, Alaska. The same methods will also be applied to similar data from the 2010 survey. These estimates are highly relevant to the AWMP SWG since they constitute one foundation upon which a future population abundance estimate will be calculated from the 2011 survey counts. This abundance estimate will then be used as input to the *Bowhead SLA*. The data for these analyses were produced by observer teams from two nearby ice perches who recorded sightings of whale groups independently, along with a wide variety of covariates. Then, the data were scrutinised *post hoc* to identify possible matches, i.e. whale groups seen from both perches. Whale groups seen from both perches constitute recaptures in the context of a capture-recapture analysis. However, standard capture-recapture model fitting methods are not directly applicable to the 2011 survey dataset for several reasons. First, a single perch may make multiple sightings of the same whale group, but these re-identifications and the links between them are uncertain. Second, the between-perch matches declared *post hoc* are also uncertain, and the analysts performing the matching task must rate each declared match with a confidence rating. Third, the group sizes recorded for multiple sightings both within and between perches are not always consistent, so it is necessary to estimate when or if extra group members belong to a partially unseen recaptured group or an independent individual that is not recaptured. Thus, bias correction methods are essential to produce accurate detection probability estimates. After developing and incorporating these corrections, the authors applied the general framework of Huggins (1989) and reported that detection probabilities depend on group size and the distance of the sighting from the perches. Specifically, group sizes of only one whale and increasing distance from the perch are associated with lower detection probabilities. For example, the detection probability estimates for a single whale at 3,000m and a group of whales at 1,000m are 0.377 and 0.645, respectively. The sample-weighted mean estimated detection probability is 0.495; most standard errors are less than 0.03. Thus, about half the bowheads migrating within the range of potential visual detection are not sighted by observers at the primary perch.

In discussion, the SWG noted that the independent observer (IO) method used in the 2010 and 2011 surveys is entirely different than the removal method protocol used in 1985 and previously to estimate detection probabilities (Zeh and Punt, 2005). Thus, the detection probability estimates from the two methodologies are not exchangeable. The authors of SC/64/BRG4 indicated their intent to estimate 2011 abundance using detection probability estimates based only on the new IO data, abandoning the irrelevant, older estimates. The SWG **endorsed** this approach, while also recognising that any possible implications of the shift to the superior IO method might merit future consideration. However, it was also noted that abundance estimates based on photo-identification have been added to the time series of abundance estimates (SC/64/AWMP5), and an abundance estimate from the new IO study would be another important contribution. The SWG and other Committee members interested in abundance estimation are **encouraged** to contact the authors of SC/64/BRG4 intersessionally with comments and suggestions so that the future abundance estimate for use in the *Bowhead SLA* could be based on an approved estimate of detection probabilities.

SC/64/BRG3 described an aerial photographic survey for B-C-B bowhead whales conducted from 19 April to 6 June 2011. The field season was very successful, both in terms of total flight days and the very large number of whale images (approximately 6,800) obtained during this time. These photographs are a significant contribution to the bowhead whale photographic catalogue. The SWG recognised the importance of this work as potentially providing an estimate of population abundance for use with the *Bowhead SLA*. This estimate would be entirely independent of the ice-based survey estimate described in SC/64/BRG4. Analyses of the photo-id data may also provide better precision in estimates of bowhead whale life-history parameters such as adult survival rate. A detailed discussion of this paper is provided in the BRG sub-committee report (Annex F).

3.1.2 Other

SC/64/AWMP8 provides a preliminary summary of the subsistence harvest of bowhead whales in Alaska from 1974 to 2011. Bowhead whales fill an important nutritional and cultural need for villages in northern and western Alaska. In total, 1,149 whales have been landed by 12 villages from 1974-2011, primarily during migration. The implementation of a quota in 1978 led to an abrupt drop in the number of whales harvested, but as more information became available about bowhead whales, the quota and the number of animals landed increased. The efficiency (no. landed/no. struck) of the hunt has also increased over this period. The average efficiency has reached a plateau at approximately 75% to 80%. In the past 5-10 years, not all strikes have been used. This is due in part to deteriorating ice conditions in the spring, which has made it very difficult for some villages to hunt and land whales. The total strike allocation has never exceeded what was allowed within a block quota based on the *Bowhead SLA*.

The SWG welcomed this information and noted that strikes have remained within the need envelope tested during development of the *Bowhead SLA*. It therefore **agreed** that no additional trials were warranted in this regard.

3.2 Discussion of new trials

In consideration of the evidence described in Item 3.1, the SWG **agreed** that there was no need for new trials or simulation testing of the *Bowhead SLA*.

3.3 Conclusions and recommendations

The SWG thanked the US scientists, the North Slope Borough, Alaska, and the native communities for continuing to provide a considerable body of high-quality scientific work which facilitated the SWG's *Implementation Review* process. The SWG **agreed** that the *Bowhead SLA* continues to be the most appropriate way for the Committee to provide management advice for the B-C-B population of bowhead whales. This completes the *Implementation Review* for the B-C-B bowhead whales.

4. CONSIDERATION OF WORK REQUIRED TO DEVELOP *SLA*S FOR ALL GREENLAND HUNTS

This topic had been advanced at the intersessional Workshop held in La Jolla in March 2012. Donovan summarised the discussions which had taken place at the Workshop (SC/64/Rep3), commenting on the different nature of the requirements for each of the four species (common minke whale, fin whale, humpback whale and bowhead whale) to be considered. He explained that separate *SLA*s would be considered for each species despite Greenlands request for a multi-species approach, as that would be too complex an exercise to undertake at this stage of the process.

The SWG referred to the benefits in previous *CLA* and *SLA* developments in the Committee of a co-operative competition amongst more than one *SLA* developer, and the Chair asked which groups might be interested in participating in such an exercise for the development of Greenland hunt *SLA*s: Witting, Butterworth and Givens (for the bowhead whale only) responded positively to this enquiry. He also drew attention to previous discussions within the SWG on the development of long-term *SLA*s. In particular, he noted the multi-species nature of the Greenland hunts and Greenland's desire for flexibility amongst species in meeting its subsistence needs. The SWG **reiterated** that its approach will first be to develop *SLA*s for individual species before considering whether and how to address multispecies considerations (IWC, 2010; 2011; 2012b).

4.1 Common minke whales

SC/64/AWMP15 had been submitted in response to a recommendation from the March intersessional Workshop in relation to common minke whales. This document dealt with stock structure issues, abundance estimates and aspects of simulation trial structure. The SWG thanked Witting for responding to this request. A summary of the information provided by Witting for each of the Greenland species is given as Appendix 5.

Donovan advised of a planned Workshop on the stock structure of this species in the North Atlantic, which is planned to inform the RMP *Implementation Review* process for common minke whales in the North Atlantic scheduled for 2014. The operating models developed in this process should (perhaps with minor adjustment to take account of focus on different populations) also serve for the *SLA* development process, which would accordingly be informed by expertise in RMP development for this species.

The SWG noted the need for a co-ordinated approach to the issue of stock structure and it **endorsed** the collaborative proposal given in Annex D, Appendix 6 that would culminate in a joint AWMP/RMP Workshop on stock structure in spring 2014.

4.2 Fin whales

SC/64/AWMP12 had been submitted in response to a recommendation from the March 2012 intersessional Workshop in relation to fin whales. This document dealt with stock structure and assessment issues, abundance data and aspects of simulation trial structure. The SWG thanked Witting for responding to this request.

The sub-committee noted that a pre-meeting for a North Atlantic fin whale RMP *Implementation Review* is scheduled before the 2013 Scientific Committee meeting. The stock structure discussions at this meeting would provide useful input to the fin whale *SLA* development process.

4.3 Humpbacks whales

SC/64/AWMP13 had been submitted in response to a recommendation from the March 2012 intersessional Workshop in relation to humpback whales. This document dealt with need envelopes, *SLA* development, stock structure and assessment issues, abundance data and aspects of simulation trial structure. The SWG thanked Witting for responding to this request.

Witting suggested that the ENP gray whale trial structure offered a framework around which trials for the single humpback stock involved could be developed. Punt supported this, commenting that this offered a process which should prove straightforward to implement.

4.4 Bowhead whales

SC/64/AWMP14 had been submitted in response to a recommendation from the March 2012 intersessional Workshop in relation to bowhead whales. This document dealt with stock structure, assessment and simulation trial issues. Here the earlier B-C-B bowhead trial structure may provide a helpful basis around which to design trials. The SWG thanked Witting for responding to this request.

4.5 Conclusions

The SWG **re-emphasised** the importance of developing long-term *SLA*s for the Greenlandic hunts as soon as possible and certainly before 2018. It **agreed** that it should be possible to develop appropriate trial structures and operating models for the humpback and bowhead whale hunts before the next Annual Meeting to enable potential *SLA*s to be evaluated in the future. It **endorsed** the proposal outlined in Appendix 6 to support this work.

It also **emphasised** the importance of developers beginning to consider the development of *SLA*s for fin whales and common minke whales in the context of the work being undertaken on stock structure with the RMP sub-committee especially the joint AWMP/RMP proposal for work on the stock structure of North Atlantic common minke whales (see

Annex D, Appendix 6). It noted that the development of an AWMP/RMP-lite program as outlined in Appendix 6 would also assist developers in beginning to investigate potential *SLA*s for common minke whales and fin whales.

In order to progress this essential *SLA* development work, the SWG **agreed** that an intersessional Workshop (to be held in winter 2012, probably in Copenhagen, at a cost of £8,000) was essential to maintain progress. As in previous years, maintenance of the AWMP Developer's Fund was also supported.

5. IMPLICATIONS OF NEW INFORMATION ON BROAD GRAY WHALE STOCK STRUCTURE (WITH BRG)

5.1 Summary of relevant BRG discussions

The SWG was informed that the sub-committee on BRG had received a number of interesting papers (see Annex F, item 4.1), but that at present its work on the basinwide review of gray whale stock structure was incomplete.

5.2 Conclusions with respect to *Implementation Review*

The SWG **agreed** that it was premature at this stage to consider whether the new information about western gray whales may warrant an *Implementation Review* (although see the discussion under Item 2).

6. ANNUAL REVIEW OF MANAGEMENT ADVICE

6.1 Common minke whales off West Greenland

6.1.1 New information

In the 2011 season, 174 minke whales were landed in West Greenland and six were struck and lost (SC/64/ProgRep Denmark). Of the landed whales, there were 133 females, 39 males, and two whales of unreported sex. Genetic samples were obtained from 90 of these whales. The SWG **re-emphasised** the importance of collecting genetic samples from these whales, particularly in the light of the proposed joint AWMP/RMP Workshop (see Item 4.1).

Witting noted that the next large whale survey off West Greenland is planned for 2015. The SWG agreed that next year it would review its best estimate of abundance in light of a slightly revised estimate provided in Heide-Jørgensen *et al.* (2010).

6.1.2 Management advice

In 2007, the Commission agreed that the number of common minke whales struck from this stock shall not exceed 200 in each of the years 2008-12, except that up to 15 strikes can be carried forward. In 2009, the Committee was for the first time ever able provide management advice for this stock based on a negatively biased estimate of abundance of 17,307 (95% CI 7,628-39,270) and the method for providing interim management advice which was confirmed by the Commission. Such advice can be used for up to two five year blocks whilst *SLA*s are being developed (IWC, 2009, p.16). Based on the application of the agreed approach, and the lower 5th percentile for the 2007 estimate of abundance, the SWG **repeats** its advice of last year that an annual strike limit of 178 will not harm the stock.

Table 7

Most recent abundance estimates for minke whales in the Central North Atlantic.

Small Area(s)	Year(s)	Abundance and CV
CM	2005	26,739 (CV=0.39)
CIC	2007	10,680 (CV=0.29)
CG	2007	1,048 (CV=0.60)
CIP	2007	1,350 (CV=0.38)

6.2 Common minke whales off East Greenland

6.2.1 New information

Nine common minke whales were struck (and landed) off East Greenland in 2011, and one was struck and lost (SC/64/ProgRepDenmark). All landed whales were females. The SWG noted that catches of minke whales off East Greenland are believed to come from the large Central stock of minke whales. No genetic samples were obtained from minke whales caught in East Greenland. The SWG **re-emphasised** the importance of collecting genetic samples from these whales, particularly in the light of the proposed joint AWMP/RMP Workshop (see Item 4.1).

6.2.2 Management advice

In 2007, the Commission agreed to an annual quota of 12 minke whales from the stock off East Greenland for 2008-12, which the Committee stated was acceptable in 2007. The present strike limit represents a very small proportion of the Central stock (and see Item 4.1). The SWG **repeats** its advice of last year that the present strike limit would not harm the stock.

6.3 Fin whales off West Greenland

6.3.1 New information

A total of five fin whales (all females) were landed, and none were struck and lost, in West Greenland during 2011 (SC/64/ProgRepDenmark). No genetic samples were obtained from caught fin whales in 2011. The SWG **re-emphasised** the importance of collecting genetic samples from these whales, particularly in the light of the proposed work to develop a long-term *SLA* for this stock (see Item 4.2).

6.3.2 Management advice

In 2007, the Commission agreed to a quota (for the years 2008-12) of 19 fin whales struck off West Greenland. The Committee agreed an approach for providing interim management advice in 2008 and this was confirmed by the Commission. It had agreed that such advice could be used for up to two blocks whilst *SLA*s were being developed (IWC, 2009). Based on the agreed estimate of abundance for fin whales (4,539 95%CI 1,897-10,114), and using this approach, the SWG **repeats** its advice that an annual strike limit of 19 whales will not harm the stock.

6.4 Humpback whales off West Greenland

6.4.1 New information

A total of eight (three males; five females) humpback whales were landed (none were struck and lost) in West Greenland during 2011 (SC/64/ProgRepDenmark). Genetic samples were obtained from three of these whales. The SWG **re-emphasised** the importance of collecting genetic samples from these whales, particularly with respect to the YoNAH and MoNAH initiatives (Clapham, 2003; EC YoNAH, 2001).

6.4.2 Management advice

In 2007, the Committee agreed an approach for providing interim management advice and this was confirmed by the Commission. It had agreed that such advice could be used for up to two five year blocks whilst *SLA*s were being developed (IWC, 2009, p.16). Based on the agreed estimate of abundance for humpback whales (3,039, CV 0.45, annual rate of increase 0.0917 SE 0.0124) and using this approach, the SWG **agreed** that an annual strike limit of 10 whales will not harm the stock.

6.5 Humpback whales off St Vincent and The Grenadines

6.5.1 New information

Last year the SWG noted that it had received no catch data from St Vincent and The Grenadines for 2010-11. This year the Secretariat received information that a 35-foot whale was taken on 18 April 2011. It was reported that its girth was 18.6 feet, its flukes 9.7 feet and its 'tail length' was 17.9 feet. It also received information on a 33.75 foot female taken on 14 April 2012. Its girth was 18.25 feet. Genetic samples and photographs were taken.

Brownell reported that the USA and St Vincent and The Grenadines are discussing the transfer of tissue samples from this whale for analysis and storage at SWFSC (the IWC archive where *inter alia* SOWER samples are stored).

The SWG **welcomed** this information.

It also repeats its previous strong **recommendations** that St Vincent and The Grenadines:

(1) provide catch data, including the length of harvested animals, to the Scientific Committee; and
(2) that genetic samples be obtained for any harvested animals as well as fluke photographs, and that this information be submitted to appropriate catalogues and collections.

6.5.2 Management advice

The Committee has agreed that the animals found off St Vincent and The Grenadines are part of the large West Indies breeding population (11,570 95% CI 10,290-13,390). The Commission adopted a total block catch limit of 20 for the period 2008-12.

The SWG **repeats** its advice of last year that this block catch limit will not harm the stock.

6.6 Implications of possible move to biennial meetings with respect to length of block quotas

The Commission is considering a change from annual to biennial meetings. This has raised the issue within two Commission working groups as to whether there are any scientific implications for the Commission moving to setting block quotas for an even number of years rather than the present five-year intervals. This issue was addressed at the intersessional Workshop (see SC/64/Rep3).

The Workshop had recalled that trials for the B-C-B bowhead and Eastern North Pacific gray whale *SLA*s had shown satisfactory performance for surveys at intervals of 10 years (and even for some *Robustness Trials* for 15 years). The Workshop agreed that there are no scientific reasons for the Commission not to set catch limits for blocks of even numbers of years up to eight years for these stocks. However, it drew attention to its discussions of the AWS where it noted that despite the trial results it would not be appropriate for catches to be left unchanged if new abundance estimates were not available after 10 years (IWC, 2004 and see Item 7.2).

The Workshop had noted that this would not mean that the Committee would need to change its regular process of *Implementation Reviews* approximately every five years (with the provision for 'special' reviews should circumstances arise) or an annual examination of new information and provision of advice.

The Workshop had also noted that the interim safe *SLA* for the Greenland hunts (see Items 6.1-6.4 above) had also been tested for surveys at 10-year intervals and shown satisfactory performance and had been adopted by the Committee and the Commission in 2008. However, as noted at the time those tests had been for a restricted number of scenarios than the wider range of hypotheses customarily considered for such trials. It had thus been agreed that this *SLA* was appropriate for the provision of advice for up to two blocks (i.e. approximately 10 years) or to approximately 2018. The Workshop agreed that there were no scientific reasons why the next quota block for the Greenland hunts could not be for a six-year period, noting that the long-term *SLA*s will be available for implementation for the following block quota.

The SWG **endorsed** the views of the Workshop.

7. ABORIGINAL WHALING MANAGEMENT SCHEME

7.1 Draft guidelines for *Implementation Reviews*

An integral part of the AWMP process is the undertaking of regular or 'special' *Implementation Reviews*, as noted for example during the development process of the *Bowhead Whale SLA* (IWC, 2003b).

The first Bering-Chukchi-Beaufort Seas stock bowhead whale *Implementation Review* took place over two years and was completed in 2007 with most focus being on the issue of stock structure (IWC, 2007b; 2008a; 2008b; 2008c; 2008d). No changes needed to be made to the *Bowhead SLA* after the review. The first *Implementation Review* for gray whales was completed in 2010 and the *Gray Whale SLA* was not changed with respect to providing advice on the Russian hunt off Chukotka (IWC, 2011). However, as discussed above, during that review, information was received that led to the need to call for an immediate *Implementation Review* before providing advice for a potential hunt of gray whales by the Makah Tribe on the west coast of the USA.

The SWG had agreed that it would be useful to develop guidelines for *Implementation Reviews*, given the experience gained thus far. The adopted guidelines, which cover the issues outlined below, are provided in Appendix 7.

(1) Objectives.
(2) Timing of regular and special *Implementation Reviews.*
(3) Outcomes.
(4) Data availability.
(5) Computer programs.

The SWG **commends** these guidelines to the Committee.

7.2 Scientific aspects of an Aboriginal Whaling Scheme (AWS)

In 2002, the Committee strongly recommended that the Commission adopt the Aboriginal Subsistence Whaling Scheme (IWC, 2003a, pp.22-23). This covers a number of practical issues such as survey intervals, carryover, and guidelines for surveys. The Committee has stated in the past that the AWS provisions constitute an important and necessary component of safe management under AWMP *SLA*s and it **reaffirms** this view. It noted that discussions within the Commission of some aspects such as the 'grace period' are not yet complete.

8. PROGRESS ON FOLLOW-UP WORK ON CONVERSION FACTORS FOR THE GREENLANDIC HUNT

In 2009, the Commission appointed a small working group (comprising several Committee members) to visit Greenland and compile a report on the conversion factors used by species to translate the Greenlandic need request which is provided in tonnes of edible products to numbers of animals (Donovan *et al.*, 2010). At that time the group provided conversion factors based upon the best available data, noting that given the low sample sizes, the values for species other than common minke whales should be considered provisional. The group also recommended that a focused attempt to collect new data on edible products taken from species other than common minke whales be undertaken, to allow a review of the interim factors; and that data on both 'curved' and 'standard' measurements are obtained during the coming season for all species taken.

Last year the Committee had welcomed an initial report, recognising the logistical difficulty of collecting this kind of data. However, it had noted that considerably more detail is needed and requested that a detailed report be presented for consideration at the next meeting.

In particular, it had requested that the report should provide:

(1) a description of the field protocols and sampling strategy, including effort and likely sample sizes;
(2) a description of analysis methods and models; and
(3) presentation from results thus far, including from preliminary analyses with the available data.

It had noted that such information will assist the SWG in addressing issues such as appropriate sample size.

This year, the SWG received further information on the data collected thus far from the Greenlandic authorities which can be summarised as follows.

(1) Humpback whales (*n*=4). The average in kg ± SE:
- meat: 4,823 ± 3,020;
- mattak: 3,140 ± 1,282;
- ventral grooves: 2,670 ± 454; and
- total weight: 10,633 ± 4,217.

(2) Fin whales (*n*=2). The average in kg ± SE:
- meat: 3,075 ± 955;
- mattak: 1,998 ± 1,241;
- ventral grooves: 1,238 ± 902; and
- total weight: 6,311 ± 2,390.

(3) Bowhead whales (*n*=5). The average in kg ± SE:
- total weight: 8,673 ± 2,127.

The SWG welcomed this information and the provision of data. It noted that a comparison of these values and the Recommended Conversion Factors Per Animal (RCPFA) from Donovan *et al.* (2010) showed reasonable agreement for humpback and bowhead whales (within 1 SD), but the yield for fin whales was lower than expected. It was not possible to examine this difference *inter alia* because no lengths of the animals included in the analysis were provided.

Although welcoming this information, the SWG expressed a number of concerns over the insufficient level of detail provided, the efficiency of the sampling regime (relatively poor sample sizes) and the extrapolation procedure in which only one meat tote or box is weighed.

In response to the concern over the lack of samples, Witting informed the SWG that the Greenland Institute of Natural Resources (GINR) has been asked to investigate this and is working with the hunters and authorities to improve the sample size in the future. The SWG greatly **encourages** this and looks forward to a report on progress made. It also encourages the GINR to develop improved protocols including weighing as many of the meat, mattak, and qiporaq bins as possible (i.e. not just 1 bin). Providing a breakdown of products from bowhead whales would be valuable both for conversion factors and biological information.

Given these concerns, the SWG **recommends**:

(1) the provision of a full scientific paper to the next Annual Meeting that details *inter alia* a full description of the field protocols and sampling strategy, analytical methods; and a presentation of the results thus far, including information on the sex and length of each of the animals for which weight data are available; and
(2) the collection and provision of data on Recommendation No. 2 of Donovan *et al.* (2010) comparing standard *vs.* curvilinear whale lengths. This should be done for all three species on as many whales as possible. Guidelines and protocols are suggested in Donovan *et al.* (2010).

9. WORK PLAN

The SWG draws attention to the following work identified in the report for completion intersessionally or at the 2013 Annual Meeting (note that item (7) was raised during review of report).

(1) Item 2.5.3. Present *Evaluation* and *Robustness Trial* results to the SWG of an *SLA* variant that corresponds exactly to the management plan proposed by the Makah Tribe to the US Government (co-ordinator: Brandon).
(2) Item 2.6. Present a revised document on the probability of a gray whale that regularly feeds in the western North Pacific being taken in a Makah hunt (Moore and Weller, with assistance from an advisory group comprising Brandon, Givens, Punt and Scordino).
(3) Item 4. Develop trial structures and operating models for the Greenland hunts of bowhead and humpback whales to be presented initially at an intersessional workshop (Punt – see Appendix 6).
(4) Item 4. Develop an AWMP/RMP-lite program to assist developers of *SLA*s for the Greenland hunts of fin and common minke whales (Punt – see Appendix 6).
(5) Item 4. Hold an intersessional Workshop to progress work on the development of *SLA*s for the Greenland hunts (estimated cost £8,000).
(6) Item 8. Present a full scientific paper on the work in Greenland related to the collection of information on conversion factors (co-ordinator: Witting; paper: Greenlandic authorities).
(7) Present a document that provides advice on the development of *SLA*s and their evaluation (co-ordinators: Donovan, Punt and Scordino).

10. ADOPTION OF REPORT

The Report was adopted at 18:00 on 19 June apart from Item 2.5.3 and Item 8 that were adopted by email at 09:15 on 20 June 2012. The Chair thanked the participants for their extremely hard work in completing a very full agenda, and especially Punt, Brandon, Butterworth, Givens and Scordino for their rapporteuring work and initial examination of trial results.

AGENDA

1. Introductory items
   1.1 Convenor's opening remarks
   1.2 Election of Chair
   1.3 Appointment of rapporteurs
   1.4 Adoption of agenda
   1.5 Documents available
2. *Implementation Review* of gray whales with emphasis on the PCFG
   2.1 Summary of intersessional Workshop
   2.2 New information
   2.3 Progress with intersessional tasks
   2.4 Finalise the specifications for the trials and presentation of results
   2.5 Review results of trials
      2.5.1 *Evaluation Trials*
      2.5.2 *Robustness Trials*
   2.6 Other business
3. *Implementation Review* for B-C-B bowhead whales
   3.1 Consideration of new information with a focus on whether this implies a need for new trials
      3.1.1 Stock structure
      3.1.2 Abundance and rate of increase
      3.1.2 Other
   3.2 Discussion of new trials
   3.3 Conclusions and recommendations
4. Consideration of work required to develop *SLA*s for all Greenland hunts before the end of the interim period
   4.1 Common minke whales
   4.2 Fin whales
   4.3 Humpback whales
   4.4 Bowhead whales
5. Implications of new information on broad gray whale stock structure (with BRG)
   5.1 Summary of relevant BRG discussions
   5.2 Conclusions with respect to *Implementation Review*
6. Annual review of management advice
   6.1 Common minke whales off West Greenland
      6.1.1 New information
      6.1.2 Management advice
   6.2 Common minke whales off East Greenland
      6.2.1 New information
      6.2.2 Management advice
   6.3 Fin whales off West Greenland
      6.3.1 New information
      6.3.2 Management advice
   6.4 Humpback whales off West Greenland
      6.4.1 New information
      6.4.2 Management advice
   6.5 Humpback whales off St Vincent and The Grenadines
      6.5.1 New information
      6.5.2 Management advice
   6.6 Implications of possible move to biennial meetings with respect to length of block quotas
7. Aboriginal Whaling Management Scheme
   7.1 Draft guidelines for *Implementation Reviews*
   7.2 Scientific aspects of an Aboriginal Whaling Scheme
8. Progress on follow-up work on conversion factors for the Greenlandic hunt
9. Work plan
10. Adoption of report

Appendix 2

TRIALS SPECIFICATIONS

This document outlines a set of trials to evaluate the performance of *SLA*s for hunting in the Pacific Northwest, with a primary focus on the PCFG (Pacific Coast Feeding Group). The operating model assumes the two groups (the 'north' group and the PCFG) are separate stocks, but with possible immigration of 'north' group animals into the PCFG group. The operating model considers four strata (north of 52°N, south of 41°N, PCFG December-May, and PCFG June-November) because the relative vulnerability of the two stocks to whaling and incidental mortality differs among these strata.

A. The population dynamics model

The underlying population dynamics model is deterministic, age- and sex-structured, and based on a two-stock version of the Baleen II model (Punt, 1999).

A.1 Basic dynamics

Equation A1.1 provides the underlying 1+ dynamics.

$$\begin{aligned} R^{s,m/f}_{t+1,a+1} &= (R^{s,m/f}_{t,a} + I^{s,m/f}_{t,a} - C^{s,m/f}_{t,a})\, \tilde{S}^s_t\, S^s_a + U^{s,m/f}_{t,a}\, \tilde{S}^s_t\, S^s_a\, \delta_{a+1} & 0 \le a \le x-2 \\ R^{s,m/f}_{t+1,x} &= (R^{s,m/f}_{t,x} + I^{s,m/f}_{t,x} - C^{s,m/f}_{t,x})\, \tilde{S}^s_t\, S^s_x + (R^{s,m/f}_{t,x-1} + I^{s,m/f}_{t,x-1} - C^{s,m/f}_{t,x-1})\, \tilde{S}^s_t\, S^s_{x-1} & \\ U^{s,m/f}_{t+1,a+1} &= U^{s,m/f}_{t,a}\, \tilde{S}^s_t\, S^s_a\, (1-\delta_{a+1}) & 0 \le a \le x-2 \end{aligned} \quad \text{(A1.1)}$$

$R^{s,m/f}_{t,a}$ is the number of recruited males/females of age a in stock s at the start of year t;

$U^{s,m/f}_{t,a}$ is the number of unrecruited males/females of age a in stock s at the start of year t;

$C^{s,m/f}_{t,a}$ is the catch of males/females of age a from stock s during year t (whaling is assumed to take place in a pulse at the start of each year);

δ_a is the fraction of unrecruited animals of age a-1 which recruit at age a (assumed to be independent of sex, time, and stock);

S^s_a is the annual survival rate of animals of stock s and age a in the absence of catastrophic mortality events (assumed to be the same for males and females):

$$S^s_a = \begin{cases} S^s_0 & \text{if } a = 0 \\ S^s_{1+} & \text{if } 1 < a \end{cases} \quad \text{(A1.2)}$$

S^s_0 is the calf survival rate for animals of stock s;

S^s_{1+} is the survival rate for animals aged 1 and older for animals of stock s;

$\tilde{S}^s_t$ is the amount of catastrophic mortality (represented in the form of a survival rate) for stock s during year t (catastrophic events are assumed to occur at the start of the year before mortality due to whaling and natural causes; in general $\tilde{S}^s_t$=1, i.e. there is no catastrophic mortality);

$I^{s,m/f}_{t,a}$ is the net migration of female/male animals of age a into stock s during year t; and

x is the maximum (lumped) age-class (all animals in this and the x-1 class are assumed to be recruited and to have reached the age of first parturition). x is taken to be 15 for these trials.

Catastrophic mortality is assumed to be zero (i.e., $\tilde{S}^s_t$=1) except for the north stock for 1999 and 2000 when it is assumed to be equal to the parameter $\tilde{S}$. This assumption reflects the large number of dead ENP gray whales observed stranded along the coasts of Oregon and Washington during 1999 and 2000 relative to annual numbers stranding there historically (Brownell *et al.*, 2007; Gulland *et al.*, 2005). The mortality event is assumed to have only impacted the north stock because the abundance estimates for the PCFG stock increased when the mortality event occurred, in contrast to those for the north stock which declined substantially.

Immigration only occurs from the north stock to the PCFG stock and only animals aged 1+ immigrate. The annual number of animals immigrating is either $\bar{I}_t = I\ N_t^{\text{north},1+}/20{,}000$ where $\bar{I}$ is the hypothesized recent average number of individuals recruiting into the PCFG from the north stock (i.e., 2, 4 or 6) or a fixed level (0, 10, 20 or 30). The annual number of immigrants by age and sex is given by:

$$I^{s,m/f}_{t,a} = I_t \frac{(R^{\text{north},m/f}_{t,a} + U^{\text{north},m/f}_{t,a})}{N_t^{\text{north},1+}} \quad \text{(A1.3)}$$

Emigration from the PCFG stock is modelled by implementing an extra survival rate, S after 1930 (immigration or emigration are ignored when carrying capacity and the parameters which determine the productivity of the population are calculated). Owing to the different sizes of the two stocks, emigrants from the PCFG stock are assumed to die rather than join the north stock. The value of $\tilde{\tilde{S}}$ is set so that at carrying capacity immigration and emigration are balanced, i.e.:

$$\bar{I}\, K_{1+}^{\text{north}} = K_{0+}^{\text{PCFG}} (1-\tilde{\tilde{S}}) \quad \text{(A1.4)}$$

A.2 Births

The number of births to stock s at the start of year t+1, B^s_{t+1}, is given by:

$$B_{t+1}^{s} = b_{t+1}^{s} N_{t+1}^{s,f} \quad \text{(A2.1)}$$

$N_t^{s,f}$ is the number of mature females in stock s at the start of year t:

$$N_t^{s,f} = \sum_{a=a_m}^{x} (R_{t,a}^{s,f} + U_{t,a}^{s,f}) \quad \text{(A2.2)}$$

a_m is the age-at-maturity (the convention of referring to the mature population is used here, although this actually refers to animals that have reached the age of first parturition);

b_{t+1}^s is the probability of birth/calf survival for mature females:

$$b_{t+1}^{s} = b_{-\infty}^{s} \{1 + A^s (1 - (D_{t+1}^s / D_{-\infty}^s)^{z^s})\} \quad \text{(A2.3)}$$

$b_{-\infty}^s$ is the average number of live births per year per mature female in the pristine (pre-exploitation) population for stock s;

A^s is the resilience parameter for stock s;

z^s is the degree of compensation for stock s;

D_t^s is the size of the component of stock s in year t upon which the density-dependence is assumed to act; and

$D_{-\infty}^s$ is the pristine size of the component of stock s upon which the density-dependence is assumed to act.

The number of female births, $B_t^{s,f}$, is computed from the total number of the births during year t according to the equation:

$$B_t^{s,f} = 0.5\, B_t^s \quad \text{(A2.4)}$$

The numbers of recruited/unrecruited calves is given by:

$$\begin{aligned} R_t^{s,f} &= \pi_0\, B_t^{s,f} & R_t^{s,m} &= \pi_0\, (B_t^s - B_t^{s,f}) \\ U_t^{s,f} &= (1-\pi_0)\, B_t^{s,f} & U_t^{s,m} &= (1-\pi_0)(B_t^s - B_t^{s,f}) \end{aligned} \quad \text{(A2.5)}$$

π_0 is the proportion of animals of age 0 which are recruited (0 for these trials).

For the trials $D_t^s = N_t^{s,1+}$ and $D^s_{-\infty} = K^s_{1+}$ because density-dependence is assumed to act on the 1+ component of the population and affects fecundity and infant survival. $N_t^{s,1+}$ and K^s_{1+} are defined according to the equations:

$$N_t^{s,1+} = \sum_{a=1}^{x} (R_{t,a}^{s,\text{f}} + U_{t,a}^{s,\text{f}} + R_{t,a}^{s,\text{m}} + U_{t,a}^{s,\text{m}}) \qquad K_{1+}^{s} = \sum_{a=1}^{x} (R_{-\infty,a}^{s,\text{f}} + U_{-\infty,a}^{s,\text{f}} + R_{-\infty,a}^{s,\text{m}} + U_{-\infty,a}^{s,\text{m}}) \quad \text{(A2.6)}$$

A.3 Catches

The historical (t<2010) catches by stratum (north, south, PCFG December-May, and PCFG June-November) are taken to be equal to the reported catches (Table 1). The historical catches are allocated to stocks in fixed proportions as follows:

- North area catches: all north animals;
- PCFG area catches in December-May: PCFG animals with probability ϕ_{PCFG} - base-case value 0.3, as determined by the photo-ID data (Calambokidis *et al.*, 2012);
- PCFG area catches in June-November: all PCFG animals; and
- South area catches: PCFG animals with probability ϕ_{south} (base-case value 0.01, as determined by relative abundance).

Table 1

Historical catches of eastern north Pacific gray whales.

	South			PCFG Jun.-Nov.			PCFG Dec.-May			North			Total

The future catches by stratum are incidental catches and the catches arising from application of the *SLA*s. Subsistence catches are only assumed to occur in the north and the PCFG area from December-May. The sex-ratio of future catches is assumed to be 50:50 except for a sub-set of the robustness trials. The catches are allocated to stock as outlined above, except that the subsistence catches from the PCFG area in June-November are modelled individually. Thus, the catch from the PCFG area is allocated to the PCFG stock based on Bernoulli trials with probability:

$$\frac{\sum_{\text{m/f}}\sum_{a'} R_{y,a'}^{\text{PCFG,m/f}}}{\delta\sum_{\text{m/f}}\sum_{a"} R_{y,a"}^{\text{north,m/f}} + \sum_{\text{m/f}}\sum_{a"} R_{y,a"}^{\text{PCFG,m/f}}} \tag{A3.1}$$

where δ is the relative probability of harvesting a PCFG versus a north animal had the sizes of the two populations been the same. δ is calculated from ϕ under the assumption that the number of PCFG animals is 200 and north animals is 20,000, i.e.:

$$\delta=(200 / \phi) - 200 / 20{,}000 \tag{A3.2}$$

The incidental catches by stratum for the historical period are computed using the equation:

$$C_y^{\text{I}/s} = 0.5\begin{cases}\left\{1-\frac{0.5}{69}[1999-y]\right\}\bar{C}^I & \text{if } y \le 1999 \\ \bar{C}^I N_y^{1+} / \bar{N}^{1+} & \text{otherwise}\end{cases} \tag{A3.3}$$

$C_y^{\text{I}/s}$ is the incidental catch of animals of sex *s* during year *y*;
$\bar{C}^I$ is the mean catch in the stratum (see Table 2); and
$\bar{N}^{1+}$ is the mean 1+ abundance (in the stratum concerned from 2000-09).

The catches from the PCFG and north stocks are then allocated to age and size using the formula:

$$C_{t,a}^{s,m} = C_t^{s,m} R_{y,a}^{s,m} / \sum_{a"} R_{y,a"}^{s,m}; \quad C_{t,a}^{s,\text{f}} = C_t^{s,\text{f}} R_{y,a}^{s,\text{f}} / \sum_{a"} R_{y,a"}^{s,\text{f}}; \tag{A3.4}$$

The probability of not identifying a PCFG whale as such, is p_2, (base-case value 0) while the probability of incorrectly identifying a north whale as a PCFG whale is p_1 (base-case 0.01). If the survey frequency for the PCFG area is not annual, p_2 is defined as:

$$p_{2,t} = 1 - \frac{\sum_{a\ge SF}(R_{t,a}^{\text{north,m}} + R_{t,a}^{\text{north,f}} + U_{t,a}^{\text{north,m}} + U_{t,a}^{\text{north,f}})}{\sum_{a\ge 1}(R_{t,a}^{\text{north,m}} + R_{t,a}^{\text{north,f}} + U_{t,a}^{\text{north,m}} + U_{t,a}^{\text{north,f}})} \tag{A3.5}$$

where *SF* is the survey frequency for the PCFG area.

Stratum	Average incidental catch
North	0[1]
PCFG [Dec.-May]	2
PCFG [Jun.-Nov.]	1.4[2]
South	3.4

[1]Obviously not actually zero, but will be small relative to population size.
[2]Includes southern whales during June-November as these whales are almost certainly PCFG animals.

A.4 Recruitment
The proportion of animals of age *a* that would be recruited if the population was pristine is a knife-edged function of age at age 0, i.e.:

$$\pi_a = \begin{cases} 0 & \text{if } \quad a = 0 \\ 1 & \text{otherwise} \end{cases} \tag{A4.1}$$

The (expected) number of unrecruited animals of age *a* that survive to age *a*+1 is $U_{t,a}^{s,m/f}\ S_a$. The fraction of these that then recruit is:

$$\delta_{a+1} = \begin{cases} [\pi_{a+1} - \pi_a]/[1-\pi_a] & \text{if } 0 \le \pi_a < 1 \\ 1 & \text{otherwise} \end{cases} \tag{A4.2}$$

A.5 Maturity
Maturity is assumed to be a knife-edged function of age at age a_m.

A.6 Initialising the population vector
The numbers at age in the pristine population are given by:

$$\begin{aligned} R_{-\infty,a}^{s,\mathrm{m/f}} &= 0.5 \quad N_{-\infty,0}^{s} \quad \pi_a \prod_{a'=0}^{a-1} S_{a'}^{s} & \text{if} \quad 0 \le a < x \\ U_{-\infty,a}^{s,\mathrm{m/f}} &= 0.5 \quad N_{-\infty,0}^{s} \quad (1-\pi_a) \prod_{a'=0}^{a-1} S_{a'}^{s} & \text{if} \quad 0 \le a < x \\ R_{-\infty,x}^{s,\mathrm{m/f}} &= 0.5 \quad N_{-\infty,0}^{s} \prod_{a'=0}^{x-1} \frac{S_{a'}^{s}}{(1-S_x)} & \text{if} \quad a = x \end{aligned} \tag{A6.1}$$

$R_{-\infty,a}^{s,\mathrm{m/f}}$ is the number of animals of stock *s* of age *a* that would be recruited in the pristine population;
$U_{-\infty,a}^{s,\mathrm{m/f}}$ is the number of animals of stock *s* of age *a* that would be unrecruited in the pristine population; and
$N_{-\infty,0}^{s}$ is the total number of animals of stock *s* of age 0 in the pristine population.

The value for $N_{-\infty,0}^{s}$ is determined from the value for the pre-exploitation size of the 1+ component of the population using the equation:

$$N_{-\infty,0}^{s} = K_{1+}^{s} / \left(\sum_{a'=1}^{x-1} \prod_{a'=1}^{a-1} S_a^s + \frac{1}{1-S_x} \prod_{a'=0}^{x-1} S_{a'}^{s} \right) \tag{A6.2}$$

It is well-known that it is not possible to make a simple density-dependent population dynamics model consistent with the abundance estimates for the eastern north Pacific stock of gray whales (Butterworth *et al.*, 2002; Cooke, 1986; Lankester and Beddington, 1986; Reilly, 1981; 1984). This is why recent assessments of this stock (Punt and Wade, 2012) have been based on starting population projections from a more recent year (denoted as τ) than that in which the first recorded catch occurred. The trials are therefore based on the assumption that the age-structure at the start of τ=1930 is stable rather than that the population was at its pre-exploitation equilibrium size at the start of 1600, the first year for which catch estimates are available. The choice of 1930 for the first year of the simulation is motivated by the fact that the key assessment results are not sensitive to a choice for this year from 1930-68 (Punt and Butterworth, 2002; Punt and Wade, 2012). Note that even though the operating model ignores the catch data for 1600-1929, these catches are nevertheless provided to the *SLA* for the north area.

The determination of the age-structure at the start of 1930 involves specifying the effective 'rate of increase', γ, that applies to each age-class. There are two components contributing to γ, one relating to the overall population rate of increase (γ^+) and the other to the exploitation rate. Under the assumption of knife-edge recruitment to the fishery at age 1, only the γ^+ component (assumed to be zero following Punt and Butterworth, 2002) applies to ages a of age 0. The number of animals of age a at the start of τ=1930 relative to the number of calves at that time, $N^{s,*}_{\tau,a}$, is therefore given by the equation:

$$N^{s,*}_{\tau,a} = \begin{cases} 1 & \text{if } a=0 \\ N^{s,*}_{\tau,0}\, S^s_0 & \text{if } a \le 1 \\ N^{s,*}_{\tau,a-1}\, S^s_{a-1}\,(1-\gamma^+) & \text{if } 1<a<x \\ N^{s,*}_{\tau,x-1}\, S^s_{x-1}(1-\gamma^+)/(1-S^s_x(1-\gamma^+)) & \text{if } a=x \end{cases} \tag{A6.3}$$

B^s_τ is the number of calves in year τ (=1930) and is derived directly from equations A2.1 and A2.3 (for further details see Punt, 1999):

$$B^s_\tau = \left(1-\left[1/(N^{s,f}_\tau b^s_{-\infty})-1\right]/A^s\right)^{1/z^s} \frac{D^s_{-\infty}}{D^{s,*}_\tau} \tag{A6.4}$$

$D^{s,*}_\tau$ is the number of animals in the density-dependent component of the population relative to the number of births at that time (see equation A2.6).

The effective rate of increase, γ^s, is selected so that if the population dynamics model is projected from 1930 to 1968, the size of the 1+ component of the population (both stocks) in 1968 equals a pre-specified value, P^s_{1968} .

A.7 z and A

A^s, z^s and S^s_0 , are obtained by solving the system of equations that relate $MSYL^s_{1+}$, $MSYR^s_{1+}$, S^s_0 , S_{1+}, $f_{\max}$ a_m, A^s and z^s, where $f_{\max}$ is the maximum theoretical pregnancy rate (Punt, 1999).

A.8 Conditioning

The method for conditioning the trials (i.e. selecting the 100 sets of values for the parameters a_m, S^s_0 , S_{1+}, S, K^{north}_{1+}, K^{PCFG}_{1+}, A^{north}, A^{PCFG}, z^{north}, and z^{PCFG}) is based on a Bayesian assessment of the eastern North Pacific stock of gray whales (Punt and Butterworth, 2002; Punt and Wade, 2012; Wade, 2002). The algorithm for conducting the Bayesian assessment is as follows:

Draw values for the parameters S_{1+}, $f_{\max}$, a_m, K^{north}_{1+}, K^{PCFG}_{1+}, P^{north}_{1968}, P^{PCFG}_{1968}, $\tilde{S}$, CV^{north}_{add} (the additional variance for the estimates of 1+ abundance at Carmel, California in 1968), CV^{PCFG}_{add} (the additional variance for the estimates of 1+ abundance from northern California to southeast Alaska in 1968, had such a survey taken place) from the priors in Table 3. It is not necessary to draw values for $MSYL^s_{1+}$ and $MSYR^s_{1+}$ because the values for these quantities are pre-specified rather than being determined during the conditioning process.

Solve the system of equations that relate $MSYL^s_{1+}$, $MSYR^s_{1+}$, S^s_0 , S_{1+}, $f_{\max}$, a_m, A^s and z^s to find values for S^s_0 , A^s and z^s.

Calculate the likelihood of the projection for each area, given by[1]:

$$-\ell nL = 0.5\ell n\,|\mathbf{V}+\Omega| + 0.5\sum_i\sum_j(\ell n N^{\text{obs}}_i - \ell n\hat{P}^{1+}_i)[(\mathbf{V}+\Omega)^{-1}]_{i,j}(\ell n N^{\text{obs}}_j - \ell n\hat{P}^{1+}_j) \tag{A8.1}$$

N^{obs}_i is the i^{th} estimate of abundance[2] (Tables 4a, 4b),

$\hat{P}^{1+}_i$ is the model-estimate corresponding to N^{obs}_i ,

$\mathbf{V}$ is the variance-covariance matrix for the abundance estimates, and

Ω is a diagonal matrix with elements given by $E(CV^2_{add,t})$:

$$E(CV^2_{add,t}) = CV^2_{add}\frac{0.1+0.013P^*/\hat{P}_t}{0.1+0.013P^*/\hat{P}_{1968}} \tag{A8.2}$$

Steps (a)-(c) are repeated a large number (typically 1,000,000) of times.

[1]This formulation assumes that the observed data relate to the medians of sampling distributions for the data. Alternative assumptions (such as that the observed data relate to the means of the sampling distribution) will be inconsequential given the extent of uncertainty associated with the estimates of abundance.

[2]The shore-based abundance estimate for year y/y+1 is assumed to pertain to abundance at the start of year y+1.

100 sets of parameters vectors are selected randomly from those generated using steps (a)-(c), assigning a probability of selecting a particular vector proportional to its likelihood. The number of times steps (a)-(c) are repeated is chosen to ensure that each of the 100 parameter vectors are unique.

The expected value for the estimate of abundance of the north area is taken to the total 1+ abundance (PCFG and north stocks combined) while the abundance estimates for the PCFG area are assumed to pertain to the PCFG stock only.

Table 3

The prior distributions for the eastern north Pacific stock of gray whales.

Parameter	Prior distribution
Non-calf survival rate, S_{1+}	U[0.95, 0.99]
Age-at-maturity, a_m	U[6, 12]
K_{1+}^{north}	U[16,000, 70,000]
K_{1+}^{PCFG}	U[100, 500]
Maximum pregnancy rate, f_{max}	U[0.3, 0.6]
Additional variation (population estimates) CV_{add}, in 1968	U[0, 0.35]
1968 abundance, P_{1968}^{north}	U[8,000, 16,000]
1968 abundance, P_{1968}^{PCFG}	U[50, 300]
Catastrophic mortality, $\tilde{S}$	U[0.5,1.0]

B. Data generation

B.1 Absolute abundance estimates

The historic (t<2011) abundance estimates (and their CVs) are provided to the *SLA*s and are taken to be those in Tables 4a, 4c. Future estimates of absolute abundance (and their estimated CVs) are generated and provided to the *SLA* once every F years during the management period (starting in year 2011 where the default values for F are 10 for the northern area and F=1 for the PCFG area). The CV of the abundance estimate (CV_{true}) may differ from the CV provided to the *SLA* (further details are provided below).

The survey estimate, $\hat{S}$, may be written as:

$$\hat{S} = B_A PY\, w / \mu = B_A\, P^*\, \beta^2\, Y\, w \quad \text{(B1.1)}$$

B_A is the bias (the bias for the bulk of the simulations for the north area is 1 while the bias for PCFG area is generated from $\ell n B_A \sim N(-0.305, 0.108)$ – this bias reflects the difference between the abundance estimates on which the ABL is based [which pertain to Oregon to Southern Vancouver Island] and the abundance of the entire stock];

P is the current total 1+ population size ($= N_t^{1+}$); (B1.2)

Y is a lognormal random variable: $Y = e^{\phi}$ where: $\phi \sim N[0; \sigma_\phi^2]$ and $\sigma_\phi^2 = \ell n(1+\alpha^2)$ (B1.3)

w is a Poisson random variable, independent of Y, with $E(w) = \text{var}(w) = \mu = (P / P^*) / \beta^2$; and (B1.4)

P^* is the reference population level (the pristine 1+ population, $= K^{1+}$).

The steps used in the program to generate the abundance estimates and their CVs are given below[3].

The *SLA* is provided with estimates of CV_{est} (the estimation error associated with factors considered historically) for each future sightings estimate. The estimate of $CV_{est,t}$ is given by:

$$\hat{C}V_{est,t} = \sqrt{\sigma_t^2 \, (\chi_n^2 / n)} \qquad \sigma_t^2 = \ell n(1 + E(CV_{est,t}^2)) \quad \text{(B1.5)}$$

$E(CV_{est,t}^2)$ is the sum of the squares of the actual CVs due to estimation error:

$$E(CV_{est,t}^2) = \theta^2 (a^2 + b^2 / w\beta^2) \quad \text{(B1.6)}$$

[3]The steps used to generate estimates of abundance and their CVs are as follows (steps (i)-(iii) are part of the conditioning process).

(i) Read in CV_{est}. Generate values of CV^2_{add} for 1968.

(ii) Set η using equation B1.6b and the value of CV_{add} generated in step (i).

(iii) Set θ^2 using equation B1.7a and the values for CV_{est} from step (i) and $w\beta^2 = P/P^* = P_{1968} / P^*$. Set α^2 and β^2 using equation B1.8.

(iv) Generate w (Poisson random variable – see equation B1.4) and ϕ (lognormal random variable – see equation B1.3).

(v) Set abundance estimate $\hat{S}$ using equation B1.1.

(vi) Set E($CV^2_{est,t}$) using eqn B1.6a.

(vii) Generate $CV_{est,t}$ from χ^2_n distribution using equation B1.5.

χ^2_n is a random number from a χ^2 distribution with n (=19; the value assumed for the single stock trials for the RMP) degrees of freedom;

a^2, b^2 are constants and equal to 0.02 and 0.012 respectively;

The relationship between CV_{est} and CV_{true} is given by:

$$\eta = [E(CV^2_{true}) - E(CV^2_{est})] / (0.1 + 0.013P^* / P) \quad \text{(B1.7a)}$$

where η is a constant known as the additional variance factor. The value of η is based on the population size and CVs for 1968 (for consistency with the way the CV for P_{1968} is generated in Table 3):

$$\eta = CV^2_{add} / (0.1 + 0.013P^* / P_{1968}) \quad \text{(B1.7b)}$$

The values of α and β are then computed as:

$$\alpha^2 = \theta^2 a^2 + \eta 0.1 , \qquad \beta^2 = \theta^2 b^2 + \eta 0.013 \quad \text{(B1.8)}$$

Table 4a

Estimates of absolute abundance (with associated standard errors) for the eastern north Pacific stock of gray whales based on shore counts (source: table 9 in Laake *et al.*, 2012).

Year	Estimate	CV	Year	Estimate	CV

C. Need

The level of need in each year, Q_t, will be supplied to the *SLA*s. The need is given by $Q_t = Q_{2011} + \frac{t - 2011}{100} (Q_{2111} - Q_{2011})$ where Q_{2011} (=150 for the north area and =7 for the PCFG area) is the need at the start of the first year in which the AWMP is applied and Q_{2111} is the value 100 years later.

D. Implementing the Makah harvest regime

The overall application of the Makah management regime is as follows:

- compute the ABL (Allowable Bycatch Limit of PCFG whales);
- strike an animal;
- if the animal is struck and lost in December-April[4]:
  - if the total number of struck and lost animals is 3, stop the hunt;
  - if the total number of struck animals equals the need of 7 stop the hunt;

If the animal is struck-and lost in May:

- add one to the number of whales counted towards the ABL;
- if the ABL is reached; stop the hunt;
- if the total number of struck and lost animals is 3, stop the hunt;
- if the total number of struck animals equals the need of 7; stop the hunt;

If the animal is landed and is matched against the catalogue[5]:

- add one to the number of whales counted towards the ABL;
- if the ABL is reached; stop the hunt;
- if the total number of landed whales equals 5; stop the hunt;
- if the total number of struck animals equals the need of 7; stop the hunt;
- if the number of landed whales for the current five-year block equals 20; stop the hunt;

If the animal is landed and does not match any whale in the catalogue:

- if the total number of landed whales equals 5; stop the hunt;
- if the total number of struck animals equals the need of 7; stop the hunt;
- if the number of landed whales for the current five-year block equals 20; stop the hunt;

The base-case and the 10 alternative variants are listed in Table 5.

Table 5

The Makah Tribe's proposed hunt and suggested Variants for evaluation noting which management measure is altered as compared to the Makah Tribe's proposed management plan.

Variant number	Bycatch limit	Modelled time period of hunt	Availability of PCFG
Makah proposal	ABL formula	December to April	Trial specified
2	ABL formula	May only	Trial specified
3	ABL formula	May only	PCFG=100%
4	1	December to April	Trial specified
5	1	May only	Trial specified
6	1	May only	PCFG=100%
7	2	December to April	Trial specified
8	2	May only	Trial specified
9	2	May only	PCFG=100%
10	No limit	December to May	Trial specified
11	No limit	May only	PCFG=100%

E. Trials

There three 'broad' hypotheses to capture possible reasons for the trend in the abundance data for the PCFG area:

- The 1998 abundance estimate is biased due to 'discovery', and 20 whales immigrated into the PCFG stock from the northern stock in each of 1999 and 2000 (hypothesis 'P').
- There has been no pulse immigration into the PCFG stock; rather the abundance estimates are subject to time-varying bias (Table 6) (hypothesis 'B').
- Ten whales immigrated into the PCFG stock from the northern stock in each of 1999 and 2000 and the abundance estimates are subject to time-varying bias (but not the extent as for hypothesis P; Table 6) (hypothesis 'I').

Table 6

Bias for the 'B' and 'I' hypotheses.

Year	Hypothesis B	Hypothesis I
1998	0.513	0.7565
1999	0.631	0.8155
2000	0.750	0.8750
2001	0.869	0.9345
2002	0.988	0.9940
2003+	1.000	1.0000

[4]Whether a whale is struck and lost is determined from a Bernoulli trial with probability 0.5 (base-case).

[5]PCFG whales are mismatched as north stock whales with probability p_2 while north stock whales are matched to the catalogue with probability p_1.

Table 7 lists all of the factors considered in the trials. Table 8 summarises the trials. Note that some trials do not apply to some of the 'broad' hypotheses. Table 8 also indicates which trials need to be conditioned.

Table 7

Details of factors considered in trials.

Factors	Levels (reference levels shown bold and underlined)
$MSYR_{1+}$ (north)	**2%**, **4.5%**
$MSYR_{1+}$ (PCFG)	**1%**, **2%**, **4.5%**
Immigration rate (annual)	**0, 1, 2**, 4, 6
Pulse immigration (1999/2000)	**0**, 10, **20**, 30
Proportion of PCFG whales in PCFG area, ϕ_{fut}	0, **0.3**, 0.6, 1
Struck and lost rate (PCFG area)	0, **50%**, 75%
Northern need in final year (linear change from 150 in 2010)	**340**, 530
Historic survey bias	**None/Appendix 2, Table 6**, increasing between 1967 to 2002 from 0.5→1 (north only) 50% (PCFG only)
Future episodic events[1]	**None**, 3 events occur between yrs 1-75 (with at least 2 in yrs 1-50) in which 20% of the animals die. Events occur every 5 years in which 10% of the animals die[2]
Time dependence in K	**Constant**, halve linearly over 100yr; double linearly over 100yr
Time dependence in natural mortality, M *	**Constant**, double linearly over 100yr
Parameter correlations	Yes, **No**
Probability of mismatching north whales, p_2	0, **0.01**, 0.01-0.05
Probability of mismatching PCFG whales, p_1	**0**, 0.5
Frequency of PCFG surveys	**Annual**, 6-year
Incidental catch	**Reference**, double reference, half reference
Future sex ratio	**0.5:0.5**, 0.2:0.8 (M:F)
Episodic events with future pulse events[1]	**None**, 3 events occur between yrs 1-75 (with at least 2 in yrs 1-50) in which 20% of the north stock die and a pulse of 20 animals is added to the PCFG stock.

[1]The average value for adult survival needs to be adjusted to ensure the population is stable for these trials. [2]Selected to mimic the implications of stochasticity in the population dynamics.

Table 8a

The *Evaluation Trials*. Values given in bold type show differences from the base case trial. The final three columns indicate which trials apply to which 'broad' hypotheses. For 'broad' hypotheses B and I, the number given is the plus in 1999/2000. Unless specified otherwise ϕ_{PCFG}=0.3, the struck and lost rate is 0.5, and there are no stochastic dynamics or episodic events.

Trial	Cond-ition	Description	$MSYR_{1+}$ North	$MSYR_{1+}$ PCFG	Final Need	Annual immigration	Survey freq.	Survey bias (north)	Hypothesis P	B	I

13B		Relative probability of harvesting a PCFG whale, ϕ_{PCFG} =1	4.5%	2%	10/1	20	Y

F. Statistics

The risk- and recovery-related performance statistics are computed for the mature female and for the total (1+) population sizes (i.e. P_t is either the size of the mature female component of the population, N_t^f, or the size of the total (1+) population, N_t^{1+}). P_t^* is the population size in year t under a scenario of zero strikes in the northern and PCFG area (but allowing for incidental catches) over the years $t \geq 2011$ (defined as t=0 below), P_t^{**} is the population size in year t under a scenario of zero strikes in the PCFG area (but allowing for incidental catches and strikes in the north area) over the years $t \geq 2011$ (defined as t=0 below), and K_t^* is the population size in year t if there had never been any harvest.

The trials are based on a 100-year time horizon, but a final decision regarding the time horizon will depend *inter alia* on interactions between the Committee and the Commission regarding need envelopes and on the period over which recovery might occur. To allow for this, results are calculated for T=20 and 100 (T^* denotes the number of blocks for a given T; for the PCFG area T^* is 19 and 99 respectively for T=20 and T=100 while for the north area T^* is 3 and 19 respectively for T=20 and T=100).

Statistics marked in bold face have previously been considered the more important. Note that the statistic identification numbers have not been altered for reasons of consistency. Hence, there are gaps in the numbers where some statistics have been deleted.

E.1 Risk

D1. Final depletion: P_T/K. In trials with varying K this statistic is defined as P_T/K_t^*.

D2. Lowest depletion: $\min(P_t/K)$:t=0,1,…,T. In trials with varying K this statistic is defined as $\min(P_t/K_t^*)$:t=0,1,…,T.

D6. Plots for simulations 1-100 of $\{P_t : t = 0,1,..,T\}$, $\{P_t^* : t = 0,1,..,T\}$, $\{P_t^{**} : t = 0,1,..,T\}$.

D7. Plots of $\{P_{t[x]} : t = 0,1,...,T\}\{P^*_{t[x]} : t = 0,1,...,T\}$ and $\{P^{**}_{t[x]} : t = 0,1,..,T\}$ where $P_{t[x]}$ is the xth percentile of the distribution of P_t. Results are presented for x = 5 and x = 50.

D8. Rescaled final population: P_T / P_T^* and P_T / P_T^{**}.

D9. Minimum population level in terms of mature females, $\min(P_t)$: t = 0,1,…,T.

D10. Relative increase P_T/P_0.

E.2 Need

N1. Total need satisfaction: $\sum_{t=0}^{T-1} C_t / \sum_{t=0}^{T-1} Q_t$

N2. Length of shortfall = (negative of the greatest number of consecutive blocks in which $C_t < Q_t$) / T^*

N4. Fraction of blocks in which $C_t = Q_t$

N7. Plot of $\{V_{t[x]}$: $t = 0,1,T^* -1\}$ where $V_{t[x]}$ is the xth percentile of the distribution of $V_t = C_t/Q_t$ [catch for the PCFG area].

N8. Plots of V_t for simulations 1-100.

N9. Average need satisfaction: $\frac{1}{T}\sum_{t=0}^{T-1}\frac{C_t}{Q_t}$

N10. AAV (Average Annual Variation): $\sum_{b=0}^{T^*-1} \left| C_{b+1} - C_b \right| / \sum_{t=0}^{T^*-1} C_b$ where C_b is the catch in block *b*.

N11. Anti-curvature: $\frac{1}{T^*-1} \sum_{b=0}^{T^*-2} \left| \frac{C_b - M_b}{\max(10, M_b)} \right|$ where $M_b = \left(C_{b+1} + C_{b-1} \right) / 2$.

N12. Mean downstep (or modified AAV): $\sum_{t=-1}^{T^*-1} \left| \min\left(C_{b+1} - C_b, 0 \right) \right| / \sum_{t=-1}^{T^*-2} C_b$.

N13. Average annual number of animals landed.

N14. Average annual number of animals struck and lost.

The following key plots are to be produced for each trial:

Time-trajectories of 1+ population size (northern and PCFG stock) in absolute terms and relative to carrying capacity, along with the fits to the abundance estimates. This plot allows an evaluation of whether conditioning has been achieved satisfactorily.

Histograms of the 100 parameter vectors for each trial. This plot allows an evaluation of whether and how conditioning has impacted the priors for these parameters.

Individual time-trajectories of 1+ population size for the northern and PCFG stocks, individual time-trajectories of strikes for the northern and PCFG area, a summary (median and 95% intervals) for the depletion of the PCFG stock, and a summary (median and 95% intervals) for the time-trajectories of 1+ population size when: (a) there are no future catches; (b) there are only incidental catches; and (c) there are incidental catches and catches due to hunts in the PCFG and northern area.

Appendix 5

BIOLOGICAL INFORMATION RELATING TO *SLA* DEVELOPMENT FOR THE LARGE WHALE HUNTS IN WEST GREENLAND

Lars Witting

Humpback whale

Agreed abundance estimates for West Greenland humpback whales are listed in Table 1. Other information include a 2007 estimate of 4,365 (CV:0.20) humpback whales in Canadian waters (NAMMCO, 2010; 2011).

The latest assessment paper is Witting (2011) that use an age- and sex-structured population model to examine if the long-term dynamics of West Greenland humpback whales is best described by density regulated growth or by selection-delayed dynamics (earlier referred to as inertia dynamics). Discussion of the results of this exercise and implications for the operating model(s) for *SLA* development will form part of the development process.

There is no estimate of the age of the first reproductive event (a_m) for humpback whales in West Greenland. There are, however, several estimates from other areas (Clapham, 1992; Gabriele *et al.*, 2007; Ramp, 2008; Robbins, 2007). For North Atlantic humpback whales, Ramp (2008) estimated a_m to exceed 12 years in the Gulf of St. Lawrence, Clapham (1992) estimated it to a range from five to seven years for humpback whales in the Gulf of Maine, and a later estimate from this area obtained an average estimate of seven years, ranging from five to 13 (Robbins, 2007).

There is no estimate of the birth rate for humpback females in West Greenland, but estimates exist for other areas. Gabriele *et al.* (2007) found that adult females in Alaska typically give birth every second to third year, with a documented range from one to six, and a mode every second year. Robbins (2007) found a comparable range for humpback whales in the Gulf of Maine, with a mean estimated annual birth rate of 0.57 and a process variance of 0.042 for 201 adult in the south-west of the area. The assessment model (Witting, 2011) used the latter estimate as an informative beta prior on the birth rate (a=2.741, b=2.111). As for a_m, for density-regulated growth and selection-delayed dynamics, the prior on the birth rate should reflect the expected range for the average birth rate among the individuals in a population that increases at its maximum growth rate. As West Greenland humpbacks are estimated to increase at a rate faster than humpbacks in the Gulf of Maine (Clapham *et al.*, 2003; Heide-Jørgensen *et al.*, 2008c), the applied prior may be in the lower range of the true value.

Larsen and Hammond (2004) estimated an annual survival rate (p) of 0.957 (SE=0.028) for humpback whales off West Greenland. This is similar to estimates of 0.951 (SE=0.010) and 0.960 (SE=0.008) for the Gulf of Maine feeding aggregation of humpbacks (Barlow and Clapham, 1997; Buckland, 1990), and an estimate of 0.963 (95% CI:0.944-0.978) for humpbacks in the central North Pacific (Mizroch *et al.*, 2004). In the Gulf of Maine, calf survival was estimated at 0.664 (95% CI:0.517-0.784), and yearly adult survival at 0.991 (95% CI:0.919-0.999) when excluding animals younger than five years of age (Robbins, 2007). From age zero to five, yearly survival was found to increase by an approximate straight line.

Table 1

Abundance estimates for West Greenland humpback whales with CV in parenthesis (given in %). I_a is an index series from aerial surveys. I_b is an index series of mark-recapture estimates, and N a fully corrected line transect survey from 2007. Data from Larsen and Hammond (2004), Heide-Jørgensen *et al.* (2008c).

Year	I_a	I_b	N
1984	138 (54)	-	-
1988	231 (70)	357 (16)	-
1989	-	355 (12)	-
1991	-	376 (19)	-
1992	-	348 (12)	-
1993	873 (53)	-	-
2005	1,218 (38)	-	-
2007	-	-	3,270 (50)

Bowhead whale

Abundance estimates for EA-WG bowhead whales are listed in Table 2. Abundance estimates that relate to the two stock hypothesis are 6,340 (CV: 0.38) for Baffin Bay-Davis Strait in 2002 and 1,350 (CV: 0.78) for Foxe Basin-Hudson Bay in 2003 (Givens *et al.*, 2009; IWC, 2009).

Table 2

Abundance estimates for bowhead whale N_{bd} is an agree estimate from 2002 for Baffin Bay and Davis Strait (1+ component), with CV in % in parenthesis. N_{wg} is (†) a fully corrected line-transect and (‡) a mark-recapture estimate from West Greenland (mainly mature animals), with CV in parenthesis. I_{wg} is sighting rates (number/km) from aerial surveys in West Greenland (mature animals), with the total number of sightings given in parenthesis. Data from Heide-Jørgensen *et al.* (2007; 2008b), Givens *et al.* (2009), IWC (2009) and Wiig *et al.* (2011).

Year	N_{bd}	N_{wg}	I_{wg}
1981	-	-	0.0011 (1)
1982	-	-	0.0004 (1)
1990	-	-	0.0017 (1)
1991	-	-	0.0028 (3)
1993	-	-	0.0000 (0)
1994	-	-	0.0000 (0)
1998	-	-	0.0042 (5)
1999	-	-	0.0000 (0)
2002	6,340 (38)	-	-
2006	-	1,229† (47)	0.0109 (18)
2010	-	1,410‡ (23)	-

Under the two stock hypothesis there appears to be no stock structure uncertainty associated with the allocation of the West Greenland catches, which in this case will be allocated to the Baffin Bay-Davis Strait stock. While the assumed Foxe Basin-Hudson Bay and the Baffin Bay-Davis Strait stocks may mix on the wintering ground at the northern Labrador coast and the entrance to Hudson Strait, in spring, Foxe Basin-Hudson Bay animals would have to migrate in the opposite direction of the Baffin Bay-Davis Strait animals that migrate to West Greenland (Heide-Jørgensen *et al.*, 2006; Heide-Jørgensen *et al.*, 2010a).

Fin whale

Agreed abundance estimates for West Greenland fin whales are listed in Table 3. Other abundance information includes a 2007 estimate of 1,716 (CV:0.40) fin whales in Canadian waters (NAMMCO, 2010; 2011).

To examine annual growth rates and life-histories in North Atlantic fin whales, an age- and sex-structured

Table 3

Abundance estimates for North Atlantic fin whales with CV in parenthesis (given in %). WG estimates from IWC (1992), Heide-Jørgensen *et al.* (2008a) and pro-rated estimates for EG, WI and EI from IWC (2010).

Year	N_{WG}	N_{EG}	N_{WI}	N_{EI}
1987	-	-	-	5,260 (28)
1988	1,100 (35)	5,270 (22)	4,240 (23)	-
1995	-	10,200 (29)	7,360 (22)	7,170 (29)
2001	-	14,200 (19)	7,430 (19)	9,550 (26)
2005	3,230 (44)	-	-	-
2007	4,360 (45)	15,800 (20)	8,900 (26)	-

Table 4

Abundance estimates for West Greenland minke whales with CV in parenthesis (given in %). *N* absolute estimates; 1987/88, 1993 and 2005 cue count estimates; 2007: fully corrected line-transect estimate. *I* time series of relative abundance. Data from Larsen (1995), Heide-Jørgensen and Laidre (2008), Heide-Jørgensen *et al.* (2008a; 2010b).

Year	*N*	*I*
1984	-	446 (36)
1985	-	198 (38)
1987	-	297 (31)
1988	-	1,841 (37)
1987/8	3,266 (31)	-
1989	-	636 (37)
1993	8,371 (43)	1,055 (86)
2005	10,792 (59)	663 (33)
2007	16,610 (43)	1,365 (25)

population model with exponential growth was fitted to recent abundance estimates (Table 3) for the West Greenland (WG), East Greenland (EG), West Iceland (WI) and East Iceland/Faroese (EI) summer aggregations of North Atlantic fin whales. Discussion of the results of this exercise and implications for the operating model(s) for *SLA* development will form part of the development process.

Minke whale

Abundance estimates for West Greenland minke whales are listed in Table 4. Other abundance information include a 2007 estimate of 5,675 (CV:0.24) minke whales in Canadian waters (NAMMCO, 2010; 2011).

SC/64/AWMP15 also presented a model for sex and density dependent dispersal between summer aggregations of minke whales. Discussion of the results of this exercise and implications for the operating model(s) for *SLA* development will form part of the development process.

Appendix 6

DEVELOPMENT OF AN OPERATING MODEL FOR WEST GREENLAND HUMPBACK AND BOWHEAD WHALES

1. Relevant Agenda item (no. and title)
Annex E, Item 4

2. Brief description of project and why it is necessary to your sub-committee
The Committee developed interim *Strike Limit Algorithms* (*SLA*s) for the minke, fin, humpback and bowhead whales off West Greenland. These *SLA*s need to be reviewed and perhaps revised, ideally by the 2017 Annual Meeting. Development of *SLA*s for the hunts of minke and fin whales can be co-ordinated with the *Implementation Reviews* for these whales which are being conducted by the RMP sub-committee. In contrast, the situations for humpback and bowhead whales are relatively straightforward (essentially single-stock situations), but without a fully-specified and coded operating model progress on these cases will be limited. The first step in the process of developing *SLA*s is constructing an operating model and associated trials, and this project aims to make sufficient progress that an AWMP Workshop (in late 2012) could finalise trials and initiate testing.

The key activities covered by the proposal are as follows.

(1) Extend the single-stock gray whale trials so that trials can be conducted for humpback and bowhead whales.
(2) Outline a set of *Evaluation* and *Robustness Trials* which could form the basis for the evaluation of *SLA*s for these two groups of whales.
(3) Present the trial specifications and results for: (a) the interim *SLA*s; and (b) an alternative *SLA* at an intersessional AWMP Workshop.
(4) Develop an AWMP/RMP-lite to assist developers of *SLA*s for the cases of fin whales and common minke whales.

3. Timetable
(1) Obtain the latest version of the gray whale trials from the Secretariat (July-August 2012).
(2) Update the trials as needed: (a) update the catch streams; (b) add the ability to condition to existing data for West Greenland; and (c) add the ability to test user-specified *SLA*s (before the AWMP Workshop).
(3) Draft full technical specifications for the proposed trials (before the AWMP Workshop).

4. Researchers name
André Punt (University of Washington).

5. Estimated total cost with breakdown as needed
Total budget: £5,000.

Appendix 7

DRAFT GUIDELINES FOR AWMP *IMPLEMENTATION REVIEWS*

1. Objectives of *Implementation Reviews*
The primary objectives of an *Implementation Review* are to:

(1) review the available information (including biological data, abundance estimates and data relevant to stock structure issues) to ascertain whether the present situation is as expected (i.e. within the space tested during the development of a *Strike Limit Algorithm* (*SLA*)) and determine whether new simulation trials are required to ensure that the *SLA* still meets the Commission's objectives; and
(2) to review information required for the *SLA*, i.e. catch data and, when available at the time of the *Review*, new abundance estimates (note that this can also occur outside an *Implementation Review* at an Annual Meeting).

2. Timing of *Implementation Reviews*
Regular Implementation Reviews
Implementation Reviews are undertaken regularly, normally every five years. This does not have to coincide with the renewal of catch/strike limits in the Commission. For logistical and resource reasons, only one major *Implementation Review* shall be undertaken at a time. The Committee shall begin planning for the *Review* at the Annual Meeting at least two years before the Annual Meeting at which the *Review* is expected to be finished. This is to enable the Committee to schedule additional work or Workshops if it believes that new information or analyses are likely to be presented that will necessitate the development of new simulation trials. Early planning will enhance the likelihood that the Committee will complete an *Implementation Review* on schedule. It is not expected that every *Implementation Review* will entail a large amount of work.

Special Implementation Reviews
In addition to regular *Implementation Reviews*, under exceptional circumstances the Committee may decide to call for special *Implementation Reviews,* should information be presented to suggest that this is necessary and especially if there is a possibility that the Commission's conservation objectives may not be met.

Calling such a *Review* does not necessarily mean revising the Committee's advice to the Commission, although it may do so. The Committee has not tried to compile a formal comprehensive list of what factors might 'trigger' such an early review, which implies unexpected/unpredictable factors. However, the following list is provided to give examples of some possible factors.

(1) Major mortality events (e.g. suggested by large numbers of stranded animals).
(2) Major changes in whale habitat (e.g. the occurrence of natural or anthropogenic disasters or changes, an oil spill, dramatic change in sea-ice, development of a major oil/gas field, etc.).
(3) Major ecological changes resulting in major long-term changes in habitat or biological parameters.
(4) A dramatically lower abundance estimate (although the *SLA* has been tested and found to be robust to large sudden drops in abundance, the Committee would review the potential causes of unexpected very low estimates).
(5) Information from the harvest and hunters (this might include very poor harvest results, reports of low abundance despite good conditions, reports of large numbers of unhealthy animals).
(6) Changes in biological parameters that may result in changes to management advice (e.g. reproduction, survivorship).
(7) If there are cases when need is not being satisfied, strong information that might narrow the plausibility range and allow an increase in block limits.
(8) A new harvest regime (e.g. the potential hunt of gray whales by the Makah Tribe on the west coast of the USA).

3. Outcomes of *Implementation Reviews*

There are a number of possible conclusions of *Implementation Reviews:*

(1) there is no need to run additional trials and that the existing *SLA* is acceptable;
(2) the results from the additional trials developed and run reveal that the existing *SLA* is acceptable;
(3) there is no need for any immediate additional trials or changes to management advice but work is identified that is required for consideration at the next *Implementation Review*; or
(4) the results of the additional trials require the development of a new (or modified and then retested) *SLA* in which case management advice will have to be reconsidered until that work is complete.

4. Data availability

Implementation Reviews fall under the Committee's Data Availability Agreement Procedure A (IWC, 2004). By the time of the Annual Meeting prior to that at which the *Implementation Review* is expected to be completed, the scientists from the country or countries undertaking the hunts, or others intending to submit relevant analyses, shall develop a document or documents that explains the data that will/could be used for the *Implementation Review*. Such a document will:

(a) outline the data that will be available, including by broad data type (e.g. sighting data, catch data, biological data): the years for which the data are available; the fields within the database; and the sample sizes.
(b) provide references to data collection and validation protocols[1] and any associated information needed to understand the datasets or to explain gaps or limitations; and
(c) where available, provide references to documents and publications of previous analyses undertaken of data.

The data themselves shall be available in electronic format one month after the close of that Annual Meeting.

In the case of complex *Implementation Reviews* that may last more than one year and involve one or more workshops, new data can be submitted, provided that the data are described and made available at least nine months before the Annual Meeting at which the *Implementation Review* is expected to be completed.

5. Computer programs

All non-standard programs used in analyses submitted to the *Implementation Review* shall be lodged with the Secretariat at least at the same time (in accordance with the time schedule provided in DAA Procedure A) as the submission of the papers to which they pertain. The Committee may decide that the programmes need independent validation.

All final trial runs shall be undertaken by the Secretariat using validated programmes.

Report of the Scientific Committee

The meeting was held at the Shilla Jeju Hotel, Republic of Korea from 3-15 June 2013 and was chaired by Toshihide Kitakado. This meeting is SC/65a. The next meeting of the Scientific Committee in May or June 2014 will be SC/65b, and the next meeting of the Commission (IWC/65) will take place during September or October 2014. A list of participants is given as Annex A.

1. INTRODUCTORY ITEMS

1.1 Chair's welcome and opening remarks

Kitakado, the Committee Chair for the first time, welcomed the participants to the 2013 Annual Scientific Committee meeting. He thanked the Government of Korea for hosting the meeting and for providing the excellent facilities and an opening reception. He also expressed his thanks to the IWC Commissioner for Korea, Mr Bok-Chul Chung, for his assistance. The Committee then paused for a moment of silence, with great sorrow, for those who had passed away since the last meeting.

Graham Chittleborough died in October 2012. He gained an international reputation for his work on humpback whales based on the commercial catches off Australia and in the Antarctic following World War II. Graham contributed his knowledge of humpback whales to the work of the 'Committee of Three Scientists on the Special Scientific Investigation of the Antarctic Whale Stocks', attending meetings to review its progress and findings in Rome (1961) and Seattle (1963). He was also the first scientist to recognise the extent of illegal hunting of humpback whales taking place in the Antarctic in the late 1950s-early 1960s.

Malcolm Clarke died in May 2013. He was recognised internationally for his work on oceanic squid, and was well known to and respected by many members of the Scientific Committee for his investigations of squid as the food of sperm whales, in particular his *Discovery Report* based on stomach contents of sperm whales in Southern Hemisphere catches. He also undertook ground-breaking research on sperm whale anatomy, including the use of the spermaceti organ in diving.

Rebecca Leaper died unexpectedly just before the meeting, well before her time. She was a dedicated and passionate marine conservation scientist and spent two years on the Australian delegation as an ecosystem modeller. She had been a key member of science teams at the Australian Antarctic Division, the Tasmanian Aquaculture and Fisheries Institute, CSIRO and most recently at the University of Tasmania's Institute of Marine and Antarctic Science, working on issues ranging from the role of whales in their marine ecosystems through to conservation mechanisms for marine biodiversity. Her passion for her work was matched only by her generosity of spirit.

Captain Leif Petersen, who died in March 2013, never attended the Scientific Committee. However, his dedication, skill and courage as a pilot for pioneering aerial surveys beginning in Greenland and Iceland in the 1980s and eventually for many parts of northern Europe including the more recent SCANS and NASS programmes meant that he contributed as much to conservation and management as any of the scientists who participated. It is important that scientists never underestimate the contribution of pilots, skippers and crews to their work. Leif became an indispensable colleague and lasting friend to many scientists attending the Scientific Committee meeting; several of us are still alive because of him.

Vyacheslav Alekseevich Zemsky died at the age of 93 after a distinguished career in the Soviet Union and the Russian Federation. In the 1970s, he was very active in IWC related issues and the new Russia-US marine mammal working group. Between 1993-2000, Zemsky, with a number of members of the Soviet whaling expeditions, collated all the materials and documents preserved in departmental archives to create a corrected catch history of the whales hunted in the Southern Hemisphere.

1.2 Appointment of rapporteurs

Donovan was appointed rapporteur with assistance from various members of the Committee as appropriate. Chairs of sub-committees and Working Groups appointed rapporteurs for their individual meetings.

1.3 Meeting procedures and time schedule

The Committee agreed to the meeting procedures and time schedule outlined by the Chair.

1.4 Establishment of sub-committees and working groups

As agreed last year (IWC, 2013c, p.59) and included in the draft agenda, a pre-meeting of the sub-committee on the Revised Management Procedure (RMP) met in Jeju on 1-2 June 2013 to begin the *Implementation Review* for North Atlantic fin whales. The report of the pre-meeting is given as Annex D, Appendix 2.

A number of sub-committees and Working Groups were established. Their reports were either made Annexes to this report (see below) or subsumed into the main text of this report.

Annex D – Sub-Committee on the Revised Management Procedure;
Annex D1 – Working Group on the *Implementation Review* for Western North Pacific Common Minke Whales;
Annex E – Standing Working Group on Aboriginal Subsistence Whaling Management Procedures;
Annex F – Sub-Committee on Bowhead, Right and Gray Whales;
Annex G – Sub-Committee on In-Depth Assessments;
Annex H – Sub-Committee on Other Southern Hemisphere Whale Stocks;
Annex I – Working Group on Stock Definition;
Annex J – Working Group on Non-deliberate Human-Induced Mortality of Large Whales;
Annex K – Standing Working Group on Environmental Concerns;
Annex K1– Working Group to Address Multi-species and Ecosystem Modelling Approaches;
Annex L – Sub-Committee on Small Cetaceans;
Annex M – Sub-Committee on Whalewatching;
Annex N – Working Group on DNA;
Annex O – *Ad hoc* Working Group on National Progress Reports;
Annex P – Working Group on Special Permits; and
Annex Q – *Ad hoc* Working Group on Abundance Estimates.

Table 1
List of data received by the IWC Secretariat since the 2012 meeting.

Date	From	IWC ref.	Details
Catch data from the previous season:			
25/04/13	Norway: N. Øien	E108 Cat2012	Individual minke records from the Norwegian 2012 commercial catch.
01/06/13	Japan: T. Sakamoto	E108 Cat2012	Individual data for Japan special permit catch 2012 North Pacific (JARPN II) and 2012/13 Antarctic (JARPA II).
02/06/13	Russia: V. Ilyashenko	E108 Cat2012	Individual catch records from the aboriginal harvest in the Russian Federation in 2012.
03/06/13	Iceland: G. Víkingsson	E108 Cat2012	Individual catch records from the Icelandic 2012 commercial catch.
Sightings data:			
17/04/13	Japan: K. Matsuoka	E106	POWER North Pacific cruise sightings data 2012.
17/04/13	Japan: K. Matsuoka	E107	Data from dedicated sightings surveys in 2012 in the North Pacific under JARPN II.

1.5 Computing arrangements
Allison outlined the computing and printing facilities available for delegate use**.**

2. ADOPTION OF AGENDA
The adopted agenda is given as Annex B.

3. REVIEW OF AVAILABLE DATA, DOCUMENTS AND REPORTS

3.1 Documents submitted
The documents available are listed in Annex C. As agreed last year, for the first time, primary papers were only available at the meeting in electronic format (IWC, 2013c, pp.78-9).

3.2 National Progress Reports on research
As agreed last year, all National Progress Report information usually submitted in paper form was submitted electronically through the IWC National Progress Reports data portal (IWC, 2013c, p.1). Developing such a portal and then expanding it to allow multiple data entry users for each country (the latter had not originally been envisaged two years ago when the portal was agreed) was a major undertaking. The Committee thanked Miller of the Secretariat for the considerable amount of work he had undertaken during the year to make this possible. Inevitably, a number of issues to be addressed and potential improvements to be made arose during the year as the portal began to be used. These were referred to an *ad hoc* Working Group and the Committee **endorses** the report of that Group (Annex O) and its recommendations. It again **recommends** that all member states submit National Progress Reports through the IWC portal (*http://portal.iwc.int*).

3.3 Data collection, storage and manipulation
3.1.1 Catch data and other statistical material
Table 1 lists data received by the Secretariat since the 2012 meeting.

3.1.2 Progress of data coding projects and computing tasks
Allison reported that Version 5.5 of the catch databases was released in February 2013. Work has continued on the entry of catch data into both the IWC individual and summary catch databases, including data received from the 2011 season and some additional information for records from Durban in the 1960s and 1970s. Sightings data from the 2011 POWER cruise (see Annex G, Appendix 2) are being validated.

Programming work during the past year has focused on completing the North Pacific common minke whale *Implementation* trials including amending the control program and conditioning and running trials. Further details are given under Item 6.1.

4. COOPERATION WITH OTHER ORGANISATIONS
The Committee noted the great value of co-operation with other international organisations to its work. The observers' reports below briefly summarise relevant meetings of other organisations. The contributions of several collaborative efforts are dealt with in the relevant sub-committees.

4.1 Convention for the Conservation of Antarctic Marine Living Resources (CCAMLR)
The report of the IWC observer at the 31st Meeting of the CCAMLR Scientific Committee (CCAMLR-SC), held in Hobart, Australia from 22-26 October 2012 is given as IWC/65/4(2013)A. The main items considered at the CCAMLR meeting of relevance to the IWC included: (1) fishery status and trends of Antarctic fish stocks, krill, squid and stone crabs; (2) incidental mortality of seabirds and marine mammals in fisheries in the CCAMLR Convention Area; (3) harvested species; (4) ecosystem monitoring and management; (5) management under conditions of uncertainty about stock size and sustainable yield; (6) scientific research exemption; (7) CCAMLR Scheme of International Scientific Observation; (8) new and exploratory fisheries; and (9) joint CCAMLR-IWC Workshop with respect to ecosystem modelling in the Southern Ocean.

Reports of the Scientific Committee (SC-CCAMLR) and its Working Groups on Ecosystem Monitoring and Management (WG-EMM) and Fish Stock Assessment (WG-FSA) and their various subgroups are available through the CCAMLR secretariat and on the CCAMLR website[1].

The CCAMLR Working Group on Incidental Mortality in Fisheries (WG-IMAF) did not meet in 2012 and no new information on cetacean-fisheries interactions in the Southern Ocean became available to CCAMLR. The next meeting of the Working Group is likely to take place prior to the annual meeting of CCAMLR in 2013.

The Committee thanked Kock for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next CCAMLR-SC meeting.

4.2 Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES)[2]
The Committee did not receive a report from an observer at the 2013 meeting of the Conference of the Parties (3-14 March 2013).

4.3 Convention on the Conservation of Migratory Species (CMS)[3]
4.3.1 Scientific Council
There was no meeting of the Scientific Council during the intersessional period.

[1] *http://www.ccamlr.org/.*
[2] *http://www.cites.org.*
[3] *http://www.cms.int.*

4.3.2 Conference of Parties (COP)
There was no Meeting of the Parties during the intersessional period.

4.3.3 Agreement on Small Cetaceans of the Baltic and North Seas (ASCOBANS)[4]
The report of the IWC observer at the 7th Meeting of the Parties (MoP) to ASCOBANS, held in Brighton, UK from 22-24 October 2012 is given as IWC/65/4(2013)G. The main results from the meeting are summarised below.

(1) The Conservation Plan for the Harbour Porpoise Population in the Western Baltic, the Inner Danish Waters and the Kattegat was adopted. The main aim of the plan is to intensify research and conservation efforts for harbour porpoises in this area.
(2) Work on the Baltic Sea Recovery Plan (Jastarnia Plan) and the North Sea Conservation Plan were reviewed. The implementation of these will continue to be of importance over the next three years.
(3) Bycatch and underwater noise were identified as future priorities. The impact of marine debris on cetaceans will also be considered.
(4) A better understanding of how new and often lesser-studied contaminants affect individuals and populations is needed. Limiting the introduction of chemical substances into the marine environment should be considered.
(5) The western part of the ASCOBANS area has a large diversity of whale and dolphin species, but knowledge of their abundance and distribution as well as the magnitude of different threats remains scarce. Collaboration for research and conservation action in this area is needed.
(6) In general, cooperation and interaction with the European Commission, other international organisations, fishery and other economic sectors, NGOs and non-Party Range States should be strengthened.
(7) The 4th ASCOBANS Outreach and Education Award 2012 was given to Mats Amundin of Kolmården Djurpark in Sweden for his work in promoting the conservation of harbour porpoises.

No observer for the IWC attended the 20th meeting of the Advisory Committee to ASCOBANS.

The Committee thanked Scheidat for her report and **agrees** that she should represent the Committee as an observer at the next ASCOBANS Meeting of Parties and Advisory Committee meeting.

4.3.4 Agreement on the Conservation of Cetaceans of the Black Sea, Mediterranean Sea and Contiguous Atlantic Area (ACCOBAMS)[5]
Donovan attended the 2012 meeting of the ACCOBAMS Scientific Committee (ASC) held in Monaco from 13-15 November 2012 and his report is given as IWC/65/4(2013) L. The full report of the meeting can be found on the ACCOBAMS website.

A number of recommendations were made. The first concerned the long-standing (nine-year) recommendation, also endorsed by the IWC Scientific Committee, for an ACCOBAMS Survey Initiative. The ASC strongly endorsed an updated basinwide survey plan, agreed on the need for synergies with other efforts in the North Atlantic and on the need to hire a co-ordinator. It noted news of a survey funded by DG-Mare that will cover about 25% of the Black Sea in summer 2013. However, it strongly recommended that the whole of the Black Sea be covered synoptically and urged ACCOBAMS to do all it could to ensure this and not miss a unique opportunity.

A second recommendation addressed the continued live removals of bottlenose dolphins in the Black Sea. The ACCOBAMS Secretariat was asked to send a letter of concern to the Georgian and Ukrainian governments (copied to the Bern Convention Secretariat, the Black Sea Commission and the CITES Secretariat) recalling the illegality of live removals of cetaceans from the Black Sea and asking them to carry out an inventory and thorough assessment of individual identity of all bottlenose dolphins kept in captivity by means of genetic, morphological and photo-id methods and to provide appropriate administrative measures in order to prevent substitution of dolphins that die in captivity by animals taken from the wild. The ASC noted that the IWC Scientific Committee has guidelines on the practical aspects of the use of DNA registers for cetaceans.

The ASC also agreed to work towards a Conservation Plan for fin whales of the Mediterranean. It noted: (1) the importance of continuing work to elucidate the stock structure and movements of fin whales in the ACCOBAMS area; (2) the importance of the ACCOBAMS Survey initiative to provide a summer snapshot of distribution throughout the whole region as well as a reliable estimate of total abundance; (3) that all of the groups working in the area be asked to update available information on fin whales, including those related to potential threats (e.g. see the work of Fossi on micro-plastics, Fossi *et al.*, 2012) and to consult on priorities for future work with a focus on conservation; and (4) that an outline draft Conservation Plan be developed for consideration at the next ASC, with a view to reviewing whether the time is ripe to engage with stakeholders to develop a full plan.

The ASC also developed a statement of concern over the ongoing seismic survey work in the area of the Hellenic Trench. In particular, it requested all involved in the planned surveys to provide information to the ASC and take urgent precautionary action to protect the local cetaceans. The ASC offered to provide advice and drew attention to the ACCOBAMS guidelines for seismic surveys, and urged that: duplicate surveys should be avoided across the same area, alternative approaches to seismic airgun survey should be sought and deployed and efforts should be made to avoid ensonifying adjacent areas simultaneously.

ACCOBAMS and the IWC have been working together on ship strikes for some time. ACCOBAMS agreed that the work should continue, welcomed the appointment of the ship strikes co-ordinators (one of whom is the Chair of the ASC ship strikes working group) and reiterated its support for the global database and existing monitoring and mitigation efforts. The ASC ship strikes working group will continue to work on these issues and foster collaboration with IWC, ASCOBANS, CMS and IMO and develop priority actions and studies, including the consideration of a project to develop a standard training module.

Finally, the ASC developed a recommendation on scientific aspects of whalewatching. It noted that an 'ACCOBAMS certificate of accreditation for whale watching' will be developed and agreed that this should take into account the ACCOBAMS Whale Watching Guidelines. It also supported the continuation and expansion of national or regional training courses (based on the PELAGOS expertise) for operators covering the biology of animals,

[4]*http://www.ascobans.org.*
[5]*http://www.accobams.org.*

risks, boat behaviour around the animals, how to achieve ACCOBAMS accreditation, involvement in scientific research, etc. The ASC will continue to consider potential adverse effects on cetaceans and means to mitigate these. It also urged monitoring the activity of whale-watching operators in each country in order to obtain information on growth and development to try to identify potential problems before they become too difficult to manage. Finally it agreed to assist in the development of methods to better inform the general public about responsible boat behaviour around cetaceans. The ASC noted the importance of continued co-operation with IWC and others on this issue.

The Committee thanked Donovan for his report and **agrees** that he should represent the IWC at the next ACCOBAMS meeting.

4.4 Food and Agriculture Organisation of the United Nations (FAO)

No observer for the IWC attended the 2012 meeting of FAO.

4.5 Inter-American Tropical Tuna Commission (IATTC)

The reports of the IWC observer at the 83rd and 84th meetings of the IATTC held in La Jolla, USA 25-29 June 2012 and 24 October 2012 respectively are given as IWC/65/4(2013) E. The Antigua Convention came into force on 27 August 2010 and under this the IATTC is expected to give greater consideration to non-target and associated species, including cetaceans, in taking management decisions. A summary was given of ongoing work describing what is known about the direct impact of the fisheries on other species in the ecosystem and the environment. This ongoing work will shape future directions of AIDCP (see Item 4.6) and IATTC measures aimed at managing fisheries and conserving dolphins.

The Committee thanked Rusin for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next AIDCP meeting.

4.6 Agreement on the International Dolphin Conservation Program (AIDCP)

The report of the IWC observer at the 25th and 26th Meetings of the Parties to the AIDCP held in La Jolla, USA on 19 June 2012 and 23 October 2012 respectively is given as IWC/65/4(2013)F. The AIDCP mandates 100% coverage by observers of fishing trips by purse seiners of carrying capacity greater than 363t in the agreement area and in 2012 all trips (746) by such vessels were sampled by independent observers.

The overall dolphin mortality limit (DML) for the international fleet in 2012 was 5,000 animals and the unreserved portion of 4,900 was allocated to 84 qualified vessels that requested DMLs. In 2012, no vessel exceeded its DML. The number of sets on dolphin associated schools of tuna made by vessels over 363t has been increasing in recent years, from 9,246 in 2008 to 10,910 in 2009 to 11,645 in 2010, however fewer were made in 2011 (9,604) and 2012 (9,220). While fewer dolphin sets were made in 2011 and 2012, this remains a frequent practice and the predominant method for catching yellowfin tuna by purse-seine in the ETP. There have been insufficient resources to conduct dolphin and ecosystem assessment surveys since 2006 so it is unclear when updated abundance estimates for cetaceans in the ETP will be available.

In 2011 and 2012, the AIDCP focused significant discussion on consideration of reducing observer coverage and developing an 'Ecosystem Friendly' certification scheme for tuna caught in association with dolphins. Due to the increasing sentiment among some Parties that the dolphin problem has been solved and that dolphin-fishing methods are better economically and environmentally than dolphin-safe methods, in 2013 the AIDCP Parties are expected to continue consideration of these proposals and others that have the potential to increase fishing effort on dolphins and the magnitude of associated direct and indirect effects of this practice.

The Committee thanked Rusin for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next AIDCP meeting.

4.7 International Committee on Marine Protected Areas (ICMMPA) and IUCN Marine Mammal Protected Areas Task Force

The International Committee for Marine Mammal Protected Areas was formed as an international committee of experts in 2006 to address common issues and challenges faced by scientists and managers using spatial management tools to manage and conserve important cetacean habitats or populations. In 2008, the IWC endorsed and supported a proposal by ICMMPA to host the first international conference on marine mammal protected areas, in 2009. Since that time, the ICMMPA has undertaken several initiatives and has co-hosted, with France, a second conference in Martinique, in 2011[6]. In October 2012 the ICMMPA met in La Rochelle, France, hosted by l'Université de La Rochelle. The primary agenda for the meeting was to develop the mission statement, terms of reference and structural organisation of the newly approved IUCN arm of ICMMPA. This partner organisation is a Task Force on Marine Mammal Protected Areas. These documents were developed and will be available from the new Task Force co-chairs Erich Hoyt and Giuseppe Notarbartolo di Sciara, once the Task Force is officially announced. The IUCN MMPA Task Force membership includes all of the ICMMPA members, with several IUCN member additions. The ICMMPA remains a non-governmental partner for the Task Force and, amongst other tasks, will convene conferences and other initiatives that may not fit the IUCN Task Force terms of reference. The IUCN MMPA Task Force will be officially announced at IMPAC3 in October 2013.

ICMMPA is currently working with the Government of Australia, who will host the third International Conference on Marine Mammal Protected Areas, at a venue in Adelaide in November 2014.

4.8 International Council for the Exploration of the Sea (ICES)[7]

The report of the IWC observer documenting the 2012 activities of ICES is given as IWC/65/4(2013)B. The ICES Working Group on Marine Mammal Ecology (WGMME) met 5-8 March 2012.

The WGMME built on the work of the ASCOBANS/HELCOM small cetacean population structure workshop to determine Management Units (MUs) for the more common species as such information is relevant to the development of biodiversity indicators. Based on the available information, there were single MUs in the European North Atlantic for common dolphins, white-beaked dolphins, white-sided dolphins and common minke whale. For bottlenose dolphins there are ten separate units closely associated with the mainly

[6] *http://second.icmmpa.org.*
[7] *http://www.ices.dk.*

resident inshore populations in the European North Atlantic and a separate MU for the wider ranging mainly offshore animals. For harbour porpoises, MUs are proposed for the Iberian Peninsula, Bay of Biscay, Celtic Sea and northwest Ireland/west Scotland and the North Sea. The MUs for harbour porpoises will need to be revisited as indicators for the Marine Strategy Framework Directive (MSFD) become better defined.

The WGMME considered biodiversity indicators and bycatch was the only indicator suggested that had a clear link with a particular human activity. The indicator metric proposed by ICG-COBAM was very clearly linked to OSPAR's EcoQO on harbour porpoise bycatch in the North Sea. With pressure for the rapid development of biodiversity indicators for good environmental status through the Marine Strategy Framework Directive (MSFD), it is essential that they are based on sound science and take a pragmatic approach to the incorporation of fisheries data. As such, it was proposed that a management framework approach is adopted (rather than the EcoQO approach) and further developed in 2013 for relevant species.

WGMME conducted a review of the effects of wave energy converters on marine mammals and provided recommendations on research, monitoring and mitigation schemes. These are at a relatively early stage of development when compared to other renewable energy technologies and this is reflected in the lack of knowledge of their effects on the marine environment. It is essential that full advantage is taken of test deployments and early arrays to gather information on the actual interactions between devices and wildlife. A review of such work is being undertaken during 2013.

The ICES Working Group on Bycatch of Protected Species (WGBYC) met on 7-10 February 2012. It reviewed the status of information on recent bycatch estimates and assessed the extent of the implementation of bycatch mitigation measures. Reports from 17 member states indicated extrapolated estimates of bycatch for 2010 of about 870 cetaceans. The species involved were striped dolphins, common dolphins, harbour porpoises and bottlenose dolphins. Estimates are patchy and monitoring obligations not being met by several member states. Implementation of bycatch mitigation measures was also found to be poor, with few countries able to confirm that obligations for pinger deployment were being met.

The 2012 ICES Annual Science Conference (ASC) was held in Bergen, Norway 17-21 September 2011. Some sessions were designed with marine mammals included as an integral part. A number of sessions were of relevance to the Committee, including those describing:

(1) bycatch and discards;
(2) consequences of improved survey performance on assessments and management advice; and
(3) how does renewable energy production affect aquatic life?

The Committee thanked Haug for the report and **agrees** that he should represent the Committee as an observer at the next ICES meeting.

4.9 International Maritime Organization (IMO)[8]

The report of the IWC observer to the IMO is given as IWC/65/4(2013)J. The IWC has contributed to IMO discussions on addressing ship strikes and the impacts of underwater noise from shipping. In December 2012, IMO adopted changes to the shipping lanes in the Santa Barbara Channel, and off San Francisco, California, USA in order to reduce ship strike risk to blue whales (COLREG.2/Circ.64).

The IMO has been developing non-mandatory technical guidelines to minimise underwater noise from commercial ships. These include available options for ship-quieting technologies and operational practices. In April 2013, the IMO correspondence group working on the issue (including participation by the IWC Secretariat) presented draft guidelines to the IMO sub-committee on ship design and equipment (DE57/17). The guidelines help establish a consistent approach to assist designers, ship owners and ship operators in evaluating how much noise reduction is possible for new and existing ships when compared to existing ships of similar type, size and propulsion system. The IMO Marine Environment Protection Committee (MEPC) is expected to approve the guidelines in early 2014 and make them available as an MEPC circular.

The IMO also continued to develop a mandatory Polar Code. This is intended to augment existing measures to reduce the environmental impacts of shipping in polar waters, taking into account their greater environmental sensitivity. This work will continue through 2013.

The Committee thanked Leaper for his report and **agrees** that he (or the Secretariat) should represent the Committee at the next IMO meeting.

4.10 International Union for the Conservation of Nature (IUCN)[9]

Cooke and Reeves, the IWC observers, reported on the considerable cooperation with IUCN that had occurred during the past year and this is given as IWC/65/4(2013)I.

World Conservation Congress

The World Conservation Congress was held on Jeju Island, Korea in September 2012. There were three cetacean-related events at the Congress: a workshop on lessons learned from the IUCN western gray whale conservation initiative; a poster presentation on the local population of Indo-Pacific bottlenose dolphins found around Jeju; and a workshop on cetacean conservation and whalewatching in Africa. IUCN issued a number of statements on Korean environmental issues, including on the possible resumption of whaling in Korean waters.

Western gray whales

Two further meetings of the IUCN Western Gray Whale Advisory Panel have been held in the past year, in November 2012 in Korea and in May 2013 in Japan. At the time of writing, the report of the May meeting is not yet available but a summary of results can be found in Annex F, Appendix 5. An updated population assessment was received by the Panel but the data from the two independently collected series of photo-id data yielded apparently discrepant results, one indicating an increasing population and the other indicating a stable or declining population. An assessment based on one of these data sets is available as SC/65a/BRG27.

Red List updates

Updates since the last Annual Meeting include listing of the Mediterranean 'subpopulations' of the following species: sperm whale (Endangered), fin whale (Vulnerable), striped dolphin (Vulnerable), common bottlenose dolphin (Vulnerable), Cuvier's beaked whale (Data Deficient), long-finned pilot whale (Data Deficient) and Risso's dolphin (also Data Deficient).

[8]*http://www.imo.org.*

[9]*http://www.iucn.org/.*

A current list of all cetacean species and populations that have been assessed for the Red List, and their current Red List classification, is maintained on the Cetacean Specialist Group site[10] with links to the assessments which are held on the Red List website[11].

Cetacean Specialist Group
IUCN Cetacean Specialist Group members have continued to actively assist with cetacean conservation and research projects around the world. Of particular current interest is the ongoing project on study of the status and management options for the Critically Endangered Mekong river population of Irrawaddy dolphins run by WWF Cambodia in co-operation with relevant public authorities. The website of the IUCN Cetacean Specialist Group[12] contains regular updates on IUCN's cetacean-related activities and other work in which group members are involved.

The Committee thanked Cooke and Reeves for their report and **agrees** that Cooke should continue to act as observer to IUCN for the IWC.

4.11 North Atlantic Marine Mammal Commission (NAMMCO)[13]

4.11.1 Scientific Committee
The report of the IWC observer at the 19th meeting of the NAMMCO Scientific Committee (NAMMCO SC) held in Tasiilaq, East Greenland from 19-22 April 2012 is given as IWC/65/4(2013)K.

A joint Norwegian-Russian Ecosystem Survey examined habitat use and prey associations of white-beaked dolphins in late summer. Dolphins used the southern Atlantic waters and the Polar Front area farther north, with a general overlap with most prey species and positive association with blue whiting in the southern habitat.

Catch and bycatch data from 2006-08 from a monitored segment of the Norwegian fleet of coastal gillnetters were used to estimate bycatch rates of harbour porpoises in Norway. Landings statistics were used to extrapolate to the entire fishery, estimating a total annual bycatch of 6,900 porpoises by the two fisheries. The bycatch numbers of harbour porpoises could also be high in Iceland, based on preliminary information presented to the NAMMCO-ICES workshop in 2010. The NAMMCO-SC recommended that total bycatch estimates be attempted and that assessments of sustainability proceed through the relevant Working Groups.

NARWHALS-WEST GREENLAND/CANADA
The NAMMCO-SC agreed on the metapopulation structure for narwhals in Baffin Bay, Hudson Bay and adjacent waters as a useful approach for identifying summer aggregations as management units in narwhals. Satellite tracking of whales that return to summering grounds the following year suggest interannual site fidelity, with summer aggregations to some extent being demographically-independent sub-populations with minimal or no exchange of animals. Narwhals in Canada constitute five separate stocks with some limited exchange between three of the stocks.

There had been an overall increase in West Greenland narwhal catches during the 20th century which was especially pronounced after 1950. However since 1993, a significant decline in overall catches has been observed. Aerial surveys conducted in the North Water in May resulted in fully corrected abundance estimates of 10,677 (95% CI: 6,120-18,620) narwhals in 2009 and 4,775 (95% CI: 2,417-9,430) in 2010.

Age estimation by racemization was used to estimate biological parameters of narwhals, including a maximal lifespan expectancy of ~100 years of age.

NARWHALS IN EAST GREENLAND
Satellite tracking showed that narwhals in East Greenland have a yearly migration where they leave the fjords and move off the coast in winter. Whales from the Scoresby Sound area seem to belong to a stock separate from other narwhal aggregations in East Greenland. Age-structure data from Ittoqqortormiit was applied to assessments of both East Greenland areas, and the harvest was found to select for older animals. The current annual growth rate in the absence of harvest was estimated between 1.2% (95% CI:0-3.5) and 3.7% (95% CI:1.6-5.9), depending upon model and area.

It was noted that there is little information on the predicted response of marine mammals to changing Arctic conditions including changes in sea ice, climate and prey species as well as increased human development activity such as seismic, shipping, and drilling. The NAMMCO-SC recommended holding an international symposium on the effect of seismic and other development activities on Arctic marine mammals with a focus on white whales and narwhals.

WHITE WHALES
Aerial surveys conducted in the North Water in May resulted in fully corrected abundance estimates of 2,008 (95% CI 1,050-3,850) white whales in 2009 and 2,482 (95% CI 1,439-4,282) in 2010.

The assessment of West Greenland white whales was updated with age-structured data, recent abundance estimates and catches. Results from different scenarios provided annual growth rate estimates from 3.2% to 5%, in the absence of harvest. The depletion ratio for 2012 was estimated as 44% (95% CI: 16%-88%), with a yearly replacement of 510 (95% CI:170-780) individuals. The NAMMCO-SC agreed that the revised assessment confirmed that the current removals based on the 2009 advice are sustainable. Based on a 70% probability of population increase, it concluded that a total annual removal of 310 white whales in West Greenland is sustainable (excluding Qaanaaq).

No specific advice was given on the North Water (Qaanaaq), since the current removals remain at a low level relative to the population size. No advice was given for the harvest in Canada.

AGE DETERMINATION WORKSHOPS
Recognising that there are a number of problems with age determination for white whales and narwhals, three age determination workshops were organised. The first in Tampa (FL, USA) examined the state of the art of general ageing techniques; the second in Beaufort (NC, USA) focused on age estimation of belugas using teeth; and the third in Copenhagen (Denmark) focused on the use of tusks for age estimation in narwhals.

The NAMMCO-SC agreed that an annual deposition rate of tooth GLG was to be the accepted standard in white whales, and it recommends that aspartic acid racemisation is applied to white whales, including fore known history/age animals in the analyses in order to calibrate the technique and provide an alternative ageing method.

PILOT WHALES
The NAMMCO-SC agreed that it was unlikely that a full pilot whale assessment could be attempted in the near future.

[10]*http://www.iucn-csg.org/index.php/status-of-the-worlds-cetaceans.*
[11]*http://www.redlist.org.*
[12]*http://www.iucn-csg.org/.*
[13]*http://www.nammco.no/.*

It was noted that both an adapted 'AWMP' procedure as well as the PBR approach could be used for an inverse advice calculation of the minimum abundance required to sustain the average take by the Faroese.

With the average annual catch by the Faroese since 1997 being 678, and the CV of the latest abundance estimate being 0.27, the AWMP procedure estimates that an abundance estimate around 50,000 pilot whales and a similar precision is required to sustain the catch. In comparison, the PBR approach calculates an abundance estimate around 80,000 whales. These calculations reflect precautionary estimates of the minimum abundance estimates required to sustain the Faroese hunt. However, the geographical range of the stock(s) that supply the Faroese hunt is unknown, and it is unresolved how the calculated estimates compare with the accepted estimate of 128,000 (95% CI: 75,700-217,000) pilot whales from the Icelandic and Faroe Islands area of T-NASS.

The average annual catch of long-finned pilot whales in West Greenland during 1993-2007 was 126 whales and an aerial survey estimated 7,440 (95% CI 3,014-18,367) animals in 2007. Applying a PBR approach, the sustainable harvest level of pilot whales would be around 50 whales per year. An estimate based on the AWMP procedure suggests that an annual take of 70 whales is sustainable. However, the survey did not cover the entire range of pilot whales in West Greenland and the summer aggregation cannot be considered an isolated stock. Instead, it is likely connected to pilot whales along Labrador and at Newfoundland.

The NAMMCO-SC noted that humpback whales are present in previously unsurveyed areas off East Greenland, in agreement with information provided by observers on seismic surveys.

The average annual catch of white-beaked dolphins in West Greenland during 1993-2007 was 30 dolphins. An aerial survey estimated 11,801 (95% CI 7,562-18,416) animals in 2007. Applying a PBR approach suggests that the sustainable harvest level would be around 125 whales per year.

A bowhead whale male tagged in Disko Bay in May 2010 moved into the Northwest Passage where it spent about two weeks in September 2010 in close proximity to a bowhead whale tagged in Alaska in spring the same year. Both returned to their normal seasonal range, but the excursions suggest that bowhead whales from the Pacific and the Atlantic occasionally may be connected in years with little sea ice in the Northwest Passage.

Based on an increase in sightings, the NAMMCO-SC recommended monitoring of trends and abundance of the Spitsbergen population of bowhead whales. Norway will continue passive acoustic monitoring with two extra devices in the northern Fram Strait and north of Svalbard.

SURVEY PLANNING

A new large-scale T-NASS survey of cetaceans in the North Atlantic is desirable within the near future, and the NAMMCO-SC discussed how best to approach such a large-scale survey effort. The most optimal year for a large scale coordinated survey is 2015. The survey plans for the different countries are generally similar to those of the last T-NASS survey.

4.11.2 Council

The report of the IWC observer at the 21st Annual Council Meeting of NAMMCO held in Svolvær, Norway from 11-13 September 2012 is given as IWC/65/4(2013)C. In 2010, the Council approved the go-ahead for a manual on hunting. It will be the first comprehensive manual for hunters that details weaponry and ballistics information with a focus on safety.

An international expert group on killing methods for small cetaceans met in November 2011. Significant reductions in killing times have been recorded in recent years in the Faroe Islands, Greenland, Japan and Nunavut Canada, due to development of new equipment and practices. Several recommendations were made regarding further improvement in killing methods, safety and training of hunters.

The Council has concluded that an abundance of pilot whales in the range of 50,000-80,000 animals will sustain the annual Faroese drive hunt. The most recent abundance estimate for the pilot whale stock is 128,000 in the Iceland-Faroese survey area. This means that the annual Faroese catch of pilot whales is well within sustainable limits.

Based on a NAMMCO initiative, a project has been designed to test different modelling approaches of interactions between marine mammals and fisheries. The project, which includes scientists both from NAMMCO and other relevant countries, will start as soon as funding is obtained.

The Committee thanked Sakamoto for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next NAMMCO Council Meeting.

4.12 North Pacific Marine Science Organisation (PICES)[14]

The report of the IWC observer at the 21st annual meeting of PICES held from 12-21 October 2012 in Hiroshima, Japan is given as IWC/65/(2013)H. The Marine Birds and Mammals Advisory Group (AP-MBM) requested that a seabird observer be included in the IWC-POWER cruise and it also revised its terms of reference as follows:

(1) provide information and scientific expertise to BIO and the FUTURE Program, and, when necessary, to other scientific and technical committees with regard to the biology and ecological roles of marine mammals and seabirds in the PICES region;
(2) identify important problems, scientific questions, and knowledge gaps for understanding the impacts of climate change and anthropogenic factors on MBMs in ecosystems of the PICES region through Workshops, Theme Sessions and Science Reports;
(3) assemble information on the status and key demographic parameters of marine mammals and seabirds and contribute to the Status Reports; and
(4) improve collaborative, interdisciplinary research with marine mammal and seabird researchers and the PICES scientific community.

Two sessions at the 2012 AP-MBM workshop were of relevance to the IWC, these were:

(1) the feasibility of updating prey consumption by marine birds, marine mammals, and large predatory fish in PICES regions; and
(2) environmental contaminants in marine ecosystems: seabirds and marine mammals as sentinels of ecosystem health.

The Committee thanked Kato for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next PICES meeting.

[14]*http://www.pices.int/.*

4.13 Protocol on Specially Protected Areas and Wildlife of the Cartagena Convention for the Wider Caribbean (SPAW)[15]

The report of the IWC observer to SPAW is given as IWC/65/4(2013)D. At its 5th meeting of the Scientific and Technical Advisory Committee, held 22nd October 2012, SPAW recommended that collaboration with the IWC should be strengthened through the possible conclusion of a Memorandum of Cooperation.

The three-year Spain-UNEP LifeWeb Project comes to an end in December 2013. Under this, a number of activities have been completed including:

(1) broad-scale regional mapping of migration routes, critical habitats and human threats after compilation of available information and datasets; and
(2) a regional workshop on integration, mapping, GIS analysis of marine mammal migration routes, critical habitats and human threats in the wider Caribbean Region (WCR) held in Miami, Florida, 9-11 May 2011.

As a result of this work, regional maps and factsheets have been produced on the following issues:

(1) distribution of the 25 marine mammals species that occur regularly in the WCR (24 cetaceans and the West Indies manatee);
(2) species' richness;
(3) main threats and human impacts faced by marine mammals: pollutions, interactions with fisheries, maritime traffic, etc.; and
(4) existing policies, marine protected areas and governance for the conservation of marine mammals.

SPAW has developed a management plan for the Marine Mammal Sanctuary of the Dominican Republic and a learning exchange on the economic benefits of whalewatching was organised in March 2013 in Samaná, Dominican Republic.

A workshop on broadscale marine spatial planning and transboundary marine mammal management was held in Panama in May 2012. Participants were trained in marine spatial planning applied to marine mammals. As a result of this workshop, two sub-regional areas have been approved for the future scenario work in the WCR, due to their importance as habitats for marine mammals and to existing work and ongoing cooperation dynamics on marine mammals. The first sub-region proposed ranges from the Dominican Republic down to Trinidad and Tobago through the Lesser Antilles, with a focus on strengthening the links between existing or projected marine mammal sanctuaries and on developing other cooperation activities with the neighbouring islands.

The second sub-region encompasses the continental coast of Latin America from Venezuela to the border between Brazil and French Guiana, together with the Dutch Caribbean islands of Aruba, Bonaire and Curacão being included in the area. The scenario work in this second area will foster support to the already started cooperation between these countries and territories, particularly through a technical workshop held in Suriname in March 2013.

The IWC and Caribbean Environmental Programme (CEP) Secretariats have partnered in order to convene three workshops on the topics of entanglement and ship strike for the wider Caribbean countries. It was recognised that the IWC has the international technical expertise in understanding and responding to these human impacts and as such can provide the countries of the WCR access to this expertise through capacity building training and workshops. The first of two capacity building trainings on determining human impact and entanglement response training was conducted in English and Spanish in Mexico in November 2012.

The Committee thanked Carlson for attending on its behalf and **agrees** that she should represent the Committee as an observer at the next SPAW meeting.

4.14 Commission of the South Pacific (CPPS, Comisión Permanente del Pacífico Sur)

The report of the observers at the Meeting of the Parties to CPPS, held in Guayaquil, Ecuador from 10-12 April 2013 is given as IWC/65/4(2013)F. Mattila presented an overview of the global scope of the large whale entanglement issue and described the training currently offered through the IWC by the technical adviser and other members of the IWC expert advisory panel on this topic. Subsequently, the national representatives of the CPPS countries consulted with the Government of Ecuador, which had made an earlier formal request of the IWC Secretariat for National training for Ecuador. As a result of these consultations, Ecuador has agreed to host an IWC entanglement response training that will include participation by up to three participants from the other CPPS countries. Ecuador, CPPS and NGOs will provide the logistical and financial support for the training, and the IWC will provide the trainers and curriculum. The training will be held in Salinas, Ecuador, 27-28 June 2013.

It is anticipated that this training may stimulate requests for full national training from some other CPPS member countries. It may also represent a model or mechanism by which the two Conventions can conduct cooperative work in order to advance common goals to reduce human impact to cetaceans.

The Committee thanked Mattila and Félix for their joint report and also Mattila for attending on its behalf and **agrees** that he should represent the Committee at the next CPPS meeting.

5. REVISED MANAGEMENT PROCEDURE (RMP) – GENERAL ISSUES

5.1 Complete the MSY rates review

Since 2007, the Committee has been discussing maximum sustainable yield rates (MSYR) in the context of a general reconsideration of the plausible range to be used in population models used for testing the *Catch Limit Algorithm* (*CLA*) of the RMP (IWC, 2008b; 2009a; 2009c; 2010b; 2010c; 2010e; 2011d; 2011g; 2012b). The current range is 1% to 7%, in terms of the mature component of the population. Last year, the Committee agreed that no more than one further year should be allowed to complete the review, and that if it could not be completed this year, the current range (MSYR 1-7% in terms of the mature component of the population) would be retained.

5.1.1 Report of the intersessional Workshop

As part of the work plan agreed last year to complete the review, an intersessional Workshop was held in La Jolla, USA in March 2013 and a detailed summary and review of its report (SC/65a/Rep5) is given in Annex D, item 2.1.1. While the Workshop made considerable progress, it was not able to develop recommendations on the appropriate range of MSYR rates. Rather, it identified four areas of work that would assist discussions at this meeting. It also identified three main issues requiring discussion at the Annual Meeting:

[15]*http://www.cep.unep.org/cartagena-convention*.

(1) limitations of the modelling approach itself;
(2) limitations within the approach (e.g. paucity of data); and
(3) interpretation of the results in the context of the RMP.

The Committee thanked Donovan for chairing the intersessional Workshop and the participants for their work during it and subsequently, without which it would not have been possible to conclude the MSYR review at this meeting (see below).

5.1.2 Discussion including work completed since the Workshop

SC/65a/RMP09 presented results from an energetic model presented to the MSYR Workshop. The model was used to predict variability in the realised rate of increase (r_0) in a generic depleted whale population given estimates of the variability and autocorrelation in birth-rates. The Committee thanked de la Mare for conducting the analyses. The individual-based population dynamics model was reviewed by the EM group (see Annex K1).

None of the model runs conducted in SC/65a/RMP09 led to estimates of MSYL that were 0.6 or larger. In addition, Cooke (2007) had shown that MSYL was closer to 0.5 than to 0.6 based on simulations in the context of a model with environmental effects for a wide range of parameter values. The Workshop had identified two scenarios for consideration with respect to the relationship between $MSYR_{1+}$ and r_0: $MSYR_{1+}=r_0/2$ and $MSYR_{1+}=r_0/1.619$. The latter scenario corresponds to $MSYL_{1+}=0.6$. Given the results in SC/65a/RMP09 and in Cooke (2007), the Committee **agrees** that $MSYR_{1+}=r_0/2$ was more appropriate for drawing inferences regarding the range of MSY rates for use in trials.

A key component of the work over the period of the review had been directed at a meta-analysis of observed rates of increase at low population size. SC/65a/RMP08 provided the results of a final sensitivity test for the Bayesian hierarchical meta-analysis using the data for rates of increase for the 13 baleen whale stocks selected in SC/65a/Rep05. The extent of environmental variation in r_0 as a function of r_0/r_{max} in SC/65a/RMP08 was determined from Equation 2 in SC/65a/RMP09. The lower 5% and 10% points of the posterior predictive distribution for r_0/r_{max} for an unknown stock for this sensitivity test were 0.419 and 0.512 respectively. SC/65a/RMP02 constructed a posterior predictive distribution for an unknown stock for r_0 rather than r_0/r_{max}. The lower 5% and 10% points of this posterior predictive distribution were 0.029 and 0.037 respectively. The Committee thanked Punt for his work in undertaking these analyses.

The Committee recognised the considerable additional work that had been undertaken since the current range for (1% to 7% in terms of the mature component of the population) was selected in 1993 (IWC, 1994c, p.57). In particular, since 2007, the Committee had *inter alia:*

(1) assembled and evaluated information on rates of increase for stocks at low population size;
(2) explored some of the impacts of environmental effects on r_0 relative to r_{max} and the shape of the yield curve for exploited baleen whales; and
(3) developed a meta-analysis framework to integrate this information, along with information on demographics, to derive a probability distribution for r_0 and r_0/r_{max}.

Given the available information and knowledge, the Workshop had explored the sensitivity of the distribution for r_0/r_{max} to a number of factors, including choices of stocks from amongst those for which suitable data were available and to the potential effects of environmental variation on rates of increase (see Annex D, table 4). The Committee recognised that while the meta-analysis was an important advance, it was inevitably limited for a number of unavoidable reasons including uncertainty over a number of factors, as described in Annex D, item 2.1.3.

In conclusion, despite these uncertainties, the Committee **agrees** that it has a better basis to select the range for MSYR for use in trials than when the 1% to 7% choice had been made in 1993. In completing the review this year it recognised that this did not mean that additional work should not continue and be periodically reviewed by the Committee, both in a general sense and as part of *Implementations* and *Implementation Reviews.*

Given its importance in terms of meeting conservation objectives, discussion focused on the lower bound for MSYR for use in trials, based on the assumption MSYR $\sim r_0/2$. A number of options were considered when examining the results of the meta-analysis relating to choice of percentile (5% or 10%), the value for r_{max}, and whether the meta-analysis should be based on r_0 or r_0/r_{max}. A broad consideration of the full set of sensitivity tests in SC/65a/Rep05, SC/65a/RMP02 and SC/65a/RMP08, suggests a range of 1% to 2.5% for the lower bound for MSY rate expressed in terms of the age 1+ component of the population (during the RMP development process and to date, MSYR has been expressed in terms of the mature component of the population; the AWMP development process by contrast expresses MSYR in terms of the 1+ component).

Recognising the uncertainties in the meta-analysis and the need for precaution, the Committee **recommends** that $MSYR_{1+}=1\%$ be adopted as a pragmatic and precautionary lower bound for use in trials. The value corresponds to the lower of the two percentiles in table 5 of SC/65a/Rep05, and the lowest of the r_{max} values; all of the point estimates of r_0 used in the meta-analysis correspond to $MSYR_{1+}$ values larger than 1% under $MSYR_{1+}\sim r_0/2$. In essence, $MSYR_{1+}=1\%$ is roughly the equivalent of 1.5% $MSYR_{mat}$. The Committee also **recommends** that the current upper bound of $MSYR_{mat}=7\%$ be changed to the roughly equivalent $MSYR_{1+}=4\%$. These recommendations have the additional practical advantage of unifying the MSYR 'currencies' of the RMP and AWMP processes.

In making this practical recommendation, the Committee **recognises** that much remains to be learnt regarding MSYR for baleen whales and that the issue of the appropriate range for MSYR should continue to be reviewed as new information becomes available. In particular, should data become available for more species and populations, the meta-analysis should be revisited with a view to making it more representative. The Committee **emphasises** in particular the need for information relating to stocks of species of interest for the RMP, including fin, sei, Bryde's and minke whales (although of course information on MSYR is important in assessing the status of all species within the Committee's work). Work should also continue to better understand the impact of environmental variation on MSYR and the biological and ecological processes leading to density-dependence, together with the shape of yield curves and hence the relationship between r_0 and $MSYR_{1+}$. As is already the case, consideration of MSYR for particular species and stocks should also occur during *Implementations* and *Implementation Reviews,* particularly where other information for the stock or species concerned suggests alternative plausible values to those discussed above.

The Committee also **recommends** that the '*Requirements and Guidelines for Implementations under the RMP*' (IWC, 2012h) be updated as given in Annex D, item 2.1.3.

The Committee thanked Brandon, Butterworth, Cooke, de la Mare, Donovan, Kitakado and Punt, as well as the other participants of the many intersessional meetings without whom it would not have been possible to complete the MSYR review. Above all, it acknowledged the contribution and dedication of the field researchers, whose data, particularly on bowhead, blue, right and humpback whales, collected over periods of up to 40 years, formed the backbone of the meta-analysis and the MSYR review.

5.2 Finalise the approach for evaluating proposed amendments to the *CLA*

In 2006, the Committee agreed that two steps needed to be completed in order to finalise the approach for evaluating proposed amendments to the *CLA*: the review of MSY rates, completed this year (see Item 5.1 above), and specification of additional trials for testing the *CLA* and amendments to it. Last year, the Committee re-established a working group under Allison to develop and run such trials for consideration at this year's meeting. However, Allison reported that there had been insufficient time during the intersessional period to conduct the work.

The Committee noted that the Working Group on Ecosystem Modelling had identified a set of possible issues to be addressed using individual-based simulation and other models (see Annex K1, item 3). These issues could form the basis for additional trials to further explore the behaviour of the RMP. The Committee **agrees** to re-establish the working group under Allison (see Annex R) to formulate and run trials related to environmental degradation, taking account of the discussions in Annex K1, and to report the results to the next Annual Meeting.

5.3 Evaluate the Norwegian proposal for amending the *CLA*

In 2004, Norway had indicated that it might submit a proposal for the revision of the *CLA* and the base-case and *Robustness Trials* (IWC, 2006a, pp.79-80). In 2007, the Committee received a paper (Aldrin and Huseby, 2007) documenting the results for all single stock trials for a proposed alternative *CLA*, as required for consideration of a proposed revision of this nature (IWC, 2007a, p.89).

The Committee noted in the past that evaluation of this proposal required: (a) completion of the MSYR review, (b) review of the trials conducted in Aldrin and Huseby (2007); and (c) review of additional trials which explore the performance of the RMP given environmental degradation. This year, the Committee has completed the MSYR review (see Item 5.1), but it was not able to complete the trial specifications related to environmental degradation (see Item 5.2) and it did not have time to review Aldrin and Huseby (2007).

The Committee **agrees** that: (a) Aldrin and Huseby (2007) should be a primary document for SC/65b; and (b) it would not be necessary to have all of the trials related to environmental degradation completed before a decision on amending the *CLA* could be made, given the time required to parameterise trials based on individual-based models. It also **agrees** that the *Implementation Review* for the North Atlantic common minke whales could take place even though a decision had yet to be made regarding the Norwegian proposal to amend the *CLA*.

5.4 Modify the 'Catch Limit' program to allow variance-covariance matrices

Last year, it was noted that the Norwegian 'CatchLimit' code for the current *CLA* allows variance-covariance matrices for the abundance estimates to be specified, and Allison was tasked to work intersessionally with the Norwegian Computing Center to develop a final version of the program. She reported that the Norwegian version of the current *CLA* version was used in the trials for western North Pacific minke whales, although some coding issues remain. The Committee **recommends** that Allison contact the Norwegian Computing Center to resolve any final coding issues.

5.5 Update the 'Requirements and Guidelines for Conducting Surveys'

Last year, the Committee recommended that a review covering model-based abundance estimation in theory and practice, and its relation to the design-based approach, be conducted. The review was to provide draft text for inclusion in the 'Requirements and Guidelines for Conducting Surveys' (IWC, 2012g). Hedley was contracted to conduct the review, but was unable to complete it on time. The Committee looks forward to receiving the review at the 2014 Annual Meeting.

5.6 Update the list of accepted abundance estimates to include western North Pacific common minke whales

The Committee noted that last year it had developed a list of accepted abundance estimates related to RMP stocks (IWC, 2013d, p.105). It **agrees** that the list of accepted abundance estimates for the RMP be updated using the values provided by the Working Group on western North Pacific minke whale (see Annex D1, item 9). The broader question of accepted abundance estimates is addressed under Item 22.

5.7 Other business

A number of issues arose during the 'second' western North Pacific common minke whale *Implementation Review* Workshop (SC/65a/Rep04) that were of general relevance to the RMP process and required the Committee's attention. The issues, and the rationale for the sub-committee's recommendations, are given in Annex D, item 2.7. The recommendations arising are as follows.

(1) Imbalanced sex ratio in incidental catches: the Committee **agrees** to consider this matter at the 2014 Annual Meeting and encourages papers on this topic.
(2) Review of abundance estimates in an RMP context: the Committee **endorses** the recommendation that the specified set of associated information be provided along with abundance estimates in its 'Requirements and Guidelines for *Implementations* and *Implementation Reviews*'.
(3) Changing survey coverage in time-series of abundance estimates: the Committee **agrees** to consider the matter at the 2014 Annual Meeting and encourages papers on the topic. It will at that time re-examine the set of core robustness trials which relate to this issue.
(4) Use of surveys carried out in different months in both the *Implementation* process and in actual implementation of the RMP: the Committee **agrees** to consider the matter at the 2014 Annual Meeting and encourages papers on the topic.

5.8 Work plan

The Committee's views on the work plan developed by the RMP sub-committee are given in Item 24, and the financial implications in Item 26.

6. RMP – *IMPLEMENTATION*-RELATED MATTERS

6.1 North Pacific common minke whales

Since 2010, the Committee has been following the process of an *Implementation Review* for western North Pacific common minke whales according to its 'Requirements and Guidelines for *Implementations* under the RMP' (IWC, 2012b). The scheduled period for an *Implementation* or *Implementation Review* is normally two years but, given the complexities of this particular *Implementation Review*, it has not been possible to keep to this schedule. This year's Annual Meeting was thus the third of the *Implementation Review*, but its objectives were those of the 'Second Annual Meeting' as described in the Requirements and Guidelines for *Implementations*, which are to complete the *Implementation Review* by examining the results of the final *Implementation Simulation Trials* and agreeing recommendations for implementation of the RMP.

6.1.1 Review report of intersessional Workshop

The Committee reviewed the report of the intersessional Workshop held in La Jolla, California in March 2013 and chaired by Donovan (SC/65a/Rep04). The Workshop is referred to as the '2nd Intersessional Workshop', although it is actually the third such Workshop because of the extended schedule of this *Implementation Review*.

The Workshop was primarily a technical Workshop, the objectives of which were to review the results of work agreed at the 2012 Annual Meeting of the Scientific Committee (IWC, 2013c) and to consider the results of the final trials using the agreed approach that forms part of the *Implementation* process (IWC, 2012h). The ultimate objectives were to develop recommendations for consideration by the Committee on: management areas; RMP variants (e.g. catch-cascading, catch-capping); suggestions for future research to narrow the range of plausible hypotheses or eliminate some hypotheses; and 'less conservative' variants(s) with their associated required research programmes and duration.

A detailed summary of the Workshop report is given in Annex D1, item 2. A map defining the sub-areas used for the *Implementation Review* is given as Fig. 1.

The Workshop made considerable progress but it had not been possible to consider final trial results because decisions necessary for finalising the trials were only able to be taken at the Workshop. However, some preliminary results for some trials were available and review of these led to refinement and reduction of the total number of management variants (see Item 6.1.3.1) to be considered at this Annual Meeting.

The Workshop had developed a work plan for the remainder of the intersessional period aimed at completing the final trials and providing results well in advance of this Annual Meeting. Considerable progress was made but because of the complexities of this *Implementation Review* it had not been possible to complete this work prior to the Annual Meeting. The Workshop had also identified a number of generic issues related to conducting trials which were referred to the RMP sub-committee (see Annex D, item 2.7).

The Committee **endorses** the conclusions and recommendations from the Workshop report (SC/65a/Rep04) and expressed its thanks to Donovan and all participants for their hard work and progress.

6.1.2 Progress since intersessional Workshop

6.1.2.1 UPDATE TO TRIAL SPECIFICATIONS

Changes to the trial specifications and the code implementing these specifications since the 2nd Intersessional Workshop are described in Annex D1, item 3.1. The Committee **endorses** these changes to the trial specifications; the final trial specifications are given in Annex D1, Appendix 2.

6.1.2.2 REVIEW OF FINAL CONDITIONING RESULTS

Regarding conditioning the *Implementation Simulation Trials*, the Committee had reviewed the fit diagnostics for the base-case trials and those for many of the sensitivity tests implemented in other trials at the 2012 Annual Meeting (IWC, 2013c). Work on conditioning trials continued during the intersessional period and the conditioning diagnostics for all trials conducted during this period had been reviewed by Punt. The Committee had agreed that the *ad hoc* Working Group established under the Working Group on the *Implementation Review* for Western North Pacific common minke whales to review trial results should check the conditioning of any trials that may be influential in the final decisions regarding the selection of RMP variants. The

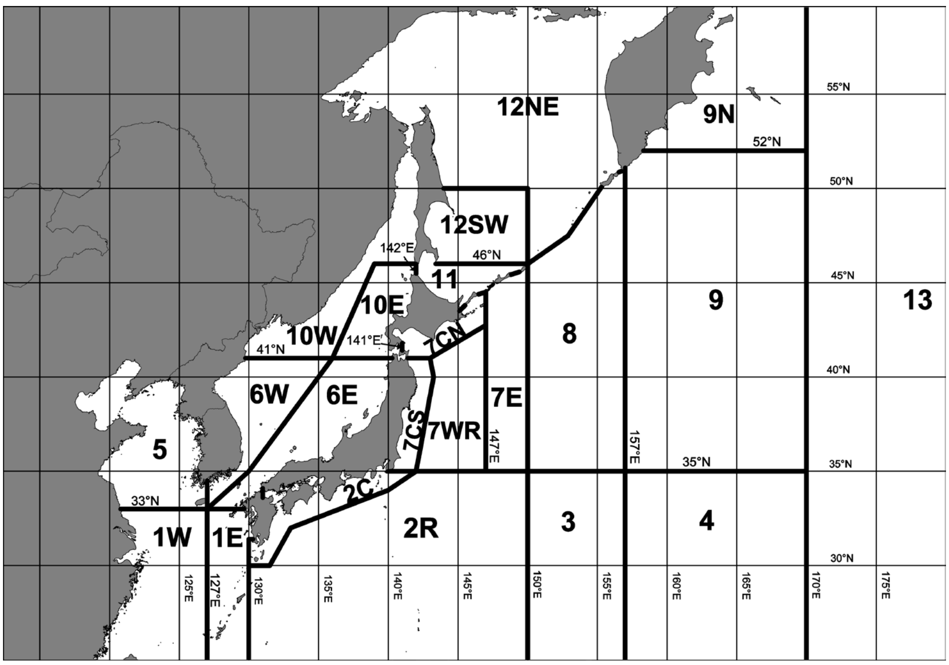

Fig.1. The 22 sub-areas used for the *Implementation Simulation Trials* for North Pacific minke whales.

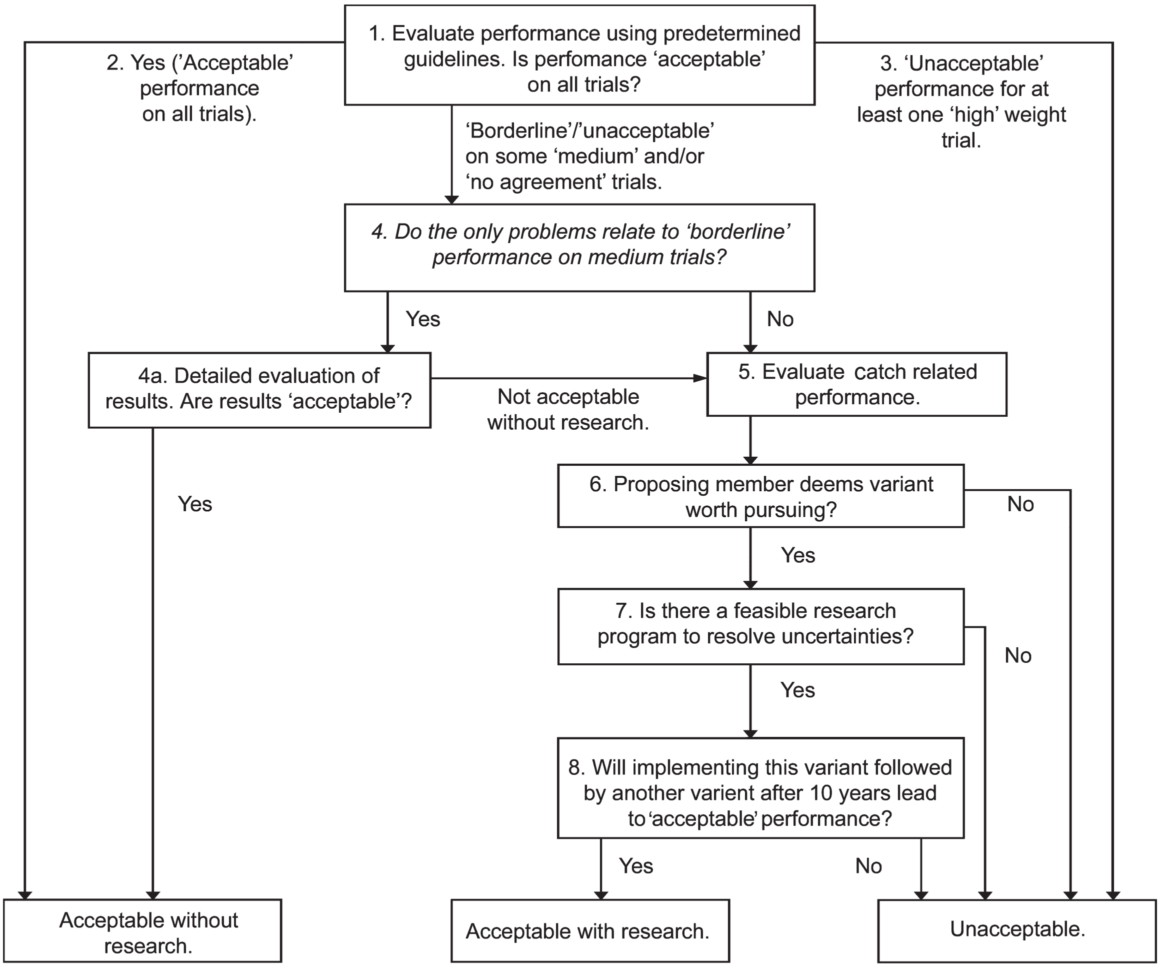

Fig.2. Flowchart summarising the procedure for review of *IST*s (from IWC, 2005a, pp.91-92).

Committee confirms that conditioning had been successfully achieved for all influential trials (Annex D1, item 3.2).

6.1.3 Complete Implementation Review

According to the Requirements and Guidelines for *Implementations,* completing the *Implementation Review* involves reviewing the results of the final *Implementation Simulation Trials* and making recommendations on: Management Areas; RMP variants; and inputs to the *CLA* for use in actual applications of the RMP.

6.1.3.1 REVIEW RESULTS OF FINAL *IMPLEMENTATION SIMULATION TRIALS*

The procedure for reviewing results of the final trials is given in the Committee's Requirements and Guidelines for *Implementations* (IWC, 2012h). A very brief summary is given below.

Fig. 2 shows a flow chart of the decision process to be followed.

The procedure first involves consideration of specified diagnostics to evaluate conservation performance generated from trial results, and determining from them whether the performance of each trial is 'acceptable', 'borderline' or 'unacceptable' under each of the defined RMP variants (see Annex D1, item 4.1). The style in which these results should be presented is detailed in Annex D1, item 4.2. RMP variants are defined by the *Management Areas* to be used (*Small Areas*, etc.) and how any catches are to be taken from them (see Annex D1, item 5). This part of the procedure is a technical exercise that follows directly from the results and requires no judgement.

The second stage is to evaluate each RMP variant by considering the results of all trials together in order to decide whether each variant is 'acceptable without research', 'acceptable with research' or 'unacceptable' (see Annex D1, item 5). This part of the procedure does require judgement because consideration is needed of the overall balance of the trials and the characteristics of any specific trials for which performance is questionable. The process for evaluating each variant can be summarised as follows:

(1) if the performance is close to 'acceptable' for a small number of 'borderline' trials then the Committee may agree that the variant is 'acceptable without research';
(2) if the performance is close to 'unacceptable' or is 'unacceptable' for a number of trials based on a specific hypothesis, then the Committee may agree that this is a candidate for the 'acceptable with research'; and
(3) if the performance is close to 'unacceptable' or is 'unacceptable' for a number of trials under several hypotheses, then the Committee may agree that the variant is 'unacceptable' and thus eliminated from further consideration.

Ten RMP variants to be evaluated had arisen from the 2nd Intersessional Workshop.

(1) *Small Areas* equal sub-areas. For this option, the *Small Areas* for which catch limits are set are 5, 6W, 7CS, 7CN, 7WR, 7E, 8, 9*, and 11.
(2) Sub-areas 5, 6W, 7+8, 9* and 11 are *Small Areas* and catches are taken from sub-areas 5, 6W, 7CN, 9 and 11.
(3) Sub-areas 5, 6W, 7+8, 9* and 11 are *Small Areas* and catches are taken from sub-areas 5, 6W, 7CS, 9 and 11.

(4) Sub-areas 5, 6W, 7CS, 7CN, 7WR+7E+8, 9* and 11 are *Small Areas* and catches are taken from sub-areas 5, 6W, 7CS, 7CN, 7WR, 9 and 11.
(5) Sub-areas 5 and 6W are *Small Areas* and catches are taken from sub-areas 5 and 6W. Sub-areas 7+8+9*+11+12 form a combination area and catches are cascaded to the sub-areas within the combination area. The catch limits for sub-areas 12SW and 12NE are not taken.
(6) Sub-areas 5, 6W, 7+8, 9* and 11 are *Small Areas* except that the catches from the 7+8 *Small Area* are taken from sub-areas 7CS and 7CN using the same method as for catch cascading to allocate the catch across the two sub-areas.
(7) Sub-areas 5+6W+6E+10W+10E and 7+8+9*+11 are *Small Areas*; catches from the 5+6W+6E+10W+10E *Small Area* are taken from subareas 5 and 6W using the same method as for catch cascading to allocate the catch across those five sub-areas, and catches from the 7+8+9+11 *Small Area* are taken in sub-area 7CN.
(8) Sub-areas 5, 6W and 7+8+9*+11+12 are *Small Areas* and catches from the 7+8+9*+11+12 *Small Area* are taken from sub-areas 8 and 9 using the same method as for catch cascading to allocate the catch across the two sub-areas.
(9) Sub-areas 5, 6W and 7+8+9*+11+12 are *Small Areas* and catches from the 7+8+9*+11+12 *Small Area* are taken from sub-areas 7CS, 7CN, 7WR, 7E, 8 and 9 using the same method as for catch cascading to allocate the catch across these sub-areas.
(10) Sub-areas 5, 6W and 7+8+9*+11+12 are *Small Areas* and catches from the 7+8+9*+11+12 *Small Area* are taken from sub-areas 7CS, 7CN, 7WR, 7E, 8, 9 and 11 using the same method as for catch cascading to allocate the catch across these sub-areas. Catches from sub-area 11 occur in May and June only.

After reviewing the initial results at the meeting, Japan requested that an 11th variant be evaluated.

(11) Sub-areas 5, 6W and 7+8+9*+11+12 are *Small Areas* and catches from the 7+8+9*+11+12 *Small Area* are taken from sub-areas 7CS, 7CN, 7WR, 7E, 8 and 9 using the same method as for catch cascading to allocate the catch across these sub-areas, except the catches from sub-areas 7CS, 7CN, 7WR and 7E are reduced by 50% after first subtracting the bycatches in these sub-areas.

The Committee's Requirements and Guidelines for *Implementations* allow for additional variants to be proposed for evaluation during the 2nd Intersessional Workshop as part of the *Implementation* process. However, due to the complexities of this *Implementation Review*, the results of only a few trials had been available during the 2nd Intersessional Workshop rather than the complete set as envisioned in the Requirements and Guidelines. Recognising these exceptional circumstances, the Committee **decided** to evaluate this additional variant noting that it was in accord with the RMP in that catches from all *Small Areas* cannot exceed the RMP catch limit (except when the bycatch exceeds the RMP catch limit when the commercial catch is set to zero).

In doing so, the Committee **reiterates** that, under normal circumstances, proposal and evaluation of additional variants should not take place at the 2nd Annual Meeting.

Annex D1, table 2 lists the factors considered in the trials and the plausibility assigned to each. Some of the factors were assigned 'medium' plausibility because the Committee had not been able to reach agreement on whether they should be 'low', 'medium' or 'high' (IWC, 2013c, p.11). A list of all the trials is given in Annex D1, table 1. In all there were 66 trials of which none were given 'high' weight. More details are given in Annex D1, item 5.

Annex D1, tables 3 and 4 summarise the application of the procedure for evaluating conservation performance. Results are shown in Annex D1, table 3 by stock-structure hypothesis and in Annex D1, table 4 by RMP variant. Annex D1, table 5 lists the average catches by sub-area for each RMP variant for the six base-case trials, reported for years 1-10 and for the entire 100-year projection period. The results in this table are illustrative only; the actual catches will depend on the application of the *CLA* to the abundance estimates and catches selected by the Committee (see Items 6.1.4.2 and 6.1.4.3).

The full set of trial results is available from the Secretariat upon request. Results for each variant are given in Annex D1, item 5 and are summarised below.

Variants 1, 2, 3, 4 and 6
These variants did not have 'unacceptable' performance for any trials, but had 'borderline' performance for one trial (B04) as shown in Annex D1, fig. 3. Given that the 'borderline' performance was close to 'acceptable', and that 'borderline' performance occurred only once out of 66 trials, these variants can be considered as candidates which are 'acceptable without research' (step 4a in Fig. 2).

Variant 5
Variant 5 had 'unacceptable' performance for trial B04 (Annex D1, fig. 3). It had 'borderline' performance for trials A04 (Annex D1, fig. 4), B03 (Annex D1, fig. 5), C03 (Annex D1, fig. 6), and C04 (Annex D1, fig. 7). Given that this variant fails for only one trial (B04) and is 'borderline' on four trials in which it is close to 'acceptable' for trial A04, this variant can be considered 'acceptable with research' because it fails only for stock structure hypothesis B (step 4a in Fig. 2).

Variant 7
Variant 7 performed 'unacceptably' on 22 out of 27 trials for stock-structure hypothesis C and 'borderline' on two (C14, C17). It also had 'borderline' performance for two trials based on stock-structure hypotheses A and B (A04, B04). This variant was close to 'acceptable' for these two trials (Annex D1, figs 3 and 4). This variant can thus be considered as a candidate for 'acceptable with research' because it was 'borderline' for only two out of 39 trials for hypotheses A and B, while its performance was 'unacceptable' for hypothesis C; that is, this variant fails for only one stock structure hypothesis (step 4a in Fig. 2).

Variant 8
Variant 8 was acceptable for all 'medium' weight trials. Therefore this variant can be considered to be 'acceptable without research' (steps 1 and 2 in Fig. 2).

Variant 9
Variant 9 performed 'unacceptably' on 20 out of 27 trials for stock-structure hypothesis C, and had 'borderline' performance for four trials (C11, C14, C17 and C30). It had 'borderline' performance on only two out of 39 trials based on stock-structure hypotheses A and B (A04, B04). This variant can thus be considered as a candidate for 'acceptable with research' because it fails only for stock structure hypothesis C (step 4a in Fig. 2).

Variant 10

Variant 10 performed 'unacceptably' on 23 out of 27 trials for stock-structure hypothesis C and had 'borderline' performance for two trials (C17 and C27). It also performed 'unacceptably' for one trial for stock structure hypothesis B (B04) and 'borderline' for 8 trials (B03, B05, B06, B09, B18, B20, B22, B28). 'Borderline' performance was also observed for three trials for stock structure hypothesis A (A03, A04, A28). This variant is therefore 'unacceptable'.

Variant 11

Variant 11 performed 'unacceptably' on three out of 27 trials for stock-structure hypothesis C (C13, C20, C23) and had 'borderline' performance for 16 stock structure hypothesis C trials. The conservation performance of this variant is between that of variants 5 and 9, which were both considered to be candidates for variants with research. Therefore, this variant can be considered as a candidate for 'acceptable with research'.

Variants with research

With respect to variants that are candidates for 'acceptable with research', it is the responsibility of relevant government(s) to inform the Committee whether it wishes additional trials to be run to determine the conservation performance of proposed 'hybrid variants'. A 'hybrid variant' is one for which catches for the first 12 years are set using the candidate 'acceptable with research' variant followed by a 6-year phase down/phase out period and then catches set by an 'acceptable without research' variant. The conservation performance of the 'hybrid variant' must be 'acceptable' under the criteria described above.

If the 'hybrid variant' performs acceptably then, before it can be recommended, the Committee must agree a research programme that it believes has a realistic chance of determining whether the trial(s) for which this variant performed poorly should be accorded low weight. The Committee will review progress with the research programme annually and may recommend early reversion to the 'acceptable' variant if progress is not sufficient.

The Committee noted that any research proposal submitted would be reviewed at next years' meeting.

6.1.4 Recommendations

6.1.4.1 RMP VARIANTS

Under the management options recommended (see below), the *Management Area* designations for each RMP variant are as follows.

(1) Variant 1: sub-areas 5, 6W, 7CS, 7CN, 7WR, 7E, 8, 9* and 11 are *Small Areas*.
(2) Variant 2: sub-areas 5, 6W, 7+8, 9* and 11 are *Small Areas* (all of the catch from the 7+8 *Small Area* is taken from sub-area 7CN).
(3) Variant 3: sub-areas 5, 6W, 7+8, 9* and 11 are *Small Areas* (all of the catch from the 7+8 *Small Area* is taken from sub-area 7CS).
(4) Variant 4: sub-areas 5, 6W, 7CS, 7CN, 7WR+7E+8, 9* and 11 are *Small Areas* (all of the catch from the 7WR+7E+8 *Small Area* is taken from sub-area 7WR).
(5) If Variant 5 proves to be acceptable with research: sub-areas 5 and 6W are *Small Areas* and catches are taken from sub-areas 5 and 6W. Sub-areas 7+8+9*+11+12 form a Combination Area (catch limits for sub-areas 12SW and 12NE are not taken).
(6) Variant 6: sub-areas 5, 6W, 7+8, 9* and 11 are *Small Areas* (catches from the 7+8 *Small Area* are taken from sub-areas 7CS and 7CN using the same method as for catch cascading).
(7) If Variant 7 proves to be acceptable with research: sub-areas 5+6W+6E+10W+10E and 7+8+9*+11 are *Small Areas*; (catches from the 5+6W+6E+10W+10E *Small Area* are taken from sub-areas 5 and 6W using the same method as for catch cascading; catches from the 7+8+9+11 *Small Area* are taken in sub-area 7CN).
(8) Variant 8: sub-areas 5, 6W and 7+8+9*+11+12 are *Small Areas* (catches from the 7+8+9*+11+12 *Small Area* are taken from sub-areas 8 and 9 using the same method as for catch cascading).
(9) If Variant 9 proves to be acceptable with research: sub-areas 5, 6W and 7+8+9*+11+12 are *Small Areas* (catches from the 7+8+9*+11+12 *Small Area* are taken from sub-areas 7CS, 7CN, 7WR, 7E, 8 and 9 using the same method as for catch cascading).
(10) If Variant 11 proves to be acceptable with research: sub-areas 5, 6W, and 7+8+9*+11+12 are *Small Areas* (catches from the 7+8+9*+11+12 *Small Area* are taken from sub-areas 7CS, 7CN, 7WR, 7E, 8 and 9 using the same method as for catch cascading).

The Committee **agrees** that, according to the Committee's Requirements and Guidelines for *Implementations* (IWC, 2012h):

(1) variants 1, 2, 3, 4, 6 and 8 are 'acceptable without research';
(2) variants 5, 7, 9 and 11 are candidates for 'acceptable with research'; and
(3) variant 10 is 'unacceptable'.

Some members stated that with only two exceptions, all of the 'unacceptable' trials were under stock structure hypothesis C. Under the Committee's current Requirements and Guidelines for *Implementations* under the RMP, when there is no agreement on plausibility of the hypotheses, the plausibility is automatically assigned as 'medium'. In the case of stock structure hypothesis C, there was no agreement and therefore the plausibility became 'medium' as for the other stock structure hypotheses. However these members reiterated their view that the plausibility of stock structure hypothesis C is 'low' (IWC, 2011c, p.138). Whilst agreeing that the review of trials had appropriately followed the Committee's current Requirements and Guidelines for *Implementations*, under these circumstances they could not accept the recommendations on management based on the conservation performance of the *Implementation Simulation Trials* using hypothesis C reviewed at this meeting. They pointed out that the problem of assigning plausibility has been an ongoing problem and suggested that it is necessary to review the method of determining plausibility.

6.1.4.2 ESTIMATES OF ABUNDANCE

The Committee did not have sufficient time to finalise the estimates of abundance for use in actual applications of the RMP. Annex D1, table 6 summarises the current status of abundance estimates for use in the trials and in actual applications of the RMP. Work to determine whether the abundance estimates that need further consideration can be accepted for use in actual applications of the RMP is included in the work plan. Final decisions regarding which abundance estimates can be used in actual applications of the RMP will be made at next year's meeting, taking into account any revision to the Requirements and Guidelines for Conducting Surveys (see Item 5.5, Annex D, item 2.5).

6.1.4.3 HISTORICAL AND FUTURE REMOVALS

The Committee has previously agreed that the best estimates of the direct catches and the average predicted bycatch from the six baseline trials would be used in actual applications of the RMP (IWC, 2013c). The calculated average predicted bycatch from the six baseline trials are given in Annex D1, Appendix 2.

6.1.4.4 CONSIDERATION OF DATA/ANALYSES TO REDUCE HYPOTHESES IN FUTURE

The Committee did not have sufficient time to discuss this item fully. It **encourages** those Contracting Governments which are contemplating application of the RMP to review previous discussions on this matter in the Committee.

The Committee highlighted that the *Implementation Simulation Trials* structure provided a way to identify the value of information to resolve uncertainties. In particular, analyses could be undertaken to assess where data on mixing proportions and abundance would be most informative in terms of resolving the plausibility of various hypotheses. The Committee recognised that becoming familiar with how to use the *Implementation Simulation Trials* structure to evaluate the value of information could be complicated, and **encourages** members of the Committee to work with the Secretariat to develop the ability to condition and run trials.

6.1.5 Surveys and estimates of abundance

6.1.5.1 RESULTS FROM RECENT SURVEYS

SC/65a/NPM01 presented the results of satellite tracking of common minke whales in the Sea of Japan in autumn 2012. Little information on migration behaviour was obtained because of the short transmission duration (14 days). More details are given in Annex D1, item 8.1. The Committee welcomes this information and **recommends** that researchers conducting tagging studies on North Pacific minke whales work together with those conducting similar work in other areas, particularly in relation to tag technology and deployment.

SC/65a/NPM04 provided a cruise report on a sighting survey in the East Sea in spring 2012. More details are given in Annex D1, item 8.1.

6.1.5.2 PLANS FOR FUTURE SURVEYS

SC/65a/NPM02 presented the research plan for a sighting survey for common minke whales in the Sea of Okhotsk, including the Russian EEZ, in summer 2014. The primary objective of the survey is to obtain a new estimate of abundance for sub-areas 11 and 12. The secondary objective of the survey will be biopsy sampling and satellite tagging for common minke whales, if permission is obtained from the Government of the Russian Federation. This latter objective is important given the need to obtain information on the mixing rate of J- and O-stocks, and the distribution of J-stock in the Okhotsk Sea. Further details are given in Annex D1, item 8.2.

SC/65a/NPM05 reported that a sighting survey for common minke whale will be conducted in the Yellow Sea in spring 2014. This survey is part of a four-year programme to survey the waters of sub-areas 5 and 6W and increase survey coverage from 13% to 35%. Further details are given in Annex D1, item 8.2.

The Committee welcomes these plans and noted that there have been no surveys in sub-area 12 in recent years. It appointed Miyashita and An to provide oversight of these surveys on behalf of the Committee. The Committee **strongly recommends** that the Government of the Russian Federation give permission for the survey to take place in its EEZ in the Sea of Okhotsk throughout sub-area 12, given the importance of abundance estimates for sub-area 12 to the understanding of the status of common minke whales in the western North Pacific.

6.1.5.3 UPDATED LIST OF ACCEPTED ABUNDANCE ESTIMATES

Annex D1, Appendices 3 and 4 summarise information on primary effort, primary sighting position, survey blocks, sub-areas and area definitions for surveys for western North Pacific minke whales. The Committee thanked Miyashita, Hakamada and An for providing this information, which had been requested by the 2nd Intersessional Workshop.

Annex D1, table 7 lists these estimates of abundance in a format consistent for collation with estimates from other species and areas.

6.1.6 Conclusions

The Committee re-established the Intersessional Steering Group (see Annex D1, item 11 for membership) to co-ordinate intersessional work and prepare for the 2014 Annual Meeting.

The Committee recognised that this *Implementation Review* had been the most complicated to date and thanked all those who had contributed over the last three years to its completion, especially Hammond and Donovan who chaired the Working Group and intersessional Workshops, respectively. In particular, the Committee expressed its appreciation for the large amount of work done by Allison and De Moor without which it would not have been possible to complete the *Implementation Review*. The Committee noted that the need to take three years to complete this complicated *Implementation Review* may have implications for conducting other *Implementations* and *Implementation Reviews.* The Committee **agrees** to review its Requirements and Guidelines for *Implementations* under the RMP in this context at next year's meeting.

6.2 North Atlantic fin whales

6.2.1 Implementation Review

The Committee reviewed the report of the pre-meeting to initiate the *Implementation Review* (see Annex D, Appendix 2) and **endorses** its conclusions, recommendations and work plan. It established an intersessional group (see Annex R) under Elvarsson to develop revised specifications for the trials. It **recommends** that a two-day Workshop is held back-to-back with an AWMP intersessional Workshop in early 2014 to reduce travel costs.

6.3 North Atlantic common minke whales

6.3.1 Review new information

The Committee received five papers which had either been presented to the Special Permit Review Workshop held in Iceland (SC/65a/Rep03), or were revised versions of papers presented then. Details are given in Annex D, item 3.2.1.

The Committee **welcomes** the information in SC/F13/SP17 and SC/F13/SP20rev. It should be useful for the upcoming *Implementation Review,* and, in particular, the work of the joint AWMP/RMP Working Group on stock structure.

The Committee recognised the value of the satellite tracking of minke whales, reported in SC/F13/SP18, for the development of *Implementation Simulation Trials*. It **reiterates** the recommendations of the Special Permit Review that such tagging should continue, as much information as possible should be collected from each tagged individual, and that the results from the various stock definition approaches should be integrated.

The Committee **agrees** that data from satellite tracking could be used in *Implementation Simulation Trials* both qualitatively and quantitatively. There would be benefits in identifying the analysis methods to apply to data from satellite-tagged animals to determine the minimum number of animals needed for meaningful quantitative estimates and the point at which tagging additional animals leads to minimal additional information. If such analysis methods are developed, they should be reviewed by the Working Group on Stock Definition.

The Committee noted that SC/F13/SP06 stated the main objective of the aerial survey component of the research programme is to obtain a seasonal profile of relative abundance in coastal Icelandic waters in the off-season. This is discussed in Annex D, item 3.2.1.

6.3.1.1 NEW SURVEYS

SC/65a/RMP10 presented Norway's plans to conduct a new series of annual partial surveys over the period 2014-19 to collect data for a new estimate of minke whale abundance in the Northeast Atlantic in accordance with the requirements of the RMP. The survey and analytical methods will follow the procedures used in the previous survey cycles.

The Committee noted that the upcoming *Implementation Review* could lead to changes to the definitions of the *Small Areas*. It recognised that there are some advantages in agreement between survey and *Small Area* boundaries, but **agrees** that an approach has been developed which can address changes in *Small Area* boundaries.

6.3.2 Prepare for 2014 Implementation Review

The Committee was informed that the joint AWMP/RMP group is coordinating discussions and analyses on using genetics to examine stock structure for North Atlantic minke whales. It reviewed the report of the group (Annex D, Appendix 3) and **endorses** its recommendations. It **reiterates** its recommendation from last year that the work plan for the group (IWC, 2013d) be completed, and **recommends** the holding of a joint AWMP/RMP intersessional Workshop to consider stock structure hypotheses for common North Atlantic minke whales. It **recommends** a research proposal to conduct simulation analyses to support the deliberations of the intersessional Workshop (Annex D, Appendix 4) and future considerations of stock structure for other populations (see Item 26).

6.3.3 Recommendations

The Committee **recommends** that a Steering Group under Walløe be established to co-ordinate planning for the 2014 *Implementation Review* (see Annex R). It **recommends** that a three day pre-meeting be held prior to the 2014 Annual Meeting to ensure that sufficient progress is made on the *Implementation Review*, noting that this *Implementation Review* could be more complicated than previous ones because the original *Implementation* was not conducted under the current Requirements and Guidelines for *Implementation.*

6.4 North Atlantic sei whales

Last year, the Committee established an intersessional group to review the available data for North Atlantic sei whales in the context of a possible *pre-Implementation assessment* and provide a report to the 2013 Annual Meeting. Unfortunately, insufficient progress was made during the intersessional period to warrant starting the *pre-Implementation assessment* at this year's meeting. The Committee therefore **recommends** that the intersessional group be re-established and progress evaluated at the 2014 Annual Meeting. The decision whether to initiate an *Implementation* after a *pre-Implementation assessment* is made by the Commission. The Committee noted that this procedure might lead to delays now that the Commission will meet biennially; it may consider possible recommendations to the Commission at next year's meeting.

6.5 Western North Pacific Bryde's whales

6.5.1 Prepare for 2016 Implementation Review

The Committee received an update on progress and plans for the 2016 *Implementation Review* (Annex D, item 3.4). A sighting survey will be conducted in western North Pacific minke whales sub-areas 7 and 8 in 2013. IWC-POWER cruises will also take place in 2013 and 2014. Sightings data will be collected and attempts will be made to biopsy Bryde's whales. Bryde's whale genetic samples were collected during JARPN II cruises in 2012 and additional samples will be collected during the 2013 JARPN II cruises.

6.6 Work plan

The Committee's views on the work plan for the sub-committee on the RMP are given in Item 24, and the financial implications in Item 26.

7. NON-DELIBERATE HUMAN-INDUCED MORTALITY OF LARGE WHALES

The report of the Working Group on Non-deliberate Human-induced Mortality of Large Whales is given as Annex J.

7.1 Criteria for determining cause of death

The objective of this Item is to assist the Committee in its general attempts to assess human caused mortality and in particular to agree to specific criteria by which the Ship Strike Data Review Group can assess ship strikes reported to the ship strike database. If standardised criteria became internationally accepted, this will also assist countries as they report ship strikes through their National Progress Reports.

Moore reported via videolink on a workshop held in the USA (1-2 February 2012) that defined criteria for degrees of confidence in the diagnosis of sharp or blunt vessel trauma, and peracute or chronic fishery trauma in cetaceans. The amount of data needed to make an adequate diagnosis depends on the scenario as is discussed in Moore *et al.* (2013b) and summarised in Annex J, item 6. Their criteria are for 'Confirmed', 'Probable' and 'Suspect' outcomes and this approach had been used to examine large whale mortalities in the northwest Atlantic in the context of management strategies designed to mitigate these impacts (Van der Hoop *et al.*, 2012). They found that trends in numbers (and location) of reports of vessel strikes and entanglements did not differ significantly before or after 2003, when a number of management mitigation initiatives were begun along the Atlantic coast of the USA.

A handbook was presented for recognising, evaluating and documenting human interactions in stranded cetaceans and pinnipeds was presented (Moore and Barco, 2013). The Committee **recognises** the value of standardising approaches to enable more consistent data collection which in turn can assist in obtaining information on the likely extent of causes of death and necessary priorities for mitigation. Details are provided in Annex J, item 6.

The above two papers describe complementary actions and criteria and represent important tools for stranding networks globally. While a full forensic necropsy is often very difficult this should nevertheless be the goal to aim for. The two papers provided a progression of data collection options, and the visual options in the handbook should be feasible almost anywhere. Data collected using these protocols are being archived with the ultimate intent of making some images available for consultations and training. The Committee **encourages** this work and broader use of the handbook.

One hundred and eight ship strike reports from Alaskan waters between 1978-2011 are described in Neilson *et al.* (2012). In order to assess the reliability of these reports, which ranged from well documented reports with full necropsies to secondhand reports with sparse documentation, the authors developed 'confidence criteria' for categorising the reports. The Committee **welcomes** this summary and noted that this information will provide valuable input into the IWC's ship strikes database.

The criteria developed in these papers have been used to develop the criteria and definitions in Annex J, Appendix 2. The Committee **recommends** that these be adopted for the IWC ship strike database.

7.2 Reporting to National Progress Reports

This matter is discussed under Item 3.2.

7.3 Entanglement of large whales

7.3.1 Estimation of rates of entanglement, risks of entanglement and mortality

SC/65a/HIM02 describes a recent incidental catch of a baleen whale in a long-line fishery off the Brazilian coast. The incident demonstrates the need for more investigation of such interactions in the southwest Atlantic Ocean. A large long-line fleet operates out of ports along Brazil's southern coast in the path of migratory whales. The fleets are not monitored and they are unlikely to report whales entangled in their gear since, while it is forbidden to entangle a whale and there are regulations requiring that they are reported, these measures are not effective. In September 2012, just south of this area, a meeting was held to develop an action plan to mitigate bycatch and entanglement in similar Argentine fisheries. It is hoped that a report of the action plan developed will be available at next year's meeting. The Committee looks forward to receiving a report of the plan.

7.3.2 Methods to estimate time-series of bycatch

This item was not discussed by the Working Group this year but will be considered next year in light of discussions in e.g. Annexes D1 and E.

7.3.3 Collaboration with FAO and FIRMS

The IWC is currently an observer to the FIRMS partnership (Fisheries Resources Management System). It had been hoped that FIRMS may hold data on fishing effort that could be useful in estimating bycatch but FIRMS appears to have changed its focus somewhat since initial discussions with the IWC. Leaper will follow up on any new developments intersessionally to see if there is progress to discuss next year.

7.3.4 Collaboration with Commission initiatives on entanglement, including consideration of mitigation measures

Much of the work of the Secretariat's technical advisor, Mattila (generously seconded by the USA since 2012) has been devoted to capacity building on the issue of large whale entanglement. The strategy has provided an overview for over 500 scientists and government managers from 20 countries, followed by detailed training and assistance with setting up entanglement response networks. Over the remainder of 2013, training is scheduled for Ecuador (with participants from the Permanent Commission for the South Pacific (CPPS) countries), Panama, and a joint IWC-UNEP-SPAW session for the French and English Caribbean. The Committee **commends** this work, noting that besides assisting countries to establish relatively safe entanglement response capabilities which have already released a number of individual whales, it has stimulated other local and national initiatives on the issue of entanglement, including actions intended to both understand and mitigate them. The Committee **reiterates** that prevention rather than disentanglement is the ultimate solution. It **encourages** members to submit information and papers on prevention studies to next year's meeting.

7.4 Ship strikes

7.4.1 Progress on the global database

Last year, in response to a Committee recommendation (IWC, 2013h), Ritter and Panigada had been contracted jointly as co-ordinators for the ship strikes database. The primary objective was to raise awareness about the ship strike database and to stimulate its use. Outreach activities have resulted in a large number of new data entries compared to previous years. Data from around 100 incidents have been entered in the last year and the data from around a further 200 incidents are expected to be incorporated during the rest of 2013. These data cover some areas not previously covered including the Gulf of St Lawrence (Canada) and Alaskan waters. Contact was also made with researchers and authorities in Sri Lanka. A total of 111 entries of collisions between sailing vessels and cetaceans are expected to be entered by the end of 2013. A new edition of the multi-lingual IWC ship strike leaflet, supported by Belgium, has been distributed to a range of stakeholders. A self-standing banner display has been developed and two copies were produced; one was displayed at the recent European Cetacean Society conference in Portugal.

The Committee **commends** this work, noting that a modest financial investment by the IWC has produced good results. It noted the value of the leaflet to highlight the issue and create an ongoing dialog on whale avoidance in the maritime industry; for example, Neilson *et al.* (2012) had recommended its wide distribution. The Committee **recommends** that this work continues and is funded (see Item 26). The Committee also **agrees** that the co-ordinators should give priority to populations identified for CMPs for proactive data gathering outreach efforts.

The Committee noted that Australia and the USA have ship strike databases and have worked to ensure that these are compatible with the IWC database, and that data fields can be accurately mapped between them to facilitate data exchange. The Committee **reiterates** previous recommendations that member nations should submit data to the IWC's global database as soon as possible.

7.4.2 Estimating rates of ship strikes, risk of ship strikes and mortality

SC/65a/HIM01 provided information from the Canary Islands. A large fleet of commercial ferries operates on a year-round basis in the area and ship strikes are a known problem. Different ferry types exhibit distinct noise spectra. Based on certain assumptions, especially on hearing thresholds, the authors concluded that whales may be capable of hearing approaching vessels at distances that should enable them to react fast enough to avoid a collision. However, numerous factors need to be considered in evaluating the actual collision risk. Jet-driven ferries travelling at high speed, combined with comparably low intensity bow-radiated noise, result in an especially high risk of collision. These results confirm the role of vessel speed and the need to reduce vessel speed so as to minimise the risk of collision.

SC/65a/HIM03 reported that two pygmy blue whales were struck and killed in Sri Lankan waters in early 2012. The southern coast of Sri Lanka is one of the busiest shipping routes in the world and overlaps with an area of high whale sightings. The reported deaths can only be considered minimum values. These deaths and the unknown population size highlight an urgent need for long-term monitoring of the blue whale population in Sri Lankan waters and elsewhere in the northern Indian Ocean.

Vaes and Druon (2013) presented a novel approach to considering the seasonal ship strike risk to fin whales in the western Mediterranean Sea using satellite-derived data (surface temperature and chlorophyll-a content) as a proxy for fin whale habitat in addition to using AIS data for vessel traffic. The Committee agreed that further comparisons using this approach with contemporary whale sighting data are required to assess its value.

Neilson *et al.* (2012) reported data on collisions in Alaska between 1978 and 2011; these have been made available to the IWC database as noted above. There were 108 reports classified as definite, probable or possible ship strikes, mostly from collisions witnessed at sea. It was noted that even in this relatively large data set there were only a few cases in which the circumstances of the collision and outcome could be related to the size, speed and type of the vessel involved. This highlights the need for a central global database, which will increase the likelihood of obtaining a sample size sufficiently robust for meaningful analyses of factors related to risk.

7.4.3 Collaboration with the Commission's ship strikes working group including consideration of mitigation measures

An IWC-endorsed Ship Strike Mitigation Workshop was held in Tenerife in October 2012 (Tejedor *et al.*, 2013). This was primarily aimed at management and mitigation. There was broad recognition and acceptance that currently the best way to avoid collisions with whales is to avoid areas of high density, but if this is not possible then ships should maintain a vigilant watch and slow down as appropriate. Several participants from the industry agreed that they would prefer to know of a whale 'hot spot' well in advance, and be able to plan their routes accordingly, rather than getting a message upon arrival in an area that they need to re-route.

The apparent willingness of key stakeholders at this Workshop to investigate the feasibility and utility of voyage planning to avoid high density areas represents an opportunity for the Committee to play an important role in this effort. The Committee **agrees** that this is a productive way forward on this issue and **recommends** that the topic of defining and identifying critical whale 'hot spots' and engaging the shipping industry in the process should be an agenda item for the Commission's next Ship Strike Workshop. The Committee recognised that the Tenerife Workshop was primarily concerned with management and mitigation, and as such, **recommends** that the Commission's next Ship Strike Workshop reviews the report in full, and considers endorsing it and seeking partnerships with stakeholders to carry out appropriate recommended actions.

Bryde's whales in the Hauraki Gulf, New Zealand were also discussed. The population is believed to be less than 200 individuals and there have been 16 confirmed ship strike mortalities between 1996 and 2013. A proposal for funding an aerial survey to provide an abundance estimate for Bryde's whales throughout their primary range in New Zealand and to use this and data on distribution to inform mitigation measures to reduce ship-strike mortality was received (also see Item 26).

7.5 Marine debris

7.5.1 Report of the intersessional Workshop

A summary of the first IWC Marine Debris Workshop (SC/65a/Rep06), held from 13-17 May 2013 at Woods Hole Oceanographic Institution, was presented. The original objectives are outlined in IWC (2013j, pp.261-62).

Thirty-eight participants representing eight countries attended the Workshop. The first day of the Workshop included a public seminar consisting of keynote presentations which illustrated the ways in which debris and cetaceans interact, including the long lingering deaths that can result from entanglement, and a growing realisation that ingestion of plastics, including microplastics, may be a significant problem. In 2012, 280 million tonnes of plastic were produced globally, less than half of which was consigned to landfill or recycled. If current rates of consumption continue, the planet will hold another 33 billion tonnes of plastic by 2050 (Rochman, 2013). The keynote presentations also highlighted the need for improved international cooperation.

The participants recognised the potential significant impact that marine debris has on both cetacean habitat and cetaceans through both macrodebris (such as fishing gear, plastic bags and sheeting) entanglement and ingestion and through microplastics and their associated chemical exposures through ingestion or inhalation. The Workshop encouraged debris sampling when conducting observational cetacean research at sea (i.e. water sampling and visual observations during cetacean sightings surveys) and recommended that industry partners be involved in marine debris prevention, research and response to ensure success in reducing marine debris impacts on cetaceans.

Finally, the Workshop agreed that ingestion and inhalation of marine debris may sometimes be lethal, that sub-lethal impacts may also occur with long term negative consequences and that intake of debris is a problem, both as an individual welfare concern and potentially for some populations and species. More research was encouraged. The Workshop recommended that the IWC Scientific Committee should evaluate the risks of ingestion and inhalation based upon: (1) the spatial distribution of microplastics and macro debris; and (2) the feeding strategies and location of feeding areas of cetaceans. It also recommended that the Scientific Committee prioritise studies of those cetaceans that are likely at greatest risk of ingesting or inhaling macro- and micro-debris and associated pollutants (e.g. see Fossi *et al.*, 2012). The Workshop thus recommended that the initial focus of research be on three species of baleen whale: the North Atlantic right whale, the fin whale in the Mediterranean Sea and the gray whale in the eastern North Pacific. The Workshop noted that none of its recommendations required the lethal collection of cetaceans.

7.5.2 Committee discussion

A full discussion of the Workshop report can be found in Annex K, item 11.2. For a full list of scientific recommendations see SC/65a/Rep06. Information was also presented on marine debris found in the stomach contents of common minke whales, sei whales, Bryde's whales and sperm whales sampled by JARPN II (SC/65a/O03, SC/65a/O06, SC/65a/O07). No marine debris was observed in the stomachs of Antarctic minke whales (SC/65a/O09). After review of the Workshop report and other papers, the Committee **endorses** the recommendations of the Workshop (see SC65a/Rep06 for full details), including its recommended pathology protocol and **agrees** that:

(1) legacy and contemporary marine debris have the potential to be persistent, bioaccumulative and lethal to cetaceans and represent a global management challenge; and
(2) entanglement in and intake of active and derelict fishing gear and other marine debris have lethal and sub-lethal effects on cetaceans.

Therefore the Committee **strongly agrees** that marine debris and its contribution to entanglement, exposures including ingestion or inhalation, and associated impacts, including toxicity, are welfare and conservation issues for cetaceans on a global scale and a growing concern. The Committee **recommends** that the Commission and the Secretariat take prompt action to help better understand and address this growing problem, including:

(1) providing data on rates of marine debris interactions with cetaceans into the national progress reports and supporting the second marine debris Workshop (which will have mitigation and management as its focus);
(2) strengthening capacity building in the IWC entanglement response curriculum and adding information on marine debris;
(3) building international partnerships with other relevant organisations and stakeholders including an effective transfer of information about on-going research and debris-reduction and removal programmes and the international and national marine debris communities;
(4) developing programmes to remove derelict gear and schemes to reduce the introduction of new debris; and
(5) incorporating consideration of marine debris into IWC conservation management plans where appropriate and to consider making it the focus of a plan in its own right.

The Committee thanked the Workshop Convenor, the Woods Hole Oceanographic Institution for hosting the Workshop and the tremendous work done by the Workshop organisers and participants. The Committee also appreciates the funds provided by the various organisations in support of this Workshop.

The Committee **agrees** to establish an intersessional correspondence group (see Annex R) to review and prioritise the research-related recommendations from the Workshop. It was noted that this review should give consideration to: (1) the evaluation of the efficacy of fishing practices that pose a lower risk of entanglement or loss of gear, given that active and derelict fishing gear are a major cause of injury and mortality in cetaceans; and (2) further investigations into microplastics, their associated chemical pollutants and microbes, and macrodebris ingestion. Further work on microplastics has been taken up by the POLLUTION 2020 work plan (see Annex K, Appendix 2). The intersessional correspondence group will also liaise with the steering group for the second Marine Debris Workshop.

7.6 Work plan

The Committee's views on the work plan developed by the Working Group are given in Item 24, and the financial implications in Item 26.

8. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT PROCEDURE (AWMP)

This item continues to be discussed as a result of Resolution 1994-4 of the Commission (IWC, 1995a). The report of the SWG on the development of an Aboriginal Whaling Management Procedure (AWMP) is given as Annex E. The Committee's deliberations, as reported below, are largely a summary of that Annex, and the interested reader is referred to it for a more detailed discussion. The primary issues at this year's meeting comprised: (1) finalising work on the PCFG (the Pacific Coast Feeding Group) of gray whales; (2) developing *SLAs* and providing management advice for Greenlandic hunts; and (3) reviewing management advice for the humpback whale fishery of St Vincent and The Grenadines. Considerable progress on items (1) and (2) was made as a result of an intersessional Workshop (see SC/65a/Rep02).

8.1 Matters arising out of the *Implementation Review* for eastern North Pacific gray whales

8.1.1 SLAs for the potential Makah hunt

In 2010, the Committee agreed that PCFG (Pacific Coast Feeding Group) whales should be treated as a separate management unit. The Makah Tribe would like to take gray whales in the Makah Usual and Accustomed fishing grounds (U&A) in the future and the objective of the *SLA*s tested during the *Implementation Review* process was to minimise the risk to the PCFG whales and meet the Commission's conservation objectives.

Last year, the Committee had agreed that two *SLA* variants met the conservation objectives of the Commission (IWC, 2013e):

(1) *SLA* variant 1: struck-and-lost whales do not count towards the APL (the 'allowable PCFG limit' – a protection level) i.e. there is no management response to PCFG whales struck but not landed; and
(2) *SLA* variant 2: all struck-and-lost whales count towards the APL irrespective of hunting month i.e. the number of whales counted towards the APL may exceed the actual number of PCFG whales struck.

SLA variant 2 was only acceptable if it was accompanied by a research programme (i.e. a photo-id programme to monitor the relative probability of harvesting PCFG whales, the results of which are presented to the Scientific Committee for evaluation each year).

However, the Committee also noted that the two variants did not exactly mimic the proposed hunt and expressed concern that the actual conservation outcome of the proposed hunt had not been fully tested. The reason for this relates to how strikes in May are treated in *SLA* calculations. No hunting is allowed after May since that is when the proportion of PCFG whales to migrating whales is highest (PCFG whales are defined as those photographed in multiple years from 1 June to 30 November within the PCFG area).

After discussions at the intersessional Workshop (SC/65a/Rep02), results were received for six new variants to cover the full range of possible strikes occurring in May or prior to May, i.e. variants allowing x strikes prior to May where $x = 1,\ldots,6$ (SC/65a/AWMP06). In summary, the performance of all the new variants was no worse than for Variant 1 and no better than for Variant 2.

In conclusion, the Committee **agrees** that the conservation performance of the proposed Makah whaling management plan has now been fully examined within the *SLA* evaluation framework. It **confirms** that the proposed management plan meets the conservation objectives of the Commission provided that if struck and lost animals are not proposed to be counted toward the APL, then a photo-identification research programme to monitor the relative probability of harvesting PCFG whales in the Makah U&A is undertaken each year and the results presented to the Scientific Committee for evaluation. In other words, only Variant 2 above meets the Commission's conservation objectives without the research requirement.

The Committee noted that the intersessional Workshop (SC/65a/Rep02) had recommended that the photo-id catalogue for the eastern North Pacific gray whales that will be used to assess whether landed whales are from the PCFG be made publicly available as it is a key component of the management approach. Weller reported that NOAA still has funds available to digitise the catalogue of PCFG whales. Scordino noted that work is underway to compile photographs from a few key contributors for a photo catalogue of PCFG whales to be held at NOAA's National Marine Mammal Laboratory; this catalogue, at least initially, will not be publicly available.

SC/65a/AWMP03 presented an update on the availability of PCFG whales in the Makah U&A based on photo-identification surveys. The results: (1) supported the proposed prohibition of hunting in the Strait of Juan de Fuca; and (2) confirmed that the availability of PCFG gray whales in Pacific Ocean waters of the Makah U&A was not appreciably different to the 30% availability used in the 2012 *Implementation Review*. An updated paper next year will also include an examination of possible trends.

8.1.2 Potential for western gray whales to be taken during aboriginal hunts

Given ongoing concern about the status of the gray whales that summer in the Western North Pacific (WNP), in 2011 the Scientific Committee emphasised the need to estimate the probability of a western gray whale being killed during aboriginal gray whale hunts (IWC, 2012a). The Committee noted that the work described in SC/65a/AWMP3 above can assist in this. This year, Moore and Weller (2013) updated the analysis of mortality risk to WNP whales from the proposed Makah hunt by incorporating Committee feedback last year (IWC, 2013c, p.20). Based on their preferred model, depending on assumptions, the probability of striking at least one WNP gray whale during a five-year period ranges from 0.036 to 0.170. The authors concluded that this represents a conservative initial step in assessing the potential risk.

The Committee welcomed this paper, recognising that it represents an initial approach. As detailed under Annex F, item 2.2.2, it also received information on an ongoing telemetry study of PCFG whales and considered the report of a US scientific task force that assessed gray whale stock structure in the light of US domestic legislation.

The Committee **agrees** that all of this information will make a valuable contribution to the recommended rangewide Workshop (Annex F, Appendix 2) described under Item 26.

Finally, in regard to questions on whether it should consider conducting an *Implementation Review* to evaluate the potential impacts of the Makah hunt on whales identified in the western North Pacific, the Committee **agrees** that ideally before an *Implementation Review* is conducted, the recommended rangewide Workshop be held (see Item 26).

8.2 Guidelines for *SLA* development and evaluation

Considerable effort was put into general consideration of the development of *SLA*s at the beginning of the AWMP process (IWC, 2000b; 2001b; 2001c; 2002b). This year, the Committee briefly outlined some guiding principles for *SLA*s to assist developers of candidate *SLA*s for the Greenland hunts. These are summarised below.

(1) The primary objective of any *SLA* is to meet the objectives set by the Commission with respect to need satisfaction and conservation performance, with priority given to the latter.
(2) *SLA*s must incorporate a feedback mechanism.
(3) Once need has been met for the 'high' need envelope while giving acceptable conservation performance, then there is no need to try to improve the performance of an SLA further.
(4) Simple *SLA*s are to be preferred, providing this simplicity does not compromise achieving the Commission's objectives.
(5) With respect to (4), empirical procedures may prove preferable to population model based procedures because: (a) they are more easily understood by stakeholders; and (b) there is little chance for significant updating of population model parameters (e.g. MSYR) over time as the extent of additional data will probably be limited for populations subject to aboriginal whaling only. Nevertheless, the choice of the form for any candidate *SLA* lies entirely in the hands of its developer, with selection amongst candidates to be based on performance in trials.
(6) If in developing *SLA*s, a situation arises where relatively simple *SLA*s fail on one or a few trials where the circumstances which might lead to the failure occur only many years in the future, rather than attempt to develop more complex *SLA*s to overcome this problem, a simpler *SLA* could be proposed despite this failure, and the difficulties dealt with by means of an *Implementation Review* should there be indications in the future that the circumstances concerned are arising. This principle applies only to:
    (a) circumstances in a scenario that are external and independent of the hunting/quota feedback loop, such as very high values of the future need envelope; and
    (b) are judged to be very unlikely to occur in the next few decades.

    Failure of an *SLA* to perform acceptably in some circumstances is not in itself a reason to apply this principle.

The Committee also reviewed and discussed the performance statistics, tables and plots that are required to evaluate conditioning and trial results. This discussion can be found under item 3.2.3 of Annex E. The Committee **endorses** this approach.

8.3 Progress on *SLA* development for the Greenlandic hunts

In Greenland, a multispecies hunt occurs and the expressed need for Greenland is for 670 tonnes of edible products from large whales for West Greenland; this involves catches of common minke, fin, humpback and bowhead whales. The flexibility among species is important to the hunters and satisfying subsistence need to the extent possible is an important component of management. For a number of reasons, primarily related to stock structure issues, development of *SLA*s for some Greenland aboriginal hunts (especially for common minke and fin whales) is more complex than previous *Implementations* for stocks subject to aboriginal subsistence whaling. The Committee has endorsed an interim safe approach to setting catch limits for the Greenland hunts in 2008 (IWC, 2009b), noting that this should be considered valid for two blocks, i.e. the target will be for agreed and validated *SLA*s, at least by species, for the 2018 Annual Meeting.

8.3.1 Common minke whales and fin whales off West Greenland

The Committee's discussions were informed by the work of the intersessional Workshop (SC/65a/Rep02) as well as those in Annex E. There is potential overlap between RMP and AWMP management with respect to common minke whales and fin whales in the North Atlantic. The process of developing *SLAs* and RMP *Implementations* for stocks in regions where both commercial and aboriginal catches occur should include the following steps: (a) development of a common trials structure which adequately captures uncertainties (regarding stock structure, mixing, MSYR, etc.); (b) identification of an *SLA* which performs as adequately as possible if there are no commercial catches; and (c) evaluation of the performance of RMP variants given the *SLA* selected at step (b).

With respect to common minke whales, the Workshop **reiterates its support** for a joint AWMP/RMP stock structure Workshop which will be essential to the *SLA* development process and the simulation framework (see Annex D, Appendix 2).

With respect to fin whales, in addition to working closely with intersessional work being undertaken within an RMP context (see Annex D), the Committee also noted that it may be possible to base the *SLA* for fin whales off West Greenland on operating models which considered West Greenland only. This will be investigated further (including at the intersessional RMP Workshop on fin whales) as it requires careful evaluation as to whether there may be more than one stock mixing off West Greenland.

In order to progress development work, the Committee last year funded a new computer program called RMP/AWMP-lite. It uses an age-aggregated rather than an age-structured model to considerably speed up calculations; this will allow developers to explore more easily the properties of candidate *SLA*s before they are submitted to rigorous full testing. It allows for multiple stocks of whales being exploited by a combination of commercial and aboriginal whaling operations. This was first reviewed at the intersessional Workshop (SC/65a/Rep02) and SC/65a/RMP05 implements the improvements suggested there.

The current approach to evaluating *SLA*s for the Greenlandic hunts treats each species independently even though need is expressed as a total amount of edible products over multiple species. The Committee **reiterates** that work on single-species *SLA*s should be completed before multi-species considerations are examined.

8.3.2 Humpback whales

The Committee's discussions were informed by the work of the intersessional Workshop (SC/65a/Rep02) as well as those in Annex E. Development of an *SLA* for humpback whales had been identified as one of the priorities for the Workshop and considerable progress was made.

8.3.2.1 STOCK STRUCTURE AND MOVEMENTS

The Committee has already agreed that the West Greenland feeding aggregation was the appropriate management unit to consider when formulating management advice. Whales from this aggregation mix with individuals from other similar feeding aggregations on the breeding grounds in the West Indies (IWC, 2008a, p.21).

In order to investigate whether West Greenland humpback whales are subject to mortality in other parts of the range then it is important to examine the available information from telemetry and photo-identification data. Considerable telemetry work has been undertaken off West Greenland (Heide-Jørgensen, 2012) and similarly there has been extensive photo-identification work. This has been used to inform how ship strike and bycatch data will be incorporated into the trials. This work is ongoing and Greenlandic scientists will work with the College of the Atlantic to present a review of the photo-identification data in time for an intersessional Workshop (see Item 26).

8.3.2.2 ABUNDANCE

The Committee has relative abundance data available from aerial surveys (see SC/65a/Rep02 and Annex E). It **agrees** to use the estimates of relative abundance from aerial surveys to condition the trials. The mark-recapture studies cover a shorter period and are heavily correlated so they will only be used in a *Robustness Trial*. However, given that mark-recapture abundance estimates may become common in the future for both humpback and bowhead whales, the Committee **agrees** that efforts should be made to develop ways to better integrate them into the operating models for the *SLA* trials.

With respect to absolute abundance, SC/65a/AWMP01 used information from 31 satellite-linked time-depth recorders to address the question of availability bias for the 2007 aerial survey. Fully corrected abundance estimates of 4,090 (CV=0.50) for mark-recapture distance sampling analysis and 2,704 (CV=0.34) for a strip census abundance estimate were developed. The estimated annual rate of increase is 9.4% per year (SE 0.01), unchanged from Heide-Jørgensen *et al.* (2012).

The Committee noted that the methods behind the new estimates had been discussed fully at previous meetings when considering the 2007 survey. The revised estimate was based on updated and improved information on the diving behaviour of whales from additional satellite tag data. It therefore **accepts** the new strip census abundance estimate as the best estimate. This information is also included in the trial specifications (see Annex E, Appendix 2).

8.3.2.3 REMOVALS

The Committee **agrees** that given past difficulties in modelling the full western North Atlantic (including allocation of past catches) and the decision to treat the feeding aggregation as the appropriate management unit, trials will begin in 1960 under an assumption that the age-structure in that year is steady. The direct catch series for this period is known. However, given possible migration routes (e.g. from telemetry data), it was noted that known direct catches occurred from whaling stations off the east coast of Canada after 1960 that may have included some 'West Greenland' animals. An approach to account for this has been developed. The Committee **agrees** that this will be incorporated into the catch series in the revised trial specifications, but that no future direct catches off Canada will be simulated.

In addition to direct catches, the question of bycatch in both West Greenland and of West Greenland animals elsewhere in their range needs investigation. For West Greenland, noting that the crab fishery which was primarily responsible for bycatch has now peaked, a conservative (from a conservation perspective) method for generating future bycatch has been developed. A similar method for accounting for bycatch outside West Greenland has been developed for bycatch and ship strikes. The Secretariat will work with Canadian scientists and others to investigate the available information on bycatch and ship strikes and develop a final removals table for consideration.

8.3.2.4 BIOLOGICAL PARAMETERS

Prior distributions need to be specified for three biological parameters: (a) non-calf survival rate; (b) age-at-maturity; and (c) maximum pregnancy rate. The values for these parameters used in the actual trials will encompass a narrower range than these priors because the priors will be updated by the data on abundance and trends in abundance during the conditioning process. Considerable discussion of this took place at the intersessional Workshop based on the range of estimates in the literature. The Committee **endorses** the priors shown in Annex E, Appendix 2. Recognising the considerable uncertainty, *Robustness Trials* have been developed to investigate the sensitivity to these priors.

8.3.2.5 NEED

Need envelopes are an important component of developing a trial structure and are the responsibility of the relevant Governments. They are used to allow for advice to be provided in the future on any increased need requests without having to conduct major *Implementation Reviews* or new *SLA* development. The need 'envelope' usually includes maintenance of the current limit, is bounded by a 'high need' case and then includes a middle option. A need envelope for humpback whales was submitted to the intersessional Workshop by Greenland (SC/D12/AWMP4) and these reflected the Greenlandic preference for humpback whales over fin whales and Greenland's desire for flexibility and a 'backup' to account for any unforeseen decline in the common minke whale strike limits. The need envelope is summarised in Annex E.

8.3.2.6 *SLA*S TO BE CONSIDERED

All trials will be conducted for a bounding case and for two 'reference *SLA*s', in addition to any other *SLA*s which might be proposed by developers:

(1) the *Strike Limit* is set to the need;
(2) the *Strike Limit* is based on the interim *SLA* (IWC, 2009b); and
(3) the *Strike Limit* is based on a variant of the interim *SLA* which makes use of all of the estimates of abundance, but downweights them based on how recent they are.

Guiding principles for *SLA*s are discussed under Item 8.2 above.

Developers are provided with the following information: total need for the next block; catches by sex; mortalities due to bycatch in fisheries and ship strikes; and estimates of absolute abundance and their associated CVs.

8.3.2.7 TRIAL STRUCTURE

After considering the report of the intersessional Workshop and the new information available at this meeting, the Committee agrees to the detailed trial specifications given in Annex E, Appendix 2. Some further discussion and parameterisation of one of the trials (that on asymmetric environmental stochasticity) is required and an intersessional steering group has been established to oversee this (Annex R).

The factors considered in the trials are summarised in Table 2 while the trials themselves are given in Annex E, Appendix 2, tables 5 and 6. The Committee **endorses** the trial specifications.

As noted under Item 8.2, the Committee also **endorses** the performance statistics, tables and plots proposed.

Table 2

Factors tested in the trials.

Factors	Levels (reference levels shown underlined)	
	Humpback whales	Bowhead whales
$MSYR_{1+}$	1%, 3%, 5%, 7%	1%, 2.5%, 4%
$MSYL_{1+}$	0.6	0.6, 0.8
Time dependence in K*	Constant, Halve linearly over 100 years	
Time dependence in natural mortality, M*	Constant, Double linearly over 100 years	
Episodic events*	None, 3 events occur between years 1-75 (with at least 2 in years 1-50) in which 20% of the animals die, events occur every 5 years in which 5% of the animals die	
Need envelope	A: 10, 15, 20; 20 thereafter B: 10, 15, 20; 20->40 over years 18-100 C: 10, 15, 20; 20->60 over years 18-100 D: 20, 25, 30; 30->50 over years 18-100	A: 2, 3, 5; 5 thereafter B: 2, 3, 5; 5 -> 10 over years 18-100 C: 2, 3, 5; 5 -> 15 over years 18-100
Future Canadian catches	N/A	A: 5 constant over 100 years B: 5-> 10 over 100 years C: 5-> 15 over 100 years D: 2.5 constant over 100 years?
Survey frequency	5 years, 10 years, 15 years	
Historic survey bias	0.8, 1.0, 1.2	0.5, 1.0
First year of projection, τ	1960	1940
Alternative priors	S_{1+} ~ U[0.9, 0.99]; f_{max} ~ U[0.4, 0.6]; a_m ~ U[5, 12]	N/A
Strategic surveys	Extra survey if a survey estimate is half of the previous survey estimate	
Asymmetric environmental stochasticity parameters	To be finalised by an intersessional group	

*Effects of these factors begin in year 2013 (i.e. at start of management). The adult survival rate is adjusted so that in catches were zero, then average population sizes in 250-500 years equals the carrying capacity. Note: for some biological parameters and levels of episodic events, it may not be possible to find an adult survival rate which satisfies this requirement.

8.3.3 Bowhead whales

8.3.3.1 STOCK STRUCTURE

The current working hypothesis in the Scientific Committee is a single Baffin Bay-Davis Strait stock of bowhead whales (see Annex E, fig. 2). However, pending the availability of some genetic analyses, the Scientific Committee had agreed that the possibility that there are in fact two different stocks present in the overall area, with the second located in the Foxe Basin-Hudson Strait region, cannot be ruled out (e.g. see IWC, 2009b).

Given that the objective is to develop an *SLA* for the Greenland hunt of bowhead whales, the Committee **agrees** to proceed first on a conservative basis that assumes that the absolute abundance of bowhead whales on the West Greenland wintering area is informed by abundance estimates from data for that region only (see below). Only if such an *SLA* proved unable to meet need would abundance estimate information and stock structure considerations from the wider area be taken into account.

8.3.3.2 ABUNDANCE

The absolute abundance estimates can be found in Annex E, table 3. It is not possible to combine the Foxe Basin-Hudson Bay 2003 survey with the 2002 Prince Regent Inlet survey to obtain an estimate for the entire Davis Strait-Baffin Bay-Foxe Basin area. The Committee therefore **agrees** to condition the operating model using data for Davis Strait-Baffin Bay stock only.

It is not known whether the 2002 survey in Prince Regent Inlet will be regularly conducted, although a new survey is anticipated, whereas it is known that regular surveys will be conducted off West Greenland. The Committee therefore **agrees** to conduct trials: (a) in which the estimate for Prince Regent Inlet is treated as an estimate of absolute abundance; and (b) in which the estimates from West Greenland are treated as estimates of absolute abundance.

With respect to relative estimates of abundance, the Committee **agrees** that they should be considered in a similar manner to those for humpback whales. Details can be found in Annex E, item 3.3.1.2. These estimates are also included in the trial specifications (see Annex E, Appendix 2).

While the sex ratio of animals in West Greenland is ~80:20 in favour of females (Heide-Jørgensen *et al.*, 2010), it is expected that the sex ratio for the total population is 50:50 (based on historic catches over the whole region and present Canadian catches). The trials will assume that the proportion of males available to the surveys will be the observed average male/female ratio in the biopsy samples.

The Workshop **agrees** that the information provided to the *SLA* will be the results of surveys off West Greenland (relative indices if the operating model is conditioned to the estimate of abundance for Prince Regent Inlet and absolute if the operating model is conditioned to the estimate of abundance for West Greenland).

8.3.3.3 REMOVALS

For reasons similar to those agreed for humpback whales above, the Committee **agrees** that population projections should begin from a recent year (1940). This is earlier than for humpback whales because of the extended age-structure of the population. All post-1940 direct catches of bowhead whales by Canada and Denmark (Greenland) are at present assumed known and thus that there may be no need to consider an alternative catch series. The Secretariat will consult with Reeves on post-1940 Canadian catches.

The Secretariat is consulting with Canada with respect to the agreed allowance for the hunters, to determine whether it applies to landed whales only or includes strikes.

The Workshop agreed that four scenarios regarding future Canadian catches should be considered as detailed in Annex E, item 3.3.1.3 and included in the trial specifications. The sex-ratio for the West Greenland catches will be set to the sex ratio observed in the biopsy samples taken off West Greenland over the 2002-11 period while that for the Canadian catches will be set to the observed sex-ratio which is being confirmed by the Secretariat.

Known bycatch of bowhead whales in this stock's range and further information on bycatch or ship strikes that can be found by the Secretariat in consultation with Canadian scientists will be included in the revised trials specification. The Committee noted that if the number of ship strikes increases as the Northwest Passage opens up, this could trigger an *Implementation Review*.

8.3.3.4 BIOLOGICAL PARAMETERS

In the absence of information for this region, the Workshop agreed to use the priors for f_{max}, S_{1+}, and a_m used for the *Implementation* for the Bering-Chukchi-Beaufort Seas bowhead whales, noting that these incorporate considerable uncertainty for all three parameters.

8.3.3.5 NEED

SC/D12/AWMP4 presented by Greenland had proposed three scenarios, each of which involves an increase to the need from 2 to 5 at the start of the projection period followed by either: (1) no increase of need; (2) a doubling; and (3) a tripling of need in a linear fashion over the total time period. This is shown in Annex E.

8.3.3.6 TRIALS

After considering the report of the intersessional Workshop and the new information available at this meeting, the Committee **agrees** to the detailed trial specifications given in Annex E, Appendix 2. As for the humpback whale case, some further discussion and parameterisation of one of the trials (that on asymmetric environmental stochasticity) is required and an intersessional steering group has been established to oversee this (see Annex R). The factors considered in the trials are summarised in Table 2 while the trials themselves are given in Annex E, Appendix 2, tables 5 and 6. The Committee **endorses** the trial specifications.

As noted under Item 8.2, the Committee also **endorses** the performance statistics, tables and plots proposed.

A number of the preliminary results considered under Item 8.3.4 illustrated that it would be difficult to meet conservation objectives satisfactorily when the need level was high, especially if Canadian catches (which are taken by a non-IWC member country) increase. The SWG discussed whether it would be advisable to reconsider how strike quotas and incidental removals (i.e. by Canadian hunters) are accounted for in the *SLA* computations. However, the Committee **agrees** to continue with the current framework but also **agrees** that this topic should be further considered at the next intersessional Workshop.

8.3.4 Results of initial work on SLA*s*

The Committee welcomed papers SC/65a/AWMP02, SC/65a/AWMP04 and SC/65a/AWMP05 that produced initial exploratory results by two sets of developers based on the draft trial specifications developed at the intersessional Workshop. It was noted that at this stage, each set of developers had developed their own approaches to choose amongst the *SLA* candidates which they had tested. The Committee noted that this was an acceptable approach for developers to take when investigating the performance of their initial *SLA*s before deciding to put 'official' candidates forward, but re-iterated that final choices would need to be based on the full set of performance statistics agreed for the trials.

8.4 Scientific aspects of an Aboriginal Whaling Scheme

In 2002, the Committee **strongly recommended** that the Commission adopt the Aboriginal Subsistence Whaling Scheme (IWC, 2003). This covers a number of practical issues such as survey intervals, carryover, and guidelines for surveys. The Committee has stated in the past that the AWS provisions constitute an important and necessary component of safe management under AWMP *SLA*s and it **reaffirms** this view as it has for the previous 11 years.

8.5 Greenland conversion factors

In 2009, the Commission appointed a small scientific working group (comprising several Committee members) to visit Greenland and compile a report on the conversion factors used by species to translate the Greenlandic need request which is provided in tonnes of edible products, to numbers of animals (Donovan *et al.*, 2010). At that time, the group provided conversion factors based upon the best available data, noting that given the low sample sizes, the values for species other than common minke whales should be considered provisional. The group also recommended that a focused attempt to collect new data on edible products taken from species other than common minke whales be undertaken, to allow a review of the interim factors; and that data on both 'curved' and 'standard' measurements are obtained during the coming season for all species taken. The group's report was **endorsed** by the Committee (IWC, 2011b, p.21).

Since then, the Committee has received progress reports but has commented that more detail and information is required. Last year, the Committee reiterated its recommendations from 2010 and 2011 (IWC, 2013c, p.22):

(1) the provision of a full scientific paper to the next Annual Meeting [i.e. IWC/65] that details *inter alia* at least a full description of the field protocols and sampling strategy (taking into account previous suggestions by the Committee), analytical methods, and a presentation of the results thus far, including information on the sex and length of each of the animals for which weight data are available; and

(2) the collection and provision of data on Recommendation No. 2 of Donovan *et al.* (2010) comparing standard versus curvilinear whale lengths, this should be done for all three species on as many whales as possible.

8.5.1 New information

SC/65a/AWMP07 reported on the collection of weights and length measures from fin, humpback and bowhead whales caught in West Greenland. To improve the data collection process, information meetings involving biologists, hunters, wildlife officers and hunting license coordinators were held in the larger towns in 2012, and an information folder was produced and distributed to the hunters. The data collection process was also combined with an existing research project on hunting samples in order to get a stronger involvement of biologists. When researchers participate in hunts they train the hunters in measuring the lengths (curved and standard) and they make sure that the meat is weighed.

Until now the reporting rate has been lower than expected, with the data obtained in 2012 being from only one fin whale and one humpback whale, and the total number of reports since 2009 being from six bowhead whales, six humpback whales and three fin whales. These data provide preliminary yield estimates for all edible products of 9,014kg (SE: 846) per humpback whale, of 6,967kg (SE: 2.468) per fin whale, and of 8,443kg (SE: 406) per bowhead whale. These numbers are all somewhat lower than the suggested yield in Donovan *et al.* (2010), and this is especially pronounced for fin whales. Nevertheless, the obtained estimates for fin whales fall within the range of previous yield weight estimates for fin whales in West Greenland.

A major reason for the low reporting rate has been the almost complete absence of weighing equipment where the whalers could weigh the different products. To increase the reporting rate, the Greenland Institute of Natural Resources has now purchased and distributed weighing equipment that can be fitted to cranes in major towns for the hunters to use for weighing when landing a catch. It was also realised that the 'bin system' described in previous reports (e.g. IWC/64/ASW10) is more complicated than first anticipated because there is a large variation in the size of the bins used within the same hunt and between hunters. It is therefore now recommended that hunters weigh all edible products with the crane weight when they land the meat. This approach will be investigated further in 2013 and discussed with the hunters. Owing to the logistical difficulties involved with whale hunts in Greenland (which are widespread along the huge coastline and occur at unpredictable times during a long season) and the required change in the reporting system and subsequent need for training, it is likely that it will take several years to collect sufficient data on edible products.

8.5.2 Discussion

In response to questions, a number of clarifications were made. The original intention of weighing ten boxes had been so that an average weight per box could be developed to be multiplied by the total number of boxes to obtain an estimated total weight. However, with the efficient crane weights that are now in place in three cities, and with the finding that hunters may use different sized boxes even for the same whale, it has now been decided to weigh all boxes.

There were only five cases when scientists were able to be present at a humpback catch, and this low number illustrates the logistical difficulties in having scientists present at hunts. Witting did not have the precise details of this work or of the number of wildlife officers who may be able to assist in the work but will consult in Greenland. Efficient reporting requires not only training of hunters, but also the distribution of weighing equipment, so that hunters can report on their own.

In conclusion, the Committee **agrees** that the report was an advance on those previously received (and provided the first information on curvilinear lengths). However, it also **agrees** that it still did not provide sufficient information to fulfil the recommendations of last year. While aware of the logistical difficulties involved in obtaining these data, it **repeats its recommendations** of last year given in the second paragraph of this section. It **encourages** Witting to assist in the writing of such a report to ensure that it better meets the request of the SWG next year.

9. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT ADVICE

9.1 Eastern Canada and West Greenland bowhead whales

9.1.1 New information

No new information was presented.

9.1.2 New catch information
No bowhead whales were taken off West Greenland in 2012. Official catch data have not yet been received from the Canadian Government for 2012. The Secretariat reported that it is in contact with the Canadian authorities who have acknowledged the request but not yet sent the catch data. The Committee also **encourages** the Government of Canada to continue research on Eastern Canadian bowheads.

9.1.3 Management advice
Using the interim safe approach (IWC, 2009b, p.16) as endorsed by the Commission, the Committee **agrees** that the current annual limit of two strikes for Greenland will not harm the stock. It was also aware that catches from the same stock have been taken by a non-member nation, Canada. Should Canadian catches continue at a similar level as in recent years, this would not change the Committee's advice with respect to the strike limits agreed for West Greenland.

9.2 Eastern North Pacific gray whales
9.2.1 New information
SC/65a/BRG02 presented new estimates of abundance for eastern North Pacific gray whales. Shore-based counts of southbound migrating whales off California have formed the basis of abundance estimation since 1967. A new observation approach has been used and evaluated in four recently monitored migrations (2006/07, 2007/08, 2009/10 and 2010/11). The summed estimates of migration abundance ranged from 17,820 (95% Highest Posterior Density Intervals [HPDI]=16,150-19,920) in 2007/08 to 21,210 (95% HPDI=19,420-23,230) in 2009/10, consistent with previous estimates and indicative of a stable population size.

The Committee welcomes and **accepts** the new population estimates.

SC/65a/BRG05 reported on photographic identification research in Laguna San Ignacio, Laguna Ojo de Liebre and Bahia Magdalena, Mexico, during the 2012 and 2013 winters. These results demonstrate a greater amount of movement between different breeding and calving lagoons for female-calf pairs than for single adult whales.

SC/65a/BRG05 summarised the results of a standard boat census of gray whales in Laguna San Ignacio and Laguna Ojo de Liebre during the winters from 2007 to 2013. In Laguna San Ignacio, counts of female-calf pairs increased during January and February to their highest numbers in March and April. During the 2011 to 2013 winters the average number of pairs was 108 and numbers remained high in the lagoon in April; by contrast, this number was only 40 pairs during the 2007 to 2010 winters and there were no pairs in April. In Laguna Ojo de Liebre in 2013 numbers of adults increased from January to February and declined to mid-April. Single animals only use the lagoon for 3-5 days. Females with calves use lagoons for up to 18 days. In one season with the highest counts, there was an estimated total of approximately 2,500 whales that used Laguna San Ignacio.

The Committee thanked Urbán and his colleagues for the interesting results from the studies in the breeding lagoons and **encourages** the continuation of those studies that will contribute greatly to the proposed intersessional rangewide gray whale Workshop (see Items 23 and 26).

SC/65a/BRG21 presented information on the body condition of gray whales in northwestern Washington, USA, from 2004-10 to examine whether this can provide insights into the variability of gray whale fidelity to the region. Of particular interest was a comparison with similar studies for the animals feeding off Sakhalin Island (Bradford *et al.*, 2012) that suggested that body condition in northwestern Washington is generally not as good as at Sakhalin. The reasons for this are not clear.

SC/65a/BRG12 presented information on harvested gray whales in 2012. In June and September 2012, scientists examined 23 gray whales caught near Mechigmensky Bay. Females averaged about 10m in length. Animals between 7.7m and 9.5m were sub-adults. Yearlings had the highest body condition index (blubber thickness/body length) and immature animals had the lowest; some 67% of the examined animals had full or half-full stomachs. There were no 'stinky' gray whales in Mechigmensky Bay. An immature, 7.7m female had traces of milk in an almost empty stomach. The hunters did not see a large whale escorting this small one and believed it was feeding independently. In discussion it was noted that milk might remain in the stomach for several hours or a little more.

SC/65a/BRG13 reported on the stomach contents of 82 gray whales taken in Mechigmensky Bay (63 from Lorino) from 2007-09; amphipods and polychaetes predominated by biomass and frequency of occurrence. Information was also presented on coastal counts.

The Committee thanked the authors for this interesting and important work examining harvested gray whales. It encouraged the work on photo-identification of harvested whales which is now beginning.

9.2.2 Catch information
SC/65a/BRG24 and SC/65a/BRG25 presented catch data for gray and bowhead whales in Russia. The quota is expressed in terms of landed animals not strikes and the 2007-12 block quota was for 620 gray whales (maximum 140 in any one year). A total of 143 gray whales were struck in 2012 of which 139 were landed (50 males and 89 females); eight were inedible ('stinky' whales). Body length and weight data were presented. In general some 10% of the whales are stinky. While stinky whales can sometimes be detected at sea and avoided, sometimes the whale has to be butchered before it is found to be stinky. For the period 2008-12, 638 gray whales were struck, 11 were lost and 627 whales were landed of which 24 were inedible, i.e. 603 edible whales were landed. Ilyashenko stated that stinky whales were not counted against the quota by the Russian authorities, since they do not meet the food needs of the indigenous people.

The Committee noted that the total number of gray whales struck during the 2008-12 period was 638 animals of which 24 of the 627 whales landed were inedible ('stinky') whales. The Commission expressed its limits for the 2008-12 period in terms of whales taken (620). While matters related to struck, landed and 'stinky' whales are matters for the Commission, the Committee noted that from an *SLA* perspective, all struck whales are considered removals.

9.2.3 Management advice
As was the case last year, the Committee **agrees** that the *Gray Whale SLA* remains the appropriate tool to provide management advice for eastern North Pacific gray whales taken off Chukotka; the question of the Makah hunt and whales from the Pacific Coast Feeding Group (PCFG) is considered under Item 8.1. The Commission adopted catch limits for a six-year block in 2012, i.e. 2013-18. The total number of gray whales taken shall not exceed 744 with a maximum in any one year of 140. The Committee **agrees** that these limits will not harm the stock.

9.3 Bering-Chukchi-Beaufort (B-C-B) Seas bowhead whales

9.3.1 New information

Three papers (SC/65/BRG01, SC/65a/BRG09 and SC/65a/BRG11) presented the improvements in field methods, the details of the acoustic and visual field observations and the new estimation method that underlie a new abundance estimate of this bowhead stock for 2011. The 2011 survey was among the most successful. The details are discussed fully in Annex F, item 2.1 and only a short summary is provided here.

SC/65a/BRG11 presented an overview of the spring 2011 bowhead whale abundance survey conducted near Point Barrow, Alaska. The 2011 survey was unique in that it included multiple simultaneous data collection efforts, these included: ice-based visual observations, an independent observer (IO) survey (to estimate detection probabilities), acoustic surveillance and an aerial photo identification survey. A total of 3,379 new whales was seen from the primary perch. This is close to the record (3,383 in 1993); however in that year it was estimated that 93% of the whales passed within view of the perch in contrast to 58% in 2011. Information was also provided on extensive photo-identification effort (aerial) and acoustic work.

SC/65a/BRG09 reported much higher levels of bowhead acoustic activity in comparison to recording efforts in past seasons that included high rates of singing and call sequences. The mean rate of acoustically located events in 2011 (calls/hr) was some 5.7 times higher than in 1993. Viewing conditions were similar to past surveys including substantial periods of watch missed due to poor visibility and closed leads. Telemetry and acoustic data suggest several hundred whales passed without the possibility of being seen.

SC/65a/BRG01 presented a new estimate of the total abundance for this population. The estimate is based on two large datasets: visual sightings and acoustic locations from spring 2011. A Horvitz-Thompson type estimator was used, based on the numbers of whales counted at ice-based visual observation stations. It divided sightings counts by three correction factors: (1) for detectability (and see Givens *et al.*, 2012, discussed by the Committee last year); (2) for whale availability using the acoustic location data (SC/65a/BRG09); and (3) for missed visual watch effort. The mean correction factors are estimated to be 0.501 (detection), 0.619 (availability) and 0.520 (effort). The resulting 2011 abundance estimate is 16,892 (95% CI; 15,704, 18,928). The annual increase rate is estimated to be 3.7% (95% CI; 2.8%, 4.7%). These abundance and trend estimates are consistent with previous findings.

The Committee thanked the authors, recognising the substantial field and analytical work that underlies the new abundance estimate. Discussion of the analytical approach can be found in Annex G, item 2.1. In conclusion, the Committee **accepts** this estimate and **endorses** it for use with the *Bowhead Whale SLA*. It further notes that under the guidelines outlined in the proposed Aboriginal Whaling Management Scheme (see Item 8.4), which has not been agreed by the Commission, a new survey would be required by 2021.

In discussion, it was noted that ice-based surveys depend very much on the availability of suitable ice conditions. The ice conditions may change within and between years and may become more difficult in the light of the climate changes observed in the Arctic. Aerial photographic surveys, which also were conducted during 2011, can form the basis of an independent mark recapture estimate of abundance (Koski *et al.*, 2010) although their precision is less than ice-based surveys.

SC/65a/BRG22 presented a study of DNA sequence variation for X- and Y-chromosome linked genes (USP9X and USP9Y) in bowhead whales using two methods to discover variable sites. The authors noted that with the PCR and sequencing primers reported, the X and Y chromosomes could be used to assess population variation in bowheads and other great whales to provide new perspectives on genetic issues such as stock structure, male reproductive success, gene flow and evolution. In discussion it was noted that bowhead whales have a relatively low level of variation in the Y chromosome due to skewness in male reproductive success. Population studies are underway.

9.3.2 New catch information

SC/65a/BRG19 provided harvest data for the Alaska hunt. In 2012, 69 bowhead whales were struck resulting in 55 animals landed. Total landed in 2012 was higher than the past 10 years (2002-11: mean of landed=38.9; SD=7.1) but similar for efficiency (no. landed/no. struck; mean of efficiency=77%; SD=0.07). Of the landed whales, 29 were females, 24 were males, and sex was not determined for two animals. Based on total length, six of the 29 females were presumed mature (>13.4m in length). All five of the mature females that were examined were pregnant.

SC/65a/BRG25 reported the results of the Russian aboriginal whaling in the Chukota region for the period of 2008-12: four bowhead whales were struck and landed out of a possible quota of 25 animals for that period. No bowhead whales were reported as struck and lost.

9.3.3 Management advice

The Committee **endorses** the abundance estimate of 16,892 (95% CI: 15,704-18,928) for spring 2011. It was noted that the next survey should be completed by 2021 based on the provisional guidelines in the Aboriginal Whaling Scheme (see Item 8.4).

The Committee **agrees** that the *Bowhead Whale SLA* continues to be the most appropriate way for the Committee to provide management advice for this population of bowhead whales. The Commission adopted catch limits for a six-year block in 2012, i.e. 2013-18. The total number of strikes shall not exceed 336 with a maximum of 67 in any one year (with a carryover provision). The Committee **agrees** that these limits will not harm the stock.

9.4 Common minke whale stocks off Greenland

The Committee noted that the Commission had not reached agreement on strike limits for Greenland at the 2012 Annual Meeting (see IWC, 2013a). It based its management advice on the same limits considered last year. In providing this advice it noted that the Commission has endorsed the interim safe approach (based on the lower 5th percentile for the most recent estimate of abundance) for providing advice for the Greenland hunts developed by the Committee in 2008 (IWC, 2009b, p.16); it was agreed that that this should be considered valid for two blocks, i.e. up to the 2018 Annual Meeting. This applies to all of the Greenland hunts below (i.e. Items 9.4-9.6).

9.4.1 West Greenland

NEW INFORMATION

In the 2012 season, 144 minke whales were landed in West Greenland and 4 were struck and lost. Of the landed whales, there were 109 females, 33 males and 2 of unknown sex. Genetic samples were obtained from 112 of these whales. Last year, the Committee re-emphasised the importance of collecting genetic samples from these whales, particularly in the light of the proposed joint AWMP/RMP Workshop (see

Table 3
Most recent estimates of abundance for the Central stock of common minke whales.

Small Area(s)	Year(s)	Abundance and CV
CM	2005	26,739 (CV=0.39)
CIC	2007	10,680 (CV=0.29)
CG	2007	1,048 (CV=0.60)
CIP	2007	1,350 (CV=0.38)

Annex D). The Committee **welcomes** the fact that nearly 80% of the catch had been sampled in 2012 and **encourages** continued sample collection.

This year, the Committee adopted a revised estimate of abundance for the 2007 survey. The revised published estimate (16,100, CV=0.43) was slightly lower than that first agreed in 2009. The Committee noted that this estimate is an underestimate of the total population by an unknown amount.

MANAGEMENT ADVICE
In 2009, the Committee was for the first time able to provide management advice for this stock. This year, using the agreed interim approach and the revised estimate of abundance given above, the Committee **advises** that an annual strike limit of 164 will not harm the stock. It **draws attention** to the fact that this is 14 whales fewer than its advice of last year due to the revised 2007 abundance estimate.

9.4.2 East Greenland
NEW INFORMATION (INCLUDING CATCH DATA AND AGREED ABUNDANCE ESTIMATES)
Four common minke whales were struck (and landed) off East Greenland in 2012. Two were females and the sex of the other two was unknown. The Committee was **pleased** to note that genetic samples were obtained from all of minke whales caught in East Greenland (these could be used *inter alia* to determine the sex of the unknown animals). The Committee **again emphasises** the importance of collecting genetic samples from these whales, particularly in light of the proposed joint AWMP/RMP Workshop (see Annex D).

MANAGEMENT ADVICE
Catches of minke whales off East Greenland are believed to come from the large Central Stock of minke whales. The most recent strike limit of 12 represents a very small proportion of the Central Stock (see Table 3). The Committee **repeats** its advice of last year that a strike limit of 12 will not harm the stock.

9.5 Fin whales off West Greenland (AWMP)
9.5.1 New information
A total of four fin whales (all females) were landed, and one was struck and lost, off West Greenland during 2012. The Committee was **pleased** to note that genetic samples were obtained from three whales. It **re-emphasises** the importance of collecting genetic samples from these whales, particularly in the light of the proposed work to develop a long-term *SLA* for this stock.

9.5.2 Management advice
Based on the agreed 2007 estimate of abundance for fin whales (4,500; 95%CI 1,900-10,100), and using the agreed interim approach, the Committee **repeats** its advice that an annual strike limit of 19 whales will not harm the stock.

9.6 Humpback whales off West Greenland
9.6.1 New information
A total of seven (two males; four females; one unknown sex) humpback whales were landed (three more were struck and lost) in West Greenland during 2012. The Committee was **pleased** to learn that genetic samples were obtained from all of these whales and that Greenland was contributing fluke photographs to the North Atlantic catalogue – four have been submitted from whales taken since 2010. The Committee again **emphasises** the importance of collecting genetic samples and photographs of the flukes from these whales, particularly with respect to the MoNAH and YoNAH initiatives (Clapham, 2003; YoNAH, 2001).

This year, the Committee **accepts** the revised fully corrected abundance estimate for West Greenland from the 2007 survey of 2,704 (CV=0.34) for the strip census abundance estimate (see Item 8.3.2.2 above). The agreed annual rate of increase of 0.0917 (SE 0.0124) remains unchanged.

9.6.2 Management advice
Based on the revised agreed estimate of abundance for humpback whales given above and using the agreed interim approach, the Committee **agrees** that an annual strike limit of 10 whales will not harm the stock.

9.7 Humpback whales off St Vincent and The Grenadines
9.7.1 New information
No new information or catch data were provided in time for consideration by the Scientific Committee although information has been requested by the Secretariat. There is one sample collected from a humpback whale taken on 11 April 2012 in the SWFSC tissue archive. The Committee **welcomes** this information.

Iñíguez reported information obtained from local newspapers on hunts in St Vincent and The Grenadines: a 35ft male (8 March 2013); a 41ft female and a 35ft male (both 18 March 2013); and another whale with no length or sex information (12 April 2013).

Regarding the same stock, he referred to reports that residents of Petite Martinique, Grenada, spent hours attempting to drive a mature whale onto a beach using five inflatable boats, two large trader boats and a speedboat on 22 November 2012. The whale finally escaped but was harpooned four times. He has no further information on the fate of this whale.

9.7.2 Management advice
The Committee repeated its previous strong recommendations that St Vincent and The Grenadines:

(1) provide catch data, including the length of harvested animals, to the Scientific Committee; and
(2) that genetic samples be obtained for any harvested animals as well as fluke photographs, and that this information be submitted to appropriate catalogues and collections.

The Committee has agreed that the animals found off St Vincent and The Grenadines are part of the large West Indies breeding population (abundance estimate 11,570; 95%CI 10,290-13,390). The Commission adopted a total block catch limit of 24 for the period 2013-18 for Bequians of St Vincent and The Grenadines. The Committee **repeats** its advice that this block catch limit will not harm the stock.

The Committee **draws the Commission's attention** to the unofficial reports of attempts to land a humpback whale in Grenada; the Schedule specifies that the quota applies only to Bequians of St Vincent and The Grenadines. It requests that the Secretariat contacts the Government of Grenada to obtain official information on this incident.

10. WHALE STOCKS

10.1 Antarctic minke whales
The Committee is undertaking an in-depth assessment of the Antarctic minke whale. Details of the discussions summarised below can be found in Annex G. The primary abundance data are those collected from the 1978/79 to 2003/04 IWC-IDCR/SOWER cruises (e.g. Matsuoka *et al.*, 2003) that had been divided into three circumpolar series (CPI, CPII and CPIII). Two methods for estimating abundance from CPII and CPIII have been developed in recent years. Last year, the Committee formally agreed abundance estimates (IWC, 2013c, p.27). These were developed by basing the estimates on one method (the OK model, Okamura and Kitakado, 2012) and applying adjustment factors based on analyses from the other method (the SPLINTR model, e.g. Bravington and Hedley, 2012).

While the agreed estimates were suggestive of a decline in abundance between CPII and CPIII, the decline was not statistically significant either at a circumpolar level or at a *Management Area* level, given the inferred amount of annual variability in distribution (see Item 10.1.2). The Committee has been working for some time on explaining variability in abundance of Antarctic minke whales, both by the development of population dynamics models (Item 10.1.3) and by examining possible changes in environmental conditions during the period of the CPII and CPIII surveys (Item 10.1.2). Regarding the latter, the Committee has been investigating possible ways to estimate abundance of Antarctic minke whales within the unsurveyed pack ice region (since the IWC-IDCR/SOWER cruises were only able to survey in open water), and to discover the extent to which changes in sea ice concentration and many other environmental processes may have been affecting the open water abundance estimates.

10.1.1 Consideration of technical aspects of the agreed abundance estimates for CPII and CPIII
No further developments were presented to the Committee this year, although the items identified last year (IWC, 2013c, p.28) remain pertinent. The model refinements required will be assisted by the recent work described in SC/65a/IA15, in which a new IWC simulated data scenario is developed based on empirical data from Antarctic minke whale video dive time experiments conducted on the 2004/05 IWC SOWER cruise.

The Committee welcomed the new datasets, recognising that it was unlikely that improved methods would be available next year, but that further progress was expected by the meeting after. The results of this exercise (improved simulated datasets and estimation methods) should be of value not only to this species but also to many abundance estimation tasks faced by the Committee.

The estimates agreed last year were presented as two sets of numbers with two sets of CVs; Annex G, item 2.2.2, clarifies the reasons why the estimates were presented this way, and what the limitations are when interpreting these numbers.

In summary and also to provide clarity on what can be said at this stage in relation to trends, the Committee noted the following issues.

(1) At the scale of the circumpolar surveys, there is no statistically significant difference between the two population estimates. This of course does not mean that the number of Antarctic minke whales did not change at all. Rather, the uncertainty around the two estimates is sufficiently large that it is not possible to conclude with confidence whether the abundance increased, decreased, or remained about the same.

(2) The same is true at the scale of the six IWC Management Areas; there are no statistically significant trends detected.

(3) Nevertheless, the point estimate of change at a circumpolar level is quite large, and the same is true for some of the Management Areas. While not significant statistically, the differences are suggestive that some real changes in abundance may have occurred, particularly in areas near the large embayments of the Ross and Weddell Seas. The Committee is continuing to investigate issues of habitat utilisation and movement patterns of Antarctic minke whales which may further inform its understanding and ability to interpret these survey results (see Item 10.1.2).

10.1.2 Continue to examine reasons for the difference between abundance estimates from CPII and CPIII

10.1.2.1 AERIAL SURVEYS
The Committee has for some years been working towards explaining a putative decline in Antarctic minke whale abundance between CPII and CPIII. Aside from the statistical catch-at-age modelling work described in Item 10.1.3, a particular focus has been on investigating possible changes in the relative proportions of whales within the pack ice, since such regions were inaccessible to the IDCR/SOWER vessels. Papers describing Australian surveys using fixed-wing aircraft (Kelly *et al.*, 2011; 2012) and German surveys from a vessel-based helicopter (Williams *et al.*, 2011) have been considered by the Committee at previous meetings, and although no new work on these surveys was presented at SC/65a, further analyses are expected to be received next year.

10.1.2.2 NEW MODELLING WORK
Without further information from direct observations, the Committee is restricted to analyses based on extrapolations of sightings in open water areas to within-ice regions for investigating the relative proportions of whales that may have been within the ice regions during the CPII and CPIII period. SC/65a/IA11 presented one such approach for doing so, using models which assumed a relationship between whale abundance and ice concentration. It also examined causal relationships between Antarctic minke and humpback whale distribution; the Committee considered that this approach was more promising for open water areas than within pack ice regions where humpback whales do not enter.

10.1.2.3 NEW INFORMATION
SC/65a/IA12 described a study of Antarctic minke whales in their sea ice habitat during the austral summer of 2012-13, in two regions of the Antarctic: the Ross Sea and the western Antarctic Peninsula. In less than a month of fieldwork (of which only a portion was dedicated to Antarctic minke whale research), the researchers deployed 16 satellite-linked data recorders and two short-term archival data recorders; they also collected biopsy samples and took a large number of photo-identification images of well-marked individuals.

In discussion of SC/65a/IA12, the Committee congratulated the authors on their achievement: this is the first time that reliable tag deployment has been achieved on this species. For investigation of differences in abundance estimates between CPII and CPIII, the Committee noted that the diving data collected from one type of tag deployed is also directly relevant to the interpretation of aerial survey estimates of abundance in different sea-ice conditions. The Committee **recommends** that this work should continue (and see Item 26).

There was considerable discussion (see Annex G, item 2.3) about *inter alia*: the particular conditions, location and group size and behaviour needed for successful tag deployment or biopsy sampling; the utility of photo-identification for abundance estimation; the feeding behaviour inferred from the telemetry result; and the relative merits and demerits of lethal and non-lethal sampling for in-depth assessment of Antarctic minke whales.

10.1.2.4 DID MINKE WHALE ABUNDANCE DIFFER BETWEEN CPII AND CPIII?

The Committee noted the apparent contradiction in retaining this item on its agenda when the difference in point estimates of abundance are not statistically significant at the usual 5% level (Item 10.1.1; see also Annex G, item 2.4). There is some evidence of differences (for example as seen consistently from the integrated statistical catch-at-age (SCAA) modelling – see Item 10.1.3 below), but the wide uncertainty around the estimates cannot exclude the possibility that overall abundance has not changed between CPII and CPIII. The Committee **agrees** to rename this item as: 'What are the factors that drive minke whale distribution and abundance?'

10.1.3 Apply statistical catch-at-age models

Population dynamics modelling provides a way to explore possible changes in abundance and demographic parameters within Areas IIIE-VW, where appropriate data are available. The inputs are catch, length, age, and sex data from the commercial harvests and both JARPA and JARPA II programmes, as well as abundance estimates from IDCR/SOWER. For over a decade, the Committee has been developing population dynamics models of Antarctic minke whales, and following early attempts using an ADAPT-VPA approach (e.g. Butterworth *et al.*, 2002), the Committee concluded that SCAA modelling was the most appropriate framework, since *inter alia,* the latter approach is able to incorporate variability in age-reading (and consequent errors in age-at-length). Following the abundance estimates agreed from IDCR/SOWER last year, this year it has been possible for the first time to study the performance of the models using a fairly complete set of agreed inputs.

SC/65a/IA04 presented an updated statistical method for quantifying age-reading error, i.e. the extent of bias and inter-reader variability among age-readers. The method was applied to data for Antarctic minke whales taken during Japanese commercial (1971/72-1986/87) and scientific (1987/88-2004/05) whaling.

The methodology and conclusions of SC/65a/IA04 were based on a careful experimental study to compare readers (see Annex G, item 2.1). To estimate the bias and variance, the method needs to assume that at least one of the readers produces age estimates which are either unbiased or have a known degree of bias, and that ageing errors between readers but on the same earplug are independent. These assumptions are unavoidable for any analysis of ageing error where no absolute ground-truth is available, and the Committee **agrees** that the approach and results of SC/65a/IA04 provide useable input data for the SCAA analysis in SC/65a/IA01.

SC/65a/IA01 reported on the most recent application of SCAA to data for Antarctic minke whales, thus incorporating the agreed IDCR/SOWER abundance estimates and the age-at-length data for recent years of JARPA II, neither of which had been available when results from these models have been presented previously to the Committee. This work has been directed by the Committee and funded through the Committee's budget. The SCAA approach allows for multiple breeding stocks, which can be allowed to mix across several spatial strata on the summer feeding grounds where catches are taken. It also allows carrying capacity and the annual deviations in juvenile survival to vary over time. Most analyses indicated that Antarctic minke whale abundance in Antarctic Areas III-E to VI-W increased from 1930 until the mid-1970s and declined thereafter, with the extent of the decline greater for minke whales in Antarctic Areas III-E to V-W than for those further eastward.

In discussion of SC/65a/IA01, the Committee noted that the modifications to the SCAA model suggested last year plus the addition of the new data had now produced largely acceptable fits (see also table 1 of Annex G). The SCAA has received extensive scrutiny and improvement over the years of its development (far more than is usual for similar fishery assessment models used in management), and appears to have stood up well. Nonetheless, some issues do remain; detailed technical suggestions to investigate these are given in Annex G, item 8. The Committee considered the interpretation of the current results in SC/65a/IA01 (plus additional runs of the model made during the meeting), bearing in mind also the numerous sensitivity analyses and alternative formulations explored in previous years. Overall, some conclusions appear to be quite robustly supported, while others are more sensitive to details of model formulation or data selection. Resolution of the issues identified will allow more confident interpretation of the results next year.

10.1.4 Work plan

The work plan for the in-depth assessment of Antarctic minke whales is described in Annex G, item 8 and will be furthered by two intersessional Working Groups – one on SCAA issues for further investigation, and one on remaining IDCR/SOWER data management. The Committee's views on the work plan for the sub-committee on In-depth Assessments is given under Item 24.

10.2 Southern Hemisphere humpback whales

The report of the IWC Scientific Committee on the assessment of Southern Hemisphere humpback whales is given in Annex H. The Committee currently recognises seven humpback whale breeding stocks (BS) in the Southern Hemisphere, labelled A to G; (IWC, 1998b), which are connected to feeding grounds in the Antarctic. An additional population that does not migrate to high latitudes is found in the Arabian Sea. Assessments of BSA (western South Atlantic), BSD (eastern Indian Ocean) and BSG (eastern South Pacific) were completed in 2006 (IWC, 2007b), although it was concluded that BSD might need to be re-assessed with BSE and BSF in light of mixing on the feeding grounds. An assessment for BSC (western Indian Ocean) was completed in 2009 (IWC, 2010d) and for BSB in 2011 (IWC, 2012c).

10.2.1 Assessment of Breeding Stocks D, E and F

In 2011, the Committee initiated the re-assessment of BSD, and the assessment of BSE and BSF. As shown in Fig. 3, these stocks correspond, respectively, to humpback whales wintering off Western Australia (BSD), Eastern Australia (sub-stock BSE1) and the western Pacific Islands in Oceania including New Caledonia (sub-stock BSE2), Tonga (sub-stock BSE3) and French Polynesia (sub-stock BSF2). For simplicity, the combination of BSE2, BSE3 and BSF2 will be referred to as Oceania.

10.2.1.1 NEW INFORMATION

SC/65a/SH13 presented the results of an updated analysis recommended last year by the Committee (IWC, 2013g p. 217). It analysed mixing proportions of humpback whale breeding stocks BSD, BSE and BSF in Antarctic Areas IIIE to VI. The analysis was based on 575 samples obtained in the Antarctic during JARPA/JARPA II and IDCR/SOWER and 1,057 samples from low latitudes of the South Pacific and eastern Indian Ocean. Analysis of approximately the first half of the mtDNA control region yielded 137 haplotypes, and mixing proportions and Fst were analysed under two stock structure hypotheses. Under the most general hypothesis of six breeding stocks, BSD predominated in Areas IIIE, IV-W and IV-E. BSE1 predominated in Area V-W, BSE2 dominated in Area V-E and BSE3 dominated in Area VI. BSF sub-stocks did not predominate in any Antarctic area, although BSF1 was partially represented in Area VI.

The Committee thanked the authors for completing the work in time for on-going assessment modelling. Technical aspects of the paper were discussed by the Working Group on Stock Definition (see Annex I) and mixing proportions for alternate Antarctic area boundaries were calculated for the assessment models (see Item 10.2.1.2).

SC/65a/SH08 described the first photo-id and biopsy sampling surveys for humpback whales and small cetaceans around nine islands in eastern French Polynesia's Tuamotu and Gambier Islands (BSF2). The Committee welcomed this information on BSF2 and **recommends** additional sampling in this remote area of the South Pacific from which few data are available.

Rankin *et al.* (2013) estimated calving intervals of humpback whales at Hervey Bay, East Australia based on a long-term photo-id catalogue of 2,973 individuals. Two methods of calculation (multi-event mark-recapture modelling and truncation) led to similar estimates of calving intervals: 2.98 years (95% CI: 2.27-3.51) and 2.78 years (95% CI: 2.23-3.68) respectively.

The technical details of this paper were not presented, but the Committee noted that these calving intervals do not strongly suggest a population undergoing a high rate of population increase (e.g., Noad *et al.*, 2011). The cause of this apparent discrepancy requires further evaluation.

10.2.1.2 REVIEW ASSESSMENT MODELS

The Committee reviewed the progress of assessment modelling of breeding stocks BSD, BSE and BSF. Last year, a three-stock model with feeding and breeding ground interchange was proposed to address two inconsistencies that arose in single-stock assessments: (1) the model-predicted population trajectory for BSD was unable to simultaneously fit the absolute abundance estimate of 28,830 whales in 2011 (Hedley *et al.*, 2011a) and the high growth rate suggested by the relative abundance series; and (2) the model-predicted minimum population size in Oceania violated the N_{min} constraint informed from haplotype data.

Intersessionally, three-stock (BSD+BSE1+Oceania) and two-stock (BSD+BSE1) models were developed that included mixing on the feeding grounds. These did not substantially improve model fit unless customary Antarctic stock boundaries were shifted eastward to allow for more Antarctic catches to be allocated to BSD and fewer to Oceania. SC/65a/SH01 presented the results of single-stock, two-stock and three-stock models that used the original Antarctic boundaries, as well as new proposed boundaries based on this finding.

During the meeting, further model runs were attempted to improve model fits to the BSD data. An examination of

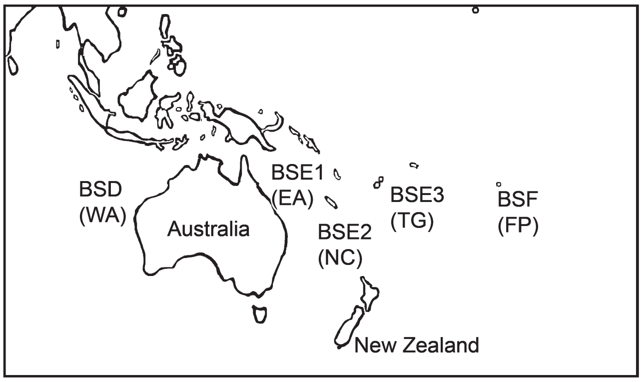

Fig.3. Distribution of Southern Hemisphere humpback whales breeding stocks grounds BSD, BSE1, BSE2, BSE3 and BSF2. Note the following abbreviations: WA=Western Australia, EA=Eastern Australia, NC=New Caledonia, TG=Tonga and FP=French Polynesia.

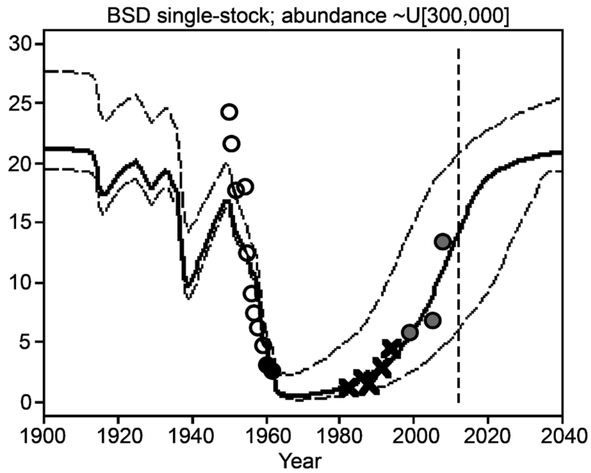

Fig.4. Posterior median population trajectories for BSD, showing the trajectories and the 90% probability envelopes. Results are shown for a single-stock model using the original catch boundaries. Plots show fits to the Chittleborough (1965) CPUE series (open circles), the Bannister and Hedley (2001) and relative abundance series (crosses), the Hedley *et al.* (2011b) relative abundance series (grey circles). The model is fit to both the Hedley *et al.* (2011b) and Bannister and Hedley (2001) relative abundance series only. The BSD abundance prior is set at U[0; 30,000]). The Chittleborough (1965) CPUE series is shown as consistency check. The trajectory to the right of the vertical dashed 2012 line shows projection into the future under the assumption of zero catch.

the BSD absolute abundance estimate (Hedley *et al.*, 2011a) identified irregularities in the underlying survey data which called into question the validity of the estimate. This could not be resolved during the meeting, but given this, and the strong influence of this estimate on the model results, single-stock BSD models were used to explore the effects of a lower, fixed abundance estimate and a model that was not fitted to absolute abundance but included an uninformative prior on this value. These models for BSD produced relatively good fits to all the relative abundance series (see Fig. 4). The Committee recognised that any abundance measurement method that could provide a lower bound to this prior (i.e. a value other than zero) would be useful in improving future model fits to BSD, and **recommends** that analyses to achieve this be attempted.

Three-stock models were also run using mixing proportions calculated with revised Antarctic area boundaries (Annex H, Appendix 2). One key result was that in order to fit the BSD relative abundance trends, the model removed more westerly Antarctic catches from BSE1, which

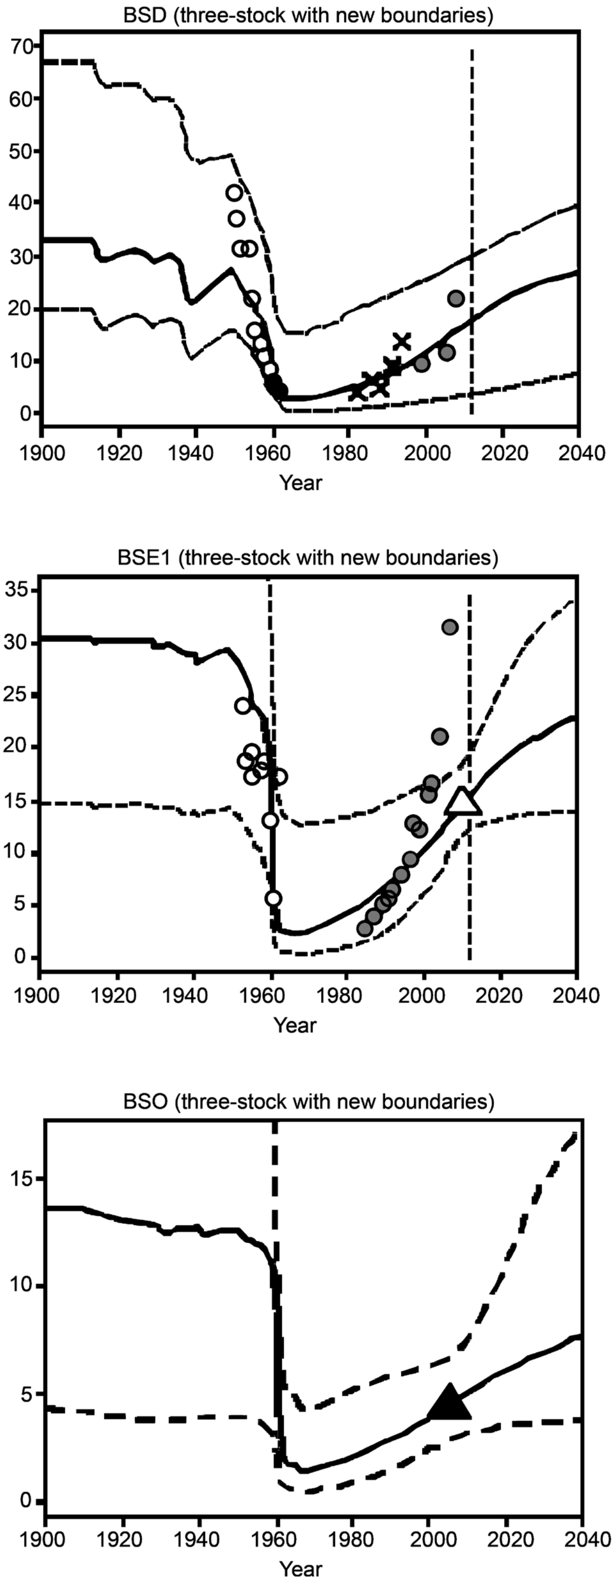

Fig.5. Three-stock model results assuming 'new' Antarctic catch boundaries proposed in SC/65a/SH01. The BSD abundance prior is set at U[0; 30,000]). BSO refers to Oceania (New Caledonia (E2)+Tonga (E3)+French Polynesia (F2)). SC/65a/SH01 details the data fitted for each breeding stock but in essence these are the Bannister and Hedley (2001) and Hedley *et al.* (2011b) relative abundance series for BSD (crosses and grey circles, respectively), the Noad *et al.* (2011) abundance estimate and relative abundance series for BSE1 (open triangles and grey circles, respectively), and the Constantine *et al.* (2011) photo-id mark-recapture data for Oceania. The black triangle for Oceania is the separate abundance estimate from mark-recapture data reported by Constantine *et al.* (2011) and the open circles for BSD and BSE1 are the CPUE data from Chittleborough (1965); these data are not fitted directly, but shown as consistency checks.

in turn led to the removal of Antarctic catches from Oceania to allocate to BSE1. Even so, the whales removed from BSE1 by the model did not deplete the population enough by the late 1960s (when most harvesting ceased) to reflect the rapid recent increases shown later by the east Australian surveys (Noad *et al.*, 2011). Use of an uninformative prior abundance on BSD in these models (with and without new Antarctic boundaries) did not improve the fit of the model to the BSE1 relative abundance data (see Fig. 5). Furthermore, none of the model formulations were consistent with the mixing proportions estimated by genetic data from the feeding grounds. Additional details of these results are provided in Annex H.

Other potential explanations for poor model fit were explored. Cooke (2009) describes situations in which attempts to fit a deterministic density-dependent population model to a recovering whale stock sometimes fail, because there are insufficient historic catches to account for the recent increase. His analyses suggested that lack of model fit should not be regarded as an anomaly to be explained, but a normal situation that is to be expected beyond a certain level of recovery and can be better fitted by accounting for environmental variability. Attempts to repair the lack of fit by allowing an arbitrary increase in carrying capacity could be expected to make the overestimation worse. Possible ways of addressing this in the current assessment models were discussed.

With respect to model fits to Oceania in SC/65a/SH01, the Committee **recommends** replacing the photo-id mark-recapture data with genetic mark-recapture data.

SC/65a/SH07 presented other progress toward modelling the population dynamics for East Australia and Oceania. This paper used logistic Bayesian FITTER models to co-measure population trajectories for pairs of South Pacific breeding grounds which share common high latitude feeding grounds. Two stock models were undertaken for East Australia (BSE1)/New Caledonia (BSE2), Tonga (BSE3)/ French Polynesia (BSF2) and East Australia (BSE1)/ Oceania (BSE2+BSE3+BSF2). In these preliminary results, East Australia carrying capacity varied between models (medians 26-42,000) while population increase rates were uniformly high. Median estimates of carrying capacity for New Caledonia ranged from 5,200-6,100, for Tonga 5,600-8,700 and for French Polynesia 4,000-5,700, with median recovery levels of 13-33%, 31-44% and 24-32% respectively.

The Committee thanked the authors for this work and noted several technical issues that still need to be addressed, including the use of a uniform prior on carrying capacity which leads to a biased estimate of MSYR.

In conclusion, the Committee **strongly agrees** that the assessment of breeding stocks D, E and F should be completed at next year's meeting. The following final **recommendations** were made to complete this work:

(1) a lower bound on the BSD abundance estimate should be obtained;
(2) a single-stock model for BSD will be run for a range of choices of the Antarctic feeding ground catches between 120°E and 150°E;
(3) two stock BSE1-Oceania models (with further breeding stock division within Oceania) will be explored; and
(4) if time permits after sufficient exploration of the models above, more complex options may be examined. These could include a three-stock model covering all of BSD, BSE1 and Oceania, together perhaps with more complex models for the dynamics of BSD, as discussed above.

The work plan for completing this work is provided in Item 10.2.6.

10.2.1.2 FUTURE WORK

SC/65a/SH09 described efforts by the South Pacific Whale Research Consortium to plan future sampling in Oceania with a view toward a future humpback whale assessment. Simulations and power analyses were used to evaluate planned field research in light of three main objectives: (1) to determine population size with a coefficient of variation of less than 20%; (2) to determine if the population is increasing or decreasing; and (3) to detect if population growth is significantly different from that of East Australia. Details are available in Annex H. The Committee welcomed this work, noting the importance of such planning and the value to future assessments of BSE2 and BSE3.

A modified POPAN model (Carroll *et al.*, 2013a) was discussed that explicitly accounts for heterogeneity in capture probability related to breeding cycles. The latter can cause substantial positive bias (+19%) in female abundance estimates and may be a consideration in the mark-recapture modelling of many cetacean species.

10.2.2 Review new information on other breeding stocks

New information was available for humpback whale Breeding Stocks B, C and G.

10.2.2.1 BREEDING STOCK B

SC/65a/SH24 collated humpback whale data from small boat surveys off Namibia (~23°S), 2005-12. Photo-id images were compared with catalogues from Gabon (2000-06) and West South Africa (WSA, 1983-2007). No confirmed matches were found, likely due to catalogue size and sampling period. However, a study of wounds from cookie cutter sharks (*Isistius brasiliensis*) and killer whales was used to infer relationships among these three areas in BSB.

The Committee welcomed this study, noting the potential utility of indirect indicators of stock structure for the Namibia region, where insights from photo-id and genetic data are still limited.

SC/65a/IA13 reported on cetacean sighting survey results in Gabon coastal waters from 4-10 September 2011 and in the Gulf of Guinea (Côte d'Ivoire, Ghana, Togo and Benin) from 23 March to 6 April 2013. The Committee thanked the authors for presenting these survey data. More information is available in Annex H, item 3.2.

10.2.2.2 BREEDING STOCK C

Two papers were received on satellite tagging projects to study the movements of humpback whales in this breeding stock. SC/65a/SH22 reported movements of twelve humpback whales satellite tagged off northeast Madagascar (BSC3). A wide range of movements were observed, including use of areas not previously recognised as preferred habitat. No tagged whales travelled to the west coast of Madagascar, Mozambique or the Mascarene Islands, where breeding aggregations are well documented. Observed movements between Madagascar and central-east Africa were likely not detected previously because of a lack of surveys in northern BSC1.

The Committee welcomed this work and noted its value for helping to clarify stock structure within BSC. Details of further discussion are available in Annex H.

SC/65a/SH02 described the results of satellite tagging eight humpback whales in the Comoros Islands (BSC2) in 2011 and 2012. Whales either remained at their breeding site for several weeks after tagging (n=3), dispersed to the northwest (n=2) or to southwest (n=3) coast of Madagascar. Of those tracked toward the Antarctic, one moved south-eastward towards the French sub-Antarctic islands and the other travelled to Antarctic Area III. These are the first detailed reports of humpback whale movement for this breeding sub-stock.

10.2.2.3 BREEDING STOCK G

SC/65a/SH04 described the results of small-boat surveys in the Gulf of Chiriqui (western Panama) during the austral winter season from 2002 through 2012. Initial catalogue comparisons have established matches to southern Costa Rica, and to feeding areas off Chile and Antarctica. Future plans include genetic analysis, comparing mother-calf habitat use to other breeding areas and long term acoustic monitoring. Discussion of this paper focused on the prevalence of mother/calf pairs in the area, which will be investigated further by the authors. This discussion can be found in Annex H.

10.2.3 Review new information on feeding grounds

Three studies (SC/65a/SH10, SC/65a/SH20 and SC/65a/O09) reported sightings of humpback whales during surveys in the Antarctic. Further details can be found in Annex H, item 3.3.

10.2.4 Antarctic Humpback Whale Catalogue

SC/65a/SH15 presented the interim report of IWC Research Contract 16, the Antarctic Humpback Whale Catalogue (AHWC). During the contract period, the AHWC catalogued 938 images representing 774 individual humpback whales submitted by 36 individuals and research organisations. Catalogue details are provided in Annex H, item 3.4.

The Committee recognises the contribution of the AHWC to humpback whales studies in the Southern Hemisphere and **recommends** its continuation (and see Item 26).

10.2.5 Other new information

SC/65a/SH05 reported on a study of Type 1 satellite tag performance and health impacts in humpback whales. This study has already informed tag modifications that have substantially increased tag duration, and are expected to reduce impacts on individuals. The Committee **thanks** the authors for this work, noting its value to future satellite tagging research.

10.2.6 Work plan

The Committee **confirms** that it will complete its assessment of Breeding Stocks D/E/F at next year's meeting, and thus also the Comprehensive Assessment of Southern Hemisphere Humpback Whales. Further details are given under Items 23 and 24.

10.3 Southern Hemisphere blue whales

10.3.1 Review new information

10.3.1.1 ANTARCTIC BLUE WHALES

Several papers reported results from the SORP Antarctic Blue Whale Project. SC/65a/SH21 provided an overview of activities undertaken on the Antarctic blue whale voyage between January and March 2013. This 47-day voyage focused on an area south of 60°S between 135°E and 170°W. Acousticians processed 26,545 Antarctic blue whale calls in 'real-time' and acoustically 'targeted' 51 groups of vocalising animals for photo-id and biopsy sampling. Further detail on tracking, sampling and other activities are provided below and in Annex H, item 5.1.1.

SC/65a/SH18 summarised the long-range acoustic tracking undertaken during the Antarctic Blue Whale Project. DIFAR sonobuoys were used to detect, localise and track Antarctic blue whales. In total, 85% of acoustic targets resulted in visual encounters and yielded 32 encounters with groups of blue whales. The project demonstrated the ability of acoustic tracking to locate Antarctic blue whales that are widely dispersed over a large area as well as the capacity to acoustically track whales for days at a time.

SC/65a/SH11 reported on the 50 Antarctic blue whales photo-identified as a result of acoustic-tracking during the 2013 voyage. The re-sighting rate of individuals during the voyage was similar to recent IWC SOWER cruises. Time between re-sights ranged from one to 27 days and straight-line distances ranged from 15km to 1,172km. Three individuals were matched to the Antarctic Blue Whale Catalogue and one had moved a minimum of 6,550km and 145° of longitude. Photo-identification data collected during the voyage will contribute towards a new abundance estimate of Antarctic blue whales using mark-recapture methods.

SC/65a/SH03 reported on the movements of satellite tagged Antarctic blue whales on their feeding grounds in 2013. Two tags collected movement data for 14 and 74 days, over 1,433km and 5,300km, respectively. Both whales performed long-scale movements interspersed with patches of searching, often in close association with the ice edge. Additional satellite tag deployments are planned to increase understanding of fine and large scale movements of Antarctic blue whales.

The Committee discussed these papers largely in the context of the ultimate aim of the Antarctic Blue Whale Project to estimate abundance through mark-recapture methods. It also highlighted the success of the SORP Antarctic Blue Whale Project to date and the significant advance it represents in non-lethal research on blue whales in the Southern Ocean. Additional details of this discussion can be found in Annex H, item 5.1.1.

SC/65a/O09 summarised sightings of blue whales during JARPAII of 2012/13. Details can be found in Annex H, item 5.1.1.

10.3.1.2 PYGMY BLUE WHALES

Three papers provided new information on blue whales off New Zealand. SC/65a/SH12 reported on blue whales observed and photo-identified in the coastal waters of New Zealand from 2004-13. Of 18 whales identified, 14 were observed during the SORP Antarctic Blue Whale Voyage in 2013, on transit to the Antarctic. Further details are available in Annex H, item 5.1.2.

SC/65a/SH19 reported additional findings from a combination of acoustics and visual observations at New Zealand, including data obtained during the 2013 SORP Antarctic Blue Whale Voyage noted above. Acoustic tracking confirmed blue whales to be the source of low frequency sounds recorded in this area. Comparison to recordings from 1964 and 1997 suggested that song types have persisted over several decades, are distinct from the Antarctic blue whales, and indicate a year-round presence around New Zealand. Blue whale song in this region has changed slowly, but consistently, over the past 50 years.

Torres (2013) presented evidence that the South Taranaki Bight is a blue whale foraging habitat and called for a greater understanding of their habitat use patterns to manage anthropogenic activities.

The Committee discussed the taxonomic status of blue whales in New Zealand waters. Based on available data on morphology, timing, distribution and acoustics, these whales are most likely to represent a form of pygmy blue whales. This is consistent with a growing body of evidence that populations of pygmy blue whales show considerable variation across the Southern Hemisphere.

The Committee **reiterates** that the relationship among pygmy blue whales in different areas is unclear and merits further investigation.

10.3.1.3 BLUE WHALES OFF CHILE

SC/65a/SH17 provided an update on surveys, photo-identification and biopsy research off the Isla de Chiloe and Isla de Chañaral (northern Chile) in 2013. Research at multiple sites has highlighted the importance of continued monitoring and increased photo-identification efforts to better understand the dynamics of the blue whales in this area. Concerns were also raised about the overlap of blue whales and vessels at the mouth of Chacao Channel. One blue whale stranding was documented north of this area in 2013, but cause of death was not determined.

The taxonomic status of Chilean blue whales was discussed by the Committee. They are intermediate in size between Antarctic and pygmy blue whales (Branch *et al.*, 2007). Furthermore, blue whales off Chile and Australia are as different genetically from each other as each is from Antarctic blue whales. Ongoing genetic analyses using additional samples from the Southern Hemisphere, Eastern Tropical Pacific and North Pacific will be undertaken to try to resolve their taxonomic status (see SC/65a/SH25).

10.3.1.4 PHOTO-IDENTIFICATION CATALOGUES

SC/65a/SH16 reported on the comparison of Antarctic blue whale photographs from JARPA to the Antarctic Blue Whale Catalogue (ABWC). Thirty-one individual Antarctic blue whales were photo-identified during JARPA cruises in the Antarctic during 12 austral summer seasons between 1992/93 and 2004/05. Photos were obtained in IWC Management Areas III, IV, V and VI. No new matches were found. This work brings the ABWC catalogue total to 305 individuals and notably increases available coverage from Area III (n=165) and in Area V (n=93). The Committee **recommends** that the 380 additional JARPA II blue whale photographs be compared to the ABWC.

SC/65a/SH23 describes efforts to consolidate all blue whale catalogues in the Southern Hemisphere. The Southern Hemisphere Blue Whale Catalogue (SHBWC) now contains 884 individual blue whales. Catalogues from South America, the Eastern Tropical Pacific (ETP) and Antarctica are now included and catalogues from the Indonesia/Australia/New Zealand area are in the process of being added. Comparisons between the eastern South Pacific and ETP have been completed and no matches were found. Comparisons between ETP and the Southern Ocean, as well as those from eastern South Pacific and the Southern Ocean are approximately 50% complete, with no matches found. The Committee **recommends** that the SHBWC continue its work and that all relevant data holders submit their photos to the catalogue.

10.3.1.5 NEW GENETIC INFORMATION

Attard *et al.* (2012) reported on hybridisation between pygmy and Antarctic blue whales, and a genetic estimate of the proportion of blue whale sub-species in the Antarctic. Further details and the discussion is provided in Annex H, item 5.1.5.

10.3.2 Work plan

The Committee's views on the work plan are given under Item 24.

10.4 North Pacific sei whale in-depth assessment

10.4.1 Review intersessional progress

Last year, an issue had been identified with the division of Japanese catch records between sei and Bryde's whales in the period 1955-72. This year the Committee heard that this had been a misunderstanding: the division of the catch figures had already been accomplished in the context of the Bryde's whale assessment.

Owing to other Committee priorities, it had not been possible to complete the incorporation of the Soviet and Canadian catch records intersessionally; this remains in the work plan for the forthcoming year (see Item 10.4.3).

10.4.2 Assessment

Although it was not possible to proceed with the assessment, analyses were presented that will inform the assessment when it is undertaken. Relating to stock structure, SC/65a/IA05 described the results of microsatellite DNA analysis conducted on North Pacific sei whale samples obtained from the 2010-12 IWC-POWER surveys (Annex G, item 5.2). The genetic data from 14 microsatellite loci from these samples were compared with previously reported genetic data from JARPN II (from 2002-07) and from commercial whaling samples (from 1972-73) across a range of locations within the North Pacific. The study supports the author's previous view that the open waters of the North Pacific were occupied by the individuals from a single stock of sei whales. This paper was discussed extensively by the Working Group on Stock Definition (Annex I), which made three recommendations for further analyses: (i) estimate the power of the data set to detect subtle population structure that might nevertheless be important for management; (ii) undertake a clustering analysis using STRUCTURE or a similar approach; and (iii) undertake a relatedness analysis when the sample size is sufficient to expert to find a reasonable number of close relatives.

It was reported that the recommended studies will be carried out, but not before 2016 because of other priorities. The Committee did not expect that these analyses would materially change the current understanding of stock structure; it **agrees** that it is not necessary to await the results before proceeding with the in-depth assessment.

Two preliminary analyses using sightings data from IWC-POWER were presented. SC/65a/IA09 provided a standard line transect analysis to estimate abundance of sei whales from the 2012 IWC-POWER survey (see Annex G, item 3 for a map showing the survey area). SC/65a/IA10 modelled the spatial distribution of fin, sei and humpback whales using data from the first three IWC-POWER surveys (2010-12). The Committee welcomed this analysis, and made a number of technical suggestions. Updated and revised analyses from both SC/65a/IA09 and SC/65a/IA10, using all available data, will be undertaken intersessionally; the Committee looks forward to receiving these and considering them in more detail at the in-depth assessment next year.

10.4.3 Work plan

Corrected Soviet catch data are documented by Ivashchenko *et al.* (2013). The Committee **agrees** that these represent the best possible reconstruction of the Soviet catch history in the North Pacific at this time, and that they should be incorporated into the IWC database (if this has not already been done). The Committee requests that Allison complete the remaining catch history additions or revisions (such as the revised Canadian catch data) during the coming intersessional period.

10.5 North Pacific gray whales

10.5.1 New information on stock structure and movements

There was considerable discussion of genetic information (see especially SC/65a/BRG16) on gray whale stock structure for the North Pacific both within the working group on stock definition (see Annex I, item 3.1.3) and the sub-committee on bowhead, right and gray whales (Annex F, item 3.1.2). Considerable attention was paid to developing the range of plausible hypotheses about the gray whales that summer in the Sea of Okhotsk near Sakhalin Island. The outcome of these discussions was the development of a list of seven hypotheses presented in Annex F, Appendix 3.

SC/65a/BRG04 summarises the results of the second year of the collaborative Pacific-wide study developed under the auspices of the IWC. The paper reported on the comparison of the gray whales photo-identified off Sakhalin Island (n=232) and the Kamchatka Peninsula (n=150) with the Mexican gray whale catalogue (n=4,352). A total of nine confirmed matches was found. Two whales were observed in the three places, three in Sakhalin and Mexico and four in Kamchatka and Mexico. These results provide new information important to the evolving understanding of gray whale population structure in the North Pacific.

The Committee thanks all the collaborators for the excellent progress on this project. The comparison of photographs between Sakhalin Island and Kamchatka, Russia with photos from lagoons in Baja California Sur, Mexico provides improved understanding of the connections between feeding and breeding/calving areas and interactions between western and eastern gray whales.

The Committee received papers summarising the work of two ongoing photo-identification and biopsy programmes off Sakhalin Island. Details are given in Annex F, item 3.2.1 and only a short summary is provided here. SC/65a/BRG03 reviewed findings from the ongoing 18-year collaborative Russia-US research programme on western gray whales summering off north eastern Sakhalin Island, Russia. When 2012 data are combined with results from 1994-2011, a catalogue of 214 photo-identified individuals has been compiled.

SC/65a/BRG08 reported on the programme being undertaken by the Russian Institute of Marine Biology (IBM) team that has been working off Sakhalin Island since 2002 and Kamchatka since 2004. The Sakhalin photo catalogue now contains 219 individual gray whales over the period of 2002-12. At present, the Kamchatka Gray Whale Catalogue contains 155 gray whales identified in 2004 and 2006-12 of which 85 were also photographed offshore of Sakhalin. Information on body condition was also presented. While the population remains small and therefore vulnerable, individual animals appeared to be in good body condition in 2012 compared with indicators from previous years. Few skinny whales were observed and those that were, had restored their body condition to normal over the course of the summer feeding season.

SC/65a/BRG18 reported on the results of the shore- and vessel-based surveys conducted in August-September 2012 under the Western Gray Whale Monitoring Program funded by Exxon Neftegas and Sakhalin Energy. The authors concluded that the results of the 2012 distribution surveys and photo-identification studies indicate that the Sakhalin gray whale feeding aggregation is gradually increasing in size and that the distribution of the whales remains similar to previous years.

The Committee welcomed these papers, recognising the importance of long-term monitoring of the animals off Sakhalin. It **strongly recommends** that the studies continue.

In addition to the work in Russia, the Committee received information from Japan and Korea. SC/65a/BGR20 reported on the status of conservation and research on North Pacific gray whales from May 2012 to April 2013 in Japan (including sightings surveys and morphological comparisons), while SC/65a/BRG26 reported on sighting surveys in Korean waters from 2003 to 2011. Neither the Japanese nor the Korean surveys saw any gray whales.

The Committee thanks Japan and Korea for providing this information and continuing work on gray whales. It **encourages** further comparison of skeletal morphology of gray whales across the North Pacific. It also thanked Japan for providing photographs of a juvenile gray whale sighted off Japan in March 2012; comparison with both Sakhalin and eastern catalogues produced no matches.

Given the large amount of new information related to population structure of gray whales in the North Pacific and the potential implications of this for conservation and management advice (see also Annex E, item 2), the Committee **endorses** a proposal for a rangewide review of the population structure and status of all North Pacific gray whales with an initial focus on an international Workshop (Annex F, Appendix 2).

10.5.2 Conservation advice

SC/65a/BRG27 presented an updated population assessment of the Sakhalin gray whale aggregation using photo-id data collected from 1994 to 2011 in the Piltun area by the Russian-US team. Details are provided in Annex F, item 3.2.1. The results showed evidence for between-year variability in calving rates and calf survival rates. The calving rate was found to be correlated with the calf survival rate with a two-year time lag. Under the assumptions made, no immigration in recent years was detected, suggesting that the population has been demographically self-contained, consistent with a high degree of maternally-directed feeding site fidelity. The 1+ (non-calf) population size in 2012 is estimated at 140 (±6) whales, increasing at 3.3 (±0.5) % per annum.

A number of matters for further consideration were raised. Work is underway to incorporate both Sakhalin catalogues into the assessment but certain issues needed to be resolved first. The Committee **agrees** that if possible both datasets should be included in a final assessment. Given the implications for conservation, a more thorough investigation of immigration should occur and the incorporation of body condition information into the model was also encouraged.

Annex F, Appendix 5 provided an update on the progress of the Western Gray Whale Advisory Panel (WGWAP), which is convened by IUCN.

10.5.4 Conservation advice

The Committee **reiterates** its support for the important work of the IUCN. As previously, the Committee **recommends** that oil and gas development activities (including exploratory seismic surveys) in areas used by gray whales be undertaken only after careful planning for mitigation and monitoring, noting the guidance provided by the WGWAP in this regard[16].

10.6 Southern Hemisphere right whales

The Committee completed an assessment of Southern Hemisphere right whales last year and the report is published as IWC (2013f).

10.6.1 Review new information

The Committee received a number of papers providing new information on southern right whales and details can be found in Annex F, item 4. A short summary of this work is provided below.

[16]*http://www.iucn.org/wgwap/wgwap/seismic_survey_monitoring_and_mitigation_plan/.*

SC/65a/BRG10 reported on the results of the aerial survey for right whales in South African waters in October 2012 funded by the IWC and part of a long-term monitoring programme. The number of identified cow-calf pairs was the fifth highest since surveys began in 1979, and an exponential fitted to the data over the 34-year period provides a significant rate of increase (0.0625±0.0035 SE per annum).

SC/65a/BRG17 extended the analyses of Brandão *et al.* (2012) which applied the three-mature-stages (receptive, calving and resting) model of Cooke *et al.* (2003) to photo-identification data from the long-term monitoring programme available from 1979 to 2010 for southern right whales in South African waters, by taking two further years of data into account. The 2012 number of parous females was estimated to be 1,321, the total population (including males and calves) 5,062, and the annual population growth rate 6.6%.

Carroll *et al.* (2013b) provided information of a return of southern right whales to former habitat around the main islands of New Zealand including the first evidence of female site fidelity to the mainland New Zealand calving ground. There was some discussion as to whether this represented a re-establishment of primary habitat by a remnant stock that survived in the New Zealand sub-Antarctic.

Carroll *et al.* (2013a) reported on methods to extend the 'superpopulation' capture-recapture model (POPAN) to explicitly account for heterogeneity in capture probability linked to reproductive cycles, such as the 2-5 year birth intervals observed in southern right whales. This model extension, referred to as POPAN-τ, has potential application to a range of species that have temporally variable life stages. The authors demonstrate the utility of this model in simultaneously estimating abundance and annual population growth rate (λ) in the New Zealand southern right whale from 1995-2009, with a total 'superpopulation' estimate from the best model of around 2,100 (95% CL1,836-2,536).

SC/65a/O09 reported that four schools and five individuals of southern right whales were sighted in 2012/13 of JARPA II in the Antarctic. One southern right whale was photographed for photo-identification.

10.6.2 Complete assessment

SC/65a/BRG15 reported on a Workshop on the ongoing southern right whale die-off at Península Valdés. The 2010 IWC Workshop on this topic (IWC, 2011f) reviewed the significant number of right whale calf deaths and *inter alia* drew attention to the increasing incidence of parasitic behaviour of kelp gulls which peck at the outer skin and then feed on the blubber of live whales, and recommended that management measures be taken with respect to kelp gulls displaying this behaviour.

SC/65a/BRG15 also reviewed the most recent information on gull lesions and calf mortality. There is a strong signal of gull attacks as a unique, increasing, and acute element of the lifecycle of young right whale calves. The participants developed hypotheses on the mechanisms by which these attacks and injuries can lead to death and agreed to continue to work on these. The Workshop commended the work of the SRWHMP team.

Solving the kelp gull harassment problem is a priority action within the CMP developed for this region. Information was received on a feasibility study was carried out last year testing the use of different gun types - a 12-gauge shotgun was deemed to be the most successful. The reactions of the southern right whales to gun discharge were also recorded and no changes in their behaviour were observed. For the 2013 southern right whale season the objective is to continue this programme.

The Committee **expresses concern** over the continued large annual mortality of calves at Península Valdés, and its potential significance to the population. The increase in gull populations is driven by anthropogenic factors such as open landfills and discharge from fisheries. It **recommends** that investigation of the causes of this mortality, including the hypothesis that gull attacks are contributing to calf deaths, should continue as a matter of priority and **recommends** that strategies and actions to reduce the risk of gull attacks on southern right whales at Península Valdés should be further developed and implemented. The Committee **commends** the SRWHMP for their hard work and diligence in trying to resolve this situation and **encourages** continuation and further support of this important work.

The Committee received information on progress with the IWC Conservation Management Plan for the Southern Right Whale Southwest Atlantic Population as a result of a Workshop held in Argentina (SC/65a/BRG07). The overall objective of the CMP is to protect SRW habitat and minimise anthropogenic threats to maximise the likelihood that SRW will recover to healthy levels and recolonise their historical range. The CMP (details in Annex F, item 4.4) developed nine high priority actions, ranging from public awareness and capacity building through research to mitigation. Iñíguez has been appointed co-ordinator of the programme for a two-year period and a Steering Committee has been established including range state representatives, the Chairs of the Conservation Committee, Scientific Committee and the CMP SWG and the IWC Head of Science. A panel of experts will also be established.

The Committee **welcomes** the progress with the CMP and is willing to assist with scientific advice if required.

The Committee also **endorses** the holding of a workshop to develop and implement a strategy to minimise kelp gull harassment on southern right whales as proposed by the CMP. Such a workshop would be held in early 2014 and developed in consultation with the Province of Chubut. A budget request for partial funding is given under Item 26.

SC/65a/BRG14 noted that the southern right whale is listed as 'least concern' in the IUCN Red List of Threatened Species. Although not a threatened species, data from a review of strandings and sightings reveal a real reduction in southern right whales records for the southeast coast of Brazil. The authors stated that this should be considered as a cause of conservation concern**.**

Galletti Vernazzani *et al.* (In press) reported on behaviour and habitat use patterns of eastern South Pacific southern right whale sub-population. This population is likely to contain less than 50 mature individuals, and has been classified as critically endangered by IUCN. In 2012, the IWC endorsed a CMP to promote its long-term recovery. One of the highest priorities of the CMP is to identify the breeding area(s) which is difficult given the length of the coastline and and the low number of individuals. The first resighting between years of a known individual, the southernmost sighting of a cow-calf pair and the first documented record of likely reproductive behaviour in these whales has been reported in a small area off coastal waters off northwestern Isla Grande de Chiloe (Isla de Chiloe), southern Chile. This new information highlights the importance of this area for this population and suggests that it is part of a breeding area. Isla de Chiloe is the northern limit of the Chilean fjord system and was a former whaling ground for southern right whales, therefore it seems that whales are reoccupying their former range. However, a large wind farm project and associated port is being proposed to be built at northwestern Isla de Chiloe and it is likely it will affect this important habitat for this critically endangered population.

The Committee welcomed this information and, in light of this critically endangered status and the importance of this area for the recovery of the population, it **strongly recommends** relocation of the wind farm project away from shore, and **reiterates** the need for the urgent development of an environmental impact assessment that considers possible impacts on cetacean habitats.

10.7 North Atlantic right whales

10.7.1 Review any new information

No new information was presented.

10.7.2 Conservation advice

The Committee **repeats** its concern over North Atlantic right whale stocks and notes that it is a matter of urgency that every effort be made to reduce anthropogenic mortality (e.g. see IWC, 2012a). It requests that updated information on the status of any of these stocks be provided to the next Annual Meeting.

10.8 North Pacific right whales

10.8.1 New information

The Committee welcomed new information of sightings of North Pacific right whales: (1) one animal amongst several bowhead whales in July 2011 in the Western Okhotsk Sea; (2) two separate animals in 2012 as part of the JARPN II programme (both photographed and one biopsy sample); and (3) one animal (photographed) southeast of Kodiak Island during the 2012 IWC-POWER cruise.

10.8.2 Conservation advice

The Committee **reiterates** its previous concern over the status of this endangered species throughout the North Pacific. Noting that significant new data has accumulated from survey work in recent decades, especially in the western North Pacific and Sea of Okhotsk, the Committee **recommends** that the survey data on North Pacific right whales (including search effort, sightings, photo-id and biopsy results) be synthesised and presented by Matsuoka and colleagues to next year's meeting.

10.9 North Atlantic bowhead whales

10.9.1 Review any new information

No new information was presented.

10.10 Okhotsk Sea bowhead whales

10.10.1 New information

The Committee received considerable new information on bowhead whales from Ulbansky Bay in the Okhotsk Sea in 2011 and 2012 (SC/65a/BRG28 and SC/65a/BRG29). Details can be found in Annex F, item 2.2. Local observations indicate bowhead whales appeared in early May and were present in the area during the study from early July to early September. Large groups (up to 43 in 2011 and 51 in 2012) were seen. An individual biopsied in 2001 was recaptured in 2012. Approximate abundance based on the 2012 genetic recaptures (105 whales genotyped in 1995-2011 with 5 recaptures in 31 whales biopsied in 2012) suggest values about twice that of the earlier estimate of about 300 animals. However, false negatives resulting from differences in laboratory analyses for earlier samples could result in fewer recaptures and cause positive bias to any estimates. For mtDNA analyses, complete sequences of the control region were obtained for 64 individuals. Seven haplotypes were found including one not found in the earlier study by MacLean (2002), who also identified seven haplotypes.

In discussion, the Committee commended Shpak and colleagues for their excellent work. It **strongly encourages** further research on this small and little-studied stock, including: (1) continue biopsy collection in the Shantar region during summer; (2) calibration of samples collected in 1994-2001 and 2011-12 via an exchange of samples between US and Russian laboratories; (3) determining if whales in the various Bays of the Shantar region represent an homogeneous group; and (4) examining the relationship between bowhead whales observed in spring in the Shelikhov Bay and those from the Shantar region.

It was further noted that combining data from bowhead genetic studies conducted in the 1990s would allow updated capture-recapture (minimum) population estimates.

Brownell reported on new plans for offshore oil and gas development in the northern Okhotsk Sea. It was noted that oil and gas exploration lease blocks were purchased 50 to 14km offshore of the city of Magadan approximately in water depths of 120 to 180m. It is expected that exploration will start in 2017 and drilling by the mid-2020s. This area is north of Sakhalin Island and likely in the areas used by Okhotsk Sea bowhead whales when they migrate back and forth across the north Okhotsk Sea. In discussion it was noted that bowhead whales use the Shelikov region in spring but that there have been no reported sightings of bowhead whales off Magadan. There have been sightings of gray whales.

10.11 Arabian Sea humpback whales

10.11.1 Review new information

SC/65a/SH06 reported recent information on a discrete and non-migratory population of humpback whales in the Arabian Sea. A small vessel survey was conducted in Oman in 2012, and made three humpback whale sightings (five individuals) in 1,250km of survey effort. Sightings occurred in the Gulf of Masirah, which was previously identified through habitat modelling as a critical area for the population. Passive acoustic data are pending analysis and units will be re-deployed over the next year. Photo-id data were not adequate to revise population estimates as requested last year. Fishing and shipping in the region were reported in the context of potential threats to this population.

Information was also provided on progress toward the regional conservation initiative mentioned in SC/65a/SH06. Members of the intersessional correspondence group on the Arabian Sea population, together with regional NGO partners have begun work to establish a regional research and conservation programme for this population. The programme would help to initiate and foster collaborative research amongst range state partners, increase local capacity and generate awareness of Arabian Sea humpback whale conservation issues. Additional details are available in Annex H, item 4.

The Committee welcomed these important updates on the Arabian Sea humpback whale population. Given the critical status of this population, it **recommends** that this research be allocated a high priority. The regional conservation initiative was strongly supported as a positive opportunity for range states to work together towards improving the status of this population. Such work could also benefit a CMP, should one ultimately be established for this population (see Item 10.11.2).

Plans were described to satellite tag Arabian Sea humpback whales with implantable tags. Tagging would involve no more than 20% of the population, which has most recently estimated at 84 individuals (Minton *et al.*, 2011), and would address priority research questions identified previously by the Committee. The proponents stated that they have carefully reviewed the present state of tag development and will be following international best practice including using a well-designed and tested tag and an expert tagging team. Further project details and precautions are outlined in Annex H, item 4.

The Committee noted the importance of the proposed work, given how little is known about the Arabian Sea humpback whale population. While the proposed sample size is modest, even a small number of tags has the potential to significantly increase what is known about this population. At least seven dead humpbacks have been detected in the last 10 years and this casts doubt on the sustainability of the population, e.g. it exceeds the estimated Potential Biological Removal (PBR) for this population (Wade, 1998). As noted above, Oman has experienced a rapid increase in the development of fisheries, high speed ferries and coastal infrastructure projects, many of which overlap with known humpback habitat. Given the observed mortality and known threats, there is an urgent need for better information on movement and habitat use. This project has the potential to considerably improve knowledge in the short term and is in fact the only way to collect this information given the nature of this population and the available resources.

It was noted in discussion that the results of recent satellite tag assessment studies on the health of animals (SC/65a/SH05) will be available in the next few years and that consideration should be given to waiting for those results. However, the Committee also recognised the urgency of this issue and the potential benefit to the conservation management of this critically endangered population. The Committee **recommends** that this work be undertaken as a high priority. An important caveat is that any untested tag modifications should be evaluated on other populations and not used first on Arabian Sea humpbacks.

10.11.2 Progress toward the development of a Conservation Management Plan

In 2010, the Committee recommended the development of a Conservation Management Plan (CMP) for Arabian Sea humpback whales. A CMP could address concerns for this population as well those for other species of large whale. To date, neither of the two range state members of the IWC (India, Oman) has yet volunteered to lead the development of a CMP, although there is some recognition of urgent conservation concerns and research needs.

10.12 International cruises

10.12.1 IWC-POWER cruises in the North Pacific

The Committee has now agreed objectives for the IWC-POWER programme, and this year reviewed the results of the 2012 cruise (Item 10.12.2), the Planning Meeting report for the 2013 survey (Item 10.12.3) and discussed plans for the 2014 cruise (Item 10.12.4).

The 2014 cruise will mark the end of the short-term phase of the programme, completing coverage of a large area of the North Pacific (see Annex G, fig. 2). This phase had been designed to cover the whole survey area in as short a time as possible to provide baseline information on distribution and abundance for several large whale species/populations. Alongside sightings data, dedicated time for biopsy sampling and photo-identification work has been allocated, providing information on stock structure, movements and potentially further information on abundance.

10.12.2 Review of the 2012 IWC-POWER sighting survey

The 3rd IWC-POWER cruise was successfully conducted from 13 July-10 September 2012, in the eastern North Pacific using the Japanese Research Vessel *Yushin-Maru No.3* (SC/65a/IA08). The cruise was organised under the auspices of the IWC. Researchers from Japan, Korea and the US participated in the survey. The cruise had five main objectives (see Annex G, item 3.1). The survey plans had been endorsed by the Committee (IWC, 2012a, p.32). The Committee **agrees** that it was duly conducted following the guidelines of the Committee.

Further details of the cruise, including summaries of the sightings made, may be found in Annex G, item 3.1. The Committee, thanks the Cruise Leader, researchers, captain and crew for completing the third cruise of the IWC-POWER programme. The Governments of Canada and the USA had granted permission for the vessel to survey in their respective waters, without which this survey would not have been possible. The Governments of the Republic of Korea and the USA provided one scientist each, and the Government of Japan again generously provided the vessel and crew, as it had done for the 2010-11 cruises. The Committee recognised the value of the data contributed by this and the other IWC-POWER cruises, collected in accordance with survey methods agreed by the Committee, covering many regions not surveyed in recent decades, and addressing an important information gap for several large whale species.

In discussion of the 2012 POWER cruise results, the Committee heard that weather conditions in the North Pacific in summer tend to be poor. For future planning of the medium- and long- term phases of the programme, the Committee agreed that the sighting conditions during the 2010-14 cruises should be investigated. This is relevant both to the feasibility of estimating abundance of various whale species from current North Pacific surveys, and also for considering any changes in design required for subsequent cruises after 2014. These considerations were referred to the IWC-POWER Technical Advisory Group (TAG) Workshop scheduled for later in 2013 (see also Annex G, Appendix 2).

10.12.3 Planning for 2013 IWC-POWER cruise

SC/65a/Rep01 presented the report of the detailed Planning Meeting for the 2013 IWC-POWER cruise. The Meeting received preliminary results from the 2012 IWC-POWER cruise and these were used, along with overall objectives of the first phase of the IWC-POWER surveys, to formulate a plan for the 2013 cruise, which will take place between 30-40°N, and from 135-160°W. The vessel (kindly supplied by Japan) will depart on 12 July 2013. The Meeting also agreed to a suggestion to highlight the IWC-POWER surveys on the IWC website with the ultimate aim of inspiring multinational collaboration in the survey programme. Fortunately, there will be no problems arising from requirements for CITES permits during the 2013 survey as the tracklines do not enter any EEZs; however, the problems will return in 2014, when the planned survey design will take the vessel into US waters (see Item 10.12.4 below). The Committee was informed that the Japanese and US authorities are working to solve this issue. SC/65a/Rep01 also covered a number of items related to the short, medium and long-term objectives of IWC-POWER, which were later discussed by the IWC-POWER TAG (Annex G, Appendix 2).

The Committee **thanks** the members of the Planning Meeting for their report and **endorses** their recommendations.

10.12.4 Recommendations for 2014 cruise

SC/65a/O05 outlined the plan for the IWC-POWER cruise in 2014. The proposed research area is the eastern north Pacific, between 170°E and 160°W, from 30°N to 40°N (Annex G, fig. 2). Photo-id and biopsy experiments are also planned. The plan was drawn up following general guidelines agreed in 2012 at the Tokyo Planning Meeting (SC/65a/Rep01). Information collected from this survey will provide essential information for the intersessional Workshop to plan for a medium-long term international survey programme in the North Pacific.

On receiving these plans, the Committee **recommends** that permission be sought to operate in the US EEZ far enough in advance for the 2014 cruise. The Committee was informed that the Japanese and US governments are working to solve the problems before the 2014 survey. It thanked the Government of Japan for its generous offer of providing a vessel for this survey.

The Steering Group for IWC North Pacific Planning appointed last year was re-established, convened by Kato (see Annex R). Final planning will take place at a Planning Workshop to be held in Tokyo (see Item 26).

10.12.5 IWC-SOWER cruises (progress on website, publications and analyses)

Last year, the Committee nominated an Editorial Board, and tasked it with responsibility for the preparation of a commemorative IDCR/SOWER volume. As Convenor, Bannister reported that in accordance with the Committee's wishes, a timetable has been developed, a contents list has been proposed and authors have been approached to prepare brief outlines of their contributions.

The volume is intended to be a book reviewing the cruises: not a series of original scientific papers, but rather a series of review chapters bringing together all the work that has been accomplished so far (see Annex G, item 4.1). The volume will provide an introduction to the IDCR/SOWER programme and its fieldwork, including its original aims and objectives, and cruise narratives. There will be major chapters on whale distribution and movements, particularly of minke and blue whales, on taxonomy and population structure, on acoustics, and on abundance (including the development of DESS). An extremely important chapter will be devoted to conclusions and lessons for the future, with emphasis on achievements and lessons learned.

The Committee thanked Bannister and the Editorial Board, and looked forward to an update next year.

In order to facilitate analyses for some of the planned contents, the Committee considered that the production of standard datasets (similar to those produced for the analysis of Antarctic minke whales) would be useful. The Secretariat will make the data available when requested although additional information must be provided if any additional verification is needed to that which is already incorporated into IWC-DESS.

10.12.6 Other cruises

10.12.6.1 REPORT OF JAPANESE CETACEAN SIGHTING SURVEYS IN THE NORTH PACIFIC IN 2012

SC/65a/O04 reported on three systematic dedicated sighting surveys conducted in 2012 summer by Japan (ICR) as a part of JARPN II to examine the distribution and abundance of large whales in the western North Pacific. Over 8,700 n.miles were searched in total, and of the baleen whales, Bryde's whales were most frequently encountered, with only five individual minke whales observed in the offshore strata.

The Committee welcomed this report and **recognises** the value of the data. As noted under Item 10.12.2, sighting conditions might need to be accounted for when estimating abundance in the North Pacific (particularly for common minke whales), and indeed when designing surveys for that purpose. Although the small number of sightings of common minke whales in the offshore strata might well be largely due to poor weather, it was considered premature to conclude that no abundance estimate could be made without first seeing a weather-stratified analysis.

10.12.6.2 PLANS FOR A JAPANESE CETACEAN SIGHTING SURVEYS IN THE NORTH PACIFIC IN 2013

Plans for a systematic dedicated sighting survey in the North Pacific by Japan (ICR) as part of JARPN II in 2013 are described in SC/65a/IA03; the survey is currently underway. The main objective is to examine the distribution and estimate the abundance of common minke and sei whales for management. Notwithstanding a possible minor trackline design issue, the Committee **endorses** the proposal.

10.12.6.3 REPORT OF CETACEAN SIGHTING SURVEYS IN THE ANTARCTIC IN 2012/13

Plans for a dedicated sighting survey in the Antarctic in the 2012/13 austral summer were presented last year and subsequently endorsed by the Committee (IWC, 2013a, p.41). Two research vessels were to survey Area III E, Area IV, and the western part of Area V, using the same methods as in the IWC-SOWER surveys, and in accordance with the guidelines agreed by the SC (IWC, 2005b). Unfortunately the research could not be conducted due to violent interference from an anti-whaling NGO (SC/65a/IA07).

The Committee noted and expressed its concurrence with the Commission's previous consideration of this issue and its 2011 Resolution on Safety at Sea (2011-12) in which the Commission and its Contracting Governments condemned any actions that were a risk to human life and property in relation to the activities of vessels at sea. In particular, the Committee expressed its regret that the actions prevented the sighting survey from being conducted, just as in 2011/12. Following the cessation of the IDCR/SOWER programme in 2009 (and notwithstanding smaller-scale national projects to collect sightings data in particular regions), surveys such as in SC/65a/IA07 provide the only dedicated cetacean sightings that are synoptic over a wide area, and as such are extremely valuable for the work of the Scientific Committee.

10.12.6.4 PLANS FOR CETACEAN SIGHTING SURVEYS IN THE ANTARCTIC IN 2013/14

A systematic cetacean sighting survey for abundance estimation is planned in the Antarctic in the 2013/14 austral summer, as part of JARPA II (SC/65a/IA06). The planned research area comprises Area IV, Area V and the western part of Area VI, from December 2013 to March 2014. Details, which also incorporate biopsy sampling and photo-id work, are in Annex G, item 4.3.

In discussion, the Committee recognised the difficulty of fully reviewing a proposal without detailed design information, but noted that this seems unavoidable given security considerations (see Item 10.12.6.3). The use of consistent protocols over time makes this series of cruises a valuable resource, not least for analysing ice effects. The Committee recalled that photos of blue, right, and humpback whales from similar surveys in the past have been submitted to the relevant catalogue-holders for those species (and will continue to be submitted in future). The Committee broadly **endorses** the proposal, **recommending** that the proposed trackline design be changed if a survey of the Ross Sea was actually able to proceed.

10.13 Other

10.13.1 Photographic archiving

SC/65a/IA14 presented a progress report of a major archiving and cataloguing exercise being undertaken by the Secretariat for the photographic collections arising out of the IDCR/SOWER and continuing IWC-POWER cruises. The photographs have a wide range of potential uses ranging from photo-identification through education to contributing to assessments of human impacts.

The Committee **expresses** its appreciation for the efforts of Taylor and Donovan in archiving and cataloguing the collections and looks forward to a further update next year.

10.13.2 Sperm whales

SC/65a/SH14 investigated the potential population recovery of sperm bulls off Albany, Western Australia. This segment of the population was reduced by commercial whaling by 74% between 1955 and 1978. In 2009, an aerial survey was undertaken to replicate the behaviour of the 'spotter' planes employed by the Albany whaling fleet from 1968-78. The mean number of sperm bulls seen on transect per day (morning) in 2009 was substantially lower than the mean number seen in any of the years between 1968 and 1978. The authors emphasised the preliminary nature of the results, but considered them indicative of a lack of increase in the number of sperm whales frequenting this area compared to when whaling was taking place.

The Committee discussed possible interpretations of these findings, including the potential for population shifts due to ecological changes. It also noted a relevant discussion on sperm whales off New Zealand in Annex M, item 8.8. However, the possibility of population decline led the Committee to discuss the feasibility of undertaking a future assessment of sperm whales. There was general agreement that such an assessment would concentrate on sperm whales in the Southern Hemisphere, but include equatorial nursery groups and the Arabian Sea. The Committee discussed the availability of data on: (1) population structure within ocean basins; (2) population size within ocean basins (and abundance in smaller areas); (3) catch history; and (4) considerations in the development of a new assessment model.

The Committee **agrees** that data availability and feasibility of future assessment would continue to be evaluated intersessionally and reported to the Committee next year. It **recommends** that a dedicated agenda item be added for this species for next year's meeting. More details can be found in Annex H, item 6.1.

11. STOCK DEFINITION

This agenda item was established in 2000, and has been handled since then by a Working Group. The Terms of Reference for this Working Group were changed in 2012 to reflect the evolving needs of the Committee. During this meeting, the Working Group continued to develop guidelines for preparation and analysis of genetic data within the IWC context (see Item 11.1), provided the Committee with feedback and recommendations concerning stock structure related methods and analyses presented to other sub-committees (see Item 11.2), and developed a draft reference glossary of stock related terms, to aid consistent definition of 'stocks' in a management context for the Committee (see Item 11.4 and Annex I, Appendix 5). The report of the Working Group is given as Annex I.

11.1 Guidelines for DNA data quality and genetic analyses

Two sets of reference guidelines have been developed and endorsed by the Committee (IWC, 2009d) and form 'living documents' that can be updated as necessary[17]. The first set addresses DNA validation and systematic quality control in genetic studies. The second set provides guidelines for some of the more common types of statistical analyses of genetic data used in IWC contexts, and contains examples of management problems that are regularly faced by the Committee. Three new sections were added to the data quality guidelines during SC/65a. Substantial progress on the genetic analysis guidelines was also made during this meeting and this document will now be completed intersessionally (see Item 11.5). Both guidelines will also be published in the peer-reviewed literature.

11.2 Statistical and genetic issues related to stock definition

A number of Committee stock related papers were discussed by the Working Group. These were submitted to the following sub-committees: Revised Management Procedure (Annex D), Bowhead, Right and Gray Whales (Annex F), In-Depth Assessments (Annex G), Other Southern Hemisphere Whale Stocks (Annex H) and Review of Special Permit Proposals (Annex P). Technical comments on these papers are given in Annex I.

Gray whale stock structure was discussed in the context of SC/65a/BRG16 and Annex I, Appendix 2. An initial set of hypotheses were developed from these documents to describe the stock structuring of western and eastern gray whales, with particular reference to the Sakhalin Island feeding ground. These initial hypotheses are shown in Annex I, Appendix 3. They will be further developed intersessionally and assigned levels of plausibility. This will contribute to the proposed rangewide Workshop on gray whale stock structure and status (see Item 26).

A general comment was raised that is relevant to many discussions of stock related papers presented to the Committee. With new 'next-generation' DNA sequencing (NGS) techniques, it is now relatively inexpensive to increase the number of genetic markers analysed, so that more information can be gained from each sample in a population study. More genetic markers are often called for in circumstances where the existing marker set cannot detect population differentiation, either due to lack of discriminatory power or lack of population subdivision. Increasing the number of genetic markers increases the power to detect subtle population structuring and can facilitate future studies of relatedness patterns among sampled animals. Simulation analysis of the power of DNA markers to measure departures from panmixia and to reject demographically significant (i.e. sufficiently high) migration rates between putative differentiated populations can provide a useful means of measuring whether the existing DNA marker dataset is sufficient to answer the management question being posed. In all Committee studies, it is important to consider the level at which structure population needs to be detected in order for it to be of management concern. Increased numbers of loci can increase power to detect subtle population structure and also allow for improved inference of the population history underlying the substructure. However, they can also increase resolution to the point where even individuals can be discriminated and can also amplify spurious signals from genotype errors and small departures from random sampling. With the rapid recent developments in NGS technology and analysis, there are some emerging issues of relevance to the Scientific Committee, in terms of: (1) assessment of NGS data quality, and how best to curate such data; and (2) new methods for measuring stock structuring and measurement of other statistical quantities of interest to the Committee. New and published papers on this topic are therefore solicited for submission next year, where they will be considered in the context of the existing Committee guideline documents on DNA analysis and quality (see Item 11.5).

[17] *http://iwc.int/scientific-committee-handbook#ten.*

11.3 Testing of Spatial Structure Models (TOSSM)

The aim of TOSSM is to facilitate comparative performance testing of population structure methods intended for use in conservation planning. From the Committee's perspective, the IWC-developed TOSSM software package allows evaluation of methods for detection of genetic structure, in terms of how well the methods can be used to set spatial boundaries for management. It is available for all to use and simulated datasets exist for three of the five stock-structure archetypes previously proposed by the Committee (IWC, 2009b, p.51). Progress has been made on the work items suggested at last year for the Pacific Coast Feeding Group (PCFG) of gray whales (see Item 8.1) and will be presented at the 2014 Annual Meeting.

The Committee noted that the potential for using simulated datasets generated by TOSSM for work to evaluate dispersal rates and new methods for genetic clustering, as proposed under RMP (Annex D, Appendices 3 and 4), particularly in relation to stock hypothesis under review for the Scientific Committee.

11.4 Terminology and unit-to-conserve

Defining and standardising the terminology used to discuss 'stock issues' is still a long standing objective of the Working Group on Stock Definition, in order to help the Committee report on these issues according to a common reference of terms. Appendix 5 of Annex I has been developed by the Working Group with the aim of encouraging consistent use of stock related terms within Committee reports and in papers submitted to the Committee. The Appendix provides initial draft definitions of Committee terms such as 'biological stock', 'sub-stock', 'population' and 'management stock' which will be further discussed and refined intersessionally by members of the Committee. A list of agreed terms will be finalised next year. A challenging example set of cetacean populations that have been discussed by the Scientific Committee over the last five years will be chosen and their stock 'definitions' agreed intersessionally, also for presentation and discussion at next year.

11.5 Work plan

The Committee's work plan is given under Item 24.

12. ENVIRONMENTAL CONCERNS

The Commission and the Scientific Committee have increasingly taken an interest in the possible environmental threats to cetaceans. In 1993, the Commission adopted resolutions on research on the environment and whale stocks and on the preservation of the marine environment (IWC, 1994a; 1994b). A number of resolutions on this topic have been passed subsequently (e.g. IWC, 1996b; 1997; 1998a; 1999a; 1999b; 2001a). As a result, the Committee formalised its work on environmental threats in 1997 by establishing a Standing Working Group that has met every year since.

12.1 State of the Cetacean Environment Report (SOCER)

SOCER provides an annual update, requested by the Commission, on: (a) environmental matters that potentially affect cetaceans; and (b) developments in cetacean populations/species that reflect environmental issues. It is tailored for a non-scientific audience. The 2013 SOCER (Annex K, Appendix 4) had the Mediterranean and Black Seas as the regional focus. Publications summarised ranged from impacts of fisheries removals on cetacean prey to strategies aimed at reducing bycatch in the severely reduced population of common dolphin, to contaminants in Mediterranean cetaceans. Disease continued to be an important issue in the Mediterranean. Finally, an overview published by ACCOBAMS identified the main threats to cetaceans in the Mediterranean and Black Seas.

Globally, numerous studies on climate change and ocean acidification are starting to show impacts on marine species. Data on the impacts of underwater noise are increasing with new models becoming available on stress responses in cetaceans linked to underwater noise.

The Committee encourages continued contributions to this effort. Next year, the focus of the SOCER will be on the Atlantic Ocean region.

12.2 Pollution

12.2.1 Update on POLLUTION 2000+ Phase II progress

At the intersessional POLLUTION 2000+ Phase II Workshop, held in 2010 (IWC, 2011a), four objectives for the cetacean pollutant exposure and risk assessment modelling component were agreed: (1) improve the existing concentration-response function for PCB-related reproductive effects in cetaceans (completed in 2011); (2) derive additional concentration-response functions to address other endpoints (e.g. survival, fecundity) in relation to PCB exposure (completed in 2012); (3) integrate improved concentration response components into a population risk model (individual-based model) for two case study species: bottlenose dolphin and humpback whale; and (4) implement a concentration-response component for at least one additional contaminant of concern.

SC/65a/E04 provided a summary of the intersessional work that was completed in POLLUTION 2000+, Phase III. The objective of this work was to develop a framework for assessing the health risks associated with contaminant exposure on cetacean populations. Two previous papers on the first phases of this work are Hall *et al.* (2011) and Hall *et al.* (2012).

Bioaccumulation of contaminants and their population level effects were explored using a stochastic model that integrates measured tissue concentrations with a dose-response relationship to estimate potential impact on population dynamics. Two examples were examined using this framework: bottlenose dolphins and humpback whales. One of the model outputs was an annual accumulation rate for blubber PCB levels (e.g. 1.2 mg/kg lipid for female bottlenose dolphins and 0.2 mg/kg lipid for Gulf of Maine humpback whales). These exposure levels would produce no discernible effects on population growth. Analyses of model parameter sensitivity and uncertainty indicate that the model is reasonably robust and would be acceptable for making population inferences and management decisions.

An approach that would allow concentrations of total blubber PCBs in cetaceans to be estimated from data on concentrations in their prey was also explored, assisting in situations where biopsy samples are not obtainable. In an example again using bottlenose dolphins, data on energy requirements and consumption rates on concentrations of total PCBs in prey were combined in a physiology-based toxicokinetic model.

These modelling approaches provide a risk assessment tool that can be used to determine the population consequences of exposure to contaminants. The model framework also has the potential for investigating the impact of a variety of stressors on cetaceans and is currently being converted into a web-based program with a user-friendly interface that will be accessible from the Commission website.

Since the Pollution 2000+ Phase III risk assessment work plan is near completion, the Committee began planning the next phase. The Committee established a Pollution 2020 steering group, which will next focus on assessing the toxicity of microplastics and polycyclic aromatic hydrocarbons and dispersants in cetaceans (see Annex K, item 11.2 and Appendix 2).

The Committee **commends** the progress on Pollution 2000+ Phase III objectives and **strongly supports** its continued work to further develop the necessary tools to assess cetacean pollutant exposure risk. The Committee **agrees** to the Pollution 2020 framework plan.

12.2.2 Oil spill impacts

After the Deepwater Horizon oil spill in April 2010, oil spill response was followed immediately thereafter by a Natural Resource Damage Assessment (NRDA) to investigate the injuries and impacts to cetaceans in the Gulf of Mexico. The NRDA investigation has included stranding response in the northern Gulf of Mexico; photo-id and biopsy surveys for bay, sound and estuary dolphins; aerial and boat-based surveys, including biopsy and tagging activities, for cetacean abundance and distribution in coastal and offshore habitats; and live capture/release health assessments.

An Unusual Mortality Event (UME) was declared in November 2010 for cetaceans in the northern Gulf of Mexico that started in February 2010 and now includes over 1,000 cetacean strandings. The Deepwater Horizon oil spill has not been ruled out as a possible contributing factor to this UME, which is the longest lasting and largest dolphin mortality event in US recorded history. In addition to the UME investigations, live capture/release health assessments of bottlenose dolphins from Barataria Bay, Louisiana (oiled area) and Sarasota Bay, Florida (reference site) were performed in 2011. Dolphins from Barataria Bay showed significant health issues, including pulmonary lesions and adrenal abnormalities, as compared to animals in Sarasota Bay. Chemical analyses associated with these stranded and live-capture dolphin studies have been completed and are currently being validated. In addition, a number of monitoring and assessment efforts on cetaceans have been conducted in offshore areas, including photo-id, passive acoustic monitoring, and tagging studies on pelagic species (e.g. sperm whales), as well as aerial and boat-based surveys.

The Committee **expresses great concern** about the continued high number of dolphin strandings in 2013. The Committee **agrees** that funding gaps are problematic for long-term monitoring projects, recognising that 3-5 year funding cycles are not geared toward such studies. The Committee welcomes the new information on marine mammal studies in the Gulf of Mexico and **encourages** scientists to provide restoration ideas for cetaceans to NOAA.

Information on oil spill preparedness was also presented. Details were provided on the Arctic Council's efforts to address oil spill preparedness (and response) based on the 1990 International Convention on Oil Pollution Preparedness

Response and Cooperation (OPRC), administered by the International Maritime Organization (IMO), to which all eight Arctic States are Parties[18]. Additionally, the Committee was given details on the US National Research Council's review of the capabilities, limitations, and needs for responding to an oil spill in the Arctic[19], as well as the US Arctic Research Commission's recently published white paper examining the state of oil spill preparedness, response and damage assessment in the Arctic[20].

Several workshops focused on Arctic resource development and policy will be held in the next year. Developing recommendations related to cetacean conservation and management may provide the Convenors of these workshops with information necessary for sound decision-making. The Committee **reiterates** its previous conclusion (IWC, 2011b, p.41) that a review of the capacity for oil spill response in the Arctic was an urgent priority in the aftermath of the Deepwater Horizon oil spill. The Committee **concludes** that it would be useful to know more about the current capacities and mechanisms of oil spill recovery. Given the amount of activity occurring related to oil spill preparedness and the fact that oil spill preparedness and response plans are being developed, the Committee **recommends** an increased exchange of information between the IWC Secretariat and the Arctic Council's Emergency Prevention, Preparedness, and Response Working Group (EPPR-WG).

12.2.3 Other pollution-related issues

In response to the statement in Resolution 2012-1 encouraging the World Health Organization (WHO) to conduct reviews of recent scientific publications regarding contaminants in certain cetacean products and give updated advice for consumers, the Committee **recommends** that the Secretariat reinitiate discussions with the WHO as a preliminary step, to ensure that they are in need of this information and would be willing to receive it, prior to moving forward on this Item.

Hunt *et al.* (2013) focused on methods that can produce information on parameters relevant to stress physiology, reproductive status, nutritional status, immune response, health and disease using non-lethal sampling techniques (see Annex K, item 7.3.2). Field application of these techniques has the potential to improve our understanding of the physiology of large whales, better enabling assessment of the relative impacts of many anthropogenic as well as ecological pressures. SC/65a/BRG23 reported on the progress of a programme to analyse biopsy samples of gray whales feeding off of Sakhalin Island, Russia that will include pregnancy testing, determination of stable isotope ratios and genetic analyses.

The Committee **commends** the recent advances in methods for non-lethal sampling, noting that information on stress physiology, reproductive status, nutritional status, immune response, health and disease are valuable to health assessment efforts. The Committee **endorses** this work and **strongly recommends** further development and improvement of these methodologies. The Committee **commends** the application of such techniques to the gray whales feeding off of Sakhalin Island, Russia.

The Committee received several contaminant-related papers associated with the Icelandic Research Programme, including those reporting concentrations of legacy persistent organic pollutants, trace elements, radioactivity and new contaminants of concern in Icelandic minke whales. A summary of the findings of these studies is listed in Annex K, item 7.3.3. The Committee thanked the Icelandic scientists for summarising these findings.

[20]*http://www.Arctic.gov/publications/oil_spills.2012.html.*

12.3 Cetacean Emerging and Resurging Disease (CERD)

In 2007, the Committee recognised the need for increased research and standardised reporting in a wide range of disciplines dealing with cetacean health (IWC, 2008d), which led to the creation of the Cetacean Resurging and Emerging Disease (CERD) Working Group.

12.3.1 Update from CERD Working Group

An update to the CERD work plan agreed in 2011 (IWC, 2012e, Appendix 3) included: (i) identification of regional and national experts/points of contact via Steering Committee membership; (ii) creation of a listserve and a website; (iii) creation of a Framework Document; and (iv) identification of and contact with organisations synergistic with the goals of CERD.

12.3.2 CERD website and work plan

Data on infectious and non-infectious diseases, general cetacean disease, nutritional disorders and biotoxins have been compiled and await entry. Additional input on skin diseases, visual health assessment and mortality events or unusual mortality events (UMEs) is needed. Although significant progress had been made the final website had not yet been completed. It was noted that an internship programme with projects aimed at expanding specific sections related to skin diseases, mortality events and visual health assessment would aid in this process.

The Committee **agrees** that supporting the aggregation of website information and input, and the ability to post and manipulate high-resolution images and video, are critical to the success of the CERD website. The Committee also **agrees** that there is value in linking to social websites in order to direct inquiries and information to the CERD website (for appropriate material). The Committee **encourages** continued development.

12.3.3 Strandings and mortality events

SC/65a/SM27 reported on a mass stranding event (MSE) in which 20-30 short-beaked common dolphins stranded on a beach in the Rio de Janeiro State, Brazil, and were returned to the water by tourists. The authors proposed that these pelagic dolphins were probably acoustically trapped or restricted by some noise source that caused them to panic and swim toward the beach and strand. An update also was received on a highly unusual event involving the long-term displacement and mass stranding of approximately 100 melon-headed whales that occurred in May-June 2008 in northwest Madagascar. An Independent Stranding Review Panel was formed to review all the information and a report is expected in a few months. Details of the response can be found in Annex K, item 8.3. The Committee **commends** industry and response organisations for a tremendous and successful effort in responding to and investigating this event.

Park *et al.* (2012) reported on a mass mortality of 249 finless porpoises that occurred on 3 February 2011 at a dyke in the Saemangeum Sea, Korea. This MSE was due to freezing surface water in the enclosed area and the animals died of suffocation. The Committee **expresses concern** about this MSE, especially with respect to the potential impact of dykes and encouraged the continued evaluation of animals in this area. The Committee **commends** the efforts made to investigate the stranding event.

SC/65a/BRG15 reported on a workshop held in April 2013 dealing with the ongoing southern right whale die-off at Península Valdés, Argentina. A previous IWC Workshop on the southern right whale die-off in 2010 (IWC, 2011f) drew attention to the increasing incidence of parasitic behaviour of kelp gulls, which peck at the outer skin and then feed on the blubber of live whales at Península Valdés. The recent workshop developed an additional hypothesis on the possible contribution of gull attacks to calf mortality at Península Valdés (see Annex F, item 4.4 for additional details).

The Committee **commends** the investigative team in Argentina for their thorough investigation. The Committee **encourages** continued work to evaluate the cause(s) of these mortalities, the implications to the population and the effectiveness of planned gull mitigation measures (and see Item 26).

Information on the International Workshop for Capacity Building on Marine Mammal Stranding (NOAA-IMARPE) was also received. The Government of Peru requested this workshop to help increase capacity for cetacean stranding response after a large die-off of common dolphins occurred in early 2012, in northern Peru. For more details see Annex K, item 8.3. Additional information on strandings and the detection of human-induced mortality was provided to a joint meeting of the SWG on Environmental Concerns and the Working Group on non-deliberate Human Induced Mortality. Furthermore, two papers on categorisation of human-induced trauma and interactions in cetaceans (Moore and Barco, 2013; Moore *et al.*, 2013a) were presented. Summaries of these papers can found in Annex J, item 6.

12.3.4 Other disease-related issues

The Committee received a summary of three disease-related papers reporting on the occurrence and prevalence of parasitic organisms and pathogens in Icelandic minke whales, associated with the Icelandic Research Programme. Discussion points related to these papers are listed in Annex K, item 8.4. The Committee thanked the Icelandic scientists for summarising these findings.

12.4 Anthropogenic sound

12.4.1 New information on the effects of anthropogenic sound on cetaceans

SC/65a/HIM01 discussed underwater bow-radiated ship noise in the Canary Islands (Spain), where a large fleet of commercial ferries operates on a year-round basis, and at the same time a high number of stranded cetacean carcasses in the area have shown injuries typically attributed to ship strikes. Whales may be capable of hearing approaching vessels at reasonable distances, enabling them to react fast enough to avoid collision; however, there are numerous factors to be considered in evaluating the actual collision risk. Overall, ferry traffic appears to contribute significantly to noise pollution in the Canary Islands archipelago.

SC/65a/E03 reported that significant progress has been made on the issue of marine noise pollution beginning in the mid-1990s. Within a few years, agencies such as the US Marine Mammal Commission had acknowledged the significance of marine noise pollution, as did some regional conventions, and later other legislative measures, such as the EU Marine Strategy Framework Directive – which specifically addresses noise – were developed.

New tools are under development to assess the cumulative effects of noise, such as cumulative noise and cetacean distribution mapping. Marine Spatial Planning and Marine Protected Areas are increasingly considering noise and disturbance, and industry is investing in noise reduction and alternative technologies. For at least some noise sources, there seems to be a general consensus that time-area closures represent one of the most effective available means of reducing impacts on marine mammals. Ship-quieting technologies for commercial vessels are also being developed. For further details see Annex K, item 9.1.

The Committee **encourages** time/area closures and the development of new quieting technologies to address noise pollution. The Committee **encourages** further scientific investigations to better understand the effects of sound on cetaceans and their habitats and to better understand the effectiveness of mitigation measures.

12.4.2 Update on new tools and approaches to mitigate effects of anthropogenic sound on cetaceans

The status of current noise management is one of traditional focus on relatively short-term and relatively small-scale human activities, emphasising thresholds of noise exposure from high intensity and short duration sources, with limited abilities to incorporate knowledge of background noise or look at the broader cumulative impacts. However, recently there has been a shift underway to focus on more ecologically-relevant spatial and temporal scales, in order to address chronic, perhaps lower intensity, sources.

Work being undertaken on soundscape mapping was presented last year. An update on progress intersessionally was provided and a joint IWC/IQOE (International Quiet Ocean Experiment) technical Workshop on soundscape modelling was proposed (see Annex K, item 9.2.1; the full proposal can be found as Annex K, Appendix 3). The goals of the Workshop are to exchange, evaluate and analyse soundscape modelling methodologies, examine and assess priority regions and important sound sources, and develop scientific recommendations.

The Committee **commends** the work on soundscape modelling. The creation of 'soundscapes' and noise maps was considered a valuable initiative. The Committee **encourages** the Workshop planners to consider not only the identification of sites of highest noise impacts, but also the direct benefits that could be realised by the reduction of noise impacts. A direct link to conservation outcomes such as reducing noise impacts on cetaceans could be of particular interest to the Commission. For additional discussion of the proposed Workshop, see Annex K, item 9.2.1.

The Committee **strongly supports** this proposal for a Workshop to be held intersessionally (Item 26).

12.5 Climate change

12.5.1 Update on recommendations from previous climate change Workshops

No updates on previous climate change Workshop recommendations were submitted for review and no papers were submitted under this topic.

12.5.2 Other climate change-related issues

The Committee recognised that climate change is an issue of increasing importance and should be kept on the agenda. In order to better identify topics for future climate change studies, the Committee **agrees** to the formation of an intersessional correspondence group (see Annex R). The Committee **agrees** to use the outputs of the intersessional group to develop future priorities under this topic.

12.5.3 Planning for Intersessional Arctic Anthropogenic Impacts Workshop

In 2010, the Commission requested that the Committee develop an agenda for a Workshop on Arctic Anthropogenic Impacts on Cetaceans. The Committee drafted an agenda and formed a Workshop steering group to further develop a plan for the Workshop (IWC, 2012f). A revised agenda that focused on anthropogenic activities related to oil and gas exploration, commercial shipping and tourism was developed by the Workshop steering group and presented last year (IWC, 2013j, p.255).

In discussion, it was noted that this will be a Commission Workshop and is planned for the next intersessional period. The agenda, venue, timing and participant list are still being developed.

The Committee recognises that the topic of anthropogenic impacts to cetaceans in the Arctic is broad and complex and **encourages** further efforts to address these impacts. The Committee noted that the activities recommended above under Item 12.2.2 on oil spill preparedness and responses represent one immediate effort to better coordinate with Arctic IGOs.

12.6 Other habitat-related issues

12.6.1 Interactions between Marine Renewable Energy Devices (MREDs) and cetaceans

SC/65a/E02 reviewed public knowledge of the Marine Renewable Energy Devices (MRED) Workshop report from last year (IWC, 2013b), as well as its larger impacts, to better understand whether the recommendations from such reports are reaching the appropriate audiences and providing them with useful information. Workshop participants were surveyed and whilst the respondents found the Workshop useful personally and the meeting generally well run, the replies provided little evidence yet that the Workshop has had any influence on policy-making or other processes related to marine renewables. There is also little sign of any footprint of the Workshop in any recent scientific or other related literature. Related to this, several participants raised concerns about the inability to find and access the report, as well as how to cite it.

The Committee **agrees** that the visibility and accessibility of its reports needs to be improved and **encourages** the Secretariat and the Committee to consider additional mechanisms to enhance access to, and distribution of, Committee reports.

12.7 Work plan

This is discussed under Item 24.

13. ECOSYSTEM MODELLING

The Ecosystem Modelling Working Group was first convened in 2007 (IWC, 2008c). It is tasked with informing the Committee on relevant aspects of the nature and extent of the ecological relationships between whales and the ecosystems in which they live.

Each year, the Working Group reviews new work on a variety of issues falling under three areas:

(1) reviewing ecosystem modelling efforts undertaken outside the IWC;
(2) exploring how ecosystem models can contribute to developing scenarios for simulation testing of the RMP; and
(3) reviewing other issues relevant to ecosystem modelling within the Committee.

The report of the Working Group on Ecosystem Modelling is given as Annex K1.

13.1 Review ecosystem modelling efforts undertaken outside the IWC

13.1.1 Modelling of the direct relationship between baleen whale populations and the abundance of their prey

Two invited presentations were made on ecosystem models of the effects on predators of fishing on forage fish, summarising the results of two large studies commissioned by the Marine Stewardship Council, MSC (Smith *et al.*, 2011) and the Lenfest Ocean Program (Pikitch *et al.*, 2012), that were completed in recent years. An important message from these studies is that fishing of forage fish down to their MSY level may have major impacts on predators, including birds and marine mammals, in some ecosystems. SC/65a/EM03, which summarised the MSC study, explored the effects of different levels of depletion of forage fish in five different ecosystems (the southern Benguela Current, the northern Humboldt Current, the California Current, the North Sea, and southeastern Australia) using three modelling frameworks (Ecopath with Ecosim [EwE], OSMOSE and Atlantis). The results showed a trade-off between yield from the forage fish species and impacts on the rest of the ecosystem. Although the broad results were relatively robust to the type of model used, predictions about impacts of and on particular species or groups varied considerably between models, suggesting that their use for 'tactical purposes' is not yet warranted.

SC/65a/EM05, which summarised the Lenfest study, conducted a meta-analysis of 72 published studies that used Ecopath models on a variety of marine ecosystems, with the goals of characterising the role of forage fishes and fisheries, and of providing general recommendations for conservative fisheries management. Further analyses using EwE models for 10 ecosystems suggested that minimum biomass levels to avoid predator declines should be about 75% of the unfished biomass – much higher than those predicted by single-species, MSY-based management. A tiered management approach was recommended where more conservative harvest limits are applied when there is high uncertainty about forage fish dynamics or predator dependencies. This study did not evaluate the impacts on marine mammals, and the general approach would need modification to address important aspects of whale populations which do not exhibit the high degree of variability that is characteristic of forage fish populations, or the effects of 'prey switching' that occurs when several forage species are present in an ecosystem.

The Committee **concurs** with the authors of the presented studies that the models used in the studies to date are useful for their broad-scale strategic conclusions, but are not yet suitable guides for short-term tactical management decisions. The Committee **agrees** that, in broad terms, the case has been established that forage fisheries are expected to impact predator populations including cetaceans, and considers that the priority for this Group should now be on more detailed models for specific cases involving whales, with more attention being paid to the dynamics, including stochastic factors. The Committee **agrees** that the framework discussed in Item 13.2 is a promising basis for modelling the effect of changes in prey species on whale populations.

13.1.2 Update from CCAMLR's Ecosystem Monitoring and Management Programme (WG-EMM) on krill and its dependent predators

The Committee held a joint Workshop with CCAMLR in 2008 (IWC and CCAMLR, 2010). Since then, the

Committee has identified significant knowledge gaps in aspects such as spatial variability and trends in prey species, on the relationships between predators and prey, and on the effects of environmental variability on predators. Given CCAMLR's considerable expertise on these aspects, the Committee **agrees** that the Chair of the Committee should write to CCAMLR in time for the meeting of the WG-EMM in Bremerhaven, Germany, in early July 2013, to discuss how to establish future collaborations.

13.2 Explore how ecosystem models can contribute to developing scenarios for simulation testing of the RMP

De la Mare (2013) described a modelling framework originally presented at the fourth MSYR Workshop (SC/65a/Rep05) that uses spatially resolved individual animal behaviour and detailed energy budgets to determine reproductive success and mortality in an environment where food has a patchy spatial distribution. One immediate application relates to the characterisation of yield curves for populations in stochastic environments, including assessing the relative advantages of defining yield curves in terms of number or biomass.

The Committee identified nine issues (listed in Annex K1, item 3) relating to ecosystem effects and the RMP that could be usefully explored either with this individual-base model (IBM) or with simplified emulator models that mimic the behaviour of the IBM. The Committee appointed a correspondence group under de la Mare to develop specific trials for the RMP for one of these issues (characterisation of yield curves for populations in stochastic environments) and **agrees** to make two of the remaining items a high priority for next year:

(1) effects of competition, including effects on whales from fisheries on prey species; and
(2) observable environmental and population characteristics likely to be indicators of ecosystem effects.

The Committee **encourages** analyses on these issues and **agrees** to invite outside expertise as needed.

13.3 Review of other issues relevant to ecosystem modelling within the Committee

13.3.1 Update on Antarctic minke whale body condition analyses

For the last three years, the Committee has discussed apparent declining trends in blubber thickness and body condition in Antarctic minke whales (Konishi *et al.*, 2008) over the 18 years (1987-2006) of the JARPA special permit programmes (e.g. IWC, 2013i). At the heart of the discussion has been the validity of the statistical methods that were used to derive these trends and more specifically whether the models fitted so far adequately captured the main sources of variability in the data, given the nature of the sampling (de la Mare, 2011; 2012). This discussion is relevant to ecosystem modelling because the findings have implications for energetics, reproductive fitness, foraging success and the prey base itself, all of which are important as input in models.

Previously, the Committee has requested further analyses of the data, including:

(1) determining whether the models fitted so far capture all the main features of the data,
(2) determining whether the estimate of trend could be made more precise,
(3) analysing the two sexes separately,
(4) including the interaction of slopes by latitudinal band with year as a random effect, and
(5) investigating independence issues by using mixed-effects models with trackline as a random effect (IWC, 2011e; 2012d).

Two reanalyses of the data were conducted at the 2011 meeting (IWC, 2012d, p.260), one using the jack-knife method with one year as the unit on the published regression model, the other using mixed-effect models to account for some of the variance structure. Both reanalyses resulted in a much higher variance of the estimated trend, but the point estimates were little changed and were still significant.

This year, SC/65a/EM04 presented jack-knife estimates of the variance of the trend by taking individual years or groups of up to three years as the jack-knifing unit. Unexpectedly, the variance of the trend estimate was much less than the variance calculated by Skaug (2012) from the model itself. This led to considerable discussions within the Working Group on the appropriate statistical procedures to use. These are detailed in Annex K1 under item 4.1 and are not repeated here. In addition, a new analysis of total body fat was also presented (Annex K1, Appendix 6) that the authors believed supported the earlier conclusion of a decline in energy storage in Antarctic minke whales during the JARPA period but that others questioned.

The Committee **reiterates** its recommendations from previous years that the outstanding issues raised at recent meetings should be examined (for details see Annex K1, item 4.1). A number of additional suggestions were also made this year. The Committee **encourages** additional analyses to be undertaken on both the blubber thickness and body fat data and noted that papers should ideally be submitted to the forthcoming JARPA II review Workshop (see Item 17.3).

13.3.2 Other, if new information is available

SC/65a/EM02 outlined plans for conducting ecosystem modelling for baleen whale species in Antarctic Area IV, based on data from the JARPA and JARPA II programs. Two types of approaches will be employed; one is a comprehensive, 'whole ecosystem' model (EwE), and the other is a 'model of intermediate complexity' for ecosystem assessments (a multi-species production model). Baleen whales and krill play key roles in both, and the results will be applied to available time series data of baleen whales, seals and krill. Results from these two approaches will be reported at the JARPA II review.

The Committee **welcomes** these plans but suggested that the aims of the modelling exercise be better clarified. The author explained that one aim is to compare the results from a broad-sweep model such as EwE that encompasses most components of the ecosystem with those from a model that includes more detail on the dynamics of the main species of interests. Documentation of the input sources will be provided and options for diagnostic tests of the predictions should be developed. This information should be included in any paper presented to the forthcoming JARPA II review.

SC65a/EM01 presented a preliminary report from a multi-species modelling effort to study the role of minke whales in the marine ecosystem around Iceland, including consumption of sand eel and cod. In its initial phase the focus is on implementing single-species models in the Gadget statistical framework, but the medium to long-term plans are to build multi-species models and to compare different modelling approaches such as Gadget, FishSums, EwE and Atlantis, in order to assess their value to the management of living resources in Icelandic waters as part of the MareFrame project.

The Committee **welcomes** these efforts and **encourages** further refinements to include the effects of environmental variability on prey species and to incorporate prey switching in the next version. It was also noted that these exercises typically require a substantial amount of exploration to determine what is driving the observed trends in the predicted abundance of the target species.

SC/F13/SP02rev, SC/F13/SP03rev and SC/F13/SP04rev were initially presented at the Icelandic Special Permit Expert Panel Review Workshop in February 2013 and then revised in the light of comments made by the expert panel (see SC/65a/Rep03). These papers presented new information on the feeding ecology of common minke whales based on analyses of stomach contents, fatty acid profiles in blubber and blood tissues, and stable isotopes measured in blood, muscle, and skin tissues. The studies showed pronounced spatial and temporal variations. The fatty acid and stable isotope analyses further revealed tissue specificity, indicating that the results need to be interpreted with their limitations in mind. Together, these papers indicated that the differences between the stomach contents, fatty acid and stable isotope analyses can best be explained by the different time periods reflected by these methods, such that the stomach content analysis represents the most recent feeding and is therefore the best measure for local diet composition within the time-frame of their model, while the other two methods reflect feeding before arrival on the Icelandic feeding grounds in spring.

Tamura and Murase welcomed the information on diet data from these studies stating that they are useful in ecosystem models. Detecting changes in prey requires long time-series of data and fatty acid analyses complement data from stomach analyses.

SC/65a/O02 presented estimates of seasonal energy deposition in minke whales from Icelandic waters, based on measured increase in weight and energy of different tissues. Minke whales increase their weight by 27% over the feeding season, but due to increases in energy density of tissues, the total increase in energy content of the body is around 90%. Most of the energy is stored in adipose tissue (blubber and visceral fat), but posterior dorsal muscle and bone tissue are also important sites for energy storage.

13.4 Development of a list of priority populations as candidates for Conservation Management Plans

The Committee **agrees** that the Ecosystem Modelling Working Group can best assist in this process in the context of provide specific advice once CMPs have been identified (see Item 21).

13.5 Work plan

The Committee's views on the work plan for Ecosystem Modelling can be found under Item 24.

14. SMALL CETACEANS

14.1 Review current status of selected populations of small cetaceans in east Asian waters (China [including Taiwan], Korea, Japan and Russia [white whales only])

This year, the priority topic was to review the current status of selected populations of small cetaceans in east Asian waters (see Annex L, fig. 1). The selection of species was based primarily on concerns about conservation status and the expectation that new information would be available.

14.1.1 Narrow-ridged finless porpoise (Neophocaena asiaeorientalis)

14.1.1.1 TAXONOMY AND NOMENCLATURE

SC/65a/O01 proposed that the general acceptance of two identified species in the genus *Neophocaena* – the narrow-ridged finless porpoise (*N. asiaeorientalis*) and the Indo-Pacific finless porpoise (*N. phocaenoides*) – should be recognised by the IWC. The change in taxonomy was based on clear morphological differences, genetic data and partial sympatry of the two forms in the Taiwan Strait (Jefferson and Wang, 2011). The Committee **endorses** the updating of the IWC list of recognised species (see Item 20).

SC/65a/SM24 presented a genetic analysis of finless porpoises in Japanese waters. The Committee **agrees** that these results confirmed previous ecological, morphological and molecular studies showing that there are at least five separate local populations of finless porpoises in Japanese waters that should be treated as different management units.

14.1.1.2 BYCATCH: REPUBLIC OF KOREA

Korea reported a total bycatch of more than 1,000 finless porpoises in 2011, including 249 that died under ice after being trapped inside a newly constructed 33km dike within the Saemangeum reclamation project (Yellow Sea). In 2012, Korea reported bycatches of 2,050 finless porpoises in the Yellow Sea and 128 in the Sea of Japan/East Sea (see details in Annex L, table 1).

Deliberate killing of cetaceans has been illegal in Korean waters since 1986 and a requirement has been in place since 1996 to monitor whale meat coming from incidental catches. This was amended in 2011 to intensify monitoring of the circulation of whale meat in markets. Currently, every incidental catch must be reported to the Korean Coast Guard and a tissue sample from each animal must be submitted to the Cetacean Research Institute for its DNA registry established to detect and trace illegal catches. The Korean government has intensified its monitoring effort since 2011 and consequently the reported number of finless porpoises bycaught in the Yellow Sea has increased dramatically. Korea will prepare a mitigation programme to reduce the finless porpoise bycatch, including consideration of gear modifications, changes to fishing practices and 'pingers'.

Zhang *et al.* (2005) provided uncorrected (and thus minimum) estimates of finless porpoises of 21,532 animals in offshore waters and 5,464 animals in near-shore waters along the west coast of the Korean Peninsula (South Korean waters) to Jeju Island. At that time (IWC, 2006b), the Committee had welcomed the studies and looked forward to their future refinement. The Committee noted that the current bycatch of 2,000 porpoises would be about 7.4% of an estimate of total uncorrected abundance of 27,000 porpoises in 2004.

The Committee **appreciates** the valuable information on finless porpoise bycatch provided by the Korean scientists. It **encourages** researchers and managers to continue their efforts to improve reporting and investigate ways to assess and manage the bycatch, particularly given the uncertainty regarding sustainability. The Committee **recommends** that an analysis be conducted to estimate past bycatches of finless porpoises using data on historical and recent fishing effort together with recently documented bycatch levels. It further **recommends** that available abundance data on finless porpoises in Korean waters be summarised for consideration at next year's meeting together with bycatch data to allow a better evaluation by area. The Committee **commends** the Korean authorities for their efforts to reduce this bycatch and **requests** that a report summarising progress on bycatch mitigation measures be submitted next year.

14.1.1.3 BYCATCH: JAPAN

Reported bycatch in Japan is low; a provisional figure of only 15 finless porpoises were reported as bycaught for January-December 2011[21]. Provisional data on strandings in Japan over the same time period indicated a total of 181 finless porpoises of which 178 were necropsied; it is not known to what extent the strandings were a result of bycatch.

14.1.1.4 IUCN RED LIST STATUS[22]

In 2012, IUCN listed *N. asiaeorientalis* as Vulnerable (see Annex L, item 3.1.4, for full details). Reeves reported that a new assessment of the Yangtze subspecies *N. asiaeorientalis asiaeorientalis* will soon be published listing the subspecies as Critically Endangered.

14.1.2 Populations of Tursiops aduncus *in Korean and Japanese waters*

Wang and colleagues (Wang *et al.*, 1999, 2000a, 2000b) distinguished the Indo-Pacific bottlenose from the common bottlenose dolphin using genetic, osteological and external morphological data. Around Japan, Kurihara and Oda (2006; 2007) concluded that the Indo-Pacific bottlenose dolphin occurs in at least three locations: (1) Amami Islands; (2) Amakusa-Shimoshima Island; and (3) Mikura Island. Kim *et al.* (2010) confirmed the presence of this species around Jeju Island, Korea.

14.1.2.1 JAPAN

SC/65a/SM26 summarised the abundance of, and threats to, nine populations of Indo-Pacific bottlenose dolphins in the Japanese Archipelago (details are given in Annex L, item 3.2.1). The Committee **notes with concern** an apparently serious bycatch problem around Amakusa-Shimoshima Island (Shirakihara and Shirakihara, 2012). It **recommends** that this problem is monitored closely and that efforts are made to reduce bycatches.

SC/65a/SM29 reported on a stranding of a 2.7m male Indo-Pacific bottlenose dolphin in Kagoshima for which gross and histological examinations suggested the animal had a Lobomycosis-like disease. Analyses are underway to confirm this diagnosis.

The Committee **agrees** that it is important to understand the origins and routes of spreading of this disease and **recommends** further investigation and continued close monitoring of the population around Amakusa-Shimoshima Island in western Kyushu.

While recognising the responsibility of the range state for the conservation and management of small cetacean species, Japan reconfirmed its position on the involvement of IWC in the management of small cetaceans and reserved its position on all management recommendations regarding small cetaceans.

14.1.2.2 KOREA

Korean scientists provided information on the year-round resident population of Indo-Pacific bottlenose dolphins in the coastal waters of Jeju Island. The total population was estimated[23] as 124 (95% CI=104-143) in 2008 and 114 (95% CI=109-133) in 2009 using photo-identification mark-recapture methods. The animals are most regularly observed along the northern coast of the island. Bycatch has been investigated since 2009 and the annual bycatch rate was estimated at 7%, with most of the animals being trapped in pound nets (a type of set net or trap). More than 80% of the dolphins have been alive when found in pound nets; if released alive, a gradual increase in the local dolphin population might be expected.

An effort is underway to release three dolphins back into the wild in summer 2013 after being instrumented with satellite tags in the area of Jeju Island (where they were caught before being sold illegally to Korean oceanaria). They are among at least 11 bottlenose dolphins brought into captivity from the Jeju population in the last four years.

The Committee thanked H-W Kim and colleagues for providing information on the small local population of bottlenose dolphins around Jeju. It **encourages** their work to continue and **requests** updates on this including the satellite-tagged released animals and efforts to release dolphins in fishing gear.

14.1.3 Short-finned pilot whales (Globicephala macrorhynchus) *in Japan*

SC/65a/SM12 reviewed available information on the status of the southern and northern form short-finned pilot whales in Japan. Available abundance estimates of both forms are more than twenty years old. Catches have declined but the cause or causes are uncertain. Changes in catch composition of the northern form in the 1980s, with a declining proportion of old and large individuals (probably mostly males) observed in the catch, was inferred to indicate a decline in the population. No recent information has been published on the catch composition of either form. In the absence of an analysis of relevant data on effort, catch locations, etc., the most parsimonious assumption would be that the decline in catches has been due to a decline in the availability of pilot whales in the whaling areas.

In the absence of new information, the Committee **recalls** its previous concerns regarding these stocks (IWC, 1987; 1992). A **recommendation** relating to catches of small cetaceans by Japan (including this species) is given under Item 14.4.1.

Morishita stated that the declines in catches of small cetaceans in Japan are largely attributable to economic factors such as low prices of the products, high fuel prices and the effects of the 2011 earthquake and tsunami.

14.1.4 Dall's porpoise (Phocoenoides dalli)

SC/65a/SM11 reviewed available information on the status of Dall's porpoise populations taken in hand harpoon hunts in Japan. Details are given in Annex L, item 3.4. The most recent available abundance estimates of the hunted *dalli*-type population date from 2003 (Miyashita *et al.*, 2007)[24]. The Committee previously recommended that a complete survey of the ranges of the populations be undertaken as soon as feasible (IWC, 2009e).

Catches of both forms have declined, particularly those of the *dalli* form, with only 16% of the quota taken in 2010. Available data are insufficient to determine the cause of catch declines and no up-to-date information on catch composition has been published for either form of the species. In 2012-13 the catch limits were set at 7,147 *dalli*-type and 6,908 *truei*-type porpoises; around 4% of the 2003 abundance estimates.

The Committee notes that abundance estimates are now ten years old and catch limits are still probably unsustainable (Wade *et al.*, 2008). The Committee **reiterates** its previous concerns (IWC, 2002a, pp.57-8; 2008a, p.51). A **recommendation** relating to catches of small cetaceans by Japan including this species is given under Item 14.4.1.

[21] *http://www.jfa.maff.go.jp/j/whale/w_document/pdf/130531_progress_report.pdf.*
[22] *http://www.iucnredlist.org/.*
[23] The Committee did not review this estimate.

[24] The estimates were not assessed by the Committee.

14.1.5 White whales of the Okhotsk Sea

SC/65a/SM23 summarised available information on population structure, abundance and historical catches of white whales in the Okhotsk Sea. Based on aerial surveys in 2009-10, the entire population was estimated to be a minimum of 6,113 (CV=0.068), and when corrected for availability bias was estimated at 12,226 (see Annex L, Appendix 2 for more details). Two-thirds of satellite-tagged animals (2007-10, *n*=22) that summered in the Sakhalin-Amur region stayed in or visited the eastern part of the Shantar region in the autumn. In the winter, the whales travelled northward and offshore, where they used different wintering grounds. None of the 22 animals went to the area which a single tagged animal from western Kamchatka visited in winter.

SC/65a/SM23 also reported genetic data that suggested the existence of at least two Okhotsk populations: northeastern Okhotsk Sea and western Okhotsk Sea. Animals from the western population have been subject to live-capture for the last 30 years under an annual quota system. The average annual catch from 2000-12 was 23 (range 0 to 44). In 2012, the quota for the North-Okhotsk subzone was increased by a factor of five (to 212) and then in 2013 to 263; 44 were live-captured in 2012. There is a quota of 45 for the West-Kamchatka subzone in 2013.

After reviewing the information from both SC/65a/SM23 and a recent assessment by Reeves *et al.* (2011) the Committee **concludes** that the Russian domestic quota of 263 for the North-Okhotsk subzone was at least 6 to 8 times higher than that likely to be sustainable for the Sakhalin-Amur portion of the total regional population. In practical terms, the live captures are likely to be conducted at a single site which means they will target only the Sakhalin-Amur summer aggregation which raises concerns about local depletion.

Given this, the Committee **recommends** that the live-capture quota for the North-Okhotsk subzone be reduced to a level that is consistent with available scientific data and that at least four summer aggregations in the North-Okhotsk subzone should be managed separately such that the total allowable quota is broken down into separate quotas for Sakhalin-Amur, Ulbansky Bay, Tugursky Bay and Udskaya Bay (a fifth aggregation, in Nikolaya Bay, should have a zero quota as the number of animals using that bay is very small; SC/65a/SM23).

The Committee further **recommends** that no removals are authorised for the West-Kamchatka subzones, until sufficiently rigorous analyses of sustainability are provided that are at least as rigorous to those currently available for the North-Okhotsk subzone.

14.2 Report on the Voluntary Fund for Small Cetacean Conservation Research

14.2.1 Update on the 2011 awarded projects

Of the nine projects awarded in 2011, four were completed in 2012 and two projects will be completed in 2013. A further three will end at the beginning of 2014. See details in Annex L, item 4.1.

At this meeting, information was received from five projects (Annex L, item 4.1). The Committee was informed that the Secretariat is preparing a dedicated section for the IWC website on projects funded by the Small Cetacean Conservation Research Fund that will summarise projects' main achievements and ongoing activities.

14.2.2 Update on the 2013 selection process

Thanks to recent voluntary funding from Italy, the Netherlands, UK, USA, WWF-International and World Society for Protection of Animals, the Small Cetacean Conservation Research Fund (SCCRF) was replenished sufficiently to allow funding of a few new projects, fully or partially depending on their budget requests. A new call for proposals was announced by the Secretariat in April 2013. A total of 19 proposals were received by the deadline. In accordance with the agreed procedure, the Review Group (Bjørge, Donovan, Fortuna, Gales, Reeves, Rojas-Bracho) recommended five projects from this year's call for proposals (Table 4). The Committee **endorses** these five projects.

Table 4

Summary of projects recommended to be funded by the Voluntary Fund for Small Cetacean Research, and their principle investigators (PI).

PI	Project title
Chen	Defining the units of conservation and historic population dynamics for two small cetacean species affected by directed and incidental catches in the North Pacific. (F)
Kelkar	Strengthening the meaning of a freshwater protected area for the Ganges river dolphin: looking within and beyond the Vikramshila Gangetic Dolphin Sanctuary, Bihar, India. (P)
Mustika	A pilot study to identify the extent of small cetacean bycatch in Indonesia using fisher interview and stranding data as proxies. (P)
Rajamani	Capacity building in conducting cetacean abundance surveys in southeast Asia through a training workshop and actual surveys. (P)
Wakid	Investigating the abundance of Ganges river dolphin (*Platanista gangetica gangetica*) and factors affecting their distribution in Indian Sundarban. (F)

Key: F=full funding; P=partial funding.

Given the large number of requests and the limited funding available, for future calls for proposals the Review Group had recommend that priority is given to projects with clear potential for effective conservation outcomes in areas of particular need (e.g. critical conservation problem known or suspected, but not likely to be addressed without support). The Committee **agrees** with this recommendation.

14.3 Progress on previous recommendations

14.3.1 Vaquita

The plight of the critically endangered vaquita has been discussed by this Committee and the International Committee for the Recovery of the Vaquita (CIRVA) for many years. In recent years, the focus of the recommendations has been that the only way to prevent the extinction of this species is to eliminate gillnets from its entire range.

SC/65a/SM13 provided information on the continuation of the Acoustic Monitoring Scheme for Vaquita. Preliminary analyses show with 60% credibility that the acoustic encounter rate has decreased between the sampling periods, indicating continued decline of the population.

The new Mexican Administration established the 'Advisory Commission to the Presidency of Mexico for the Recovery of Vaquita' which includes the Minister of Environment, the National Commissioner of Fisheries, two members of Congress, NGO representatives, four scientific advisors, fishing representatives and the Navy. At its first meeting in February 2013, one key agreement was to eliminate gillnets and other entangling nets throughout the vaquita's range and to establish a compensation programme for fishermen. At its second meeting in March 2013, it was agreed that Federal and State Government officials and representatives of civil society would visit the fishing communities to inform the fishermen of the alternatives that the federal government has prepared to address the social problems arising from vaquita conservation measures in the region. It was also agreed that the head of the National Institute of Ecology and Climate Change would explore the feasibility of carrying out a new vaquita population survey cruise in Autumn 2013.

On 6 June 2013, the Mexican government approved the new Mexican Official Standard NOM-002-PESC that requires fishermen to switch from shrimp gillnets to alternative fishing gear (specifically purpose-built light trawls) over a three-year period (30%, 30% and 40% annual reduction over the three-year period).

The Committee **commends** the Government of Mexico for establishing the Advisory Commission to the Presidency of Mexico for the Recovery of Vaquita and for the final approval of the Mexican Official Standard NOM-002-PESC.

CIRVA members produced an analysis, required by the Government of Mexico, which uses a Bayesian model to estimate current (i.e. 2013) abundance of the vaquita population. The posterior distribution for 2013 abundance indicates a best estimate of 189 individuals. This result confirms the urgent need to remove all entangling nets from the vaquita's range to allow the population to recover.

In light of the significance of this updated estimate, the Committee **agrees** to include the full analysis as an appendix to its report (see Annex L, Appendix 3). The Committee **notes with great concern** the model's prediction that if the status quo is maintained, the species population will continue to decline towards extinction.

It is a recurring problem that the rarer a species is, the harder it becomes to collect sufficient sightings to generate robust abundance estimates and detect population declines. As a result, the Committee **strongly endorses** the decision to embed empirical estimates of vaquita abundance and trends (such as in this case the acoustic monitoring data) into rigorous statistical models, using all available relevant data and information to predict population trajectories. The Committee **expresses** confidence that the best estimate of vaquita abundance in 2013 is **189 individuals** (see Annex L, Appendix 3).

In addition, the Committee **reiterates its previous recommendations** that further actions to eliminate bycatch should **not** be delayed in favour of efforts to collect more population survey data.

14.3.2 Hector's dolphin

SC/65a/SM07 reported on efforts to improve estimates of abundance for local populations of Hector's dolphins using capture-recapture (CR) methods based on genotyping and photo-identification. The authors presented three consistent abundance population estimates: (1) a genotype CR (Lincoln-Petersen estimator with Chapman Correction); (2) a photo-identification CR; and (3) a single-sample, linkage disequilibrium method, giving the effective number of breeding individuals in the parental generation. Details are given in Annex L, item 5.2.

14.3.2.1 MAUI'S DOLPHIN

Maui's dolphin is the North Island (New Zealand) coastal endemic sub-species of Hector's dolphin. The Committee was informed that the management measures it recommended last year were incorrectly attributed to a proposal by the New Zealand Government. The Committee **acknowledges and regrets** this mistake.

SC/65a/SM06 presented an update on the status of Maui's dolphins. The population has declined significantly with the latest genetic mark-recapture analysis in 2010/11 estimating a population size of 55 individuals one year and older (Hamner *et al.*, 2012). The author suggested that unless their full range out to the 100m depth contour (including harbours) is protected against gillnetting and trawling (95.5% of human-caused mortality; Currey *et al.*, 2012), Maui's dolphins will decline to 10 adult females in six years and become functionally extinct (<3 breeding females) in less than 20 years, even under maximum population growth (0.018 according to Slooten and Lad, 1991). Additional threats to Maui's dolphins (besides bycatch) include seismic survey work in or near their habitat and a plan to begin development of the world's largest marine iron sand mining operation.

SC/65a/SM22 reviewed the response of the New Zealand Government to the 2012 recommendations of the Committee for urgent action. Although some measures were taken to limit bycatch, the author considered that they were insufficient because they did not cover the entire range. The paper stated that the protected area should be expanded, all gillnetting and trawling should be banned within it (including harbours), and restrictions should be placed on oil and gas development and on other potentially harmful activities where the dolphins are found, including a buffer zone.

Currey *et al.* (2012) described the risk assessment undertaken in June 2012 to inform the Maui's Dolphin Threat Management Plan. The risk assessment identified 23 activities or processes that pose a threat to the sub-species, with bycatch in commercial set net, commercial trawl, and recreational/customary set net fisheries assessed as likely to have the greatest impacts. The risk posed by the cumulative impact of all threats was assessed as significant, resulting in a high likelihood of, and a potentially rapid rate of, population decline. The spatial overlap between dolphin distribution and commercial fishing effort helped to identify specific areas where risk posed by commercial fishing activities remained, given management measures already in place. There was a reported capture of a dolphin in the south end of the Maui's range in January 2012 but no specimen was available to determine whether it was a Maui's dolphin or a specimen of the other Hector's dolphin subspecies. In response, interim measures were put in place in July 2012 that either restrict fisheries activities or require 100% observer coverage in the set net fishery in much of the area where the risk assessment indicated a continuing risk to Maui's dolphins from commercial fisheries.

Maas stated that the 100m depth contour is used to define the offshore limit of the range for Maui's dolphins; this ranges from 4 to 39 n.miles. However, Currey noted that the risk assessment expert panel estimated the offshore distribution as out to 7 n.miles based on modelling, public sightings, strandings and historical information on the dolphins' alongshore range. The fishery restrictions are based on distance from shore and vary between 2 to 7 n.miles.

New Zealand has a limited observer programme for Maui's dolphins in the trawl fisheries and the limited data suggests some risk of bycatch in trawl gear. The great uncertainty surrounding aspects of Maui's dolphin ecology and distribution makes evaluation of the efficacy of management very difficult. Emergency measures could be triggered by further bycatch.

The Committee **agrees** that management measures must be precautionary. If any fisheries with the potential for bycatch were to remain active within the range of Maui's dolphins, 100% observer coverage would maximise the chance of identifying any bycatch and providing information that might trigger immediate further area closures.

In conclusion, the Committee **reiterates its extreme concern** about the survival of Maui's dolphin given the evidence of population decline, contraction of range and low current abundance. The Committee **agrees** that the human-caused death of even one dolphin in such a small population would increase the extinction risk for this subspecies.

The Committee therefore **recommends** that rather than seeking further scientific evidence, the highest priority should be given to immediate management actions that will lead to the elimination of bycatch of Maui's dolphins. This includes full closures of any fisheries within the range of Maui's dolphins that are known to pose a risk of bycatch of small cetaceans.

The Committee **commends** the New Zealand Government on its initial and interim measures to protect Maui's dolphins. However, the Committee **emphasises** that the critically endangered status of this sub-species and the inherent and irresolvable uncertainty surrounding information on small populations require the immediate implementation of precautionary measures. Ensuring full protection of Maui's dolphins in all areas throughout their habitat, together with an ample buffer zone, will minimise the risk of bycatch and maximise the chances of population increase.

14.3.3 Irrawaddy dolphins

SC/65a/SM05 presented work on Irrawaddy dolphins in Laos where on the Laos-Cambodia border only six individuals remain in the trans-boundary pool, compared to at least 17 present in 1993. Despite efforts at protection on both sides of the border, the continuing use of gillnets, explosives and electric fishing gear as well as the proposed Don Sahong dam will very likely cause the extirpation of this small group of dolphins.

The Committee **agrees** that the situation in Laos was of serious concern and that without urgent conservation measures in the trans-boundary pool and the surrounding area as recommended in SC/65a/SM05, the remaining dolphins will not persist for much longer.

Porter reported that individuals from six populations of Irrawaddy dolphins in Malaysia, India and Bangladesh had developed cutaneous nodules. Disease prevalence ranged from 2.2% to 13.9% with the two most affected populations inhabiting the most polluted of the six areas. In India, prevalence was significantly higher in 2009-11 than in 2004-06. The emergence of this disease in several populations is of concern given the possible link to degraded environmental conditions and the vulnerability of this species to other threat factors.

The Committee thanked Porter for this information and **encourages** further investigation in collaboration with health experts and biologists working in these (and other) regions.

14.3.4 Atlantic humpback dolphin

SC/65a/SM16rev provided an update on an IWC Small Cetacean Research and Conservation Fund (SCRCF) project on the Atlantic humpback dolphin in Congo and Gabon. Details can be found in Annex L, item 5.4.

The Committee **welcomes** the important contribution to research and conservation made by this project and looks forward to receiving further information in future meetings.

14.3.5 Indo-Pacific humpback dolphin

Updates from three projects funded under the IWC SCRCF were presented at this meeting (see Annex L, item 5.5 for details). Smith *et al.* (2013) provided an update on their project to determine the population identity for animals in the northern Bay of Bengal, Bangladesh and to contribute to the resolution of taxonomy within the genus *Sousa*; Wang (2013) reported on progress on photo-identification monitoring of the Eastern Taiwan Strait Population, and information was presented on the project on the ecology, status, fisheries interactions and conservation of coastal Indo-Pacific humpback and bottlenose dolphins on the west coast of Madagascar.

The Committee **welcomes** the important contribution to research and conservation made by these projects and looks forward to receiving further information in future meetings.

14.3.6 Harbour porpoise

SC/65a/SM21 reported on a ship board double-platform line-transect survey to assess harbour porpoise abundance in the 'GAP area' between the North Sea and the Baltic Proper. Details can be found in Annex L, item 5.6. The abundance of harbour porpoises within the survey area was estimated at 40,475 animals (95% CI: 25,614-65,041, CV=0.235). Large areas of the northern part of the study region were not surveyed due to poor weather. The GAP plan identifies key areas for porpoises and focuses conservation measures on special areas of conservation for porpoises.

The Committee **welcomes** this work and **accepts** the abundance estimate.

SC/65a/SM25 reported on a National Programme in Mauritania ('Biodiversité, Gaz, Pétrole', BGP) that includes monitoring beaches for stranded cetaceans four times per year. Between November 2012 and May 2013, high numbers of stranded harbour porpoises and other species were found. The Northwest African population of harbour porpoises is probably reproductively isolated from the Iberian and other European populations (Van Waerebeek and Perrin, 2007). No abundance estimates are available but the population is believed to be small. Of ten individuals for which the cause of death could be established (from a total of 27 examined) all appeared to be bycaught.

Based on sightings recorded from 2003-11, SC/65a/SM20 provided an uncorrected abundance estimate of 683 animals (95% CI: 345-951) of harbour porpoises in northern Spanish waters that are considered part of the separate Iberian Peninsula Management Unit (ICES, 2013). The Committee **endorses** the authors' view of the need for unbiased estimates of both abundance and bycatch for this area in order to provide reliable advice for conservation and management actions. It **strongly encourages** Portuguese and Spanish authorities to promote collaborative research projects towards this end.

14.3.7 Solomon Islands update on both live-capture and drive fisheries

Oremus *et al.* (2013) contained the final report to the Government of the Solomon Islands on small boat surveys, photo-identification and genetic sampling to assess the population status of Indo-pacific bottlenose dolphins which are subject to live capture for international trade. Since 2003, more than 100 Indo-Pacific bottlenose dolphins have been shipped from the Solomon Islands to facilities around the world. The Committee **notes** that the new survey results presented by Oremus *et al.* (2013) reinforce previously expressed concerns regarding the sustainability of live-capture removals from this small island-associated population of Indo-pacific bottlenose dolphins. This project was partially funded by the IWC SCCRF. Details are given in Annex L, item 5.7.

The Committee:

(1) **emphasises** the importance of verifying the true number of live-captures and associated dead dolphins - the new survey results **reinforce** previously expressed concerns regarding the sustainability of live-capture removals from this small island-associated population;
(2) **endorses** the recommendation of Oremus *et al.* (2013) calling for the development of a DNA register, i.e. genetic samples of all dolphins captured should be collected systematically and archived to allow verification of their origin and legitimacy; and
(3) **reiterates its previous encouragements** for comparison of existing photo-id catalogues (e.g. that of RH Defran and this study) in order to produce a synthesis of sighting information.

SC/65a/SM08 described efforts to document the numbers and species of dolphins killed recently in the traditional drive hunts on the island of Malaita in early 2013. The Committee thanked the authors for this report, and:

(1) **commends** the Government of the Solomon Islands and the Ministry of Fisheries and Marine Resources for the substantial funding provided to conduct the surveys and for facilitating the work on the traditional drive hunts;
(2) **agrees** that there is an urgent need for estimates of the abundance of small cetaceans around Malaita and, if possible, the Solomon Islands as a whole; and
(3) **expresses concern** regarding the potential depletion of local populations given the scale of the recent (and historical) catches.

In this context, the extensive programme of aerial surveys for cetaceans and other megafauna in the South Pacific being undertaken by the French Government can provide valuable and reliable baseline estimates of abundance for previously unsurveyed or little surveyed areas. It was noted that this programme is planning to survey the New Caledonia area in 2014. The Committee **recognises** the great potential conservation value that would result if it was possible to extend the surveyed area to include the Solomon Islands. The Committee therefore **recommends** that the Secretariat forward a letter on behalf of the Committee expressing its appreciation for the current survey programme, explaining the benefits of extending the 2014 survey to the Solomon Islands and respectfully requesting this to be considered if at all possible.

The Committee also **encourages** the Australian Museum, Sydney to grant the authors of SC/65a/SM08 access to pantropical spotted dolphin teeth and teeth from other specimens from the Solomon Islands hunt that could be used to compare past and modern genetic diversity.

Finally, the Committee **endorses the recommendations** of SC/65a/SM08 encouraging the Solomon Islands Ministry of Fisheries and Ministry of Environment to:

(1) collect information on all future hunts and, if possible, provide some verification of species and numbers through independent observers or photographs;
(2) collect genetic samples (e.g. skin, meat, teeth) from each hunt, to confirm species identification and monitor changes in diversity and population identity over time; and
(3) support further surveys of waters around Malaita (and other islands, if possible) to estimate the abundance of small cetaceans.

14.3.8 Boto and tucuxi

Recalling last year's recommendations regarding the illegal capture and use of botos and tucuxis for fishing within Brazilian territory, the Brazilian Government has been taking steps to counteract this activity through enforcement actions. Details of these actions can be found in Annex L, item 5.8.

The Committee **commends** Brazil for its National Action Plan for the Conservation of Aquatic Mammals and Small Cetaceans, and **welcomes** the report on implementation relative to these two species.

The Committee also **reiterates its previous recommendation** that an international scientific Workshop be organised involving scientists and managers from the range states, with the goal of addressing research and conservation priorities, standardising methodologies and planning long-term strategies.

SC/65a/SM17 reported on the distribution of botos in the Amazon delta; they are regular and widespread in Marajó Bay and the surrounding coastline of Marajó Island. To investigate genetic variation in Amazon river dolphins and make inferences about possible subspecies of boto, analyses of the control region and cytochrome b were conducted. One specimen from the east coast of Pará state appeared to represent an isolated geographic form, genetically distinct from other known subspecies.

Iriarte and Marmontel (2013) reported that interactions of botos and tucuxis with fishing activities are common in the western Brazilian Amazon, but the prevalence of incidental and intentional catches is not known.

Williams and others conducted analyses to infer trends in boto and tucuxi numbers in the Colombian Amazon. They estimated an 87% chance that the boto is declining and an 80% chance that the tucuxi is stable or increasing.

The Committee **expresses its appreciation** for this information on the boto and tucuxi.

14.4 Takes of small cetaceans

14.4.1 New information on takes

Funahashi provided the Committee with a translation of the records of directed catches and associated quotas for small cetaceans from 1997-2011 obtained from the Japanese National Research Institute of Far Seas Fisheries website (Annex L, Appendix 4, table 4).

The Committee also received from the Secretariat the summary of catches of small cetaceans in 2012 extracted from this year's National Progress Reports (Annex L, Appendix 4). The Committee agreed to further explore, intersessionally, more specific terms of reference for evaluating direct take data, including the idea of developing case studies or other analyses from this information.

The Committee thanked Funahashi and the Secretariat for their work in compiling this information for the Scientific Committee each year and reiterated the importance of having complete and accurate catch information, encouraging all countries to submit appropriately qualified and annotated catch data.

SC/65a/SM12 presented information on small cetaceans targeted by direct hunts in Japan. In 2012 there was an increase in the hunting season for Baird's beaked whales in some areas. With respect to drive hunts of other species in Taiji, the number of live captures has increased in the last decade whilst the number of animals killed has gradually declined. The increase in live captures has been accompanied by an increase in exports.

Catch limits for all species were established in 1993 and remained largely constant until 2007. Since then catch limits for most species have been reduced, with the exception of Baird's beaked whales, Pacific white-sided dolphins and northern form short-finned pilot whales which have remained constant. The catch limit for false killer whales has increased. A recent assessment submitted to the 2011 Society for Marine Mammalogy Conference indicated that for all species assessed, catch limits were above sustainable levels (Funahashi and Baker, 2011), with those of striped and spotted dolphins and false killer whales particularly high, exceeding calculated PBR values by a factor of more than five.

For all species reviewed, with the exception of Baird's beaked whales, Risso's dolphins and the Pacific white-sided dolphins (which was only recently added to the quota scheme), catches have declined and have not filled the reduced quotas. See Annex L, item 6.1 for more details.

Published assessments of the abundance of targeted populations are now ten years old or older and exceed the maximum period for which a population estimate should be considered reliable (Moore and Leaper, 2011). Given the indications of population decline in some species (IWC, 1992; 1993; 1998c; Kasuya, 1985; 1999), the long history of intensive exploitation, the lack of information on changes in catch composition and that catch limits and catches remain above sustainable levels, SC/65a/SM12 concluded that there is an urgent need to suspend catches of species taken in direct hunts in Japan and conduct up to date assessments of the exploited populations.

Regarding the species that are subject to direct exploitation in Japan (i.e. common bottlenose dolphins, striped dolphins which apparently experienced a collapse of the coastal population, spotted dolphins, Risso's dolphins, false killer whales and Pacific white-sided dolphins), the Committee expresses **concern** that catch limits exceed sustainable levels and that abundance estimates of all species are now more than ten years old, particularly given the indications of population decline in a number of the species (IWC, 1992; 1993; 1998c; Kasuya, 1985; 1999). The Committee therefore **re-iterates** its previous concerns (IWC, 1992; 1993; 1998c) and **recommends** that:

(1) up-to-date assessments of these exploited populations be undertaken, including studies of population structure and life-history;
(2) up-to-date data on struck and lost rates, bycatch rates, directed hunting effort, stock identity and reproductive status and age composition of catches be collected and made available; and
(3) catch limits take into account struck and lost and bycatch rates and be based on up-to-date population assessments, and be sustainable with allowance for population recovery.

Some members expressed a different view concerning the problems mentioned above, for example regarding the existence of coastal populations of common bottlenose dolphins and striped dolphins (see Annex L).

14.4.2 Follow up on the Workshop on 'poorly documented hunts of small cetaceans for food, bait or cash'

Ritter presented a proposal on the growing and emerging problem of poorly documented hunts of small cetaceans for food, bait or cash (sometimes referred to as the 'marine bushmeat' problem). A provisional agenda was provided for an open symposium and a two-day Workshop (Annex L, Appendix 5). The scope was limited to Africa, Madagascar, Sri Lanka and southeast Asia.

It was agreed that the Workshop steering group shall focus its initial work on:

(1) appointing new members to be included in the steering group (September 2013): new members shall be experts working in the areas the Workshop focuses on that are not related to cetacean assessment;
(2) producing a final draft budget (September 2013), including costs for the venue and for (French) interpretation;
(3) determining additional expertise to be invited to the Workshop (October 2013);
(4) identifying a definitive venue (December 2013); and
(5) liaising with international organisations dealing with bushmeat and emerging infectious diseases (e.g. Eco Health Alliance [US] and others).

The steering group shall at the same time start finding funds from NGOs and other organisations. The progress on the work on the above points shall be referred to the co-Convenors of the sub-committee on small cetaceans and the Head of Science for consideration.

14.4.3 Significant direct and incidental catches of small cetaceans: an update

Donovan drew attention to the Committee's 'Report on Significant Direct and Incidental Catches of Small Cetaceans' that was prepared for the United Nations Conference on Environment and Development (UNCED) in 1992 (Bjørge *et al.*, 1994). Whilst recognising that this was a major undertaking, he suggested that there was a need for a single, up-to-date, authoritative reference on this topic and that the sub-committee on small cetaceans was an appropriate group for producing such a document.

After a short discussion on the merit and the difficulties of this idea, the Committee **agrees** to consider it in more detail next year.

14.5 Update on the proposed joint Workshop on monodontids

In 2012, the Committee established a Steering Group (Bjørge [Convenor], Acquarone, Donovan, Ferguson, Reeves and Suydam) to plan for a global review of monodontids (IWC, 2013k, p.296). The terms of reference were: (1) continue planning for a joint Workshop on monodontids with the NAMMCO SC, the Canada-Greenland Joint Commission on Narwhal and Beluga (JCNB), the Alaska Beluga Whale Committee, and others; (2) prepare a proposal for global review with a Workshop to be held in the autumn of 2013; and (3) facilitate exchange of data between the involved groups.

After consultation with NAMMCO, the deadline of autumn 2013 was considered unrealistic. However, the NAMMCO Secretariat, with the IWC Scientific Committee as co-sponsor, has indicated it can convene a global review workshop back-to-back with the joint meeting of the NAMMCO SC Working Group on Belugas and Narwhals and the JCNB, to be held in Copenhagen in the second half of 2014 (or first half of 2015). Experts from all range states (Greenland, Canada, USA, Russia and Norway) should be invited and a list of possible participants in the workshop has been developed. NAMMCO has indicated that it is prepared to cover part of the costs for invited participants and funding for this workshop will be sought from the IWC. Suydam noted that with the workshop and funding coming together, other interested organisations would help support participant travel. In response to a question on participation of observers, Bjørge noted that he was not familiar with NAMMCO procedures but that observer participation should be possible.

The Committee **welcomes** this report and thanked the NAMMCO Secretariat for its willingness to host the meeting and help fund invited participants. Bjørge and Fortuna will work with the Secretariat to ensure that the request for IWC funding of this workshop is considered in a timely manner. The Steering Group will continue to advance the plans for the workshop intersessionally and report back at next year's meeting.

14.6 Other information on small cetaceans
The sub-committee reviewed information in several additional papers that were not relevant to its priority topics. Details are given in Annex L, item 8.

14.7 Work plan
The Committee's work plan is given under Item 24.

15. WHALEWATCHING

The report of the sub-committee on whalewatching is given as Annex M. Scientific aspects of whalewatching have been discussed formally within the Committee since a Commission Resolution in 1994 (IWC, 1995b). The Commission also has a Standing Working Group on Whalewatching that reports to the Conservation Committee.

15.1 Assess the impact of whalewatching on cetaceans
SC/65a/WW01 summarised four papers addressing the impacts of whalewatching on cetaceans: Peters *et al.* (2013) documented the effects of swim-with-dolphin tourism on the behaviour of the 'burrunan dolphin' (*Tursiops australis*[25]) in South Australia; Lundquist *et al.* (2012) sought to estimate the potential impact of dolphin watching and swimming on dusky dolphins in Kaikoura, New Zealand; Dans *et al.* (2012) investigated changes in behavioural budget of dusky dolphins in Golfo Nuevo, Patagonia, Argentina; and Ayres *et al.* (2013) collected data on hormone levels from the faeces of southern resident killer whales to assess factors in population decline. Summaries are to be found in Annex M, item 5.

The Committee noted that hormone analysis, using faecal and blow sampling, is a potentially valuable methodology for examining impacts of whalewatching. Clearly the efficacy of these methods will be species-specific. A third methodology to measure stress responses is telemetry using tags that can monitor heart rates The impact of research vessels (for all these sampling methods) can be significant and a good experimental design is needed to control for this.

The Committee **agrees** that a joint session on stress responses related to vessel presence and shipping noise be held next year by the sub-committee on whalewatching and the SWG on environmental concerns, provided sufficient information is available. The Committee **requests** the Convenors of those two sub-groups to invite experts to submit papers next year on the use of faecal and blow sampling to measure stress hormones in relation to whalewatching, as well as in relation to other stressors where the methodology could be applied to whalewatching.

New provided an update on the mathematical models for the behavioural, social and spatial interactions of bottlenose dolphins first described in New *et al.* (2012). The model has been adapted to incorporate ecological and geographical features and also has the potential to assess the relative impact of different vessel types, as well as their cumulative effects. The model is an individual-based model, so it can also be modified to assess individual characteristics. The Committee **welcomes** this work and **encourages** future development and its use in case studies.

[25]The Committee has not included *Tursiops australis* in its list of recognised species.

15.2 Review whalewatching in the Republic of Korea
Whalewatching from one vessel began in 2009 in Ulsan. Species encountered include long-beaked common dolphins, common minke whales, Pacific white-sided dolphins, false killer whales, common bottlenose dolphins and occasional finless porpoises. Tourism numbers are increasing and are expected to reach 20,000 in 2013.

There is a resident population of *T. aduncus* in the waters of Jeju Island; however, the Ministry of Oceans and Fisheries has advised against developing boat-based dolphin watching due to this population's small size, which led to a protected species designation in 2012. The local government has decided to pursue land-based dolphin watching only. The Committee **commends** the Jeju Government and the Ministry of Oceans and Fisheries for their precautionary approach and **recommends** that research be continued on the bottlenose dolphin population of Jeju.

Guidelines are being developed for Korean whale-watching and the Committee **refers** the developers to the Commission's guiding principles and the Compilation of Worldwide Whalewatching Regulations[26]. Ulsan, given the early stages of its whalewatching development, may be a suitable location for a study under the Modelling and Assessment of Whalewatching Impacts (MAWI) project (see Item 15.3.1 and Annex M, item 7.1).

15.3 Progress on Commission's Five-Year Strategic Plan including guidelines and regulations
15.3.1 Large-scale Whalewatching Experiment (LaWE) steering group
There was no intersessional communication or formal update on LaWE submitted to this year. Consequently the Committee **agrees** to re-evaluate the project.

The primary objectives of LaWE were to assess the population-level impacts of whalewatching and determine the effectiveness of suggested mitigation measures in avoiding any potential negative effects of the activity. These objectives remain relevant to the work of the sub-committee; it is important that research addressing these objectives continues. The Committee **agrees** to establish a new intersessional working group, with New as Convenor, tasked with developing a revised work plan to move forward with this project, now named the Modelling and Assessment of Whalewatching Impacts (MAWI), which will seek to build on what was learned in LaWE (see Annex M). The group, using the Five-Year Strategic Plan research objectives and actions as guidance, will seek to define the specific research questions and hypotheses that will most benefit understanding of the impact of whalewatching, identify those whalewatching locations that would be suitable and amenable for targeted studies addressing these questions, and summarise the current modelling tools available to analyse the data that will be collected. Once these issues have been addressed, it will be possible to identify a timeline, benchmarks, budgets and any additional resource or support needs.

[26]*http://iwc.int/whalewatching*.

15.3.2 LaWE budget development group
This item was not discussed, as there was no intersessional communication with this Working Group.

15.3.3 Swim-with-whale operations
A questionnaire seeking more detail on these operations was successfully beta-tested in the Dominican Republic in early 2012 and was distributed to operators in Tonga and New Caledonia in May 2013. A summary of results from these surveys will be presented at next year (see Annex M).

15.3.4 In-water interactions
A scientific study was conducted in October 2012 off La Gomera (Canary Islands), where in-water interactions with different small cetacean species were examined. During experimental in-water encounters, specific behaviours exhibited by the animals were observed, recorded and videotaped. Results from this study will be presented at next year (see Annex M).

15.3.5 Guiding principles development
SC/65a/WW03 was a draft of the guiding principles produced per Action 1.1 of the Commission's Five-Year Strategic Plan for Whalewatching. The principles include general management considerations and guidelines for cetacean watching. These guiding principles are fundamental to the development of the Handbook as part of the Commission's Five-Year Strategic Plan for Whalewatching.

The Committee **agrees** to develop a 'background document' to annotate the guiding principles, with an explanation of their origin and evolution, as well as definitions of terms and other explanatory background (which might include illustrations of descriptive content). A draft of this document will be presented next year (see Annex M).

The Committee **endorses** the guiding principles, which can be found in Annex M, Appendix 2, and **recommends** that they are posted on the Commission website.

15.4 Other issues

15.4.1 Review scientific aspects of the Commission's Five-Year Strategic Plan for Whalewatching
The Committee reviewed elements of the Five-Year Strategic Plan for Whalewatching and the Commission's Whalewatching Handbook relevant to its work. Objective 1, Research, details three action items tasked to the Committee:

1.1 Develop (and/or review), pending further comprehensive scientific research and assessment (refer to action 1.3), guiding principles to be followed in whalewatching operations including swim with and provisioning programs to minimise potential adverse impacts;
1.2 Identify data deficient and critically endangered populations likely to be subject to whalewatching. Develop precautionary guidance and advice on additional mitigation measures that may be required for whalewatching operations on such populations; and
1.3 Consider an integrated research program (a form of long term experiment) to better understand the potential impacts of whalewatching on the demographic parameters of cetacean populations. Seek to:
    - demonstrate a causal relationship between whalewatching exposure and the survival and vital rates of exposed cetacean individuals;
    - understand the mechanisms involved in causal effects, if they exist, in order to define a framework for improved management; and
    - establish standard methodologies for the conduct of assessments.

Action item 1.1 is addressed in SC/65a/WW03 and Parsons agreed to collate data for action item 1.2 and report to the Committee next year. The Committee noted that the MAWI intersessional working group will address action item 1.3 (see Annex M, item 7.1).

15.4.2 Report of 2013 IWC Whalewatch Operator's Workshop
A Whalewatch Operator's Workshop, funded by the Governments of Australia and the USA, was held in Brisbane, Australia on 24-25 May 2013. The main objective of the workshop, attended by over 60 representatives of industry, science and government, was to get input from operators and industry representatives for the Whalewatching Handbook to be posted on the Commission's website, with continued oversight by the Commission's Standing Working Group on Whalewatching and an on-going and iterative monitoring, evaluation and review of the Five-Year Strategic Plan for Whalewatching. In addition, the workshop sought to help the Commission understand what role it can play in identifying and promoting 'best practices' and responsible whalewatching, what the industry might like to see or have in an online Whalewatching Handbook, actions in the plan that might require further engagement with industry and how to continue to integrate work at the Commission with industry expertise.

The Committee **agrees** to establish an intersessional working group, with Rojas-Bracho as Convenor, to determine how the Committee can best assist and contribute to the Whalewatching Handbook (see Annex R).

15.4.3 Consider information from platforms of opportunity of potential value to the Scientific Committee
A 'citizen science' handout drafted by the Tonga Whalewatching Operators Association was examined (see details in Annex M, item 8.3).

The Committee noted that this type of handout could allow 'citizen scientists' to provide data directly to research groups and **suggests** that the simple data form developed in (the Data Reporting Scheme) is revived and made available as a resource through the Commission's website.

In late 2009, researchers began collecting data from whalewatching vessels as platforms of opportunity in Ballena Marine National Park in Costa Rica. Tour operators were trained in the use of data forms and GPS. The first year of data collection by operators has been completed and these data will be compared with data collected by researchers, to determine if there are significant differences in data quality. A paper will be prepared for next year's meeting.

Denkinger *et al.* (2013) studied cetacean presence and diversity in the Galápagos Marine Reserve (GMR) during El Niño, La Niña, and neutral conditions, using wildlife viewing vessels as platforms of opportunity. These data showed that most species seem to move out of the GMR during El Niño years.

SC/65a/SH25 reported on a meeting of the Southern Ocean Research Partnership (SORP) held on Jeju Island, Republic of Korea, on 31 May-2 June 2013. The meeting's primary objective was to present the scientific results stemming from the five on-going SORP research projects. Recommendation 4 of the meeting report asked partners in SORP to employ all platforms of opportunity and, where applicable, 'citizen science', to collect data for inclusion in SORP research projects, thereby reducing the logistical constraints of circumpolar coverage and overall expenditure. Recommendation 5 was to store and archive data collected from international, collaborative research efforts such as SORP in open-access, central repositories that have the capacity to handle both primary scientific data and information derived from 'citizen science', e.g. image catalogues.

SORP is coordinating with the International Association of Antarctic Tour Operators to solicit data from platforms of opportunity. Cruise ships were identified as excellent potential platforms, as experienced biologists are often on board as naturalist guides, making them a potential source of good-quality data. 'Citizen science' efforts should be coordinated, because photographs in particular often come from tourists and key matches can come from this source.

15.4.4 Review whalewatching guidelines and regulations

SC/65a/WW01 reviewed two studies that addressed compliance with whalewatching guidelines and regulations: Kessler and Harcourt (2013) studied the levels of compliance with regulations by commercial and recreational whalewatching boats off Sydney, Australia; and Chinon *et al.* (2013) looked at the effectiveness of a proposed regulation for white whale watching in the Saguenay-Saint Lawrence Marine Park, Quebec, Canada, using an agent-based modelling approach. Summaries are presented in Annex M, item 8.4.

The Committee noted that this modelling approach is a technique that could be applied to other locations to assess the effectiveness of whalewatching regulations.

The 2013 Compilation of Worldwide Whalewatching Regulations[27] is almost complete and should be online by August 2013.

15.4.5 Review of collision risks to cetaceans from whalewatching vessels

SC/65a/WW04 investigated the probability of vessel collisions with humpback whales in the waters of Maui County, Hawaii, USA. Surprise encounters and near-misses, defined as a group of whales sighted (at abeam and forward angles) within 300m and 80m of a vessel respectively, were used as proxies for probability of whale-vessel strikes. The rate of surprise encounters increased with vessel speed, from 1.5 encounters/hr at 5 knots to 4.2 encounters/hr at 20 knots. No near-misses occurred at 5 knots. Calves were present in 28.3% of surprise encounters and 58.3% of near-misses, which coincides with previous reports that calves may be more susceptible to vessel collisions. Continued research will contribute to developing a predictive model of vessel strikes for management purposes.

The Committee noted that risk of vessel collision should be factored into models developed under MAWI. The model to be developed in Hawaii will be compared to data from the Hawaiian reporting network for ship strikes, which also reports 'encounters' (the equivalent of near misses), to see if the model matches the network's reports.

Ritter presented relevant aspects of Neilson *et al.* (2012), which analysed all reported whale-vessel collisions in Alaska between 1978 and 2011. Many types and sizes of vessels collided with whales; however, small recreational vessels as well as commercial vessels were most commonly involved in collisions. When vessel speed was known, 49% of the collisions occurred at vessel speeds ≥12knots.

[27] *http://iwc.int/whalewatching.*

15.4.6 Swim-with-whale operations

SC/65a/WW01 summarised four papers addressing swim-with-whale operations: Curnock *et al.* (2013) explored effort and spatial distribution of tourists swimming with dwarf minke whales across time on the Great Barrier Reef, Australia; Kessler and Harcourt (2013) studied human-whale value transition in Tonga across time and the current impact of humpback whale tourism; Kessler *et al.* (2013) documented humpback whale responses to experimental swim-with-whale encounters in Tonga; and Lundquist *et al.* (2013) documented responses by southern right whales in Argentina to simulated swim-with-whale encounters. Summaries are presented in Annex M, item 8.6.

The Committee noted that Hervey Bay, Australia, is an important resting area for humpback mother-calf pairs. Currently swimming with whales is not occurring but tour operators there are interested in conducting such encounters, The Committee **recommends** that the IWC's guiding principles (see Annex M, Appendix 2) be applied to any management decisions in Hervey Bay.

SC/65a/SM26 refers to swim-with-cetacean excursions in Japan and recommends monitoring the situation. The Committee **agrees** to add this to its agenda in 2014 and invites submissions on this situation at next year's meeting.

15.4.7 Emerging whalewatching industry in Oman

The Committee received an update on the emerging whalewatching industry in Oman and an initiative to guide and regulate the industry, as previously recommended (IWC, 2013c, p.64).

The objectives of the new initiative to educate the industry are to protect whales and habitat from impact whilst raising the industry's 'best practice' standards. Progress has been made with securing support of ministries, developing an inventory of operators, assessing operator performance and drafting a set of whalewatching guidelines. Operator workshops are planned for the last quarter of 2013.

The Committee **welcomes** the progress demonstrated by this initiative, and invites the continued submission of updates on this emerging situation. It encouraged local stakeholders, including non-governmental organisations, to continue their commitment to taking this initiative forward. In addition, the Committee **recommends** that the whalewatching guidelines in Oman consider the growing body of research on swim-with-whale encounters and the guiding principles (see Annex M, Appendix 2), which discourage this activity.

15.4.8 Assessing 'whalewatching carrying capacity'

Childerhouse reported on the situation in Kaikoura, New Zealand and whalewatching targeting sperm whales. A moratorium on new commercial whalewatching permits for sperm whales at Kaikoura expired on 1 August 2012. Thus, the New Zealand Government commissioned a two-year research programme into the impact of commercial whalewatching on sperm whales at Kaikoura (Markowitz *et al.*, 2011). The research identified a decline in the abundance of sperm whales over the period since whalewatching started, although the cause of the decline is unknown. After public consultation, another 10-year moratorium was recommended and has been implemented. A 10-year period will allow for meaningful monitoring of the effects of whalewatching activity on sperm whales.

In discussion, other plausible hypotheses for the decline were suggested (see Annex M, item 8.8).

The Scientific Committee **welcomes** this research and **commends** New Zealand for active assessment and management of whalewatching in this region.

15.4.9 IWC Conservation Management Plans
This is discussed under Annex M, item 8.9 and Item 21.

15.5 Work plan
This is discussed under Item 24.

15.6 Other matters
SC/65a/WW05 reported on results from a survey of whalewatching passengers designed to identify causes of a decline in the number of whalewatchers in Hervey Bay, Australia. Details are found in Annex M, item 10.

SC/65a/SM15 summarised a genetic analysis of bottlenose dolphins in Bocas Del Toro, Panama, which showed that this small population (~150 dolphins) has a unique haplotype not seen elsewhere in the Caribbean, confirming its genetic isolation. Last year (IWC, 2013c, p.61), the Committee strongly recommended that the Panamanian authorities enforce national whalewatching regulations and recommended continued research to monitor this dolphin population and the impacts of dolphin watching. However, the Committee received information that enforcement has not happened, and that there has recently been a confirmed report of a dolphin watching vessel striking a dolphin. In light of this observed mortality, the Committee **strongly reiterates** its previous recommendations.

16. DNA TESTING

The report of the Working Group on DNA is given as Annex N. This particular agenda item has been considered since 2000 in response to a Commission Resolution (IWC, 2000a).

16.1 Review genetic methods for species, stock and individual identification
SC/65a/SD01 was prepared in response to a recommendation from the Icelandic Scientific Permit Review Workshop (SC/65a/Rep05) to provide details of the protocol used for the genetic analyses presented to the Workshop, to ensure that genetic sampling and analysis followed the IWC guidelines for genetic research. SC/65a/SD01 provided a comprehensive and clear description of the Icelandic DNA registry protocol, on which the genetic analyses presented to the Review Workshop were based. The Committee **welcomes** this document and **agrees** that it responded appropriately to the recommendation from the Icelandic Scientific Permit Review Workshop.

The Committee **encourages** the preparation of technical documents on methods for species, stock and identification for discussion at the next year meeting under this agenda item.

16.2 Review results of the 'amendments' of sequences deposited in GenBank
During the first round of sequence assessment in *GenBank* (IWC, 2009f, p.347) some inconsistencies were found but these appear to be due to a lag in the taxonomy recognised by *GenBank* or uncertainty in taxonomic distinctions currently under investigation (IWC, 2013l, pp.330). After the assessment, some of the inconsistencies were corrected but further corrections have been hampered by the fact that only the original submitter can alter taxonomy fields in *GenBank*. Last year, the Committee agreed that Cipriano should make a request to *GenBank* to add an additional field for comments (IWC, 2013c, p.64).

Cipriano contacted *GenBank* during the intersessional period and received a response that *GenBank* is willing to work with the IWC on this. They requested that a list of accession numbers associated with problematic taxonomic designations be provided. This would help *GenBank* to understand the scope of the problem while considering a mechanism to allow taxonomy corrections and notations by request.

The Committee **agrees** that the list of accession numbers involving inconsistencies (Annex N, Appendix 2) should be sent to *GenBank* by Cipriano with a letter explaining the background and the main reasons for the inconsistencies, which include:

(1) species for which the taxonomy is still being worked out (e.g. the 'Brydes whale' species complex);
(2) species that have been recently split into new (or redescribed) species (e.g. the right whales and minke whales); and
(3) subspecies for which the taxonomy is still being investigated (e.g. the recognised sub-species of blue whales and minke whales).

Cipriano will also communicate about the need for an annotation indicating uncertainty in subspecies identity for a specimen.

16.3 Collection and archiving of tissue samples from catches and bycatch
The Committee previously endorsed a new standard format for the updates of national DNA registers to assist with the review of such updates (IWC, 2013c, p.53), and the new format worked well last year. This year the updates of the DNA registers by Japan, Norway and Iceland were based on this new format. Details are given in Appendices 3-5 of Annex N for each country, respectively, covering the period up to and including 2012. The Committee **thanks** the countries involved for providing this information.

16.4 Reference databases and standards for diagnostic DNA registries
Annex N, Appendices 3-5 summarise the status of mtDNA and microsatellite analyses of the stored samples for Japan, Norway and Iceland, respectively. In almost all cases, the great majority of samples have been analysed for at least one of either mtDNA or microsatellites and in most cases both. Work on unanalysed samples is continuing although in Japan's case 100% coverage was not possible because many samples were lost in the 2011 tsunami. Details on the exact number of samples collected and analysed are provided in Annex N.

The Committee **appreciates** the efforts of Japan, Norway and Iceland in compiling and providing this detailed information of their registries. The Committee **reiterates** its view that the information provided in the new format greatly facilitated the annual review.

16.5 Work plan
The work plan is discussed under Item 24.

Members of the Committee are encouraged to submit papers in response to requirements placed on the Committee by the IWC Resolution 1999-8 (IWC, 2000a). Relevant information in documents submitted to other groups and sub-committees of the Committee will be reviewed next year. Results of the 'amendments' work on sequences deposited in *GenBank* will be reported next year.

17. SCIENTIFIC PERMITS

This Agenda Item was discussed by the Working Group on Special Permits and its report is given as Annex P. In order to assist the reader, this section provides a summary of Annex P and it also includes a summary of the expert Workshop (SC/65a/Rep03) on the Icelandic special permit held in accordance with the Committee's guidelines (IWC, 2013m).

17.1 Review report of Workshop for Icelandic special permit whaling

In 2003, Iceland presented and the Committee reviewed a special permit research programme to the Committee for review that had included proposed takes of 200 fin whales, 100 sei whales and 200 common minke whales spread over a two-year period that was intended as feasibility study (IWC, 2004). In the event, the programme was reduced to considering only common minke whales and the catch period was extended such that the 200 common minke whales were taken from 2003-07. Due to practical difficulties in Iceland, review of the final results from the programme was delayed. Following the Committee's revised guidelines and timetable for such a review (IWC, 2013m), the expert panel meeting took place in February 2013. All due dates for availability of data, documents, reports and revised documents were met.

17.1.1 Panel Chair's summary of the panel report

The Panel was chaired by Kitakado and its composition was decided upon by a steering group comprising the past four Scientific Committee chairs and the Head of Science. Difficulties in the availability of proposed candidates meant that participation by scientists who had no connection with the Committee proved very difficult. In the event, the Panel comprised the present Committee Chair and the Head of Science (in accord with the guidelines), two ex-Committee Chairs, one current member of the Committee, one scientist who has not participated in the Committee for several years and two scientists who have never participated. Expertise in all areas of the research programme was available. In addition to the proponents, four observers were present. Thirty papers were submitted by proponents (SC/F13/SP01-30) and three additional papers were submitted by other scientists (SC/F13/O01-03).

The Panel report (SC/65a/Rep03) is divided into sections based on the stated objectives of the programme: abundance; stock structure; biological parameters, feeding ecology; energetics; pollution; parasites and pathology. Each of these contained the proponents' summary of their results followed by an analysis of the results by the Panel including conclusions and specific recommendations. The final section presents the Panel's general overview and conclusions followed by a summary of all of the recommendations divided into short, medium and long-term.

The report is a long and detailed review. What follows here is a short Panel Chair's summary of only the broad conclusions (SC/65a/Rep03); it does not provide a substitute for reading the full report. In reaching its conclusions and recommendations, the Panel noted that no further special permit programme was envisaged by Iceland at present. With respect to consideration of the effect of the catches on stocks, it noted that the level of catches was considerably below the level for the CIC *Small Area* that would have been allowed under the RMP (IWC, 2011b, p.64). The Panel emphasised that its task was to provide an objective scientific review of the results of the Icelandic programme; its task was not to provide either a general condemnation or approval of research under special permit. Consideration of that would require examination of some issues way beyond the purview of a scientific panel.

The Panel made a number of general points in addition to its review of individual topics. The first related to the objectives of the programme. The general nature of the objectives of the original proposal and its characterisation as a feasibility/pilot study made it difficult for the Panel to fully review how well the programme could be said to have met its own objectives. It agreed that it is important that any special permit programme provides careful objectives and sub-objectives for which performance can more easily be assessed, as is now the case in the guidelines for proposed permits in IWC (2013m), developed since the Iceland permit was presented in 2003.

The Panel also commented that better information on sampling design and an evaluation of sample size and representativeness at the local and population level was required. While the method used was probably sufficient for a feasibility study, it would not be the case for a full programme.

A common thread throughout the report related to the need for integrated analyses of the individual components of the programme; it regarded such work as essential and this was the subject of several recommendations. Given the objective of multi-species modelling to improve management, this should also include consideration of the results in the context of a modelling framework. The Panel noted that the programme had tried to maximise the information obtained from the whales taken. It stressed the importance of archiving material collected as well as storing analytical results and data in a relational database linked to the tissue archive.

With respect to abundance, the Panel agreed that the Icelandic survey data have improved knowledge about the abundance and distribution of the common minke whale in Icelandic waters both for use in the RMP and for input to potential multispecies modelling. Despite the logistical difficulties, the spring and autumn surveys provided valuable new information, especially in the context of any future multi-species modelling.

With respect to stock structure, the Panel agreed that the data will assist in the Committee's work on this topic. With respect to feasibility component, it was of course already well-known that it is possible to collect samples to better understand stock structure from carcases (as well as from biopsy samples as the proponents' note). It welcomed the efforts to compare genetic data across the North Atlantic but recommended further effort to integrate information regarding stock structure from the variety of genetic and non-genetic sources.

With respect to biological parameters, the Panel recognised the extensive amount of field and laboratory work that had been undertaken and presented. It noted that evaluating the feasibility of collecting information on biological parameters of sufficient precision and accuracy to inform multi-species modelling requires examining the sensitivity of model results to the parameters concerned. As the modelling was not as advanced as had been originally planned, this evaluation cannot yet be conducted. One of the most important feasibility questions relates to the issue of ageing common minke whales and the Panel commended the work to examine a new approach for common minke whales, recognising that further work needs to be undertaken.

With respect to feeding ecology, a primary component of the programme, the Panel acknowledged the large amount of effort undertaken and the generally thorough analyses using a variety of techniques. The temporal changes observed as a result of the extension of the sampling period could be related to climate change or a regime shift in the waters around Iceland and this is an important issue for further research.

The general nature of the objectives made evaluation of the success of the feasibility study more complex but the Panel agreed that knowledge of the general feeding ecology of common minke whales around Iceland has been advanced. It also acknowledged the efforts to collect data in such a way as to allow a more systematic than usual examination of the results that can be obtained from lethal and non-lethal methods (see SC/65a/Rep03, table 4). Finally, the Panel strongly recommended that integrated analyses including comparison of the information from each approach be developed and submitted to the Scientific Committee.

With respect to energetics, again the Panel recognised the considerable field, laboratory and analytical effort. These provided valuable insights into aspects of the energetics of common minke whales around Iceland but further effort is required to integrate the various analyses to provide quantitative input to energetics models and multispecies modelling and allow an evaluation of the sensitivity of the results to the inevitable uncertainty.

With respect to modelling, the Panel recognised the practical difficulties explained by the proponents but concluded that this important part of the programme is as yet poorly developed. In particular, a simple preliminary model should have been developed to inform discussions of which are key parameters with respect to obtaining robust results, evaluating how sensitive results are to different levels of uncertainty and determining appropriate sample sizes. This was a major weakness in the programme. However, the Panel welcomed the modelling work presented to the Workshop as a small but valuable initial step toward the programme's overall objective.

With respect to pollutant studies, the Panel acknowledged the considerable field, laboratory and analytical work that had resulted in a number of published papers. It also appreciated the effort made to compare results across the North Atlantic and to examine relationships between concentration levels in different tissues including 'pseudo' biopsy samples. However, it agreed that the objective of assessing health status had not been fully addressed and cautioned against broad assumptions that low levels necessarily indicate no effect. The sample size of the feasibility study was insufficient to properly address any toxic-related cause-effect relationships.

With respect to parasites and pathology, the objective had been to investigate the feasibility of monitoring and evaluating the morbidity of potential pathogens. The Panel recognised the difficulty of conducting full post-mortems of animals and undertaking thorough examination for parasites and pathogens at sea. While the study of the epibiotic macro fauna has resulted in a good baseline for future analyses, overall, the Panel concluded that the approaches adopted in the feasibility study would be insufficient to achieve the objective outlined.

The Panel briefly noted that the Commission had passed several resolutions relevant to research on the ecosystem, contaminants and environmental change. It agreed that many aspects of the programme were relevant to these topics and that the information had been made available to the Scientific Committee.

With respect to the utility of lethal and non-lethal techniques the Panel referred to extensive discussions at the JARPN II review (IWC, 2010a) and the SORP conference (Baker *et al.*, 2012). The Panel welcomed the efforts of the programme to provide data to allow a more thorough and quantitative comparison of some lethal and non-lethal techniques than has previously been possible (see recommendation in IWC, 2010a). The Panel developed a simple qualitative table to summarise the situation for North Atlantic common minke whales but stressed that is not intended to represent a complete or comprehensive evaluation of lethal or non-lethal techniques, either in general or for this specific programme and drew attention to a number of caveats.

Finally the report provided a summary of its recommendations. Seventeen addressed specific issues that might be termed 'short-term' while twelve addressed 'medium to long-term' issues.

In conclusion, the Panel's Chair thanked the Panel, the proponent scientists and the observers for their constructive and patient approach to the Workshop and the Marine Research Institute for providing excellent facilities.

17.1.2 Proponents response to the Panel report

SC/65a/SP01 provides an overview of the response of scientists from the Icelandic research programme (IRP) to the report of the Panel (SC/65a/Rep03). The IRP scientists consider that in general the evaluation of the IRP by the Panel was constructive, objective and balanced.

SC/65a/SP01 also responded to the Panel's request to provide further documentation of the sampling design. The authors emphasised that the objective was to cover the Icelandic continental shelf area and not to be representative of the Central stock of common minke whales. Sampling was distributed in relation to relative abundance in nine small areas used as part of the Bormicon framework for multispecies modelling of boreal systems. In addition, sampling was stratified seasonally into five units. The purpose of such a fine-scale stratification in this feasibility study was to ensure good distribution of the sampling around Iceland and to allow for post-stratification as appropriate for the different sub-projects.

While agreeing with most of the suggestions and recommendations of the Panel, as can be seen in Table 5, the IRP scientists have not been able to fully respond to all of these within the short period determined by the review process protocol (40 days). However, the IRP plan to conclude most of these before the 2014 Annual Meeting with a particular emphasis on those considered relevant for the upcoming RMP *Implementation Review* of North Atlantic common minke whales and the joint AWMP/RMP Workshop on the stock structure of North Atlantic common minke whales (see Annex D). For example, collaboration has already been established to investigate the isotope ratios in baleen plates.

SC/65a/SP01 also noted additional collaborations and studies that were initiated during the project on subjects outside the original objectives (brain anatomy, radioactivity, climate change aspects, genetic relatedness methodology, and analysis of additional pollutants).

In conclusion, the IRP scientists noted that the Panel had acknowledged the quality and scientific relevance of the presented results to common minke whale research, while identifying areas where further work was required. IRP scientists had responded positively to the comments and recommendations of the Panel as shown in Table 1. They also noted that the guidelines for review of scientific permit programs call for special considerations of the utility of non-lethal and lethal research techniques. This comprised a special objective of the IRP and the Panel had welcomed the efforts of the IRP to provide data to allow a more thorough and quantitative comparison of some lethal and non-lethal techniques than has previously been possible. This is relevant for other populations and species. The Panel had

Table 5

IRP scientists' summary of status of progress (based on table 2 in SC/65a/SP01) in responding to the Panel's recommendations (SC/65a/Rep03), including the list of papers submitted to the Committee in response to SC/65a/Rep03 and the sub-groups at which they were presented.

Recommendations (sub-group); Item no. in SC/65a/Rep03	Status of work
Abundance (RMP)	
12.1.1.1	To be addressed in the near future. Further recommendations may be needed as to the approach to take (before the North Atlantic common minke whale *Implementation Review*).
Stock structure (RMP, SD)	
Short term recommendations	
12.1.2.1	A fully integrated stock structure paper was submitted (SC/65a/SD02).
12.1.2.2	A paper describing the genetic protocols employed during the IRP was submitted (SC/65a/SD01).
12.1.2.3	This has been dealt with in the fully integrated stock structure paper (SC/65a/SD02).
12.1.2.4	This has been partly dealt with in the fully integrated stock structure paper (SC/65a/SD02).
12.1.2.5	To be addressed in the near future.
Biological parameters (EM)	
Short term recommendations	
12.1.3.1	Addressed in SC/F13/SP15rev.
12.1.3.2	Addressed; changes in reproductive status considered in SC/F13/SP10rev and SC/F13/SP05rev.
12.1.3.3	To be addressed in the near future.
Feeding ecology (EM)	
Short term recommendations	
12.1.4.1	To be addressed in the near future.
12.1.4.2	A revised paper on the diet composition was submitted (SC/F13/SP02rev).
12.1.4.3	An update of status and response to specific recommendations is given in SC/65a/EM01 and Daníelsdóttir and Ohf (2013).
Energetics (EM)	
Short term recommendations	
12.1.5.1	A fully integrated paper was submitted (SC/65a/O02).
12.1.5.2	The revised paper was submitted (SC/F13/SP10rev).
12.1.5.3	The revised paper was submitted (SC/F13/SP05rev).
Pollution (E, EM)	
Short term recommendations	
12.1.6.1	Addressed in SC/F13/SP22rev and SP23rev.
12.1.6.2	Addressed in SC/F13/SP23rev.

also noted that the level of catches was considerably below the level that would have been allowed under the RMP. Finally the IRP scientists noted the relevance of the research programme to the work of the Scientific Committee and the RMP in particular.

17.1.3 Committee's discussion

The Committee **thanks** the Panel for its thorough review of the Icelandic programme. It also **acknowledges** the work of the IRP scientists in producing revised papers after the Workshop so that they were available 40 days prior to the Annual Meeting.

In discussion, some members noted that while the Panel had agreed that 'many aspects of the Icelandic programme were directly relevant' to a number of Commission Resolutions on the environment and climate change, they believed that it was more appropriate to say that they were 'potentially' relevant to Commission Resolutions. They also believed that the Icelandic Programme fell short of meeting the Resolution on Whaling under Special Permit (IWC, 1996a).

Some members, having taken account of the expert review, expressed some broader critical views of the Icelandic programme and these are provided in Annex P1. This was not discussed and neither was the response from the proponents given in Annex P2. Noting the previous discussions on special permit whaling, the Committee did not discuss an overall evaluation of the Icelandic program.

Without questioning the quality of the members of the Panel, the future need for increased participation from experts outside of the Scientific Committee was noted. The Steering Group explained that this was the intention but despite a long list of potential candidates developed, the availability and/or interest of outside scientists in participating in the review had proved extremely challenging.

A large number of scientific papers originated from the Icelandic programme. Several of these papers were presented to the relevant sub-committees and working groups (RMP, SD, EM and E) as shown in Table 1 of the report. However, some members of the Committee suggested that further consideration be given to how to manage the time allocated to review such papers in the future, as they felt that not enough time was available for review in some sub-groups.

17.2 Review of results from ongoing permits

As in previous years, the Committee received short cruise reports on activities undertaken but spent relatively little time on discussion of the details. For long-term programmes, the Committee has agreed that regular periodic detailed reviews (following its guidelines, IWC, 2013m) were more appropriate.

17.2.1 JARPN II

SC/65a/O03 presented the results of the 2012 JARPN II (Second Phase of the Japanese Whale Research Program under Special Permit in the Western North Pacific) offshore component. A detailed summary is given in Annex P. There were three main research components: whale sampling survey, dedicated sighting survey and whale sighting and prey survey. A total of five research vessels were used: two sighting/sampling vessels (whale sampling survey component), one research base vessel (whale sampling survey component), three dedicated sighting vessels (dedicated sighting survey component) and one whale sighting and prey survey vessel (whale sighting and prey survey component). Catches occurred between 16 May and 3 August 2012 (74 common minke, 100 sei, 34 Bryde's and three sperm whales). Sightings surveys covered over 2,300 n.miles and eight species of large whales were seen including five blue and two North Pacific right whales. Preliminary results of biological and feeding ecology analyses are presented in this document. Data obtained during the 2012 JARPN II survey will be used in the elucidation of the role of whales in the marine ecosystem through the study of whale feeding ecology in the western North Pacific.

SC/65a/O06 presented the results of the 2012 JARPN II coastal component off Kushiro, northeastern Japan (middle part of sub-area 7CN). A more detailed summary is given in Annex P. Research occurred from 9 September to 28 October 2012, using four small sampling vessels. Catches (48 common minke whales) occurred within 50 n.miles of Kushiro port, and animals were landed at the JARPN II research station for biological examination. The frequency of whales feeding on Japanese anchovy was much lower in 2012 than in previous Kushiro surveys.

In discussion, it was clarified that search areas and vessel course were determined from weather conditions, whale distribution and information on fishing ground of coastal fisheries.

SC/65a/O07 presented results of the 2012 JARPN II coastal component off Sanriku (northeastern Japan, corresponding to a part of sub-area 7). A more detailed summary is given in Annex P. Research occurred from 12 April to 26 May 2012. Catches (60 common minke whales) occurred within 50 n.miles of Ayukawa port and all animals collected were landed at the JARPN II research station for biological examination. Information on sighting distribution, biological characteristics and prey species of whales collected during the 2012 survey was similar to that recorded before the 2011 earthquake and tsunami.

In response to a question, Sakamoto explained that samples from 32 individuals of four species from 2012 JARPN II were screened for radioactivity for the purpose of food safety. Ten of them were below the detection limit and the other 22 were well below the National Food Safety Limit set by the ministry of Health, Labor and Welfare. This information is available on the website of the Fisheries Agency of Japan[28].

17.2.2 JARPA II

SC/65a/O09 presented results of the eighth cruise of the JARPA II (Second Phase of the Japanese Whale Research Program under Special Permit in the Antarctic) survey in the 2012/13 austral summer season. A more detailed summary is given in Annex P. Research was conducted from 26 January to 14 March 2013 in Areas III East, IV, V West and part of Area V East. Four research vessels were used: three sighting/sampling vessels (SSVs) and one research base vessel. The SSVs surveyed a total of 2,103.3 n.miles in a period of 48 days. Unfortunately, the research activities were interrupted several times by members of Sea Shepherd, which directed violent sabotage activities against Japanese research vessels. A total of 103 Antarctic minke whales were caught and examined on board the research base vessel. Photo-identification, biopsy sampling and oceanographic work was also conducted. The main results of were as follows: (1) humpback whales were widely distributed in the research area with a higher density index than that of the Antarctic minke whales in all areas except in Prydz Bay; (2) the ice-free extent of the research area was substantially larger than in past seasons; (3) mature female Antarctic minke whales were observed only in Prydz Bay; and (4) all Antarctic minke whales sampled in Area IV east were immature animals.

[28]*http://www.jfa.maff.go.jp/e/inspection/.*

17.3 Planning for periodic review of results from JARPA II

JARPA II is due for a periodic review during the next intersessional period. According to the revised guidelines (IWC, 2013m), the proponents should submit a document explaining the data to be made available to the Workshop one Annual Meeting prior to the review Workshop. This information is provided in SC/65a/O08.

SC/65a/O08 summarised the data available for the next JARPA II Review Workshop to be held early in 2014. The summary was made for the six first surveys of JARPA II (2005/06-2010/11). The summary of the data followed the revised guidelines (IWC, 2013m):

(a) outline of the data that will be available;
(b) references to data collection and validation protocol;
(c) references to documents and publications of previous analyses; and
(d) contact details.

Data in SC/65a/O8 were summarised into the following sections:

(a) data for abundance estimate for several baleen and toothed whale species;
(b) ecological data;
(c) biological, feeding ecology, pollutant and stock structure data of Antarctic minke whale;
(d) biological, feeding ecology, pollutant and stock structure data of fin whale; and
(e) stock structure data of other species. Details of these data are given in Annex P5.

The next step of the review process is that the proponents make data available in electronic form one month after the end of the Annual Meeting. Then the proponents will send a document to the Secretariat describing the analytical methods to be discussed at the Workshop. This will happen nine months prior to the next Annual Meeting; i.e. the beginning of September. Based on the description of analytical methods, the Steering Group (Chair[29], Vice Chair, Head of Science and the last four Scientific Committee Chairs) will begin the process of identifying experts to participate in the Workshop. The need to try to find experts from outside the Committee was stressed. The full timetable for the process is summarised in Table 6 and details can be found in IWC (2013m).

The Committee **reaffirms** its guidelines (IWC, 2013m) that when members submit substantive analyses for a review panel, the Panel Chair, in exercising their discretion, may allow presentation of such analyses in the same manner allowed for proponents.

17.4 General comments regarding Special Permit whaling

Some members of the Committee stressed that the lack of review and comment outside the periodic reviews under the Committee's revised guidelines should not be interpreted as an indication that any of the serious scientific concerns

[29]Given his involvement in the programme, the Scientific Committee Chair, Kitakado, will not take part in the Steering Group. Palka (as immediate past Chair) will act on his behalf.

Table 6

Timetable for the periodic review of JARPA II assuming that the Annual Scientific Committee Meeting is on 1 June.

Item	Schedule	Date
Information on likely analytical methods to be used in the documents to the Workshop.	9 months before Annual Meeting	1 Sep.
Distribute documents to Vice Chair, Head of Science and Standing Steering Group (SSG).	1 week later	8 Sep.
SSG suggest names for the Specialist Workshop. Announcement of review to IWC and call for observers.	2 weeks later	22 Sep.
Chair, Vice Chair and Head of Science develop draft list of specialists and reserves.	2 weeks later	6 Oct.
Final comments from SSG.	1 week later	13 Oct.
Invitation and documents to Specialists.	1 week later	20 Oct.
Receipt and circulation of results/review documents from Special Permit research (including to IWC Scientific Committee members).	>6 months prior to Annual Meeting	1 Dec.
Observer reviews/papers due at the Secretariat.		30 Dec.
Observer's reviews sent to Specialists and Proponents.		6 Jan.
Hold Workshop.	>100 days prior to Annual Meeting	23 Feb.
Final Workshop report made available to Proponents.	>80 days prior to Annual Meeting	13 Mar.
Distribution of result documents, Workshop report and comments from Proponents to the Scientific Committee.	>40 days prior to Annual Meeting	22 Apr.
Discussion and submission of documents to the Commission.	Annual Meeting	1 Jun.

expressed about Special Permit whaling programmes have been addressed. This statement is included as Annex P3. Other members opposed this view and their statement is included as Annex P4.

17.5 Review of new or continuing proposals

17.5.1 JARPA II

Japan reported that there was no plan to change the JARPA II programme.

17.5.2 JARPN II

Japan reported that there was no plan to change the JARPN II programme.

18. WHALE SANCTUARIES

There were no new proposals for IWC Sanctuaries this year. The Committee **agrees** to keep this item on the Agenda. General matters relevant to marine protected areas were dealt with by relevant sub-groups (and see Item 4.7).

19. SOUTHERN OCEAN RESEARCH PARTNERSHIP (SORP)

SC/65a/SH25 reported on a Southern Ocean Research Partnership (SORP) meeting (31 May-2 June 2013, Jeju, South Korea). The aims of the conference were to: (1) present the scientific results from the five ongoing SORP research projects; (2) update the existing project plans and discuss new research proposals (refer to Annex 1 of SC/65a/SH25rev for details of these plans); and (3) make recommendations for the continuation and development of the SORP.

The SORP meeting made key recommendations in relation to the SORP initiative:

(1) to ensure all SORP Partners are seeking funding from all suitable sources to ensure the five existing SORP research projects are resourced adequately;
(2) to improve communication with the Commission on SORP-related outcomes to ensure that they are aware of the scientific products and to encourage financial support;
(3) to improve the dissemination of information on SORP projects and initiatives;
(4) for SORP Partners to encourage all platforms of opportunity and, where applicable, citizen science, to collect data for inclusion in SORP research projects, thereby reducing the logistic constraints of circumpolar coverage and overall expenditure;
(5) that all data and samples collected from international, collaborative research efforts such as SORP are stored and archived in recognised central repositories; and
(6) that the holders of large, long-term datasets that contain valuable information relevant to SORP, particularly acoustic data, should be strongly encouraged to analyse and publish these data as soon as possible.

The Committee **congratulates** the many scientists engaged in SORP for the significant progress and new information presented to the Scientific Committee. It **endorses** the recommendations above and notes that the scientific results were being integrated into the broader work of the Committee.

The Committee **agrees** that the preliminary objective of the Antarctic blue whale project had now been met; the identification of the most appropriate survey design method. The project has also developed a passive acoustic tracking technique that has ramifications for all future whale surveys in Antarctica. The Committee **agrees** that the data from this SORP project are key to the assessment of the Antarctic blue whale population.

The Committee also **recognises** that the acoustic trends project is extremely ambitious; it will take many years to complete but may be the only way to assess the recovery of fin whales. In time it may become the most efficient way to describe the abundance and distribution of many Antarctic whale species.

The first objectives of the Oceania humpback whale project have been completed through the collaborative analysis of biopsy and photo-identification data and those results are being used in the current assessment of Breeding Stock E humpback whales. The results of SC/65a/SH13 are also informative to this project.

The Committee **agrees** that the collection of data through platforms of opportunity may be a highly effective way to collect data in the remote Southern Ocean.

20. IWC LIST OF RECOGNISED SPECIES

The recent literature in cetacean taxonomy (SC/65a/O01) was reviewed and discussed (see Annex L) and it was agreed to add two newly recognised species to the List. *Inia geoffrensis* has been split into the Amazon river dolphin, *I. geoffrensis* and the newly recognised Bolivian bufeo, *I. boliviensis* (Ruiz-García and Shostell, 2010). *Neophocaena phocaenoides* has been split into the Indo-Pacific finless porpoise, *N. phocaenoides* and the newly recognised narrow-ridged finless porpoise, *N. asiaeorientalis* (Jefferson and Wang, 2011). New analyses based on the cytochrome b gene (SC/65a/SM03) have confirmed the split of the finless porpoises. The Burrunan dolphin *Tursiops australis* was recently described (Charlton-Robb *et al.*, 2011) but its validity is uncertain[30] and the Committee **agrees** to not add it to the List at present, pending further studies. It was noted that the extent of sympatry of the two finless porpoise species (Taiwan Strait) is thought to be small, and further sampling (molecular and morphological) to investigate possible divisions within the two recognised species is encouraged.

The Committee also recalled the open questions remaining about the taxonomy of the Bryde's whale species complex and the holotype of the common minke whale. With respect to the former, the genetic identity of the holotype specimen of *Balaenoptera edeni* remains to be identified; the Committee **reiterates** its previous recommendation that this be done.

21. CONSERVATION MANAGEMENT PLANS

Conservation Management Plans (CMPs) and their role in the IWC was first discussed by the Committee in 2008 (IWC, 2009b, p.70). A key feature of CMPs is that they provide a framework for international collaboration to address threats to populations that occur within the waters of more than one country and in offshore waters i.e. they are complementary or supplementary to individual national initiatives.

The IWC has identified some key components of CMPs (see IWC/63/CC5). These are as follows.

(1) The focus should be on practical and achievable actions (including protection for critical habitats) that have the greatest chance of resulting in improved conservation status; actions fall broadly under a number of headings (co-ordination, research, monitoring, public awareness, mitigation) all of which must be driven by the need for positive conservation outcomes.
(2) CMPs are living documents that are to be reviewed periodically against measureable milestones based on monitoring, assessment, and compliance with agreed measures.
(3) CMPs are designed to complement existing measures (e.g. national recovery plans or other national or regionally agreed measures) not to replace them; in particular they can fill identified gaps given the geographical and seasonal range of the populations involved. IWC involvement can *inter alia* bring in additional range state support, the involvement of other IGOs and scientific/technical expertise.

The approach for identifying populations for which CMPs can be developed will depend on the level of information that is available on abundance, status and threats. In addition, CMPs will only be effective where there are identified threats that are practicable to address. If management measures to address threats are already being taken by the range states involved, or if there is only one range state, then there may be little additional benefit in coordinated action through a CMP. In addition, the IWC will need to give consideration as to how CMPs might interact with other efforts such as that of the Convention on Biological Diversity for defining 'Ecologically or Biologically Significant Areas (EBSAs)' or regional agreements such as ACCOBAMS.

[30]Society for Marine Mammalogy, Committee on Taxonomy. List of marine mammal species and subspecies. *http://www.marinemammalscience.org* [16 April 2013].

The Committee noted that there were different approaches to identify whether a population that meets at least one of the following criteria (1)-(4) might be considered as a candidate:

(1) population status (i.e. knowledge of where the population is now in relation to its unexploited abundance, with an estimate of future trend) has been assessed and is of concern, and actual or likely human activities that can threaten the population have been identified;
(2) population status has not been assessed but the impacts of human activities are believed by the Committee to be substantial and thus of concern;
(3) present abundance is known and actual or likely human activities that can threaten the population have been identified; and
(4) present abundance and trend are not well known but abundance is believed by the Committee to be small such that any adverse impacts as a result of human activity may be critical.

The approach taken, for example whether the primary motivation is driven by concerns over status or the level of threat, will depend on what data are available. The Committee discussed CMPs during the work of different sub-committees, some of which considered the issue from the perspective of threats while others from the perspective of population status. The Committee **agrees** that the focus for initial discussions this year is on large whales; it is a much larger and more complex task for small cetaceans. The Committee **seeks guidance** from the Commission on whether or not it wishes the Committee to develop a priority list of populations of small cetaceans for which CMPs might be of value. The Committee **recognises** that consultation with range states is an essential first step in developing a CMP.

The Committee **agrees** that those populations with draft CMPs already in place (western gray whales – collaboratively with IUCN; southwest Atlantic population of southern right whales; and southeast Pacific population of southern right whales) remain a high priority for CMPs.

The Committee also identified the populations that could be considered for a CMP if supported by the range states. This list illustrates different examples, including agreement that populations were high priorities for a CMP, populations where their status would merit a CMP but it is difficult to identify practicable conservation measures, and populations where there were different views on whether the conservation status required a CMP.

21.1 Populations considered based on assessments by the Scientific Committee

Arabian Sea humpback whales

This population was first suggested as a possible priority candidate by the Committee in 2010. It is believed to have numbered as few as 82 individuals in 2004 (95% CI 60-111) based on dorsal fin and fluke photo identification work around Oman. No trend information is available and there are few data available from other range states (India, Pakistan, Sri Lanka, with occasional sightings for Iran and Iraq) to be sure to whether this reflects total abundance of the humpback whales in the Arabian Sea or just around Oman. Known and likely threats include entanglement in fishing gear and ship strikes but the full extent of these is unknown.

The Committee **agrees** that the Arabian Sea population remains a high priority for a CMP if support was provided by the range states.

Common minke whales in the coastal waters of China, Japan (especially the west coast) and Republic of Korea
Of the common minke whale populations in the North Pacific considered by the Committee, only common minke whales in the coastal areas of Japan, China and the Republic of Korea might satisfy the guidelines for populations which could be subject to a CMP. China, Republic of Korea, North Korea, Japan, Russian Federation are the range states. Information on the animals in these waters comes primarily from the discussions of stock structure and the modelling work undertaken as part of the RMP *Implementation Review* (Annex D1, item 10). The stock structure issue led to no agreement within the Committee: there are three hypotheses (A, B, C of increasing numbers of stocks or sub-stocks). Stock structure hypothesis C leads to most concern for the 'J-like stocks' and the 'Y-stock'; the high levels of incidental take, in particular, cause substantial projected future decline (see Annex D1). In addition to the stock structure discussions, a major information gap is the poor survey coverage, particularly the sub-areas 5 and 6W.

Despite the uncertainties, some members believed that the results from assessments underlying the *Implementation Simulation Trials* undertaken during the *Implementation Review* were sufficient to warrant consideration of the value of a CMP, given the projected impact of incidental bycatch. Other members believed that it was premature to put this proposal forward given the uncertainty regarding stock structure and the poor survey coverage in some areas.

North Atlantic right whales
The Committee reiterated its concerns over the status of North Atlantic right whales, a small population subject to high levels of human impacts from entanglement and ship strikes. However, the two range states (USA and Canada) are already taking management action and the Committee did not identify any specific ways in which a CMP would assist their conservation efforts.

North Pacific right whales
The Committee noted concern over the small size of this population, particularly in the eastern part of the species' range, and the need for more research to understand distribution, assess threats and identify actions that could be taken to reduce these. It was also noted that the range states for right whales in the North Pacific were the same as for gray whales and so there may be options for integrating North Pacific right whales with the current western gray whale CMP.

21.2 Populations considered based on knowledge of threats

Blue whales in the northern Indian Ocean
The Committee noted that there are no population estimates for blue whales in the northern Indian Ocean but there have been a number of reported ship strikes of blue whales off Sri Lanka. This highlights the urgent need for long-term monitoring of the blue whales in Sri Lankan waters and elsewhere in the northern Indian Ocean. Further assessment is needed on whether this population may benefit from a CMP.

Fin whales in the Mediterranean
This population is Red-Listed as *Vulnerable* by IUCN and is known to be subject to a high level of ship strikes. The IWC and ACCOBAMS have a joint work plan to address ship strikes in the Mediterranean. Further evaluation is required as to whether an IWC CMP would assist in the current work by IWC, ACCOBAMS and range states.

Sperm whales in the Mediterranean
This population is considered as *Endangered* by IUCN and is at risk from driftnet entanglement and ship strikes. As for fin whales in the Mediterranean, further evaluation is required to determine whether an IWC CMP would assist in the current work by IWC, ACCOBAMS and range states.

Other populations that were tentatively considered in some sub-group reports as potentially benefitting from a CMP in the future include: Antarctic blue whales; a small southeast Pacific (Isla de Chiloe) group of blue whales; and a small southeast Pacific group of 'pygmy' fin whales. However, the current information on status and/or threats in these cases was not adequate to support a recommendation at this time. In particular, in the case of these blue whale and fin whale populations, no major threats amenable to practical management action have been identified. The Committee **agrees** that other populations will be re-evaluated for priority listing as additional information becomes available.

Entanglement and ship strikes are the highest cause of non-deliberate anthropogenic mortalities for large whale populations. In addition to assessments including abundance and status, the Committee has discussed ways of estimating the numbers of entanglement and ship strike mortalities and evaluating mitigation measures. The Committee also noted that any population which is known to spend significant time in areas of high entanglement risk or high density shipping may be considered, even with a low number of reports. This is especially true if there is no local stranding network or ship strike reporting infrastructure. The Committee **agrees** that it is not currently in a position to propose any populations for CMPs based only on risk analysis where reporting is very limited.

Once a CMP is developed, the mitigation aspects of measures considered within it will need to be evaluated to assess what risk reduction is expected or being achieved. The Committee therefore **encourages** studies that fill any data gaps regarding ways that entanglement or ships strikes may be reduced, for input into CMPs. This may be in areas where CMPs have already been developed (western gray whales; southwest Atlantic population of southern right whales; and southeast Pacific right whales); are currently under consideration as candidates (Arabian Sea humpback whales) or are high on the list of priority candidates. Recognising that CMPs continue to evolve, the Committee **agrees** that it would welcome requests for further scientific input into existing CMPs.

For ship strikes, the IWC has consultative status to the International Maritime Organization (IMO) and so can assist with IMO involvement. The IMO is responsible for all measures outside of national waters that affect shipping and so an effective dialogue with IMO is critical for all measures related to ship strikes. In addition it was noted that as part of the CMP for the southwest Atlantic population of southern right whales, the range states have agreed to collect information on ship strikes with this species and report them to the IWC.

For entanglements, the IWC has established a large whale entanglement expert advisory group, with members from Australia, Canada, New Zealand, South Africa and the USA, to advise countries on the issue, and has initiated a programme to build capacity in prioritised areas, when requested (IWC, 2013a). In addition, the Committee **recommends** that the Secretariat bring the IWC's most current scientific and mitigation information to the relevant bodies within the FAO.

22. COMPILATION OF AGREED ABUNDANCE ESTIMATES

The Committee has recognised the need for consistency in evaluating abundance estimates across sub-groups, recognising that to some extent 'acceptance' depends on the use to which the estimate is being put. It is also valuable for the Commission to have an updated overview of how many whales there are by broad ocean area. This year the Committee began a process to develop such lists and summaries by placing this as an item on the agendas of the relevant sub-groups. It established an *ad hoc* working group whose report is given as Annex Q.

The Committee **agrees** with the *ad hoc* group that the most appropriate way to make progress on further development of summary tables for both its use and that of the Commission is to establish an intersessional Working Group that will consider doubtful and potentially missing estimates, compile and summarise existing estimates and report to next year's Annual Meeting (Annex R).

The membership of this Working Group should comprise members representative of the Committee's relevant sub-groups and those familiar with methods for estimating abundance. It will also produce a draft strategy for discussion at the next Annual Meeting for a process to ensure:

(a) regular updating of the tables; and
(b) a strategy to ensure consistency of the review of abundance estimates across sub-committees and Working Groups.

The objective is for this group to complete its work and circulate draft tables by the beginning of January 2014.

23. RESEARCH AND WORKSHOP PROPOSALS AND RESULTS

23.1 Review results from previously funded research proposals

Table 7 shows the progress of funded proposals from last year (IWC, 2013c).

23.2 Review Workshop proposals for 2013/14

Table 8 summarises the Workshop proposals agreed at this year's meeting. Detailed information on funding is given under Item 26.

Table 7
Progress on Research Proposals and Workshops funded last year.

Title		Status
(1)	Development of an operating model for West Greenland humpback and bowhead whales	Completed (SC/65a/Rep02)
(2)	Workshop on development of *SLA*s for Greenlandic hunts	Completed (SC/65a/Rep02)
(3)	AWMP developers funds	Used to fund work in SC/65a/AWMP02
(4)	Ship strike database coordinator	Completed (SC/65a/HIM04)
(5)	Right whale survey off South Africa	Completed (SC/65a/BRG10)
(6)	Genomic diversity and phylogenetic relationships among right whales	Not funded
(7)	Photographic matching of gray whales	Completed (SC/65a/BRG04)
(8)	Contribution to the preparation of the State of the Cetacean Environment Report (SOCER)	Completed (SC/65a/E01)
(9)	Pre-meeting Workshop on assessing the impacts of marine debris	Completed (SC/65a/Rep06)
(10)	Develop simulation of Southern Hemisphere minke line transect data	Completed (S/65a/IA15)
(11)	IWC-POWER cruise	Completed (SC/65a/Rep01 and SC/65a/IA8)
(12)	Statistical catch-at-age assessment method for Antarctic minke whales	Completed (SC/65a/IA01)
(13)	'Second' *Implementation Review* Workshop for western North Pacific common minke whales	Completed (SC/65a/Rep04)
(14)	Essential computing for RMP/NPM and AWMP	Completed (Annexes D, D1, AWMP)
(15)	MSYR review Workshop	Completed (SC/65a/Rep05)
(16)	Review and guidelines for model-based and design-based line transect abundance estimates	Postponed until this year
(17)	Modelling of Southern Hemisphere humpback whale populations	Completed (SC/65a/SH01 and SC/65a/SH07)
(18)	Antarctic humpback whale catalogue	Completed (SC/65a/SH15)
(19)	Photo matching of Antarctic blue whales	Completed (SC/65a/SH16)
(20)	Southern Hemisphere blue whale catalogue 2012/13	Completed (SC/65a/SH23)
(21)	Expert workshop for review of Iceland's Special Permit programme	Completed (SC/65a/Rep03)
(22)	Whalewatching guidelines and operator training in Oman	Completed

Table 8
Summary of proposed Workshops and pre-meetings.

Subject	Annex	Dates	Venue
IWC-POWER Technical Advisory Group meeting	Annex G	September 29-30	Tokyo, Japan
IWC-POWER planning meeting for the 2014 cruise	Annex G	October 2-3	Tokyo, Japan
Oman whalewatching Workshop	Annex M	October	Oman
IWC/IQOE soundscape Workshop	Annex K	'Winter'	The Netherlands
Workshop on developing *SLA*s for the Greenland hunts	Annex E	Early January (*)	Copenhagen, Denmark
Workshop on the North Atlantic fin whale *Implementation Review*	Annex D	Early January	Copenhagen, Denmark
International gray whale Workshop on stock structure and status	Annex F	March/April	TBD
Workshop on the problem of kelp gulls and southern right whales	Annex F	April	Puerto Madryn, Argentina
AWMP/RMP North Atlantic minke whale stock structure	Annex D, E	April	CPH (or Bergen)
JARPA II review	Annex P	Late February	Japan
North Atlantic common minke whale *Implementation Review*	Annex D	Pre-meeting (3days)	TBD
Southern Hemisphere humpback whale assessment	Annex H	Pre-meeting (2days)	TBD

24. COMMITTEE PRIORITIES AND INITIAL AGENDA FOR THE 2014 MEETING

The Committee **notes** that the Commission's decision to move to biennial meetings means that it will need to develop a two-year proposed work plan at next year's meeting. The Committee **agrees** the following priorities below based on consideration in the plenary of the recommended work plans of the sub-committees and working groups. In addition, all relevant sub-groups will continue to consider updated abundance estimates and CMPs. Given its workload, the Committee **stresses** that papers considering anything other than priority topics will not be addressed at next year's meeting. The new online system for submitting papers will be updated during the year such that Convenors will be notified directly when papers are submitted for their sub-group; they may then contact authors directly if they believe that the papers are unlikely to be discussed.

Revised Management Procedure (RMP)

The following issues are high priority topics.

General issues

(1) Finalise the approach for evaluating proposed amendments to the *CLA*;
(2) evaluate the Norwegian proposal for amending the RMP;
(3) update the requirements and guidelines for conducting surveys to reflect considerations related to model-based methods for abundance estimation;
(4) specify how to deal with imbalanced sex ratios in incidental catches under the RMP;
(5) develop guidelines for handling situations in which survey coverage in time-series of abundance estimates changes over time; and
(6) consider the use of surveys carried out in different months in the *Implementation* process and in actual implementation of the RMP.

Implementation-*related issues*

(1) Finalise work on western North Pacific common minke whales:
    (a) review results from 'hybrid' variants with respect to variants with research;
    (b) review any research proposals with respect to variants with research; and
    (c) agree estimates of abundance for use in actual applications of the RMP;
(2) complete the *Implementation Review* for the North Atlantic fin whales;
(3) begin preparations for a focused basin-wide stock structure study for North Atlantic fin whales to be completed in time to inform the next *Implementation Review*;
(4) start an *Implementation Review* for the North Atlantic minke whales beginning with a three day pre-meeting (Convenor: Walløe) including review report of the joint AWMP/RMP Workshop on the stock structure of common minke whales;
(5) review the information available for North Atlantic sei whales in the context of a *pre-Implementation assessment*; and
(6) review new information on western North Pacific Bryde's whales.

Aboriginal Whaling Management Procedure (AWMP)

The following issues are high priority topics.

(1) Participate in the North Atlantic fin whale RMP process and review the implications of this for *SLA* development for the Greenland hunt;
(2) hold joint AWMP/RMP Workshop on the stock structure of common minke whales in the North Atlantic;
(3) submit need envelopes for West Greenland fin and common minke whales;
(4) finalise the trials for the West Greenland humpback and bowhead whales (including coding) to allow developers to work intersessionally. Ensure that standard software is available to produce agreed performance statistics, as well as tabular and graphical output;
(5) present overview of photo-identification work with respect to movements to inform stock structure and human induced mortality outside West Greenland;
(6) finalise removals series including consideration of human-induced mortality outside the West Greenland area;
(7) continue initial exploration of potential *SLA*s for the Greenland humpback and bowhead whale hunts; and
(8) produce a full report on the Greenlandic conversion factor programme.

Bowhead, right and gray whales (BRG)

The following issues are high priority topics.

(1) Review report from Workshop on the rangewide review of the population structure and status of North Pacific gray whales;
(2) perform the annual review of catch information and new scientific information for the B-C-B stock of bowhead whales;
(3) perform the annual review of catch information and new scientific information for eastern gray whales;
(4) review any new information on all stocks of right whales, especially results of assessments for southern right whales and the kelp gull Workshop; and
(5) review any other new information on western North Pacific gray whales and other stocks of bowhead whales.

In-depth assessment (IA)

The following issues are high priority topics.

(1) Further investigation and application of the SCAA models;
(2) further work examining the factors which drive Antarctic minke whale distribution and abundance;
(3) complete preparations for an in-depth assessment on North Pacific sei whales, specifically:
    (a) update the IWC catch data to include new data from Canadian and Soviet catches; and
    (b) analyse available survey and genetic data from the North Pacific, including from the IWC-POWER surveys;
(4) investigate the distribution and density of baleen and toothed whales in the Antarctic relative to spatial and environmental covariates;
(5) plan and undertake the 5th IWC-POWER survey in the North Pacific; and
(6) plan the next phase of the POWER cruises in the light of the Technical Advisory Group report.

Non-deliberate human-induced mortality (HIM)

The following issues are high priority topics.

(1) Review progress in including information in National Progress Reports;
(2) entanglement;

(3) ship strikes;
(4) review of information on other sources of non-deliberate human induced mortality; and
(5) develop five year plan for suggestions for priority work by the Committee to estimate and address non-deliberate human-induced mortality; review work of intersessional group.

Stock definition (SD)
The following issues are high priority topics.
(1) Genetic analysis guidelines;
(2) stock definition terminology;
(3) statistical and genetic issues concerning stock definition;
(4) testing of spatial structure models (develop new terms of reference); and
(5) providing advice to sub-groups as appropriate.

DNA
The following issues are high priority topics.
(1) Review genetic methods for species, stocks and individual identifications;
(2) review of results of the 'amendments' work on sequences deposited in *GenBank*;
(3) examine the technical information relevant to the TORs of the Group;
(4) collection and archiving of tissue samples from catches and bycatch; and
(5) reference databases and standard for diagnostic DNA registries.

Environmental concerns (E)
The following issues are high priority topics.
(1) SOCER;
(2) pollution (including POLLUTION 2020);
(3) Cetacean Emerging and Resurging Diseases (CERD) and mortality events;
(4) effects of anthropogenic sound on cetaceans and approaches to mitigate these effects (including the results of the intersessional joint Workshop);
(5) climate change;
(6) other habitat related issues including the report of the Conservation Committee's Workshop on marine debris; and
(7) Conservation Management Plans.

Ecosystem modelling (EM)
The following issues are high priority topics.
(1) Review ecosystem modelling efforts undertaken outside the IWC (competition and environmental variability);
(2) explore how ecosystem models contribute to developing scenarios for simulation testing of the RMP (linking individual based models to the RMP); and
(3) review other issues relevant to ecosystem modelling within the Committee.

Southern Hemisphere whales other than Antarctic minke whales and right whales (SH)
The following issues are high priority topics.
(1) Complete assessment of Breeding Stocks D/E/F humpback whales - this will complete the Comprehensive Assessment of Southern Hemisphere humpback whales;
(2) review new information on Southern Hemisphere blue whales in preparation for assessment;
(3) consider the feasibility of undertaking a future assessment of sperm whales; and
(4) Arabian Sea humpback whales.

Small cetaceans (SM)
The following issues are high priority topics.
(1) Voluntary funds for small cetacean conservation research;
(2) review of small cetaceans in the eastern Mediterranean and Red Seas; and
(3) progress on previous recommendations.

Whalewatching (WW)
The following issues are high priority topics.
(1) Assess the impacts of whalewatching on the physiology, behaviour, and fitness of cetaceans (individuals and populations) and their habitats;
(2) review reports from Intersessional Working Groups;
(3) review progress on Five-Year Strategic Plan for Whalewatching;
(4) review whalewatching in the region of the next meeting;
(5) consider information from platforms of opportunity of potential value to the Scientific Committee;
(6) review whalewatching guidelines and regulations; and
(7) consider emerging whalewatching industries of concern.

Scientific Permits (SP)
The following issues are high-priority topics.
(1) Review results of specialist JARPA II meeting;
(2) review of activities under existing permits; and
(3) review of new or continuing proposals.

25. DATA PROCESSING AND COMPUTING NEEDS FOR 2013/14

Allison reported on the computing needs and requirements identified for the forthcoming year. These are summarised in Table 9.

26. FUNDING REQUIREMENTS FOR 2013/14

This year, the sub-groups of the Committee's recommended projects for funding greatly exceeded (>£180,000) the allocated funding by the Commission within the two-year budget (Table 10). Reducing the budget to within the Commission's allocation was therefore a much greater task than is usually the case. For example, last year the full budget request was less than £24,000 over the available budget. The Scientific Committee's handbook states that one of the tasks for a Convenor is:

> 'f. 'To develop with other members of the Convenors' Group a prioritised list for funding that should to be made available to the full Committee at least by 6pm on the penultimate day of the Scientific Committee Annual Meeting.'

Given the difficult situation this year, the Convenors circulated to the Committee the full budget request and the full background information on the 13 June i.e. two days before the close of the meeting, before it had managed to meet to discuss a 'prioritised list' for circulation.

After a suggested budget had been developed on the afternoon of 14 June but before a document including the suggestions and rationale could be circulated to the full Committee, it was agreed to hold a Heads of Delegation meeting in the late afternoon of 14 June; this was followed by another on the morning of 15 June. During the second meeting, it was agreed that the option for a reduced budget

Table 9

Computing tasks for the coming year.

Group	Item
RMP	
(1)	Complete final compilation of tables and plots from the *Implementation Review* of North Pacific minke whales.
(2)	Run hybrid trials (variants with research) of North Pacific minke whales as required.
(3)	Redo conditioning and rerun existing trials of North Atlantic fin whales.
(4)	Other work related to the *Implementation Review* of North Atlantic fin whales (e.g. revision of the control program; conditioning and running of final trials to be specified by the intersessional Workshop (Annex D, Appendix 2).
(5)	Run a full set of trials for western North Pacific Bryde's whales and North Atlantic minke whales using the Norwegian version of the *CLA* and place the results on the IWC website.
(6)	Work with the Norwegian Computing Centre to standardise the Norwegian catch limit program code (Annex D, item 2.4).
(7)	Work to specify and run additional trials for testing amendments to the *CLA* (Annex D, item 2.2).
AWMP	
(1)	Finalise the catch and other removals series for use in trials including ship strikes and other human induced mortality outside West Greenland and data from Canada (see Annex E, item 3.2 and 3.3).
(2)	Work on the control program for the West Greenland humpback and bowhead whales (see Annex E, item 3.2 and 3.3).
IN-DEPTH ASSESSMENT	
(1)	Prepare catch series for North Pacific sei whales including inclusion of revised Canadian catch data and new analysis of Soviet North Pacific catch records to extent possible in time available, noting any discrepancies (see Annex G, item 5.1).
(2)	Validation of the POWER cruise data and work towards standard IDCR/SOWER dataset (see Annex G, item 5.3).
(3)	Complete validation of the 1995-97 blue whale cruise data and incorporate into the DESS database (carried over).
(4)	Eliminate discrepancies between the IWC individual catch data for Antarctic minke whales and the Japanese special permit data held by scientists.
BRG	
(1)	Update the catch series for North Pacific gray whales (Annex F).

developed by the Convenors should be submitted to the full Committee, noting that it had been seen by the Heads of Delegations but that there had been insufficient time for them to fully review it. In doing so, it was recognised that the Convenors had given full consideration to the reduced budget; the revised budget discussion document was annotated with comments made by individual Heads of Delegations.

The Committee **agrees** that it is important to consider possible new systems for future budget allocations; it will add this topic to its agenda next year. In this regard it also noted the need to develop a two-year budget request next year. The Heads of Delegations **requested** that the Secretary review the governance rules, procedures and practices of the Scientific Committees of the other intergovernmental organisations and report back to the Scientific Committee in 2014 in order to assist discussions of the working methods of the Committee. They also requested a more substantial role in Committee governance. Recognising that these are funds provided by the Commission, the Committee **agrees** that *inter alia* Heads of Delegations should play a substantial role in discussions of how the budget should be allocated in future. Convenors should continue to play an important role since they are familiar with the research needs and priorities of each sub-group. The advice of the Commission will also be sought on both the process and its priorities.

As noted above, trying to balance the budget this year was an extremely difficult task. The approach taken by the Convenors for the discussion document is summarised below.

Check the feasibility of voluntary reductions

Each budget line was examined to see if any proposal could be lowered (based on the knowledge of single projects, discussions with proposers where possible or discussions within the sub-committee itself) e.g. by reducing the number of participants to workshops/meetings, finding external funders (for research, workshops or participants), removing part of the research programme, etc.

Checking the feasibility of projects' postponement, in the light of the sub-group priorities

In some cases the amount was either lowered or cut, according to the feasibility to defer some work by one year.

Final cuts based on the strength of recommendations in sub-group reports and an assessment by all Convenors of overall Committee priorities

This was by far the most difficult part of the process, given a remaining overrun of more £100,000.

Table 10 summarises the complete list of recommendations for funding made by the Committee as well as the reduced budget developed in light of the known available funding. The Committee **recommends** all of these proposals to the Commission. In **recommending** its reduced budget, the Committee **stresses** that projects for which it has had to suggest reduced or no funding are still important and valuable.

(1) AWMP-1 INTERSESSIONAL WORKSHOP ON DEVELOPING *SLA*S FOR THE GREENLAND HUNTS

The Committee has identified completion of the development of long-term *SLA*s for these hunts as high priority work. In order to meet the proposed timeframe, an intersessional Workshop is required. The focus of the proposed Workshop is to: (1) to review the results of the developers of *SLA*s for humpback whales and bowhead whales; (2) finalise the modelling framework/trial structure for these hunts; (3) develop a workplan to try to enable completion of work on *SLA*s for these two hunts at the 2014 Annual Meeting; and (4) consider possible input (e.g. using AWMP/RMP-lite) for the joint AWMP/RMP Workshop on North Atlantic common minke whale stock structure. The Workshop will be held in early 2014 in Copenhagen, Denmark. It is intended to hold this back-to-back with the RMP Workshop on fin whales to save travel costs given some common participants.

(2) AWMP-2 AWMP DEVELOPERS' FUND

The developers fund has been invaluable in the work of *SLA* development and related essential tasks of the SWG. It has been agreed as a standing fund by the Commission.

Table 10

Budget requests (see text). Note that the Committee's agreement on the Small Cetacean Conservation Research Fund is given under Item 14.2. Asterisks indicate alternative funding has been found.

Number	Summary of item	Plenary Agenda Item, Annex item	Full cost (£)	Reduced budget (£)
AWMP-1	AWMP Intersessional Workshop on developing *SLA*s for the Greenlandic hunts	Item 8.3. Annex E, item 9.2	8,000	8,000
AWMP-2	AWMP developers fund	Item 8.3. Annex E, item 9.2	7,000	7,000
BRG/AWMP/SD-1	Gray whale rangewide Workshop	Items 8.1.2, 9.2.1, 10.5.3, 11. Annexes E, F and I	15,000	10,000
BRG-1	Southern right whale kelp gull Workshop	Item 10.6.2. Annex F, item 4.4	6,000	6,000
BRG-2	Southern Ocean right whale survey	Item 10.6. Annex F, item 4.1	23,000	*
E-1	State of the Cetacean Environment Report (SOCER)	Item 12.1. Annex K, item 6	5,000	4,000
E-2	POLLUTION 2020	Item 12.2.1. Annex K, item 7.1	27,000	20,000
E-3	Complete implementation of the CERD website	Item 12.3.2. Annex K, item 8.2	5,000	4,000
E-4	Joint IWC/IQOE Workshop predicting soundfields-global soundscape modelling	Item 12.4.2. Annex K, item 9.2	26,900	19,700
E-5	2nd phase Workshop on marine debris	Item 7.5.1. Annex K, item 11.2	5,000	*
HIM-1	Ship strike data coordinator	Item 7.4. Annex J, item 8.1	10,000	8,000
HIM-2	Bryde's whale abundance, distribution and risk of ship strike in the Hauraki Gulf	Item 7.4.3. Annex J, item 8.3	27,1	0,000
IA-1	Satellite tagging of Antarctic minke whales to provide information on breeding grounds, habitat utilisation and availability bias	Item 10.1.2. Annex G, item 8	69,500	0,000
IA-2	Statistical catch-at-age issues for further investigation	Item 10.1.3. Annex G, item 2.1	12,500	12,500
IA-3	2014 IWC-POWER North Pacific survey	Item 10.12.1 Annex G, item 3.3	62,600	58,600
RMP-1	Intersessional Workshop on North Atlantic fin whales	Items 6.2.1, 8.3.1. Annex D, item 5	4,000	4,000
RMP-2	Pre-meeting on North Atlantic minke *Implementation Review*	Item 6.3.2. Annex D, item 3.2	2,000	2,000
RMP/AWMP/SD	Simulations to evaluate power and precision of genetic clustering at critical [demographic] dispersal rates	Items 6.3.2, 8.3.1. Annex D, Appendix 3, adjunct 2	15,000	15,000
RMP/AWMP-1	Joint AWMP-RMP Workshop on stock structure hypotheses for North Atlantic minke whales	Items 6.3.2, 8.3.1. Annex D, item 3.2	10,000	10,000
RMP/AWMP-2	Computing support for RMP and AWMP	Item 22. Annexes D and E	8,000	4,000
SH-1	Minimum abundance estimates of Breeding Stock D humpback whales from Western Australian aerial surveys	Item 10.2.1.2. Annex H, item 3.1	4,000	4,000
SH-2	Modelling work to complete assessments of Breeding Stocks D, E and F	Item 10.2.1.1. Annex H, item 3.1	3,000	3,000
SH-3	Antarctic Humpback Whale Catalogue	Item 10.2.4. Annex H, item 3.4	15,000	10,000
SH-4	Comparison of photographs from JARPA II to the Antarctic Blue Whale Catalogue	Item 10.3.1.4. Annex H, item 5.1.4	7,500	5,000
SH-5	Southern Hemisphere Blue Whale Catalogue 2012/13	Item 10.3.1.4. Annex H, item 5.1.4	15,000	5,000
SH-6	Pre-meeting Workshop to complete the assessment of humpback whale Breeding Stocks D/E/F	Item 10.2.1. Annex H, item 3.1	7,000	7,000
SP-1	Expert Workshop to review JARPA II	Item 17.3. Annex P, item 7.3	30,000	25,000
IPs	IPs	All	64,000	64,000
Total			**498,000**	**315,800**

The primary development tasks facing the SWG are for the Greenlandic fisheries. These tasks are of high priority to the Committee and the Commission. The fund is essential to allow developers to work and thus allow progress to be made.

(3) BRG/AWMP/SD RANGEWIDE GRAY WHALE WORKSHOP ON STOCK STRUCTURE AND STATUS

Recent information has led to the need for a reappraisal of the population structure and movements of North Pacific gray whales. Sufficient new information exists to justify an international Workshop dedicated to developing new models to evaluate the question of North Pacific gray whale stock structure, and to better assess the potential impact of human activities on the status and develop appropriate strategies and mitigation measures. It will also suggested revisions to the background information sections of CMP. The issue has been an important part of discussions in AWMP, BRG, SD and is also relevant to CMPs and it is hoped the results will inform discussions at the 2014 Commission Meeting. The funding is for eight Invited Participants.

(4) BRG-1 SOUTHERN RIGHT WHALE KELP GULL WORKSHOP

The mass mortality of southern right whale calves has been an important issue for the Committee. This year, the Committee expressed concern and recommended that investigation of the causes of this mortality, and actions to reduce the risk of gull attacks on southern right whales at Península Valdés should be further developed and implemented. This is also a high priority action for the CMP.

(5) BRG-2 SOUTHERN RIGHT WHALE SURVEY

After consultation with the proposer this was reduced to zero as outside funding is expected.

(6) E-1 SOCER REPORT

SOCER is a long-standing effort to provide information to Commissioners and Committee members on environmental matters that affect cetaceans in response to several Commission resolutions. Funds are for salaries, library services, and printing.

(7) E-2 POLLUTION 2020

POLLUTION 2000+ has been a flagship programme of the Committee and the Commission has supported it and continued work on pollution in several Resolutions. POLLUTION 2020 is in effect Phase III of POLLUTON 2000+ and has two main priority areas of research; the toxicity of microplastics and the impact of polyaromatic hydrocarbons on cetaceans.

(8) E-3 COMPLETE IMPLEMENTATION OF CERD WEBSITE

The CERD website is being developed in two phases. The first phase focuses on large cetacean species and relies on a 'consultation and sharing' approach. The second phase is intended to include all cetacean species and incorporate a potential 'reporting' role. This website will have 'public' and 'registered user' levels. The public level will provide basic information on diseases in cetaceans, as well as access to selected discussion forum content. Registered users will have full access to the site, including in-depth information on cetacean disease, as well as to discussion forums and posting ability. Links will be provided for quick access to discussion boards that can be shared with groups focused on other topics such as pollution, ship strikes and marine debris.

(9) E-4 JOINT IWC/IQOE ACOUSTIC WORKSHOP

This is a co-sponsored Workshop dealing with global soundscape modeling to inform management of cetaceans and anthropogenic noise. Noise has been an important topic for the Committee since a 2004 Workshop. An increasing number of scientific efforts (International Quiet Ocean Experiment (IQOE), US's National Oceanic and Atmospheric Administration CetSound effort) directed at this topic reflect this broader scope. In September 2011, the IQOE held an open science planning meeting where research into soundscape characterisation and modelling were identified as one of the four key themes to be contained in the IQOE's draft Science Plan. This proposal for a joint IWC/IQOE Workshop will work to expand these tools and their application to a more global scale where they can be used to inform management of potential impacts on cetaceans.

(10) E-5 FUNDING FOR INVITED PARTICIPANTS FOR THE 2ND PHASE WORKSHOP ON MARINE DEBRIS

The Committee is working on this issue with the Conservation Committee. The first Workshop has taken place and the second is due. This is a high priority issue. The money (£5,000) was for two SC participants at the 2nd Workshop. The funds are available from an alternative source.

(11) HIM-1 SHIP STRIKE DATA COORDINATOR

The ongoing development of the IWC ship strike database requires data gathering, communication with potential data providers and data management. Co-ordinators were appointed last year and HIM agreed this should continue and a list of tasks was developed. It relates directly to the Commission's Conservation Committee Working Group on the topic.

(12) HIM-2 BRYDE'S WHALE ABUNDANCE, DISTRIBUTION AND RISK OF SHIP-STRIKE IN THE HAURAKI GULF

This money was requested to partially fund an aerial survey to estimate abundance of a small stock of Bryde's whales around New Zealand where the number of ship strikes has been giving cause for possible conservation concern.

(13) IA-1 DETERMINATION OF BREEDING GROUNDS, HABITAT UTILISATION AND AVAILABILITY BIAS IN ANTARCTIC MINKE WHALES

Habitat utilisation, location of breeding grounds and diving behaviour of Antarctic minke whales represent major data gaps in the Committee's knowledge in relation to four major issues. Research reported in SC/65a/IA12 has demonstrated that the deployment of these types of tags is practical and efficient and can provide a great deal of valuable data. Tags are intended to be deployed in the Ross Sea in December 2013/January 2014. One researcher has a pending research proposal with the US NSF that would provide ship time for tag deployment later in 2014-15 in the Ross Sea. The cost is for 15 Splash MK10A Satellite-linked time-depth recording LIMPET tags (location and dive data) 10 Spot 5 Satellite-linked LIMPET Tags (location only data).

(14) IA-2 DISTRIBUTION OF BALEEN AND TOOTHED WHALES RELATIVE TO SPATIAL AND ENVIRONMENTAL COVARIATES

This was reduced to zero as alternative funding was found.

(15) IA-3 STATISTICAL CATCH-AT-AGE (SCAA) ISSUES FOR FURTHER INVESTIGATION

This approach is one that has been guided and funded by the Committee for several years. The SCAA can be used to evaluate various hypotheses regarding the dynamics of Antarctic minke whales, such as whether growth and carrying capacity have changed. The Committee has identified where further work might solidify some of the conclusions, and a number of detailed technical suggestions were made by the Committee. This proposal addresses the main remaining suggestions made. The Committee also suggested that work be made available for the JARPA II review. The funds will allow the recommended analytical work to be completed.

(16) IA-4 2014 IWC-POWER NORTH PACIFIC SURVEY

The Committee has strongly advocated the development of an international medium- to long-term research programme involving sighting surveys to provide information for assessment, conservation and management of cetaceans in the North Pacific, including areas that have not been surveyed for decades. The Committee developed objectives for the overall plan and this will fund the final leg of the initial phase. The money is for: (1) IWC researchers and equipment as the vessel is provided free by Japan; (2) to allow the Committee's Technical Advisory Group to meet to review the multi-year results thus far and develop the plans for the next phase of POWER based on the results obtained from Phase I; and (3) to enable analyses to completed price to the 2014 Annual Meeting.

(17) RMP-1 INTERSESSIONAL RMP WORKSHOP ON NORTH ATLANTIC FIN WHALES

The objective of this short Workshop is to review the results of conditioning and trials for North Atlantic fin whales, modify these if necessary and determine an intersessional workplan to ensure that the *Implementation Review* can be completed at the 2014 Annual Meeting. It is also relevant to developing *SLA*s for the Greenland hunt. It will be held back-to-back with the AWMP Workshop to save costs. Costs are for five IPs. This work should allow the *Implementation Review* to be completed in 2014 and greatly assist the work on the AWMP.

(18) RMP-2 PRE-MEETING NORTH ATLANTIC MINKE *IMPLEMENTATION REVIEW*

The Committee has agreed to undertake a full *Implementation Review* of common minke whales in the North Atlantic. This is a large exercise that will build upon discussions at the joint AWMP/RMP Workshop on stock structure. A pre-meeting will maintain progress such that it should be able to be completed within two years.

(19) RMP/AWMP/SD SIMULATIONS TO EVALUATE POWER AND PRECISION OF GENETIC CLUSTERING AT CRITICAL [DEMOGRAPHIC] DISPERSAL RATES

On many occasions the Committee has found that identifying stocks from genetic analyses often yielded ambiguous results because the values of key parameters at which management recommendations change are not defined. Realising that such 'tipping points' are likely to be case specific it has been agreed to use the North Atlantic minke whale as a case study. This study will: (1) conduct demographic simulations under reasonable range of stock hypotheses and management scenarios to determine the dispersal rates such that management performance is acceptable from a conservation point; and (2) the second step is to conduct genetic simulations to assess the ability of genetic clustering methods to robustly determine the number of breeding populations and assign individuals to a breeding population. It will enable similar work to be undertaken for other large whale species of conservation and management concern.

(20) AWMP/RMP-1INTERSESSIONAL JOINT AWMP-RMP MEETING ON STOCK STRUCTURE HYPOTHESES FOR NORTH ATLANTIC MINKE WHALES

This Workshop addresses common issues for AWMP/RMP and will use the work of proposal 19 above. It was discussed and agreed last year. The costs are for eight invited participants.

(21) AWMP/RMP-2 ESSENTIAL COMPUTING FOR RMP AND AWMP

This is to provide assistance to the Secretariat with the large computing tasks it is facing in the coming year.

(22) SH-1 OBTAINING MINIMUM ABUNDANCE ESTIMATES OF BREEDING STOCK D HUMPBACK WHALES FROM WESTERN AUSTRALIAN AERIAL SURVEYS

This work was identified as of great importance if the Assessment of Breeding Stock D is to be completed. The cost is for new analyses of data from western Australian aerial surveys, 1999, 2005 and 2008. The observers' search pattern during these aerial surveys had not followed conventional protocols for conducting aerial surveys. The effect of such search patterns on the estimates is unknown, but sufficient concerns about their effect reduces confidence in the use of the resulting abundance estimates as absolute (rather than relative) estimates within the modelling exercise being undertaken (see next project).

(23) SH-2 MODELLING OF SOUTHERN HEMISPHERE HUMPBACK WHALE POPULATIONS

The project will focus on a combined assessment of humpback breeding stocks D, E1 and Oceania using a three-stock model which allows for mixing on the feeding grounds. Methods used will be based upon the Bayesian methodology as developed and presented for BSC and BSB Comprehensive Assessments recently completed. Exploration of alternative models which may be able to explain the observed data will be explored. These will include models that address anomalies identified regarding the population model fit to data for breeding stock D, and approaches suggested there to account for them, such as use of an environmental variation model and changes in carrying capacity over time.

(24) SH-3 ANTACTIC HUMPBACK WHALE CATALOGUE

The Antarctic Humpback Whale Catalogue collates photo-identification information from Southern Hemisphere humpback whales. Increasing awareness of the project among research organisations, tour operators and other potential contributors has widened the scope of the collection; research efforts in areas that had not previously been sampled have extended the geographic coverage. This catalogue has grown by 25% in the last two years, adding 1,127 new individuals, and increasing the time required to analyse photographs. In addition to these requested IWC funds, additional funds from other sources will be sought.

(25) SH-4 COMPARISON OF ANTARCTIC BLUE WHALE IDENTIFICATION PHOTOGRAPHS FROM JARPA II TO THE ANTARCTIC BW CATALOGUE

This work follows on from previous recommendations and work by the Committee on the assessment of Southern Hemisphere blue whales. It is also be of relevance to the SORP blue whale project. The sighting histories of individual Antarctic blue whales from photo-id provide data for a mark-recapture estimate of abundance as well as information on the movement of individual blue whales within the Antarctic region. The addition of more samples to the collection of Antarctic blue whale identification photographs would be extremely useful for these analyses. A total 380 blue whale identification photographs were collected during JARPA II cruises but need to be compared to the Antarctic Blue Whale Catalogue (305 individuals) and the associated sighting data added to the sighting history database.

(26) SH-5 SOUTHERN HEMISPHERE BLUE WHALE CATALOGUE 2012/13

The Southern Hemisphere Blue Whale Catalogue (SHBWC) is an international collaborative effort to facilitate cross-regional comparison of blue whale photo-identifications catalogues. In 2006, the Committee of the agreed to initiate an in-depth assessment of Southern Hemisphere blue whales and in 2008, it endorsed a proposal to establish the SHBWC. Currently the SHBWC holds photo-identification catalogues of researchers from major areas off Antarctica, Australia, Eastern South Pacific and the Eastern Tropical Pacific. A total of 884 blue whales are catalogued. Results of comparisons among different regions in Southern Hemisphere will improve the understanding of population boundaries, migratory routes and model abundance estimates. In addition, assessment of blue whales and estimates abundance of populations will require improving software capabilities to access encounter histories of individuals.

(27) PRE-MEETING WORKSHOP TO COMPLETE THE ASSESSMENT OF HUMPBACK WHALE BREEDING STOCKS D/E/F

This pre-meeting is required to facilitate the timely completion of the assessment of humpback whales breeding stocks D, E and F (Item 3.1.2). These are the last stocks remaining in the in-depth assessment of Southern Hemisphere humpback whales. The Committee has agreed that this assessment should be completed in SC/65b, as a matter of high priority. The meeting will evaluate the results of intersessional modelling efforts. Costs are for eight Invited Participants.

(28) EXPERT WORKSHOP TO REVIEW JARPA II

The Committee has agreed a procedure for periodic and final reviews of results from Special Permit research (IWC, 2013m). This procedure outlines an intersessional review meeting by an expert panel. The report from the intersessional expert meeting will be reviewed and discussed at the 2014 Scientific Committee Annual Meeting, SC/65b. The experts to the review Workshop will be identified by September 2013 and the expert Workshop will be convened during four days in February/March 2014. The requested funds are for travel for the invited experts. The Committee noted that after discussion at the Commission Meeting last year, a budget for the review of the Icelandic permit was approved.

27. WORKING METHODS OF THE COMMITTEE

27.1 Annual Meetings

Last year (IWC, 2013c, pp.78-9), after considerable discussion of the balance between cost savings and the efficiency of the Committee, it was agreed that primary documents would be distributed only electronically at Scientific Committee meetings thereby making significant cost savings in terms of freight (paper and pigeon holes) and copying (paper, Xeroxing and staff).

This year, the Committee continued to review its procedures both in terms of efficiency and cost savings. As part of this, careful consideration was given as to whether it might be possible to reduce the number of days of the Committee's meetings (e.g. removing the initial reading day from the start of the meeting, removing the rest day, reducing the length of Plenary, reducing the number of sub-committees, reducing sub-committee agendas or having some sub-committees meet only biennially). With its present workload and agenda, the Committee **agrees** that changing the number of days in an already full schedule was not practical at this time. However, it **agrees** to keep this item on its Agenda. In particular, it **agrees** to a trial period of introducing an earlier deadline for paper submission.

At present, authors are requested to submit at least preliminary titles, authors and ideally an abstract about six weeks before the meeting using an online system. Whilst authors are strongly encouraged to submit papers as early as possible, the final deadline is that primary papers must be submitted by the end of the first day of the Annual Meeting. This procedure recognises that participants voluntarily submit papers and most have other responsibilities than the IWC; some papers are also the result of recommendations made by the Committee or intersessional Workshops and are essential to the Committee's progress in a timely fashion. After considerable discussion, the Committee **agrees** to establish a deadline for primary papers as a trial for the 2014 Annual Meeting of seven days before the start of the meeting. In doing so it **agrees** that this has the potential to improve the Committee's efficiency in a number of ways; however, at least as a measure on its own, it will not result in cost savings but will provide information to inform discussions of cost savings next year.

The Committee will review the trial next year in the light of information to be provided on a number of factors to be finalised by the Convenors intersessionally including: improvements to efficiency of Convenors in terms of developing annotated agendas; number of papers available by the deadline; timing of overall submission in the weeks leading up to the meeting; download data; questionnaire to the Committee.

The Committee also agreed to improvements with the National Progress Reports database as discussed under Item 3.2 and Annex O.

27.2 Increasing the support of the Scientific Committee on conservation related issues

The Committee welcomed information that a number of scientists (Galletti Vernazzani, Iñíguez, Luna, Marzari, Peres and Rodríguez-Fonseca) will present next year a review of the Committee's reports, IWC Resolutions and information on population status since 1986. The review will highlight *inter alia* when the Committee has commented/recommended on as scientific matters (when a comment/conclusion is aimed to continue gathering scientific information), whaling management matters (when a comment/conclusion is aimed towards whaling management) and conservation matters (when a comment/conclusion is aimed to call the attention on threats and/or status, or improve the conservation of a species/subspecies/population). The objective of this work is to stimulate discussion within the Committee as to how best to improve communications on conservation matters to the Conservation Committee and Commission, in order to better contribute to the long term survival of cetacean species, sub-species and populations.

The Committee **agrees** that this item will be placed on its Agenda next year.

28. ELECTION OF OFFICERS

This is the first year for both the Chair and the Vice-Chair and so no elections were necessary.

29. PUBLICATIONS

The Committee was pleased to hear that the *Journal of Cetacean Research and Management* was now to become open access and freely available. It **agrees** that the *Supplement* should continue to be available in hard copy for participants given its central role at the meeting. The Committee **re-emphasises** the importance of the *Journal* to its work and **thanks** the Secretariat and the Editorial Board for its work.

30. OTHER BUSINESS

There was no other business.

31. ADOPTION OF REPORT

The completed parts of the report were adopted at 17:10hrs on 15 June 2013. As is customary, those parts that were only discussed on the final afternoon were agreed by the Chair, rapporteur and Convenors. The Chair thanked all of the participants for their co-operative attitude on this his first meeting, the rapporteurs, Secretariat and especially the host government and the hotel for their provision of excellent facilities. The meeting thanked the Chair for his expert and fair handling of the meeting.

Annex E

Report of the Standing Working Group on Aboriginal Subsistence Whaling Management Procedures

Members: Donovan (Convenor), Allison, Baba, Baulch, Bickham, Brandão, Broker, Brownell, Butterworth, Childerhouse, Chilvers, Cipriano, Collins, Cooke, De Moor, Double, Dupont, Efirmchuk, Elvarsson, Fortuna, Givens, Holloway, Holm, Iñíguez, Kelly, Kim, H., Kitakado, Kock, Lang, Legorreta-Jaramillo, Litovka, Marzari, Nelson, Palsbøll, Perkins, Punt, Reeves, Ritter, Robbins, Roel, Rose, Sakamoto, Scheidat, Scordino, Simmonds, Skaug, Stachowitsch, Suydam, Tajima, Tiedemann, Víkingsson, Vinnikov, Walløe, Waples, Wilson, Witting, Yasokawa, Yoshida.

1. INTRODUCTORY ITEMS

1.1 Convenor's opening remarks
Donovan welcomed the participants to the meeting. He noted that the major part of the work of the SWG this year is to build upon the progress made at the intersessional workshop (SC/65a/Rep02) held in Copenhagen in December 2012 on developing *SLA*s for the Greenlandic hunts, with an initial emphasis on humpback whales and bowhead whales. That Workshop dealt with a number of topics and they are dealt with where appropriate on the SWG's agenda. The SWG will also consider management advice for the hunts of Greenland and St Vincent and The Grenadines.

1.2 Election of Chair
Donovan was elected Chair.

1.4 Appointment of rapporteurs
Givens, Scordino, Butterworth and Punt acted as rapporteurs with assistance from the Chair.

1.5 Adoption of Agenda
The adopted agenda is given as Appendix 1.

1.6 Documents available
The new primary documents available to the SWG were SC/65a/AWMP01-07.

2. GRAY WHALES WITH EMPHASIS ON THE PCFG (PACIFIC COAST FEEDING GROUP)

2.1 Report of intersessional Workshop (SC/65a/Rep02)
In 2010, the Committee agreed that PCFG (Pacific Coast Feeding Group) whales should be treated as a separate management unit. PCFG whales are defined as gray whales observed (i.e. photographed) in multiple years between 1 June and 30 November in the PCFG area (IWC, 2011a, p.22). Not all whales seen within the PCFG area at this time will be PCFG whales and some PCFG whales will be found outside the PCFG area at various times during the year. The Makah tribe would like to take gray whales in the Makah usual and accustomed fishing grounds (U&A) in the future and the objective of the *SLA*s they proposed is to minimise the risk to the PCFG whales and meet the Commission's conservation objectives. An important component of this is to restrict hunting to the migratory season, i.e. prior to 1 June. The Committee began the evaluation process in 2011.

Last year, the Committee had agreed that two *SLA* variants (one with research provisions) met the conservation objectives of the Commission (IWC, 2013b, p.19). *SLA* variant 1 proposed that struck-and-lost whales did not count towards the APL (the 'allowable PCFG limit' – a protection level) i.e. there is no management response to PCFG whales struck but not landed. *SLA* variant 2 proposed that all struck-and-lost whales counted to the APL irrespective of hunting month, i.e. the number of whales counted towards the APL may exceed the actual number of PCFG whales struck. However, the Committee also noted that the two variants did not exactly mimic the proposed hunt and expressed concern that the actual conservation outcome of the proposed hunt had not been fully tested. The reason for this relates to how strikes in May are treated in *SLA* calculations. In the variants, the APL is adjusted to account for how many whales the Makah hunting plan would permit in May.

The two tested *SLA* variants bracketed the possible Makah hunting plans, assuming either 7 or 0 strikes in May for Variants 1 and 2, respectively. The Committee had approved Variant 2 but had stated that Variant 1 only met the Commission's conservation objectives if it was accompanied by a specific annual research programme (i.e. a photo-identification programme to monitor the relative probability of harvesting PCFG whales, the results of which are presented to the Scientific Committee for evaluation each year).

Donovan summarised progress made during the intersessional Workshop (SC/65a/Rep02). There are insufficient data to determine the proportion of strikes that would occur in May or prior to May, and the Workshop agreed to test six new variants to cover the full range of possible strikes occurring in May or prior to May, i.e. variants allowing x strikes prior to May where $x = 1,\ldots,6$. In particular, it had recommended that the full set of trials be repeated for these six variants (in addition to the two *SLA*s agreed by the Committee last year).

The Workshop also recommended that the photo-id catalogue for the eastern North Pacific gray whales (that will be used to assess whether landed whales are from the PCFG) be made publicly available as it is a key component of the management approach. It was pleased to be informed that funding is available to digitise the catalogue. Weller informed the SWG that NOAA still has funds available to digitise the catalogue of PCFG whales. Scordino noted that work is underway to compile photographs from a few key contributors for a photo catalogue of PCFG whales to be held at NOAA's National Marine Mammal Laboratory; this catalogue, at least initially, will not be publicly available.

2.2 New information and results
2.2.1 Further evaluation of proposed Makah Hunt
SC/65a/AWMP06 presented trial results for the six *SLA* variants discussed above. By examining the final depletion statistic for all evaluation and robustness trials for the six new *SLA* variants and Variants 1 and 2 used in the 2012 *Implementation Review*, the authors concluded that:

(1) the conservation performance of the new variants was intermediate between Variant 1 and Variant 2;
(2) there is not a uniform, linear increase in conservation performance caused by reducing the maximum number of strikes that occur prior to May;
(3) there is a point of saturation at which increasing the number of strikes prior to May does not lead to a decrease in conservation performance; and
(4) the results show that conservation performance changes as would be expected.

In summary, the performance of all the new variants was no worse than for Variant 1 and no better than for Variant 2. These conclusions also hold true for other conservation performance statistics examined.

The SWG thanked the authors for their work. The SWG recalled that the research requirement for Variant 1 had been imposed because its conservation performance was inferior to that of Variant 2 on a small number of trials. The SWG **agreed** that the newly tested *SLA*s performed acceptably and met the Commission's conservation objectives provided that they, like Variant 1, are accompanied by a photo-identification programme to monitor the relative probability of harvesting PCFG whales which is undertaken each year and the results presented to the Scientific Committee for evaluation.

SC/65a/AWMP03 presented an update on the availability of PCFG whales in the Makah U&A based on photo-identification surveys. With data collected from 1984 to 2011, strong evidence was found for PCFG whales being more available in the Strait of Juan de Fuca (56% of whales observed being PCFG whales) as compared to the Pacific Ocean (31%). This difference is statistically significant (Fisher's exact test, $p<0.01$). This finding supports the Makah Tribe's proposed prohibition of hunting in the Strait of Juan de Fuca. No significant differences were found for comparisons of the availability of PCFG whales by month in the Pacific Ocean. The updated availability of PCFG gray whales in Pacific Ocean waters of the Makah U&A presented in this paper was not appreciably different to the 30% availability used in the 2012 *Implementation Review*.

The SWG **welcomed** this update. It noted that the research program to monitor the availability of PCFG whales has the added benefit of collecting data that aids the assessment of risk that the Makah hunt would strike a whale identified in the western North Pacific (WNP) that has migrated to the US west coast discussed below. In response to the discussion, Scordino **agreed** to examine the possibility of trends in the data and include it in an updated paper for next year's meeting.

As noted last year (IWC, 2013b, p.20), observations of gray whales identified in the WNP migrating to areas off the coast of North America (Alaska to Mexico) raise concern about placing the WNP population at potential risk of being harmed or killed accidentally in the proposed Makah hunt. It was noted that the research programme to monitor the availability of PCFG whales has the added benefit of collecting data that aids the assessment of risk that the Makah hunt would strike a whale identified in the WNP that has migrated to the US west coast.

Given the ongoing concern about status of the gray whales in the WNP, in 2011 the Scientific Committee emphasised the need to estimate the probability of a western gray whale being killed during aboriginal gray whale hunts (IWC, 2012). Additionally, in the USA it is required that NOAA prepare an Environmental Impact Statement (EIS) pertaining to the Makah's request for a waiver under the US Marine Mammal Protection Act (MMPA) in order to hunt gray whales. The EIS will include an estimate of the likelihood of Makah hunters approaching, pursuing, and attempting to strike a WNP gray whale in addition to the likelihood of actual strikes (assumed to result in death or serious injury).

Moore and Weller (2013) estimated the probability that one or more whales identified in the WNP might be killed during the hunt proposed by the Makah Indian Tribe. This analysis updated the analysis of mortality risk provided to last year in Moore and Weller (2012) by incorporating Committee from feedback last year's meeting (IWC, 2013b, p.20). The probability of striking or taking a WNP gray whale during the proposed Makah hunt was estimated using four different sets of models (six models in total). The author's 'most plausible' model uses all available information and includes the least number of assumptions. Based on this model, the probability of striking at least one WNP gray whale in a single season ranged from 0.007 to 0.036, depending on whether the median or upper 95th percentile estimate is used and on which maximum is used for the total number of whales struck. The probability of striking at least one WNP gray whale during a five-year period ranges from 0.036 to 0.170 across the same scenarios. The expected number to be struck ranges from 0.01 to 0.04 for a single year and from 0.04 to 0.19 across 5 years.

Estimates from this analysis are considered by the authors to be precautionary since they assume that the Makah will achieve their proposed maximum strike limits. The results offer a conservative initial step in assessing the potential risk of WNP gray whales incurring mortality incidental to the proposed hunt on the ENP population by the Makah Indian Tribe.

The SWG **welcomed** this paper, recognising that it represents initial work. It notes that it will provide a contribution to the recommended workshop examining gray whales throughout the North Pacific (Annex F).

2.2.2 Other information

Mate summarised his recent satellite tagging work on PCFG gray whales. In 2012, Mate and his colleagues tagged nine additional gray whales off Oregon and northern California to those previously reported. Six of those continued transmitting until the whales visited the breeding grounds and returned to the Pacific Northwest; many are still providing data. In 2009, all of the satellite tagged whales visited the same lagoon, Ojo de Liebre, but in 2012 several whales travelled farther south to water offshore of San Ignacio Lagoon and Magdalena Bay. In 2009 and 2012 a tagged PCFG gray whale migrated as far north as Icy Bay, Alaska, beyond the management-defined range of the PCFG whales. Many of the tagged whales migrated further north initially in the spring than where they spent most of their PCFG feeding season. Considering the number of tags deployed and the success of their deployment, Mate noted that it will be possible to define home ranges and core areas for individuals. Mate also mentioned that ongoing research assessing the wound healing in tagged whales may be ready for presentation to the Scientific Committee next year. Finally, Mate reported on plans to deploy as many as 12 more tags in 2013. To the extent possible, attempts will be made to tag the same whales that were tagged in 2009 to see if those whales utilise the same home range, migration timing and routes, and breeding areas each year.

Weller briefly reported on a scientific task force (comprising eight NMFS scientists with expertise in fields relevant to stock structure assessment) workshop held by the US National Marine Fisheries Service (NMFS) to assess gray whale stock structure (Weller *et al.*, 2013). While the primary focus was to provide advice in terms of US domestic legislation, much of the work was also of scientific relevance to the IWC Scientific Committee. New information has suggested the possibility of recognising two additional stocks in US waters to the eastern North Pacific stock currently recognised: (1) the Pacific Coast Feeding Group (PCFG); and (2) the western North Pacific (WNP) stock. The task force reviewed new information relevant to gray whale stock structure, including the results of genetic, photo-identification, tagging and other studies. It agreed on a series of questions relevant to evaluating whether the PCFG and/or the WNP gray whales qualify as stocks under US guidelines and followed a structured decision-making process. The task force concluded that there was substantial uncertainty regarding whether the PCFG qualified as a separate stock and was unable to provide definitive advice. It did, however, advise that the WNP stock should be recognised as a stock. The task force provided recommendations for future work, including the continuation of field studies as well as additional analysis of the existing photo-identification and genetic data.

The SWG thanked Weller and noted that the report represented a thorough review of the current knowledge of PCFG and WNP gray whales. In response to a question on how the US defines a stock, Weller responded that the primary criterion is demographic independence. The SWG noted that the Scientific Committee continues to work on definitions relating to 'stock' and related terms and that this report will be of value to the working group on stock definition. It also **agreed** that it will provide valuable input to the recommended workshop examining gray whales throughout the North Pacific (see Annex F).

2.3 Summary and recommendations

The SWG **concluded** that the conservation performance of the proposed Makah whaling management plan has now been fully analysed within the *SLA* evaluation framework. It **agreed** that the proposed management plan meets the conservation objectives of the Commission provided that if struck and lost animals are not proposed to be counted toward the APL then a photo-identification research programme to monitor the relative probability of harvesting PCFG whales in the Makah usual and accustomed fishing grounds (U&A) is undertaken each year and the results presented to the Scientific Committee for evaluation. In other words, only Variant 2 was judged to meet the Commission's conservation objectives without the research requirement.

In regards to questions on whether the SWG should consider conducting an *Implementation Review* to evaluate the potential impacts of the Makah hunt on whales identified in the WNP, it was **agreed** that before an *Implementation Review* is conducted that the recommended workshop be held to review the range-wide population structure and status of North Pacific gray whales (see Annex F).

3. CONSIDERATION OF WORK REQUIRED TO DEVELOP *SLA*S FOR ALL GREENLAND HUNTS BEFORE THE END OF THE INTERIM PERIOD

3.1 Common minke whales and fin whales

3.1.1 Report from the intersessional Workshop (SC/65a/Rep02)

The Workshop noted the potential overlap between RMP and AWMP management with respect to common minke whales and fin whales in the North Atlantic. It agreed that the process of developing *SLA*s and RMP *Implementations* for stocks in regions where both commercial and aboriginal catches occur should include the following steps: (a) development of a common trials structure which adequately captures uncertainties regarding stock structure, mixing, MSYR, etc.; (b) identification of an *SLA* which performs as adequately as possible if there are no commercial catches; and (c) evaluation of the performance of RMP variants given the *SLA* selected at step (b). The work on RMP/AWMP-lite in this regard (see Item 3.1.3) was welcomed.

3.1.1.1 STOCK STRUCTURE

The Workshop recognised the need for consistency in stock structure hypotheses with RMP *Implementations.*

With respect to fin whales it had noted that the present hypotheses will be reviewed during the RMP *Implementation Review* scheduled for the 2013 meeting of the Scientific Committee. It also noted that it may be possible to base the *SLA* for fin whales off West Greenland on operating models which considered West Greenland only, i.e. in effect assuming that the animals found off West Greenland comprise a single stock that is adequately represented by the abundance estimates obtained off West Greenland. The rationale for this is that even if there are multiple stocks off West Greenland (as was suggested in some hypotheses considered during the RMP *Implementation*), it may be reasonable to assume that they are susceptible to capture in the aboriginal hunt proportionally to their abundance when the survey is conducted. In contrast, varying proportions of the multiple stocks over time would violate this assumption. The RMP *Implementation Review* should be asked to consider carefully any evidence that there may be more than one stock mixing off West Greenland.

With respect to common minke whales, the Workshop noted that it has been agreed that a joint AWMP/RMP stock structure workshop will be held in the intersessional period between the 2013 and 2014 annual meetings of the Scientific Committee (see Item 3.1.3 below). The results of this workshop will be essential to the *SLA* development process.

The SWG **endorsed** the conclusions and recommend-ations of the Workshop in this regard.

3.1.2 Joint RMP/AWMP Workshop(s) on stock structure

The SWG noted that the Steering Group for this meeting (which included SWG members including the Chair) had met to develop a work plan and that this had been reported to the sub-committee on the RMP (Annex D, Appendix 2). The SWG reiterated its support for this Workshop, first agreed last year (Donovan *et al.*, 2013), and the work plan developed.

3.1.3 AWMP/RMP-lite

SC/65a/Rep02 had introduced the idea of a new computer program called RMP/AWMP-lite, which is a platform written in R which implements a management strategy evaluation framework for evaluating the performance of catch and strike limit algorithms. The essence of RMP/AWMP-lite is the use of an age-aggregated model rather than an age-structured model to considerably speed up calculations; this will allow developers more easily to explore the properties of candidate *SLA*s before they are submitted to rigorous full testing. This framework can be used to evaluate management schemes where multiple stocks of whales are exploited by a combination of commercial and aboriginal whaling operations. The operating models can be conditioned to the actual data to allow an evaluation of whether stock structure assumptions and other hypotheses are comparable with the available data. The Workshop had suggested several improvements and extensions to the program. The SWG **endorsed** the conclusions and recommend-ations of the Workshop in this regard.

In discussion, Punt noted that all but one of the tasks had been completed (see SC/65a/RMP05). The ability to apply an *SLA* based on an independently-written routine has been implemented for the bowhead and humpback trials, but not in AWMP/RMP-lite. He noted that AWMP/RMP-lite had become complicated owing to the recent developments, which may warrant changing the way the code is implemented.

The Workshop recalled that the current approach to evaluating *SLA*s for the Greenlandic hunts treats each species independently even though need is expressed as a total amount of meat over multiple species. It was noted that once single-species *SLA*s are developed, a multispecies 'need surface' which expresses the trade-offs among need for several species in terms of a multi-dimensional inequality constraint could be considered because it should be easier to satisfy total need rather than satisfying maximum needs separately for several species.

The SWG **endorsed** the conclusions and recommend-ations of the Workshop in this regard, **reiterating** that work on single-species *SLA*s should be completed before multi-species considerations are examined.

The Workshop had also noted that the RMP and AWMP dealt with ship strikes and by-catch differently. The RMP catch limit is for all human-induced removals so that the commercial catch is the difference between the RMP catch limit and the expected removals due to, for example, ships strikes and bycatch. In contrast, the aim of the AWMP is not to maximize catch, but rather to satisfy need. Consequently, the strike limit is not reduced by ship strikes and by-catch. Rather, the trials used to select *SLA*s account for future levels of other human-caused removals, but the strike limit is still related only to need. Thus, the removals from the population in the case of aboriginal hunts would be the strike limit plus other human-caused removals.

The SWG **endorsed** the conclusions and recommend-ations of the Workshop in this regard, noting that this approach is used for other human-induced removals under Items 3.2 and 3.3 below.

3.1.4 Discussion and work plan

The work plan for SWG in relation to the development of *SLA*s for the hunts for fin and minke whales off West Greenland is partially dependent upon the associated work on RMP *Implementation Reviews* for fin and common minke whales. In terms of activity over the coming year the SWG will:

(1) examine the final modelling framework and trial specifications for North Atlantic fin whales being developed intersessionally including at an RMP intersessional workshop by a steering group (which includes AWMP members) and examine how this can be incorporated into *SLA* development;
(2) participate in the joint AWMP/RMP workshop on stock structure of common North Atlantic minke whales agreed last year to review stock structure hypotheses and review the results from the AWMP perspective an emphasis on Greenland;
(3) examine the discussions and results of the RMP *Implementation Review* for common North Atlantic minke whales that will start with a pre-meeting before SC/65b from an AWMP perspective; and
(4) receive need envelopes from Greenland for North Atlantic fin and common minke whale hunts off Greenland.

3.2 Humpback whales

3.2.1 Report from intersessional Workshop (SC/65a/Rep02)

Donovan briefly summarised the new information available for humpback whales off West Greenland from the Workshop (SC/65a/Rep02).

3.2.1.1 STOCK STRUCTURE

With respect to stock structure, the Committee agreed in 2007 that the West Greenland feeding aggregation was the appropriate management unit to consider when formulating management advice. Whales from this aggregation mix with individuals from other similar feeding aggregations on the breeding grounds in the West Indies (IWC, 2008, p.21).

The Committee also received valuable information from 30 satellite-tagged whales (Heide-Jørgensen, 2012). This found that few excursions were made outside the areas covered by the 2005 and 2007 aerial surveys which took place during August-September, although one animal left West Greenland in June and reached Newfoundland in July (i.e. would not have been available for counting). Two whales departed from West Greenland and took a route south along Labrador and Newfoundland. The Workshop recognised the value of such work to both stock structure and abundance and encouraged its continuation.

Photo-identification data are also valuable for stock structure and movement studies. Subsequent to the Workshop Witting confirmed that all photographs from West Greenland had been submitted to the North Atlantic humpback Catalogue who also informed the Chair that one match had been made with the Gulf of Maine in addition to matches from eastern Canada that confirmed the results from the telemetry studies.

The Workshop endorsed the previous Scientific Committee recommendation that the West Greenland feeding aggregation was the appropriate management unit and that it should be treated as a single stock in the trials.

3.2.1.2 ABUNDANCE

The Workshop reviewed the abundance estimates that had been received and adopted by the Scientific Committee. These are discussed further under Item 3.2.2.1 below.

The Workshop had agreed to use the estimates of relative abundance from aerial surveys to condition the trials. Since available abundance estimates from the mark-recapture studies covered a shorter period and were heavily correlated it was agreed that they would only be used in a *Robustness Trial*. However, the Workshop had also agreed that given that mark-recapture abundance estimates may become common in the future for both humpback and bowhead whales, efforts should be made to develop ways to better integrate them into the operating models for the *SLA* trials. It had also agreed that for future surveys, only absolute estimates of abundance would be generated.

3.2.1.3 REMOVALS

3.2.1.3.1 DIRECT CATCHES

Noting past difficulties in modelling the full western North Atlantic (including allocation of past catches) and the decision to treat the feeding aggregation as the appropriate management unit, it was agreed that trials would begin in 1960 under an assumption that the age-structure in that year is steady. The catch series for this period is known and this is treated as the best catch series and no alternatives are required. It can be found in the revised trial specifications to the present report (see Appendix 2).

None of the photographic recaptures of humpback whales from St. Vincent and the Grenadines have been made with animals from the West Greenland feeding aggregation, so these catches are not included in the catch series. However, given possible migration routes (e.g. from telemetry data), it was noted that known direct catches occurred from whaling stations off the east coast of Canada after 1960 that may have included some 'West Greenland' animals.

Making simple assumptions (Greenland whales are estimated to be off Newfoundland for ~1 month in comparison to Canadian whales which are there for ~ 6 months and taking the relative abundances of the two populations into account) leads to an estimated potential direct catch of Greenland humpbacks off Canada of up to 5% of the total direct catch. The Workshop agreed that this will be incorporated into the catch series in the revised trial specifications, but that no future direct catches off Canada will be simulated.

3.2.1.3.2 BYCATCHES AND SHIP STRIKES

The Workshop addressed the question of bycatches in both West Greenland and elsewhere. For West Greenland, noting that the crab fishery which was primarily responsible for bycatches has now peaked, it was agreed that future bycatches for Greenland will be generated assuming that the exploitation rate due to bycatch in the future equals that estimated for the trial in question over the most recent five-years. As no bycatches were reported for the 1960-2000 period for West Greenland, it was noted that this assumption is conservative in that bycatches will be assumed for the future.

With respect to bycatches of 'West Greenland' animals outside West Greenland, the Workshop agreed to an approach similar to that for direct catches, i.e. the estimated potential direct catch of Greenland humpbacks off Canada could be up to 5% of the total Canadian bycatch. Should ship strikes occur, the same approach would be used. The Secretariat agreed to investigate the available information on bycatch and ship strikes.

3.2.1.4 BIOLOGICAL PARAMETERS

The Workshop noted that prior distributions need to be specified for three biological parameters: (a) the non-calf survival rate; (b) the age-at-maturity; and (c) the maximum pregnancy rate. The objective is to develop priors (taken to be uniform for all three parameters) which are plausible based on the range of estimates in the literature. The values for these parameters used in the actual trials will encompass a narrower range than these priors because the priors will be updated by the data on abundance and trends in abundance during the conditioning process.

The Workshop agreed that the prior for non-calf survival, S_{1+}, will be U[0.9, 0.995]. The lower bound for this prior is the lower 95% confidence interval for the estimate of non-calf survival obtained by Larsen and Hammond (2004) while the upper bound is the upper 95% confidence interval for the estimate of non-calf survival rate for humpback whales in Prince William Sound, Alaska reported by Zerbini *et al.* (2010). Zerbini *et al*. (2010) based their estimates of maximum rates of increase on the non-calf survival rate estimate for this population.

The maximum pregnancy rate, f_{max}, is the pregnancy rate in the limit of zero population and thus is not measureable but is expected to be higher than observed pregnancy rates. Based on its review of the available information, the Workshop agreed that the prior will be U[0.4, 0.8]. The lower bound for this prior is close to the average of the estimates of pregnancy rate for humpback whale stocks reported by Zerbini *et al.* (2010). The upper bound was based on the view that the theoretical maximum (i.e. all mature females giving birth every year) is infeasible but that an estimate that involved a high proportion of animals on a one-year cycle (individuals have been observed to do this) should be considered.

The Workshop agreed that the prior for the age-at-maturity should be U[4, 12]. This is based on data from individually identified whales and incorporated the lower ages-at-first-parturition reported by Clapham (1992) and Gabriele *et al.* (2007) and the high value reported by Robbins (2007).

Recognising the great uncertainty in these priors given the paucity of data, the Workshop agreed that it was important to develop a *Robustness Trial* in which the priors for the biological parameters are modified by lowering the upper bounds for the priors for S_{1+} and f_{max} and increasing the lower bound for a_m.

The abundance data are not informative about carrying capacity and the Workshop agreed that trials should be based on the prior for carrying capacity, *K*, proposed in Punt (2012), U[0, 30,000], noting that the estimated total catch of North Atlantic humpback whales is approximately 30,000 (Reeves and Smith, 2002).

3.2.1.5 NEED

Need envelopes are an important component of developing a trial structure and are the responsibility of the relevant Governments. Need envelopes for humpback whales were submitted to the Workshop in Witting (2012) and these reflected the Greenlandic preference for humpback whales over fin whales and Greenland's desire for flexibility. The need envelope is summarised in Fig. 2. Reiterating that the determination of catch limits is a matter for the Commission but recognising that the Committee needs to be in a position to provide scientific advice on any need requests, the Workshop had agreed that need envelopes that increased over the initial three quota blocks from ten to twenty whales should capture this issue. Hence, the following three need envelopes were agreed [10, 15, 20-20], [10, 15, 20-40] and [10, 15, 20-60], with the middle envelope being considered the base case. Witting had also suggested consideration of an additional 'backup' scenario of initially adding ten humpback whales to the base case envelope (this was intended to compensate for any unforeseen decline in the common minke whale strike limits of up to approximately 60 minke whales).

3.2.1.6 *SLA*S TO BE CONSIDERED

The Workshop had agreed that all of the trials would be conducted for a bounding case and for two 'reference *SLA*s', in addition to any other *SLA*s which might be proposed by developers:

(1) the *Strike Limit* is set to the need;
(2) the *Strike Limit* is based on the interim *SLA* (IWC, 2009); and
(3) the *Strike Limit* is based on a variant of the interim *SLA* which makes use of all of the estimates of abundance, but downweights them based on how recent they are.

The Workshop had also agreed that the developers would be provided with:

(1) total need for the next block;
(2) catches by sex;
(3) mortalities due to bycatch in fisheries and ship strikes; and
(4) estimates of absolute abundance and their associated CVs.

3.2.1.7 TRIAL STRUCTURE
The Workshop developed proposed *Evaluation* and *Robustness* trials. These formed the basis for discussions under Item 3.2.3.

3.2.2 Discussion of the Workshop report and the results of intersessional work
The SWG **thanked** the Workshop for it comprehensive work and **broadly endorsed** its conclusions and recommendations; where appropriate they are either incorporated in the trial specifications (see Appendix 2) or provided the basis for further discussions under Item 3.2.3 below.

3.2.2.1 ABUNDANCE ESTIMATES
SC/65a/AWMP01 analysed surfacing time and availability bias for humpback whales in West Greenland, providing updated estimates of abundance. A total of 31 satellite-linked time-depth-recorders of three different types were deployed on humpback whales in West Greenland in May and July 2009-10. Over the period whales were tracked, the SLTDRs recorded the fraction of a 6-hour period that the whales spent at or above 2m depth. This depth is considered to be the maximum depth humpback whales are reliably detected on visual aerial surveys in West Greenland. Eighteen transmitters provided both data on the surface time and the drift of pressure transducer. The average surface time for these whales over the entire tracking period and during the two 6-hr periods with daylight was 28.3% (CV=0.06). Six whales that met data filtering criteria had reduced drift of the depth transmitter and their average surface time was 33.5% (CV=0.10). Previous analyses of visual aerial survey data have shown that the amount of time whales are available to be seen by observers is not an instantaneous process. Therefore the surface time needs to be corrected for a positive bias of about 10% when developing a correction factor for availability bias which increases the availability to 36.8% (CV=0.10). The most recent survey of humpback whales in West Greenland was conducted in 2007 and corrections with this availability factor provides fully corrected abundance estimates of 4,090 (CV=0.50) for mark-recapture distance sampling analysis and 2,704 (CV=0.34) for a strip census abundance estimate. These estimates are about 25% larger than previous estimates from the same survey. The annual rate of increase was 9.4% per year (SE 0.01) which was unchanged from the published paper.

The SWG noted that the methods behind the new estimates had been discussed fully at previous meetings when considering the 2007 survey. The revised estimate here was based on updated and improved information on the diving behaviour of whales from additional satellite tag data. It therefore **accepted** the new strip census abundance estimate as the best estimate. The full list of estimates accepted by the SWG is provided in Table 1. This information is also included in the trial specifications (see Appendix 2).

3.2.2.2 STOCK STRUCTURE
Noting the importance of information of photo-identification studies both to stock structure and the possibility of human-induced mortality outside the West Greenland area, the SWG **recommended** that Greenlandic scientists to work with the College of the Atlantic to develop a full overview of the available data and present this to the proposed intersessional Workshop.

3.2.2.3 REMOVALS
In the light of discussions at the workshop and at the present meeting, the SWG **agreed** that the Secretariat should continue to work with Canadian scientists and others to finalise the catch series (direct and indirect) following the guidelines agreed at the Workshop and present a final series to the proposed intersessional Workshop.

3.2.2.4 INITIAL INVESTIGATIONS OF *SLA*S
The SWG proceeded to discuss the results provided by the two sets of developers of candidate *SLA*s, which were based on trials as developed at the Intersessional Workshop. As the SWG discussed the results of this work for humpback and bowhead whales together, these are considered further under Item 3.4.

3.2.3 Trial structure
Based on the Workshop report and discussions above, the SWG revised the final trial structure for evaluation of *SLA*s for the West Greenland humpback whale hunt (also see Appendix 2).

During review of the trial specifications, it was noted that the prior distribution for f_{max} had been defined to be Unif[0.4,0.8], whereas data from Zerbini *et al.* (2010) included some lower estimates. In response to a question as to whether the lower end of the f_{max} prior should be adjusted downward accordingly, it was noted, however that the Zerbini *et al.* (2010) data referred to *observed* increase rates, whereas f_{max} referred to *theoretical maximum* rates. Values of f_{max} below 0.4 were regarded as very unlikely, and no change to the specifications was made.

The SWG **agreed** to replace need envelope D with C for trials 3A and 3B. The justification was that envelope D (involving pre-emptively higher initial need) would be very unlikely to be sought if the first survey was delayed until year 15. The SWG also agreed to add trials using need envelope C for all evaluation trials numbered 2A, 2B, and 4 or higher since it was important to consider the case when no initial jump in need was requested.

The SWG **agreed** that it was appropriate to include trials based on the environmental variability model for population dynamics developed by Cooke (2007) be included. This model reflects the impact of this variability on the population growth rate. The effect is not symmetrical because this growth rate is bounded for demographic reasons. This results in a qualitative difference being predicted in the behaviour of recovering populations. These first follow a steady exponential trend, but once somewhat higher abundance is reached much more variable behaviour can ensue (as indeed appears evident, for example, for the South West Atlantic right whale and Eastern North Pacific gray whale population). The SWG **agreed** that these environmental variability trials were plausible and thus should be considered *Evaluation Trials*. Since conditioning using this approach may prove problematic, it was also **agreed** that this model would be used only for future projections. These new trials are referred to as 'asymmetric environmental stochasticity'. Trial 8 will be parameterised intersessionally (Witting).

The factors considered in the trials are summarised in Table 1.

In preparation for evaluating *SLA*s for subsistence hunting of bowheads and humpback whales off West Greenland, the SWG reviewed the performance statistics, tables, and graphs used for past *SLA* evaluation and *Implementation Reviews*, to identify what methods were found most effective and informative.

Statistic D8 ('rescaled final population') was clarified in light of the fact that known or projected incidental removals will occur for some stocks hunted in West Greenland (e.g. Canadian hunting of bowhead whales). D8 has previously

Table 1

Factors tested in the trials.

Factors	Levels (reference levels shown bold and underlined)	
	Humpback whales	Bowhead whales
$MSYR_{1+}$	1%, 3%, **5%**, 7%	1%, **2.5%**, 4%
$MSYL_{1+}$	0.6	**0.6**, **0.8**
Time dependence in K*	**Constant**, halve linearly over 100 years	
Time dependence in natural mortality, M*	**Constant**, double linearly over 100 years	
Episodic events*	**None**, 3 events occur between years 1-75 (with at least two in years 1-50) in which 20% of the animals die. Events occur every five years in which 5% of the animals die.	
Need envelope	A: 10, 15, 20; 20 thereafter **B: 10, 15, 20; 20->40 over years 18-100** C: 10, 15, 20; 20->60 over years 18-100 **D: 20, 25, 30; 30->50 over years 18-100**	**A: 2, 3, 5; 5 thereafter** B: 2, 3, 5; 5 -> 10 over years 18-100 **C: 2, 3, 5; 5 -> 15 over years 18-100**
Future Canadian catches	N/A	**A: 5 constant over 100 years** B: 5-> 10 over 100 years C: 5-> 15 over 100 years D: 2.5 constant over 100 years?
Survey frequency	5 year, **10 year**, 15 year	
Historic survey bias	0.8, **1.0**, 1.2	0.5, **1.0**
First year of projection, τ	**1960**	**1940**
Alternative priors	S_{1+} ~ U[0.9, 0.99]; f_{max} ~ U[0.4, 0.6]; a_m ~ U[5, 12]	N/A
Strategic surveys	Extra survey if a survey estimate is half of the previous survey estimate	
Asymmetric environmental stochasticity parameters	To be finalised by an intersessional group	

*Effects of these factors begin in year 2013 (i.e. at start of management). The adult survival rate is adjusted so that if catches were zero, then average population sizes in 250-500 years equals the carrying capacity. Note: for some biological parameters and levels of episodic events, it may not be possible to find an adult survival rate which satisfies this requirement.

been defined as the ratio of the final abundance (either 1+ or mature females) after 100 years with removals given by the *SLA* to the final abundance 'under a scenario of zero strikes'. For over a decade of AWMP *SLA* development for several fisheries no incidental take has been considered, so the condition of 'zero strikes' has been equivalent to 'zero removals'. Indeed, some SWG members had believed incorrectly that D8 was calculated relative to zero removals. The possibility of non-zero incidental removals now highlighted this point of confusion.

Therefore, the SWG defined statistic D8(0) to represent rescaled final population relative to a scenario with zero removals *of any kind*, and D8=D8(inc) to refer to the existing statistic which is relative to a scenario with zero strikes but possibly non-zero incidental removals. Statistic D8(0) is boldfaced to indicate that it is 'considered …more important'.

The same confusion about incidental removals applies to the abundance in year t under a scenario of zero strikes, denoted P_t^*. The SWG defined $P_t^*(0)$ and $P_t^*(inc)$ analogously to D8(0) and D8(inc).

The SWG promoted statistic N12 ('mean downstep') to the boldfaced 'more important' category, and demoted R1 ('relative recovery') to non-boldfaced.

Consistent with past efforts, the SWG **agreed** to produce two sets of output when evaluating candidate *SLA*s. The first is a comprehensive library of all output, including the 5%tile and median values of all statistics (boldfaced 'more important' or otherwise), and all graphs and other output listed in the trial specifications. The library will be available for inspection but not used as the primary basis for SWG discussion. The second output set is a subset of the comprehensive library. It contains only the tables and graphs anticipated to be the most useful for SWG evaluation of candidate *SLA*s. The elements of this review set are discussed below.

A table of 5%tile and median values of certain statistics will be included in the review set. The most important aspect of this table is that the same quantities for different *SLA*s should be arranged in a column with aligned decimal points, so that like numbers can be compared vertically. The next paragraph summarises the contents of the table and a possible format. Apart from the columnwise comparison requirement, the format may be adjusted to partition the contents and fit on the page(s) sensibly.

Columns of the table are 5%tile and median values for D1(1+), D1(mature females), D8(0), D8(inc), D9(1+), D10(1+), N9(20) and N9(100). Row blocks of the table correspond to trial scenarios. Rows within a block correspond to different strike limit rules. Within a block, there would be one row for each candidate SLA. Also included in the block would be rows for removals=0 (i.e. no strikes or incidental removals), strikes=0 (but incidental removals do occur), and strikes=need.

In addition to this table, the following plots will be included in the review set.

(1) The 'Zeh plots' (IWC, 2013c). The statistics to be displayed in the Zeh plots will be all those described for the table above, and N12 ('mean downstep'). Note that the Zeh plots rely on more quantiles of the statistics than just the 5th and 50th ones shown in the table.
(2) The plots defined as D6, i.e. abundance trajectory plots of P_t versus t (t = 0,…,100). All 100 simulated abundance trajectories for one algorithm are superimposed on this plot. Each plot pertains to a single *SLA* and a single trial scenario. Plots for 1+ abundance will be included in the review set, and analogous plots for the mature female component will be included in the comprehensive library.
(3) Plots of C_t versus t, as a step-function over 5-year blocks (t = 0,…,100). All 100 simulated quota trajectories for one algorithm are superimposed on this plot. Each plot pertains to a single *SLA* and a single trial scenario. Superimposed in this plot (in a different color and heavier line type) will be the pointwise 5%tile trajectory of C_t.
(4) The plots defined as D7 (pointwise quantile abundance trajectories). In these plots, the three pairs of trajectory

lines (i.e. 5%tiles and medians for P_t, $P_t^*(0)$ and $P_t^*(inc)$ will be superimposed on the same plot. Colour and line type will distinguish these.

(5) A new type of plot to compare depletion performance of several *SLA*s on a single graph. In this plot (one per trial scenario), the pointwise α^{th} percentile time trajectory of 1+ abundance is plotted, as in D7. However, the trajectories for all candidate *SLA*s are superimposed on the same plot. These are distinguished by color and line type. The three reference trajectories determined by assuming 0 strikes, 0 removals, and catch=need are *not* included in these plots. Two sets of such plots will be made, corresponding to α=5 and α=50.

3.3 Bowhead whales

3.3.1 Report from the intersessional Workshop (SC/65a/Rep02)

3.3.1.2 STOCK STRUCTURE

The current working hypothesis in the Scientific Committee is a single Baffin Bay-Davis Strait stock of bowhead whales (see Fig. 1). However, pending the availability of some genetic analyses, the Scientific Committee had agreed that the possibility that there are in fact two different stocks present in the overall area, with the second located in the Foxe Basin-Hudson Strait region, cannot be ruled out (e.g. see IWC, 2009, p.23).

No new information was available to the Workshop. Given that the objective was to develop an *SLA* for the Greenland hunt of bowhead whales, the Workshop had agreed to proceed first on a conservative basis that assumed that the absolute abundance of bowhead whales on the West Greenland wintering area would be informed by abundance estimates from data for that region only (see below). Only if such an *SLA* proved unable to meet need would abundance estimate information and stock structure considerations from the wider area shown in Fig. 1 be taken into account.

3.3.1.2 ABUNDANCE

The Workshop reviewed the available abundance estimates (SC/65a/Rep02, table 8). It is not possible to combine the Foxe Basin-Hudson Bay 2003 survey with the 2002 Prince Regent Inlet survey to obtain an estimate for the entire Davis Strait-Baffin Bay-Foxe Basin area. The Workshop therefore agreed to condition the operating model using data for Davis Strait-Baffin Bay stock only.

The 2002 survey in Prince Regent Inlet might not be conducted again whereas regular surveys will be conducted off West Greenland. The Workshop therefore agreed to conduct trials: (a) in which the estimate for Prince Regent Inlet is treated as an estimate of absolute abundance; and (b) in which the estimates from West Greenland are treated as estimates of absolute abundance.

While the sex ratio of animals in West Greenland is ~80:20 in favour of females (Heide-Jørgensen *et al.*, 2010b), it is expected that the sex ratio for the current whole population is 50:50 (based on historic catches over the whole region and present Canadian catches). The Workshop agreed that the trials will assume that the proportion of males available to the surveys will be the observed average male/female ratio in the biopsy samples.

Estimates of relative abundance from aerial surveys were also considered by the Workshop which agreed that an overdispersion parameter should be estimated for these sightings data under the assumption that the data are negative binomially distributed. Estimates of relative abundance are also available from genetic mark recapture studies. For similar reasons to those given for humpback whales above,

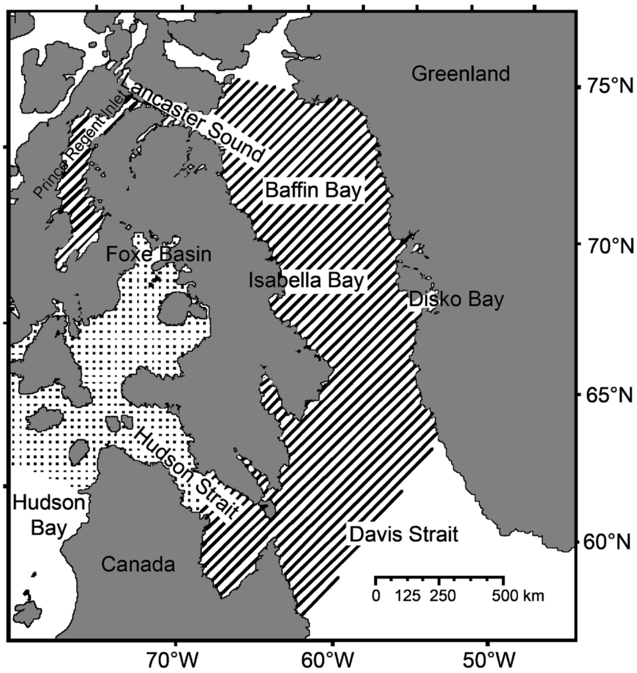

Fig. 1. Stock structure hypotheses for bowhead whales and place names referred to in the text. Hashed lines are for a Davis Strait-Baffin Bay stock while the dotted area refers to a Foxe Basin – Hudson Bay stock.

the Workshop agreed that these are not suitable for use now but that work should continue to enable these data to be used in the future; however, it accorded the work low priority at this time.

The Workshop agreed that the information provided to the *SLA* will be the results of surveys off West Greenland (relative indices if the operating model is conditioned to the estimate of abundance for Prince Regent Inlet and absolute if the operating model is conditioned to the estimate of abundance for West Greenland).

3.3.1.3 REMOVALS

For reasons similar to those agreed for humpback whales given above, the Workshop agreed that population projections should begin from a recent year (1940). This is earlier than for humpback whales because of the extended age-structure of the population.

The Workshop agreed that all the recent (post-1940) direct catches of bowhead whales by Canada and Denmark (Greenland) are known and thus that there was no need to consider an alternative catch series.

For 2011, Canada set an allowance of a maximum of four bowhead whales to be hunted in the Eastern Canadian Arctic. It is not known whether this allowance is for landed whales alone or whether it includes struck and lost whales; this is being investigated by the Secretariat.

The Workshop agreed that four scenarios regarding future Canadian catches should be considered (constant 5, 5 increasing to 10 over 100 years, 5 increasing to 15 over 100 years, constant 2.5; the last case reflects a situation in which half of the Canadian catches are taken from a different stock than the West Greenland catches). The sex-ratio for the West Greenland catches will be set to the sex ratio observed in the biopsy samples taken off West Greenland over the 2002-11 period while that for the Canadian catches should be set to the observed sex-ratio (the observed ratio for the Baffin Bay/Davis Strait whales taken by Canada is 4 male, 1 female, 4 unknown – this is being confirmed by the Secretariat).

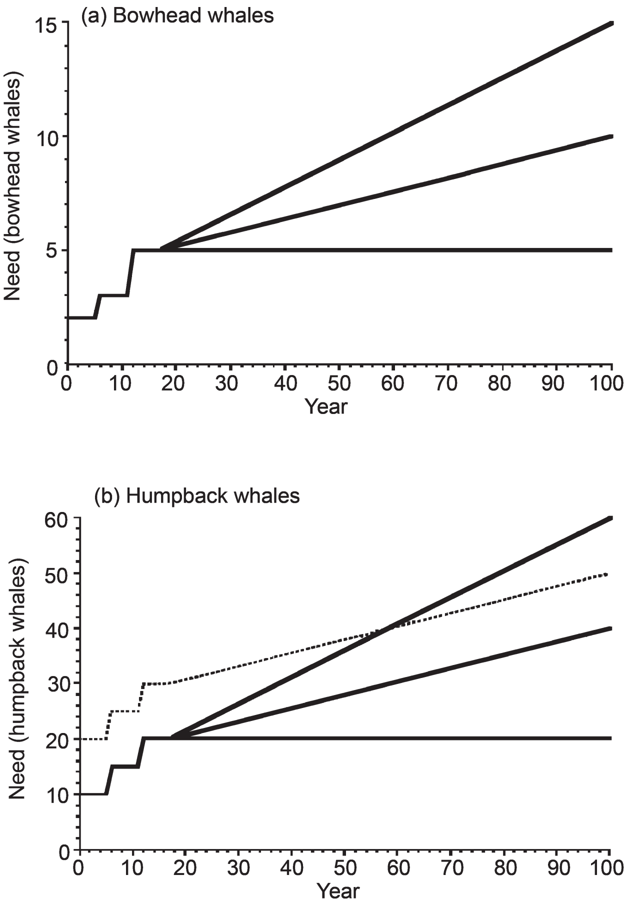

Fig. 2. Need envelopes A-D established for West Greenland bowhead and humpback whale trials.

Recent bycatches of bowhead whales by Denmark (Greenland) and any information for Canada that can be found by the Secretariat will be will be included in the revised trials specification. The Workshop noted that if the number of ship strikes increases as the Northwest Passage opens up, this could trigger an *Implementation Review*.

3.3.1.4 BIOLOGICAL PARAMETERS

In the absence of information for this region, the Workshop agreed to use the priors for f_{max}, S_{1+} and a_m used for the *Implementation* for the Bering-Chucki-Beaufort Seas bowhead whales, noting that these incorporate considerable uncertainty for all three parameters.

3.3.1.5 NEED

Brandon and Scordino (2012), presented to the Workshop, had suggested three scenarios, each of which involves an increase to the need from 2 to 5 at the start of the projection period followed by either: (1) no increase of need; (2) a doubling; and (3) a tripling of need in a linear fashion over the total time period. This is shown in Fig. 2.

3.3.1.6 TRIALS

The Workshop developed proposed *Evaluation* and *Robustness* trials. These formed the basis for discussions under Item 3.3.3.

3.2.2 Discussion of the Workshop report and the results of intersessional work

The SWG thanked the Workshop for it comprehensive work and **broadly endorsed** its conclusions and recommendations; where appropriate they are incorporated in the trial specifications (Appendix 2) or provided the basis for further discussion under Item 3.3.3 below.

3.3.2 RESULTS OF INITIAL WORK ON *SLA*S

The SWG received initial results provided by the two sets of developers of candidate *SLA*s, which were based on trials as developed at the Intersessional Workshop. As the SWG discussed the results of this work for humpback and bowhead whales together, these are considered further under Item 3.4.

3.3.3 Trial structure

The SWG finalised the trial structure (see Appendix 2) for evaluation of *SLA*s for the West Greenland bowhead whale hunt.

The SWG adopted the same planned evaluation strategies (statistics, tables, graphs) as described in Item 3.2.3 for the humpback case. This includes clarification of the abundance and depletion statistics in the situation of zero strikes and/or incidental removals.

SC/65a/Rep02 described *Evaluation Trials* 8A and 8B in which Canadian bowhead strikes tripled over 100 years. The SWG **agreed** to change these from *Evaluation Trials* to *Robustness Trials* (now 4A and 4B). It noted that a situation where Canadian bowhead strikes increased so much would trigger an *Implementation Review*, and therefore it was not necessary to incorporate such a scenario in the tested parameter space.

For the same reasons documented for humpback whales (see Item 3.2.3), the SWG **agreed** to add *Evaluation Trials* involving 'asymmetric environmental stochasticity'. It also **agreed** to include need scenario B in all *Evaluation Trials.*

A number of the preliminary results considered under Item 3.4 illustrated that it would be difficult to meet conservation objectives satisfactorily when the need level was high, especially if Canadian catches (which are taken by a non-IWC member country) increase. The SWG discussed whether it would be advisable to reconsider how strike quotas and incidental removals (i.e. by Canadian hunters) are accounted for in the *SLA* computations. However, it **agreed** to continue with the current framework but also **agreed** that this topic should be further considered at the next intersessional workshop.

3.4 Results from initial work on *SLA*s for humpback and bowhead whales

The SWG discussed the results provided by the two sets of developers of candidate *SLAs*, which were based on trials as developed at the intersessional Workshop.

Witting introduced SC/65a/AWMP04 which describes candidates *SLA*s for the West Greenland hunt on humpback whales. Two candidates based on the current interim *SLA* are proposed. They are both simple data based procedures with no internal population model, and they were selected from a total set of 48 examined procedures. All procedures were tested on a selected set of evaluation trials that included nearly all low production trials, and here they were set to pass a test of acceptable conservation performance (5th percentile of D10 larger than one) before they could be chosen as an acceptable procedure dependent upon their need satisfaction performance and other features. Both procedures estimate the strike limit as a function of 3% of the 2.5th percentile of an estimate of abundance. They put additional limits on the strike limit if the point-estimate of abundance is below 1,200, and one of the two procedures sets the strike limit to need if it exceeds 80% of need.

Witting then presented SC/65a/AWMP05 which describes candidates *SLA*s for the West Greenland hunt on bowhead whales. A similar approach to that taken in SC/65a/AWMP04 was followed. However, none of the 29

*SLA*s initially considered were able to pass the conservation criterion for the low production trials of the two alternative B and C scenarios for future Canadian catches, where annual Canadian catches are assumed to increase from 5 to 10, and from 5 to 15 over the simulation period. Not even a zero-*SLA*, which assumed zero Greenlandic catches for the whole period, was able to pass the conservation criterion when the Canadian catches increased from 5 to 15. Hence, the *SLA* development was restricted to trials where the annual Canadian catches were assumed to be no higher than five. The procedure with highest need satisfaction and acceptable conservation performance on these trials was then selected as a candidate *SLA*. This ($r_{.5}N_{2.5}$PS) procedure sets the strike limit as a function of 0.5% of the 2.5th percentile of an estimate of abundance, it puts additional limits on the strike limit if the point-estimate of abundance is below 1,200, and it sets the strike limit to need if it exceeds 80% of need. Another candidate ($r_1N_{2.5}$Pa) was selected to optimise need satisfaction should annual need not exceed 5 in the future. This procedure provides higher need satisfaction than $r_5N_{2.5}$PS, and it sets the strike limit as a function of 1% of the 2.5th percentile putting additional limits on the strike limit if the point-estimate of abundance is below 800. While selected to have acceptable D10 conservation performance only on the low need trials, conservation performance for $r_1N_{2.5}$Pa on the high need trials failed only marginally on trial B03BC.

Brandão presented results for four possible *SLA*s from SC/65a/AWMP02. One of the *SLA*s considered is the Interim *SLA* which is based on the most recent estimate of abundance, while the other three *SLA*s are variants of a weighted-average interim *SLA* which uses all abundance estimates, but earlier abundance estimates are downweighted compared to more recent ones. A simple integrative approach to provide a ready coarse comparison of the performance of each *SLA* across all the evaluation and robustness trials was put forward, based on the lower 5%-iles of the N9 (need satisfaction) and D1 (depletion) performance statistics. An index of depletion (D_{imp}) is first computed that measures the extent by which the *SLA* under consideration improves depletion compared to the *Strike Limit = Need SLA*. A statistic is put forward that gives a measure (Q) of the deviation from the ideal scenario of obtaining a result given values of the lower 5%-ile need satisfaction (N9) and of the index of depletion from a trial of both to be (close to) 1. There are two simple approaches to comparing the performance of *SLA*s under trials using this statistic, where averages are readily taken over all trials. These averages could apply either to the *Q* statistic itself or to a ranking for each trial based on the value of *Q* across the *SLA*s considered. There was generally little to choose between the four *SLA*s considered in terms of performance measured by these statistics. There was a qualitative difference between the two species: for humpback whales the *SLA* using the most recent abundance estimate only was preferred, whereas for bowheads the preference was to use all estimates with little downweighting for time since the survey. However, none of the *SLA*s considered performed adequately in terms of resource depletion for the lowest $MSYR_{1+}$ values considered.

In discussion both sets of developers responded to questions of clarification. The protection level concept introduced in the Witting *SLA*s was noted with interest, and it was suggested that this concept might be introduced to the Brandão *SLA*s to attempt to arrest the poor conservation performance on some trials. It was noted that at this stage, each set of developers had developed their own approaches to choose amongst the *SLA* candidates which they had tested. The SWG noted that this was an acceptable approach for developer to take when investigating the performance of their initial *SLA*s before deciding to put 'official' candidates forward but **re-iterated** that final choices would need to be based on the full set of performance statistics agreed for the trials.

3.5 Future consideration of multispecies advice

3.5.1 Report of intersessional Workshop (SC/65a/Rep02)

The Workshop referred to earlier discussions (IWC, 2011b; Witting, 2008) on this matter which have noted that Greenland's need is expressed in terms of tonnes of edible products, and for operational reasons some flexibility (to allow for temporal variability in the species composition of this tonnage) is important and would be preferred. The inclusion of such flexibility within a set of *SLA*s for a number of species, where these *SLA*s would need to be inter-linked, is a challenging scientific task in terms of designing the necessary simulation tests. The Workshop had re-iterated previous advice that this aspect is best pursued only after separate *SLA*s, which operate independently for each species, have been developed and accepted.

3.5.2 Conclusions and recommendations

The SWG endorsed the Workshop's conclusion and **re-iterated** previous advice (IWC, 2012) that this issue is best pursued only after separate *SLA*s, which operate independently for each species, have been developed and accepted.

4. ANNUAL REVIEW OF MANAGEMENT ADVICE

The SWG noted that the Commission had not reached agreement on strike limits for Greenland at the 2012 Annual Meeting (IWC, 2013a). It based its management advice on the same limits considered last year. In providing this advice it noted that the Commission has endorsed the interim safe approach (based on the lower 5th percentile for the most recent estimate of abundance) for providing advice for the Greenland hunts developed by the Committee in 2008 (IWC, 2009, p.16); it was agreed that that this should be considered valid for two blocks, i.e. up to the 2018 Annual Meeting.

4.1 Common minke whales off West Greenland

4.1.1 New information (incl. catch data and agreed abundance estimates)

In the 2012 season, 144 minke whales were landed in West Greenland and 4 were struck and lost. Of the landed whales, there were 109 females, 33 males and two of unknown sex. Genetic samples were obtained from 112 of these whales. Last year, the Committee has re-emphasised the importance of collecting genetic samples from these whales, particularly in the light of the proposed joint AWMP/RMP workshop (see Annex D). The SWG **welcomed** the fact that nearly 80% of the catch had been sampled in 2012 and encouraged continued sample collection.

This year, the SWG adopted a revised estimate of abundance for the 2007 survey. The revised published estimate (16,100 CV=0.43) was slightly lower than that first agreed in 2009. The SWG noted that this estimate is an underestimate of the total population by an unknown amount.

4.1.2 Management advice

In 2009, the Committee was for the first time able to provide management advice for this stock. This year, using the agreed

Table 2

Most recent estimates of abundance for the Central stock of common minke whales.

Small Area(s)	Year(s)	Abundance and CV
CM	2005	26,739 (CV=0.39)
CIC	2007	10,680 (CV=0.29)
CG	2007	1,048 (CV=0.60)
CIP	2007	1,350 (CV=0.38)

interim approach and the revised estimate of abundance given under Item 4.1.1, the SWG **advised** that an annual strike limit of 164 will not harm the stock. It **drew attention** to the fact that this is 14 whales lower than its advice of last year due to the revised 2007 abundance estimate.

4.2 Common minke whales off East Greenland

4.2.1 New information (incl. catch data and agreed abundance estimates)

Four female common minke whales were struck (and landed) off East Greenland in 2012. Two were females and the sex of the other two was unknown. The SWG was **pleased** to note that genetic samples were obtained from all minke whales caught in East Greenland (these could be used *inter alia* to determine the sex of the unknown animals). The Committee **again emphasised** the importance of collecting genetic samples from these whales, particularly in the light of the proposed joint AWMP/RMP workshop (see Annex D).

4.2.2 Management advice

Catches of minke whales off East Greenland are believed to come from the large Central stock of minke whales. The most recent strike limit of 12 represents a very small proportion of the Central Stock – see Table 2. The SWG **repeats** its advice of last year that the strike limit of 12 will not harm the stock.

4.3 Fin whales off West Greenland

4.3.1 New information (incl. catch data and agreed abundance estimates)

A total of four fin whales (all females) were landed, and one was struck and lost, off West Greenland during 2012. The SWG was **pleased** to note that genetic samples were obtained from three whales. The SWG **re-emphasised** the importance of collecting genetic samples from these whales, particularly in the light of the proposed work to develop a long-term *SLA* for this stock.

4.3.2 Management advice

Based on the agreed 2007 estimate of abundance for fin whales (4,500 95%CI 1,900-10,100), and using the agreed interim approach, the SWG **repeated** its advice that an annual strike limit of 19 whales will not harm the stock.

4.4 Humpback whales off West Greenland

4.4.1 New information (incl. catch data and agreed abundance estimates)

A total of seven (two males; four females; one unknown sex) humpback whales were landed (three more were struck and lost) in West Greenland during 2012. The SWG was **pleased** to learn that genetic samples were obtained from all of these whales and that Greenland was contributing fluke photographs to the North Atlantic catalogue – four have been submitted from whales taken since 2010. The SWG again **emphasised** the importance of collecting genetic samples and photographs of the flukes from these whales, particularly with respect to the MoNAH and YoNAH initiatives (Clapham, 2003; YoNAH, 2001).

This year, the SWG **endorsed** the revised fully corrected abundance estimate for West Greenland from the 2007 survey of 2,704 (CV=0.34) for the strip census abundance estimate (see Item 3 above). The agreed annual rate of increase of 0.0917 (SE 0.0124) remains unchanged.

4.4.2 Management advice

Based on the revised agreed estimate of abundance for humpback whales given above and using the agreed interim approach, the SWG **agreed** that an annual strike limit of 10 whales will not harm the stock.

4.5 Humpback whales off St Vincent and The Grenadines

4.5.1 New information (incl. catch data and agreed abundance estimates)

No new information or catch data were provided in time for consideration by the SWG although information has been requested by the Secretariat. Lang reported that there is one sample collected from a humpback whale taken on 11 April 2012 in the SWFSC tissue archive. The SWG **welcomed** this information.

Iñíguez reported information obtained from local newspapers on hunts on St Vincent and the Grenadines: a 35ft male (8 March 2013); a 41ft female and a 35ft male (both 18 March 2013); and another whale with no length or sex information (12 April 2013).

Regarding the same stock, he referred to reports that residents of Petite Martinique, Grenada, spent hours attempting to drive a mature whale onto a beach using five inflatable boatss, two large trader boats and a speedboat on 22 November 2012. The whale finally escaped but was harpooned four times. He has no further information on what happened with this whale.

4.5.2 Management advice

The SWG repeated its previous strong recommendations that St. Vincent and The Grenadines:

(1) provide catch data, including the length of harvested animals, to the Scientific Committee; and
(2) that genetic samples be obtained for any harvested animals as well as fluke photographs, and that this information be submitted to appropriate catalogues and collections.

The SWG has agreed that the animals found off St. Vincent and the Grenadines are part of the large West Indies breeding population (abundance estimate 11,570 95%CI 10,290-13,390). The Commission adopted a total block catch limit of 24 for the period 2013-18 for Bequians of St. Vincent and The Grenadines. The SWG **repeated** its advice that this block catch limit will not harm the stock.

The SWG draws the Commission's attention to the unofficial reports of attempts to land a humpback whale in Grenada; the Schedule specifies that the quota applies only to Bequians of St. Vincent and The Grenadines. The SWG requests that the Secretariat contact the Government of Grenada to obtain official information on this incident.

5. ABORIGINAL WHALING MANAGEMENT SCHEME

5.1 Guiding principles for *SLA* development and evaluation

The SWG noted that considerable effort had been put into general consideration of the development of *SLA*s at the beginning of the AWMP process (IWC, 2000; 2001; 2002).

It **agreed** that it would be useful to briefly outline some guiding principles for *SLA*s to assist developers of candidate *SLA*s for the Greenland hunts. These are summarised below.

(a) The primary objective of any *SLA* is to meet the objectives set by the Commission with respect to need satisfaction and conservation performance, with priority given to the latter.
(b) *SLA*s must incorporate a feedback mechanism.
(c) Once need has been met for the 'high' need envelope while giving acceptable conservation performance, then there is no need to try to improve the performance of an *SLA* further.
(d) Simple *SLA*s are to be preferred, providing this simplicity does not compromise achieving the Commission's objectives.
(e) With respect to (d), empirical procedures may prove preferable to population model based procedures because (1) they are more easily understood by stakeholders and (2) there is little chance for significant updating of population model parameters (e.g. MSYR) over time as the extent of additional data will probably be limited for populations subject to aboriginal whaling only. Nevertheless, the choice of the form for any candidate *SLA* lies entirely in the hands of its developer, with selection amongst candidates to be based only on performance in trials.
(f) If in developing *SLA*s, a situation arises where relatively simple *SLA*s fail on one or a few trials where the circumstances which might lead to the failure occur only many years in the future, rather than attempt to develop more complex *SLA*s to overcome this problem, a simpler *SLA* could be proposed despite this failure, and the difficulties dealt with by means of an *Implementation Review* should there be indications in the future that the circumstances concerned are arising. This principle applies only to: (1) circumstances in a scenario that are external and independent of the hunting/quota feedback loop, such as very high values of the future need envelope; and (2) are judged to be very unlikely to occur in the next few decades. Failure of an *SLA* to perform acceptably in some circumstance is not in itself a reason to apply this principle.

5.2 Scientific aspects of an aboriginal whaling scheme

In 2002, the Committee **strongly recommended** that the Commission adopt the Aboriginal Subsistence Whaling Scheme (IWC, 2003). This covers a number of practical issues such as survey intervals, carryover, and guidelines for surveys. The Committee has stated in the past that the AWS provisions constitute an important and necessary component of safe management under AWMP *SLA*s and it **reaffirms** this view as it has for the previous 11 years.

6. PROGRESS ON FOLLOW-UP WORK ON CONVERSION FACTORS FOR THE GREENLANDIC HUNT

6.1 New information

In 2009, the Commission appointed a small working group (comprising several Committee members) to visit Greenland and compile a report on the conversion factors used by species to translate the Greenlandic need request which is provided in tonnes of edible products to numbers of animals (Donovan *et al.*, 2010). At that time the group provided conversion factors based upon the best available data, noting that given the low sample sizes, the values for species other than common minke whales should be considered provisional. The group also recommended that a focused attempt to collect new data on edible products taken from species other than common minke whales be undertaken, to allow a review of the interim factors; and that data on both 'curved' and 'standard' measurements are obtained during the coming season for all species taken. The report was endorsed by the Scientific Committee (IWC, 2011a, p.21).

Since then the Committee has received progress reports but has commented that more detail and information is required. Last year the Committee recommended:

(1) the provision of a full scientific paper to the next annual meeting that details *inter alia* at least: a full description of the field protocols and sampling strategy (taking into account previous suggestions by the Committee); analytical methods; and a presentation of the results thus far, including information on the sex and length of each of the animals for which weight data are available; and
(2) the collection and provision of data on Recommendation No. 2 of Donovan *et al.* (2010) comparing standard versus curvilinear whale lengths. This should be done for all three species on as many whales as possible.

SC/65a/AWMP07 reports on the collection of weights and length measures from fin, humpback and bowhead whales caught in West Greenland. To improve the data collection process, information meetings involving biologists, hunters, wildlife officers and hunting license coordinators were held in the larger towns in 2012, and an information folder was produced and distributed to the hunters. The data collection process was also combined with an existing research project on hunting samples in order to get a stronger involvement of biologists. When researchers participate in hunts they train the hunters in measuring the lengths (curved and standard) and they make sure that the meat is weighed.

Until now the reporting rate has been lower than expected, with the data obtained in 2012 being from only one fin whale and one humpback whale, and the total number of reports since 2009 being from six bowhead whales, six humpback whales and three fin whales. These data provide preliminary yield estimates for all edible products of 9,014kg (SE:846) per humpback whale, of 6,967kg (SE:2,468) per fin whale, and of 8,443kg (SE:406) per bowhead whale. These numbers are all somewhat lower than the suggested yield in Donovan *et al.* (2010), and this is especially pronounced for fin whales. Nevertheless, the obtained estimates for fin whales fall within the range of previous yield weight estimates for fin whales in West Greenland.

A major reason for the low reporting rate has been the almost complete absence of weighing equipment where the whalers could weigh the different products. To increase the reporting rate, the Greenland Institute of Natural Resources has now purchased and distributed cranes to major towns for the hunters to use for weighing when landing a catch. It was also realised that the 'bin system' described in previous reports is more complicated than first anticipated because there is a large variation in the size of the bins used within the same hunt and between hunters. It is therefore now recommended that hunters weigh all edible products with the crane weight when they land the meat with the crane in the harbor. This approach will be investigated further in 2013 and discussed with the hunters. Owing to the logistical difficulties involved with whale hunts in Greenland (which

Table 3

Summary of absolute abundance estimates. Relative abundance estimates for use in the trials are given in Appendix 2 (Table 3).

Area	Year	Corr*	Estimate and approx. 95% CI and CV	IWC reference	Original reference

*Indicates whether the estimate has been corrected for availability bias and/or perception bias.

are widespread along the coast and occur at unpredictable times during a long season) and the required change in the reporting system and subsequent need for training, it is likely that it will take several years to collect sufficient data on edible products.

6.2 Discussion

In response to questions, a number of clarifications were made. The original intention of weighing ten boxes had been so that an average weight per box could be developed to be multiplied by the total number of boxes to obtain an estimated total weight. However, with the efficient crane weights that are now in place in three cities, and with the finding that hunters may use different sized boxes even for the same whale, it has now been decided to weigh all boxes.

There were only five cases when scientists were able to be present at a humpback catch, and the low number illustrates the logistical difficulties in having scientists present at hunts. Witting did not have the precise details of this work or of the number of wildlife officers who may be able to assist in the work but will consult in Greenland. Efficient reporting requires not only training of hunters, but also the distribution of weighing equipment, so that hunters can report on their own.

In conclusion, the SWG **agreed** that the report was an advance on those previously received (and provided the first information on curvilinear lengths). However, it also **agreed** that it still did not provide sufficient information to fulfil the recommendations of last year. While aware of the logistical difficulties involved in obtaining these data, it **repeated its recommendations** of last year given in the second paragraph of this section. It **encouraged** Witting to assist in the writing of such a report to ensure that it better meets the request of the SWG next year.

7. CONSERVATION MANAGEMENT PLANS (CMPS)

The SWG noted the request for sub-groups to consider potential priority candidates for CMPs (SC/65a/SCP01). After considering the criteria given in that document the SWG **agreed** that it had no candidates for CMPs.

8. UPDATED LIST OF ACCEPTED ABUNDANCE ESTIMATES

The SWG noted the request to develop a list of accepted abundance estimates for consideration as part of an overall summary for all species to be developed by the Plenary. This was developed and has been forwarded for Plenary compilation. The abundance estimates agreed by this SWG are summarised above in Table 3.

9. WORK PLAN AND BUDGET REQUESTS

9.1 Work plan

The SWG **agreed** that the Chair should develop the work plan based upon the substantive items in the report. This is give in Table 4.

9.2 Budget requests

Intersessional Workshop on Developing SLA*s for the Greenlandic hunts*

The existing interim safe procedure for the Greenlandic hunts agreed in 2008 (IWC, 2009, p.16) was agreed to be valid for up to quota blocks so up to 2018. The Committee has identified completion of the development of long-term *SLA*s for these hunts as high priority work. In order to meet the proposed timeframe, an intersessional Workshop is required. The focus of the proposed Workshop is to: (1) to review the results of the developers of *SLA*s for humpback whales and bowhead whales; (2) finalise the modelling framework/trial structure for these hunts; (3) develop a work plan to try to enable completion of work on *SLA*s for these two hunts at the 2014 Annual Meeting; and (4) consider possible input (e.g. using AWMP/RMP-lite) for the joint AWMP/RMP workshop on North Atlantic common minke whale stock structure. The Workshop will be held in early 2014 in Copenhagen, Denmark, hosted by the Greenland representation; the costs are for IPs travel. It is intended to hold this back-to-back with and RMP Workshop on fin whales to save travel costs given some common membership.

AWMP Developers' fund

The developers fund has been invaluable in the work of *SLA* development and related essential tasks of the SWG.

Table 4

Work plan.

Item	Topic	Responsible persons	Deadline/target
3.1	Participate in the RMP North Atlantic fin whale RMP *Implementation* process and report back on the implications of this for *SLA* development for the Greenland hunt.	Donovan, Punt, Witting, Butterworth.	2014 Annual Meeting
3.1	Hold joint AWMP/RMP workshop on the stock structure of common minke whales in the North Atlantic (also see Annex D).	Joint Steering Group under Palsbøll.	Expected spring 2014
3.1	Submit need envelopes for West Greenland fin and common minke whales.	Witting.	Early Jan. 2014
3.2 and 3.3	Finalise the trials for the West Greenland humpback and bowhead whales (including coding) to allow developers to work intersessionally. Ensure that standard software is available to produce agreed performance statistics, as well as tabular and graphical output.	Steering Group convened by Donovan (Punt, Givens, Butterworth, Witting). Coding to be undertaken by Punt and Allison and developers.	(1) Agree specification and parameterisation by email and Skype: end Jul. 2013. (2) Complete coding and supply to developers: end Aug. 2013
3.2	Present overview of photo-identification work with respect to movements to inform stock structure and human induced mortality outside West Greenland.	Greenlandic scientists and College of the Atlantic (to be co-ordinated by Witting).	As soon as possible – ideally end of Aug. to assist Allison (see below), at latest in time for intersessional Workshop in early Jan. 2014
3.2 and 3.3	Finalise removals series including consideration of human-induced mortality outside the West Greenland area.	Allison.	End Aug. 2013
3.2 and 3.3	Continue initial exploration of potential *SLA*s for the Greenland humpback and bowhead whale hunts.	Developers.	For presentation at intersessional Workshop in early Jan. 2014
6.2	Produce full report on Greenlandic conversion factor programme.	Greenlandic authorities (assisted by Witting).	2014 Annual Meeting

It has been agreed as a standing fund by the Commission. The primary development tasks facing the SWG are for the Greenlandic fisheries. These tasks are of high priority to the Committee and the Commission. The fund is essential to allow progress to be made. It now stands at £8,000 and a request of £7,000 is made to restore it to the initial target level of £15,000.

10. ADOPTION OF REPORT

The report was adopted at 1900hrs on 11 June 2103. The SWG authorised the Chair to make editorial changes to the report as necessary to improve clarity. It also agreed that he should develop the work plan based upon the substantive items. The Chair thanked the participants for the constructive and co-operative attitude throughout these important discussions, some of which are highly technical. In particular, he thanked the developers for their work during the intersessional period that had greatly facilitated progress and the rapporteurs for their dedicated work. The SWG thanked the Chair for his efficient and good-humoured guidance.

Appendix 1

AGENDA

1. Introductory items
    - 1.1 Convenor's opening remarks
    - 1.2 Election of Chair
    - 1.4 Appointment of rapporteurs
    - 1.5 Adoption of Agenda
    - 1.6 Documents available
2. Gray whales with emphasis on the PCFG (Pacific Coast Feeding Group)
    - 2.1 Report of intersessional Workshop (SC/65a/Rep02)
    - 2.2 New information and results
        - 2.2.1 Further evaluation of proposed Makah Hunt
        - 2.2.2 Other information
    - 2.3 Summary and recommendations
3. Consideration of work required to develop *SLAs* for all Greenland hunts before the end of the interim period
    - 3.1 Common minke whales and fin whales
        - 3.1.1 Report from the intersessional Workshop (SC/65a/Rep02)
        - 3.1.2 Joint RMP/AWMP Workshop(s) on stock structure
        - 3.1.4 Discussion and work plan
    - 3.2 Humpback whales
        - 3.2.1 Report from the intersessional workshop (SC/65a/Rep02)
        - 3.2.2 Discussion of the Workshop report and the results of intersessional work
        - 3.2.3 Trial structure
    - 3.3 Bowhead whales
        - 3.3.1 Report from the intersessional Workshop (SC/65a/Rep02)
        - 3.2.2 Discussion of the Workshop report and the results of intersessional work
        - 3.3.3 Trial structure
    - 3.4 Results from initial work on *SLA*s for humpback and bowhead whales
        - 3.5.2 Conclusions and recommendations
4. Annual review of management advice
    - 4.1 Common minke whales off West Greenland
        - 4.1.1 New information (incl. catch data and agreed abundance estimates)
    - 4.2 Common minke whales off East Greenland
        - 4.2.1 New information (incl. catch data and agreed abundance estimates)
        - 4.2.2 Management advice
    - 4.3 Fin whales off West Greenland
        - 4.3.1 New information (incl. catch data and agreed abundance estimates)
        - 4.3.2 Management advice
    - 4.4 Humpback whales off West Greenland
        - 4.4.1 New information (incl. catch data and agreed abundance estimates)
        - 4.4.2 Management advice
    - 4.5 Humpback whales off St Vincent and The Grenadines
        - 4.5.1 New information (incl. catch data and agreed abundance estimates)
        - 4.5.2 Management advice
5. Aboriginal Whaling Management Scheme
    - 5.1 Guiding principles for *SLA* development and evaluation
    - 5.2 Scientific aspects of an aboriginal whaling scheme
6. Progress on follow-up work on conversion factors for the Greenlandic hunt
    - 6.1 New information
    - 6.2 Discussion
7. Conservation Management Plans (CMPs)
8. Updated list of abundance estimates
9. Work plan and budget requests
    - 9.1 Work plan
    - 9.2 Budget requests
10. Adoption of report

Appendix 2

TRIAL SPECIFICATIONS FOR HUMPBACK AND BOWHEAD WHALES OFF WEST GREENLAND

[NB: Aspects of these specifications, including those highlighted, will be finalised prior to the 2014 Annual Meeting by an Intersessional Steering Group and Workshop]

A. The population dynamics model

The underlying dynamics model is deterministic, age- and sex-structured, and based on the Baleen II model (Punt, 1999).

A.1 Basic dynamics

Equations A1.1 provide the underlying 1+ dynamics.

$$\begin{aligned} R^{m/f}_{t+1,a+1} &= (R^{m/f}_{t,a} - C^{m/f}_{t,a})S_a + U^{m/f}_{t,a} S_a \delta_{a+1} && 0 \le a \le x-2 \\ R^{m/f}_{t+1,x} &= (R^{m/f}_{t,x} - C^{m/f}_{t,x})S_x + (R^{m/f}_{t,x-1} - C^{m/f}_{t,x-1})S_{x-1} && \\ U^{m/f}_{t+1,a+1} &= U^{m/f}_{t,a} S_a (1-\delta_{a+1}) && 0 \le a \le x-2 \end{aligned} \quad \text{(A1.1)}$$

$R^{m/f}_{t,a}$ is the number of recruited males/females of age a at the start of year t;

$U^{m/f}_{t,a}$ is the number of unrecruited males/females of age a at the start of year t;

$C^{m/f}_{t,a}$ is the catch of males/females of age a during year t (whaling is assumed to take place in a pulse at the start of each year);

δ_a is the fraction of unrecruited animals of age a-1 which recruit at age a (assumed to be independent of sex and time);

S_a is the annual survival rate of animals of age a:

$$S_a = \begin{cases} S_0 & \text{if } a = 0 \\ S_{1+} & \text{if } 1 < a \le a_a \\ & \text{if } a > a_a \end{cases} \quad \text{(A1.2)}$$

S_0 is the calf survival rate;

S_{1+} is the survival rate for animals aged 1 and older; and

x is the maximum (lumped) age-class (all animals in this and the x-1 class are assumed to be recruited and to have reached the age of first parturition). x is taken to be 15 for humpback whales and 35 for bowhead whales for these trials.

A.2 Births

The number of births at the start of year t+1, B_{t+1}, is given by Equation A2.1:

$$B_{t+1} = b_{t+1} N^f_{t+1} \quad \text{(A2.1)}$$

N^f_t is the number of mature females at the start of year t:

$$N^f_t = \sum_{a=a_m}^{x} (R^f_{t,a} + U^f_{t,a}) \quad \text{(A2.2)}$$

a_m is the age-at-maturity (the convention of referring to the mature population is used here, although this actually refers to animals that have reached the age of first parturition);

b_{t+1} is the probability of birth/calf survival for mature females:

$$b_{t+1} = \max(0, b_K\{1 + A(1 - [N^{1+}_{t+1} / K^{1+}]^z)\}) \quad \text{(A2.3)}$$

$$N^{1+}_t = \sum_{a=1}^{x} (R^f_{t,a} + U^f_{t,a} + R^m_{t,a} + U^m_{t,a})$$

$$K^{1+} = \sum_{a=1}^{x} (R^f_{-\infty,a} + U^f_{-\infty,a} + R^m_{-\infty,a} + U^m_{-\infty,a}) \quad \text{(A2.4)}$$

b_K is the average number of live births per year per mature female at carrying capacity;
A is the resilience parameter; and
z is the degree of compensation.

The number of female births, B_t^f, is computed from the total number of the births during year t using Equation A2.5:

$$B_t^f = 0.5 \;\; B_t \tag{A2.5}$$

The numbers of recruited/unrecruited calves is given by:

$$\begin{aligned} R_t^f &= \alpha_0 \, B_t^f & R_t^m &= \alpha_0 \,(B_t - B_t^f) \\ U_t^f &= (1-\alpha_0)\, B_t^f & U_t^m &= (1-\alpha_0)(B_t - B_t^f) \end{aligned} \tag{A2.6}$$

α_0 is the proportion of animals of age 0 which are recruited (0 for these trials).

A.3 Catches

The historical (t<2013) removals are taken to be equal to the total reported removals (including struck and lost, by-catch, ship strikes, etc.) catches (Table 1). The sex-ratio of future aboriginal catches is assumed to be 50:50 F:M (bowheads) and 20:80 F:M (humpbacks) while the sex ratio of by catches, ship strikes and Canadian catches is assumed to be 50:50 F:M. Catches are taken uniformly from the recruited component of the population:

$$C_{t,a}^m = C_t^m \, R_{t,a}^m / \sum_{a'} R_{t,a'}^m \, ; \qquad C_{t,a}^{m/f} = C_t^f \, R_{t,a}^f / \sum_{a'} R_{t,a'}^f \tag{A3.1}$$

$C_t^{m/f}$ is the catch of males/females during year t.

The total catch in a given future year is the sum of: (a) the minimum of the need for that year, Q_t, and the corresponding strike limit; (b) bycatches in fisheries; (c) ship strikes; and (d) aboriginal catches in Canada (only bowheads).

The total bycatch during future year y is computed by applying the average exploitation rate during 2007-11 to the number of 1+ animals in year y, i.e.:

$$\tilde{C}_t = \tilde{F} \, N_t^{1+} \tag{A3.2}$$

$\tilde{F}$ is the average exploitation rate due to by-catch during 2007-11:

$$\tilde{F} = \sum_{t=2007}^{2011} (\tilde{C}_t^f + \tilde{C}_t^m) / \sum_{t=2007}^{2011} N_t^{1+} \tag{A3.3}$$

A.4 Recruitment

The proportion of animals of age a that would be recruited if the population was pristine is a knife-edged function of age at age a_r, i.e.:

$$\alpha_a = \begin{cases} 0 & \text{if } \; 0 \le a < a_r \\ 1 & \text{otherwise} \end{cases} \tag{A4.1}$$

a_r is the age-at-recruitment (assumed to be 5 for humpbacks and 1 for bowhead whales).

The (expected) number of unrecruited animals of age a that survive to age a+1 is $U_{t,a}^{m/f} \; S_a$. The fraction of these that then recruit is:

$$\delta_{a+1} = \begin{cases} [\alpha_{a+1} - \alpha_a]/[1-\alpha_a] & \text{if } 0 \le \alpha_a < 1 \\ 1 & \text{otherwise} \end{cases} \tag{A4.2}$$

A.5 Maturity

Maturity is assumed to be a knife-edged function of age at age a_m.

A.6 Initialising the population vector

The numbers at age in the pristine population are given by:

$$\begin{aligned} R_{-\infty,a}^{m/f} &= 0.5 \;\; N_{-\infty,0} \;\; \alpha_a \prod_{a'=0}^{a-1} S_{a'} & & \text{if } \; 0 \le a < x \\ U_{-\infty,a}^{m/f} &= 0.5 \;\; N_{-\infty,0} \;\; (1-\alpha_a) \prod_{a'=0}^{a-1} S_{a'} & & \text{if } \; 0 \le a < x \\ R_{-\infty,x}^{m/f} &= 0.5 \;\; N_{-\infty,0} \prod_{a'=0}^{x-1} \frac{S_{a'}}{(1-S_x)} & & \text{if } \; a = x \end{aligned} \tag{A6.1}$$

Table 1
Total removals? of bowhead and humpback whales.

Year	M	F	Year	M	F	Year	M	F

1977	8	9	1997	0	0			
1978	12	12	1998	0	1			
1979	7	8	1999	0	1			

$R^{m/f}_{-\infty,a}$ is the number of animals of age *a* that would be recruited in the pristine population;

$U^{m/f}_{-\infty,a}$ is the number of animals of age *a* that would be unrecruited in the pristine population; and

$N_{-\infty,0}$ is the total number of animals of age 0 in the pristine population.

The value for $N_{-\infty,0}$ is determined from the value for the pre-exploitation size of the 1+ component of the population using the equation:

$$N_{-\infty,0} = K^{1+} / \left(\sum_{a=1}^{x-1} \left(\prod_{a'=0}^{a-1} S_{a'} \right) + \frac{1}{1-S_x} \prod_{a'=0}^{x-1} S_{a'} \right) \quad \text{(A6.2)}$$

In common with the trials for the Eastern North Pacific gray whales (IWC, 2013), the trials are based on the assumption that the age-structure at the start of year τ is stable rather than that the population was at its pre-exploitation equilibrium size at the start of (say) 1600, the first year for which catch estimates are available. The determination of the age-structure at the start of year τ involves specifying the effective 'rate of increase', γ, that applies to each age-class. There are two components contributing to γ, one relating to the overall population rate of increase (γ^+) and the other to the exploitation rate. Under the assumption of knife-edge recruitment to the fishery at age a_r, only the γ^+ component (assumed to be zero following Punt and Butterworth [2002] applies to ages a of a_r or less. The number of animals of age a at the start of year τ relative to the number of calves at that time, $N^*_{\tau,a}$, is therefore given by the equation:

$$N^*_{\tau,a} = \begin{cases} 1 & \text{if } a = 0 \\ N^*_{\tau,a-1} S_{a-1} & \text{if } a \le a_r \\ N^*_{\tau,a-1} S_{a-1}(1-\gamma^+) & \text{if } a_r < a < x \\ N^*_{\tau,x-1} S_{x-1}(1-\gamma^+)/(1-S_x(1-\gamma^+)) & \text{if } a = x \end{cases} \quad \text{(A6.3)}$$

B_τ is the number of calves in year τ and is derived directly from equations A2.1 and A2.3 (for further details see Punt, 1999).

$$B_\tau = \left(1 - \left[1/(N^f_\tau b_K) - 1\right]/A\right)^{1/z} \frac{K^{1+}}{N^{1+,*}_\tau} \quad \text{(A6.4)}$$

The effective rate of increase, γ, is selected so that if the population dynamics model is projected from year τ to a year Ψ, the size of the 1+ component of the population in a reference year Ψ equals a value, P_Ψ which is drawn from a prior.

A.7 z and A

A, z and S_0, are obtained by solving the system of equations that relate $MSYL$, $MSYR$, S_0, S_{1+}, $f_{\max}$ $a_{\rm m}$, A and z, where $f_{\max}$ is the maximum theoretical pregnancy rate (Punt, 1999).

A.8 Conditioning

The method for conditioning the trials (i.e. selecting the 100 sets of values for the parameters $a_{\rm m}$, S_0, S_{1+}, K^{1+}, A and z) is based on a Bayesian assessment. The algorithm for conducting the Bayesian assessment is as follows:

(a) Draw values for the parameters S_{1+}, $f_{\max}$, $a_{\rm m}$, $MSYR_{1+}$, $MSYL_{1+}$, K^{1+}, P_Ψ, CV_{add} (the additional variance for the estimates of 1+ abundance in Ψ) from the priors in Table 2. The additional variance for the estimates of absolute abundance and indices of relative abundance are assumed to be the same. It is not necessary to draw values for $MSYR_{1+}$ and $MSYL_{1+}$ because the values for these quantities are pre-specified rather than being determined during the conditioning process.

(b) Solve the system of equations that relate $MSYL$, $MSYR$, S_0, S_{1+}, $f_{\max}$, $a_{\rm m}$, A and z to find values for S_0, A and z.

(c) Calculate the likelihood of the projection which is given by[1]:

$L=L_1L_2$ (L_2 applies only to the sighting rates for bowheads) where:

$$L_1 = \prod_t \frac{1}{\sqrt{\Omega_t^2 + CV^2_{add2}}} \exp\left(-\frac{(\ell n P_t^{obs} - \ell n\left(B_c \hat{P}_t\right))^2}{2(\Omega_t^2 + CV^2_{add2,t})}\right) \quad \text{(A8.1a)}$$

$$L_2 = \prod_t (\rho \hat{P}_t)^{N_t^{obs}} e^{-\rho \hat{P}_t} \quad \text{(A8.1a)}$$

P_t^{obs} is the estimate of the (1+) abundance at the start of year t (Table 3);

$\hat{P}_t$ is the model-estimate of the (1+) abundance which pertain to the survey estimates of abundance at the start of year t;:

$$\hat{P}_t = \tilde{S}^f \sum_{a=1}^{x} (R^f_{t,a} + U^f_{t,a}) + \tilde{S}^m \sum_{a=1}^{x} (R^m_{t,a} + U^m_{t,a}) \quad \text{(A.8.2)}$$

Ω_t is the (sampling) standard deviation of the logarithm of P_t^{obs} (approximated by its coefficient of variation, $CV^{obs}_{est,t}$ - see Table 3);

$\tilde{S}^f, \tilde{S}^m$ is the relative selectivity for females and males (1:1 for humpbacks and 1:0.25 for bowheads);

$E(CV^2_{add2,t})$ is the square of the actual CV of the additional variation for year t:

[1]The priors for the survey bias and additional variation are integrated out as these are nuisance parameters.

$$E(CV^2_{add2,t}) = \eta(0.1 + 0.013P^* / \hat{P}_t) = CV^2_{add2}\frac{0.1 + 0.013P^* / \hat{P}_t}{0.1 + 0.013P^* / \hat{P}_\Psi} \qquad \text{(A8.3)}$$

N_t^{obs} is the number of animals counted during year t (a relative index of abundance; Table 3b),

ρ is the constant of proportionality between the number of 1+ animals and the population counts, and

B_c is the bias associated with a relative index of abundance (different for each relative index).

Steps (a)-(c) are repeated a large number (typically 1,000,000) of times.

100 sets of parameters vectors are selected randomly from those generated using steps (a)-(c), assigning a probability of selecting a particular vector proportional to its likelihood. The number of times steps (a)-(c) are repeated is chosen to ensure that each of the 100 parameter vectors are unique.

The bulk of the trials for humpbacks are conditioned on the estimate of absolute abundance (Table 3a) and the time series of relative abundance based on aerial surveys (Table 3b). The relative indices of abundance based on mark-recapture are used when conditioning one of the *Robustness Trials*.

Table 2
The prior distributions.

Parameter	Prior distribution (humpbacks)	Prior distribution (bowheads)
Non-calf survival rate, S_{1+}	U[0.90, 0.995]	N(1.059, 0.0378[2]), truncated at 0.995
Age-at-maturity, a_m	U[4, 12]	N(20,32) truncated at 13.5 and 26.5
Transition age	0	U[1,9]
K^{1+}	U[0, 30,000]	U[0, 40,000]
$MSYL_{1+}$	Pre-specified	Pre-specified
$MSYR_{1+}$	Pre-specified	Pre-specified
Maximum pregnancy rate, $1/f_{max}$	U[1.25, 2.5]	U[2.5, 4]
Additional variation (population estimates), CV_{add}, in year Ψ	U[0, 0.35]	U[0, 0.35]
Abundance in year Ψ, P_Ψ	$\ell nP_{2007} = N(\ell n2{,}154, (0.36^2 + CV_{add}^2))$	A: $\ell nP_{2002} = N(\ell n6{,}340; (0.38^2 + CV_{add}^2))$ B: $\ell nP_{2007} = N(\ell n1{,}229, (0.47^2 + CV_{add}^2))$
Additional variation (relative indices), CV_{add2}	U[0.2, 0.6]	U[0.2, 0.6]
Bias of relative abundance indices, B_c	$\ell nB_c \sim U[-\infty, \infty]$ (see[1])	$\ell nB_c \sim U[-\infty, \infty]$ (see[1])

[1]This is the non-informative prior for a scale parameter.

Table 3
Estimates of absolute abundance (a) and estimates of relative abundance (b).

[1]Not used in the *Evaluation Trials*.

B. Data generation

B.1 Absolute abundance estimates

The historic (t<2013) abundance estimates (and their CVs) are provided to the *SLA* and are taken to be those in Table 3a for humpback whales and the relative indices of abundance for bowhead whales in Table 3b. An estimate of abundance together with an estimate of its CV is generated, and is provided to the *SLA,* once every F years during the management period (starting in year 2017 for humpbacks and 2022 for bowheads; F=10 years beyond the year with the last estimate of abundance). The CV of the abundance estimate (CV_{true}) is different from the CV provided to the *SLA*.

The survey estimate, $\hat{S}$, may be written as:

$$\hat{S} = B_A \; P \; Y \; w / \mu = B_A \; P^* \; \beta^2 \; Y \; w \quad \text{(B1.1)}$$

B_A is the bias;

P is the current 1+ population size ($= \hat{P}_t$); (B1.2)

Y is a lognormal random variable: $Y=e^{\phi}$ where: $\phi \sim N[0;\sigma_\phi^2]$ and $\sigma_\phi^2 = \ell n(1+\alpha^2)$ (B1.3)

w is a Poisson random variable, independent of Y, with $E(w) = \text{var}(w) = \mu = (P / P^*) / \beta^2$; and (B1.4)

P^* is the reference population level (the pristine size of $\hat{P}_t$).

The steps used in the program to generate the abundance estimates and their CVs are given below[2].

The *SLA* is provided with estimates of CV_{est} for each future sightings estimate. The estimate of $CV_{est,t}$ is given by:

$$\hat{C}V_{est,t} = \sqrt{\sigma_t^2 (\chi_n^2 / n)} \qquad \sigma_t^2 = \ell n(1 + E(CV_{est,t}^2)) \quad \text{(B1.5)}$$

$E(CV_{est,t}^2)$ is the sum of the squares of the actual CVs due to estimation error:

$$E(CV_{est,t}^2) = \theta^2 (a^2 + b^2 / w\beta^2) \quad \text{(B1.6)}$$

χ_n^2 is a random number from a χ^2 distribution with n (=19; the value assumed for the single stock trials for the RMP) degrees of freedom; and

a^2, b^2 are constants and equal to 0.02 and 0.012 respectively.

The relationship between CV_{est} and CV_{true} is given by:

$$\eta = [E(CV_{true}^2) - E(CV_{est}^2)] / (0.1 + 0.013 P^* / P) \quad \text{(B1.7)}$$

where η is a constant known as the additional variance factor. The value of η is based on the population size and CVs for year Ψ:

$$\eta = CV_{add}^2 / (0.1 + 0.013 P^* / P_\Psi) \quad \text{(B1.8)}$$

The values of α and β are then computed as:

$$\alpha^2 = \theta^2 a^2 + \eta \;\; 0.1, \qquad \beta^2 = \theta^2 b^2 + \eta \;\; 0.013 \quad \text{(B1.9)}$$

C. Need

The level of need supplied to the *SLA* is the total need for the 6-year period for which strike limits are to be set. The scenarios regarding need are listed in Table 4.

D. Trials

Table 4 lists all of the factors considered in the trials. The set of *Evaluation Trials* is given in Table 5 and the *Robustness Trials* in Table 6.

[2]The steps used to generate estimates of abundance and their CVs are as follows (steps (i)-(iii) are part of the conditioning process).

(i) Read in CV_{est} (Table 3). Generate values of CV_{add}^2 for year Ψ.

(ii) Set η using equation B1.8 and the value of CV_{add} from step (i).

(iii) Set θ^2 using equation B1.6 and the values for CV_{est} from step (i) and $w\beta^2 = P/P^* = P_{1968}/P^*$. Set α^2 and β^2 using equation B1.9.

(iv) Generate w (Poisson random variable – equation B1.4) and ϕ (lognormal random variable –equation B1.3).

(v) Set abundance estimate $\hat{S}$ using equation B1.1.

(vi) Generate $\hat{C}V_{est,t}$ from a χ_n^2 distribution using equation B1.5.

Table 4

Factors tested in the trials.

Factors	Levels (reference levels shown bold and underlined) Humpback whales	Bowhead whales
$MSYR_{1+}$	1%, 3%, **<u>5%</u>**, 7%	1%, **<u>2.5%</u>**, 4%
$MSYL_{1+}$	0.6	<u>0.6</u>, 0.8
Time dependence in K*	**<u>Constant</u>**, Halve linearly over 100yr	
Time dependence in natural mortality, M*	**<u>Constant,</u>** Double linearly over 100yr	
Episodic events*	**<u>None</u>**, 3 events occur between years 1-75 (with at least 2 in years 1-50) in which 20% of the animals die, Events occur every 5 years in which 5% of the animals die	
Need envelope	A: 10, 15, 20; 20 thereafter B: 10, 15, 20; 20->40 over years 18-100 C: 10, 15, 20; 20->60 over years 18-100 D: 20, 25, 30; 30->50 over years 18-100	**<u>A: 2, 3, 5; 5 thereafter</u>** B: 2, 3, 5; 5 -> 10 over years 18-100 C: 2, 3, 5; 5 -> 15 over years 18-100
Future Canadian catches	N/A	**<u>A: 5 constant over 100 years</u>** B: 5-> 10 over 100 years C: 5-> 15 over 100 years D: 2.5 constant over 100 years?
Survey frequency	5 yr, **<u>10 yr</u>**, 15 yr	
Historic survey bias	0.8, **<u>1.0</u>**, 1.2	0.5, **<u>1.0</u>**
First year of projection, τ	1960	1940
Alternative priors	$S_{1+} \sim U[0.9, 0.99]$; $f_{max} \sim U[0.4, 0.6]$; $a_m \sim U[5, 12]$	N/A
Strategic surveys	Extra survey if a survey estimate is half of the previous survey estimate	
Asymmetric environmental stochasticity parameters	To be finalised by an intersessional group	

*Effects of these factors begin in year 2013 (i.e. at start of management). The adult survival rate is adjusted so that in catches were zero, then average population sizes in 250-500 years equals the carrying capacity. *Note*: for some biological parameters and levels of episodic events, it may not be possible to find an adult survival rate which satisfies this requirement.

Table 5

The *Evaluation Trials*. Values given in bold type show differences from the base trial.

Trial	Description	$MSYR_{1+}$	Need scenarios	Survey freq.	Historic survey bias	Conditioning option

*Trial which needs to be conditioned.

F. Statistics

The risk- and recovery-related performance statistics are computed for the mature female and for the total (1+) population sizes (i.e. P_t is either the size of the mature female component of the population, N_t^f, or the size of the total (1+) population, N_t^{1+}). P_t^* is the population size in year t under a scenario of zero strikes over the years t≥2013 (defined as t=0 below) Note that incidental removals may still occur in the absence of strikes. To emphasize this distinction, $P_t^*(0)$ is used to denote the population size in year t under a scenario of zero strikes or removals of any kind, and $P_t^*(\text{inc})=P_t^*$ reflects the case when there are zero strikes but some incidental removals may occur. K^* is the population size in year t if there had never been any harvest or incidental removals???.

The trials are based on a 100-year time horizon, but a final decision regarding the time horizon will depend *inter alia* on interactions between the Committee and the Commission regarding need envelopes and on the period over which recovery might occur. To allow for this, results are calculated for T=20 and 100 (T^* denotes the number of blocks for a given T; T^* is 3 and 19 respectively for T=20 and T=100).

Statistics marked in bold face are considered the more important. Note that the statistic identification numbers have not been altered for reasons of consistency. Hence, there are gaps in the numbers where some statistics have been deleted.

F.1 Risk

D1. Final depletion: P_T/K. In trials with varying K this statistic is defined as P_T / K_t^*.

D2. Lowest depletion: $\min(P_t / K) : t = 0,1,...,T$. In trials with varying K this statistic is defined as $\min(P_t / K_t^*):\ t = 0,1,...,T$.

D6. Plots for simulations 1-100 of $\{P_t: t = 0,1,..,T\}$ and $\{P_t^*: t = 0,1,..,T\}$.

D7. Plots of $\{P_{t[x]}: t = 0,1,..,T\}$ and $\{P^*_{t[x]}: t = 0,1,..,T\}$ where $P_{t[x]}$ is the xth percentile of the distribution of P_t. Results are presented for x=5 and x=50.

D8. Rescaled final population: P_T / P_T^* . There are two versions of this statistic: D8(0)= $P_T / P_T^*(0)$ and D8(inc)= $P_T / P_T^*(\text{inc})$.

D9. Minimum population level: $\min(P_t)$: t=0,1,…,T.

D10. Relative increase P_T/P_0.

F.2 Need

N1. Total need satisfaction: $\sum_{t=0}^{T-1} C_t / \sum_{t=0}^{T-1} Q_t$

N2. Length of shortfall = (negative of the greatest number of consecutive years in which $C_b < Q_b$) / T^*, where C_b is the catch for block b, and Q_b is the total need for block b.

N4. Fraction of years in which $C_t = Q_t$

N7. Plot of $\{V_{t[x]} : t = 0, 1, T-1\}$ where $V_{t[x]}$ is the xth percentile of the distribution of $V_t = C_t / Q_t$

N8. Plots of V_t for simulations 1-100.

N9. Average need satisfaction: $\frac{1}{T}\sum_{t=0}^{T-1}\frac{C_t}{Q_t}$

N10. AAV (Average Annual Variation): $\sum_{b=0}^{T^*-1}\left|C_{b+1}-C_b\right| / \sum_{b=0}^{T^*-1}C_b$

N11. Anti-curvature: $\frac{1}{T^*-1}\sum_{b=0}^{T^*-2}\left|\frac{C_b-M_b}{\max\left(10,M_b\right)}\right|$ where $M_b=\left(C_{b+1}+C_{b-1}\right)/2$

N12. Mean downstep (or modified AAV): $\sum_{b=0}^{T^*-1}\left|\min\left(C_{b+1}-C_b,0\right)\right| / \sum_{b=0}^{T^*-1}C_b$

F.3 Recovery

R1. Relative recovery: $P_{t_r^*} / P_{t_r^*}^*$ where t_r^* is the first year in which P_t^* passes through *MSYL*. If P_t^* never reaches *MSYL*, the statistic is P_T / P_T^*. If P_0>*MSYL* the statistic is min (1, P_T/*MSYL*).

The following plots are to be produced to evaluate conditioning:

- Time-trajectories of 1+ population size in absolute terms and relative to carrying capacity, along with the fits to abundance estimates. This plot allows an evaluation of whether conditioning has been achieved satisfactorily.
- Histograms of the 100 parameter vectors for each trial. This plot allows an evaluation of whether and how conditioning has impacted the priors for these parameters.

International Convention

for the

Regulation of Whaling, 1946

Schedule

As amended by the Commission at the 66th Meeting

Portorož, Slovenia, October 2016

INTERNATIONAL
WHALING COMMISSION

International Convention

for the

Regulation of Whaling, 1946

Schedule

EXPLANATORY NOTES

The Schedule printed on the following pages contains the amendments made by the Commission at its 66th Meeting in October 2016. The amendments, which are shown in ***italic bold*** type, come into effect on 5 February 2017.
In Tables 1, 2 and 3 unclassified stocks are indicated by a dash. Other positions in the Tables have been filled with a dot to aid legibility.
Numbered footnotes are integral parts of the Schedule formally adopted by the Commission. Other footnotes are editorial.
The Commission was informed in June 1992 by the ambassador in London that the membership of the Union of Soviet Socialist Republics in the International Convention for the Regulation of Whaling from 1948 is continued by the Russian Federation.
The Commission recorded at its 39th (1987) meeting the fact that references to names of native inhabitants in Schedule paragraph 13(*b*)(4) would be for geographical purposes alone, so as not to be in contravention of Article V.2(c) of the Convention (*Rep. int. Whal. Commn* 38:21).

I. INTERPRETATION

1. The following expressions have the meanings respectively assigned to them, that is to say:

A. Baleen whales

"baleen whale" means any whale which has baleen or whale bone in the mouth, i.e. any whale other than a toothed whale.

"blue whale" (*Balaenoptera musculus*) means any whale known as blue whale, Sibbald's rorqual, or sulphur bottom, and including pygmy blue whale.

"bowhead whale" (*Balaena mysticetus*) means any whale known as bowhead, Arctic right whale, great polar whale, Greenland right whale, Greenland whale.

"Bryde's whale" (*Balaenoptera edeni*, *B. brydei*) means any whale known as Bryde's whale.

"fin whale" (*Balaenoptera physalus*) means any whale known as common finback, common rorqual, fin whale, herring whale, or true fin whale.

"gray whale" (*Eschrichtius robustus*) means any whale known as gray whale, California gray, devil fish, hard head, mussel digger, gray back, or rip sack.

"humpback whale" (*Megaptera novaeangliae*) means any whale known as bunch, humpback, humpback whale, humpbacked whale, hump whale or hunchbacked whale.

"minke whale" (*Balaenoptera acutorostrata*, *B. bonaerensis*) means any whale known as lesser rorqual, little piked whale, minke whale, pike-headed whale or sharp headed finner.

"pygmy right whale" (*Caperea marginata*) means any whale known as southern pygmy right whale or pygmy right whale.

"right whale" (*Eubalaena glacialis*, *E. australis*) means any whale known as Atlantic right whale, Arctic right whale, Biscayan right whale, Nordkaper, North Atlantic right whale, North Cape whale, Pacific right whale, or southern right whale.

"sei whale" (*Balaenoptera borealis*) means any whale known as sei whale, Rudolphi's rorqual, pollack whale, or coalfish whale.

B. Toothed whales

"toothed whale" means any whale which has teeth in the jaws.

"beaked whale" means any whale belonging to the genus Mesoplodon, or any whale known as Cuvier's beaked whale (*Ziphius cavirostris*), or Shepherd's beaked whale (*Tasmacetus shepherdi*).

"bottlenose whale" means any whale known as Baird's beaked whale (*Berardius bairdii*), Arnoux's whale (*Berardius arnuxii*), southern bottlenose whale (*Hyperoodon planifrons*), or northern bottlenose whale (*Hyperoodon ampullatus*).

"killer whale" (*Orcinus orca*) means any whale known as killer whale or orca.

"pilot whale" means any whale known as long-finned pilot whale (*Globicephala melaena*) or short-finned pilot whale (*G. macrorhynchus*).

"sperm whale" (*Physeter macrocephalus*) means any whale known as sperm whale, spermacet whale, cachalot or pot whale.

C. General

"strike" means to penetrate with a weapon used for whaling.

"land" means to retrieve to a factory ship, land station, or other place where a whale can be treated.

"take" means to flag, buoy or make fast to a whale catcher.

"lose" means to either strike or take but not to land.

"dauhval" means any unclaimed dead whale found floating.

"lactating whale" means (a) with respect to baleen whales - a female which has any milk present in a mammary gland, (b) with respect to sperm whales - a female which has milk present in a mammary gland the maximum thickness (depth) of which is 10cm or more. This measurement shall be at the mid ventral point of the mammary gland perpendicular to the body axis, and shall be logged to the nearest centimetre; that is to say, any gland between 9.5cm and 10.5cm shall be logged as 10cm. The measurement of any gland which falls on an exact 0.5 centimetre shall be logged at the next 0.5 centimetre, e.g. 10.5cm shall be logged as 11.0cm.

However, notwithstanding these criteria, a whale shall not be considered a lactating whale if scientific (histological or other biological) evidence is presented to the appropriate national authority establishing that the whale could not at that point in its physical cycle have had a calf dependent on it for milk.

"small-type whaling" means catching operations using powered vessels with mounted harpoon guns hunting exclusively for minke, bottlenose, beaked, pilot or killer whales.

II. SEASONS

Factory Ship Operations

2. (*a*) It is forbidden to use a factory ship or whale catcher attached thereto for the purpose of taking or treating baleen whales except minke whales, in any waters south of 40° South Latitude except during the period from 12th December to 7th April following, both days inclusive.

   (b) It is forbidden to use a factory ship or whale catcher attached thereto for the purpose of taking or treating sperm or minke whales, except as permitted by the Contracting Governments in accordance with sub-paragraphs (*c*) and (*d*) of this paragraph, and paragraph 5.

   (c) Each Contracting Government shall declare for all factory ships and whale catchers attached thereto under its jurisdiction, an open season or seasons not to exceed eight months out of any period of twelve months during which the taking or killing of sperm whales by whale catchers may be permitted; provided that a separate open season may be declared for each factory ship and the whale catchers attached thereto.

   (d) Each Contracting Government shall declare for all factory ships and whale catchers attached thereto under its jurisdiction one continuous open season not to exceed six months out of any period of twelve months during which the taking or killing of minke whales by the whale catchers may be permitted provided that:

   (1) a separate open season may be declared for each factory ship and the whale catchers attached thereto;

   (2) the open season need not necessarily include the whole or any part of the period declared for other baleen whales pursuant to sub-paragraph (*a*) of this paragraph.

3. It is forbidden to use a factory ship which has been used during a season in any waters south of 40° South Latitude for the purpose of treating baleen whales, except minke whales, in any other area except the North Pacific Ocean and its dependent waters north of the Equator for the same purpose within a period of one year from the termination of that season; provided that catch limits in the North Pacific Ocean and dependent waters are established as provided in paragraphs 12 and 16 of this Schedule and provided that this paragraph shall not apply to a ship which has been used during the season solely for freezing or salting the meat and entrails of whales intended for human food or feeding animals.

Land Station Operations

4. (*a*) It is forbidden to use a whale catcher attached to a land station for the purpose of killing or attempting to kill baleen and sperm whales except as permitted by the Contracting Government in accordance with sub-paragraphs (*b*), (*c*) and (*d*) of this paragraph.

   (b) Each Contracting Government shall declare for all land stations under its jurisdiction, and whale catchers attached to such land stations, one open season during which the taking or killing of baleen whales, except minke whales, by the whale catchers shall be permitted. Such open season shall be for a period of not more than six consecutive months in any period of twelve months and shall apply to all land stations under the jurisdiction of the Contracting Government; provided that a separate open season may be declared for any land station used for the taking or treating of baleen whales, except minke whales, which is more than 1,000 miles from the nearest land station used for the taking or treating of baleen whales, except minke whales, under the jurisdiction of the same Contracting Government.

   (c) Each Contracting Government shall declare for all land stations under its jurisdiction and for whale catchers attached to such land stations, one open season not to exceed eight continuous months in any one period of twelve months, during which the taking or killing of sperm whales by the whale catchers shall be permitted; provided that a separate open season may be declared for any land station used for the taking or treating of sperm whales which is more than 1,000 miles from the nearest land station used for the taking or treating of sperm whales under the jurisdiction of the same Contracting Government.

   (d) Each Contracting Government shall declare for all land stations under its jurisdiction and for whale catchers attached to such land stations one open season not to exceed six continuous months in any period of twelve months during which the taking or killing of minke whales by the whale catchers shall be permitted (such period not being necessarily concurrent with the period declared for other baleen whales, as provided for in sub-paragraph (*b*) of this paragraph); provided that a separate open season may be declared for any land station used for the taking or treating of minke whales which is more than 1,000 miles from the nearest land station used for the taking or treating of minke whales under the jurisdiction of the same Contracting Government.

   Except that a separate open season may be declared for any land station used for the taking or treating of minke whales which is located in an area having oceanographic conditions clearly distinguishable from those of the area in which are located the other land stations used for the taking or treating of minke whales under the jurisdiction of the same Contracting Government; but the declaration of a separate open season by virtue of the provisions of this sub-paragraph shall not cause thereby the period of time covering the open seasons declared by the same Contracting Government to exceed nine continuous months of any twelve months.

(e) The prohibitions contained in this paragraph shall apply to all land stations as defined in Article II of the Whaling Convention of 1946.

Other Operations

5. Each Contracting Government shall declare for all whale catchers under its jurisdiction not operating in conjunction with a factory ship or land station one continuous open season not to exceed six months out of any period of twelve months during which the taking or killing of minke whales by such whale catchers may be permitted. Notwithstanding this paragraph one continuous open season not to exceed nine months may be implemented so far as Greenland is concerned.

III. CAPTURE

6. The killing for commercial purposes of whales, except minke whales using the cold grenade harpoon shall be forbidden from the beginning of the 1980/81 pelagic and 1981 coastal seasons. The killing for commercial purposes of minke whales using the cold grenade harpoon shall be forbidden from the beginning of the 1982/83 pelagic and the 1983 coastal seasons.*

7. (*a*) In accordance with Article V(1)(*c*) of the Convention, commercial whaling, whether by pelagic operations or from land stations, is prohibited in a region designated as the Indian Ocean Sanctuary. This comprises the waters of the Northern Hemisphere from the coast of Africa to 100°E, including the Red and Arabian Seas and the Gulf of Oman; and the waters of the Southern Hemisphere in the sector from 20°E to 130°E, with the Southern boundary set at 55°S. This prohibition applies irrespective of such catch limits for baleen or toothed whales as may from time to time be determined by the Commission. This prohibition shall be reviewed by the Commission at its Annual Meeting in 2002.☼

(*b*) In accordance with Article V(1)(*c*) of the Convention, commercial whaling, whether by pelagic operations or from land stations, is prohibited in a region designated as the Southern Ocean Sanctuary. This Sanctuary comprises the waters of the Southern Hemisphere southwards of the following line: starting from 40 degrees S, 50 degrees W; thence due east to 20 degrees E; thence due south to 55 degrees S; thence due east to 130 degrees E; thence due north to 40 degrees S; thence due east to 130 degrees W; thence due south to 60 degrees S; thence due east to 50 degrees W; thence due north to the point of beginning. This prohibition applies irrespective of the conservation status of baleen and toothed whale stocks in this Sanctuary, as may from time to time be determined by the Commission. However, this prohibition shall be reviewed ten years after its initial adoption and at succeeding ten year intervals, and could be revised at such times by the Commission. Nothing in this sub-paragraph is intended to prejudice the special legal and political status of Antarctica.**+

Area Limits for Factory Ships

8. It is forbidden to use a factory ship or whale catcher attached thereto, for the purpose of taking or treating baleen whales, except minke whales, in any of the following areas:
   (a) in the waters north of 66°N, except that from 150°E eastwards as far as 140°W, the taking or killing of baleen whales by a factory ship or whale catcher shall be permitted between 66°N and 72°N;
   (b) in the Atlantic Ocean and its dependent waters north of 40°S;
   (c) in the Pacific Ocean and its dependent waters east of 150°W between 40°S and 35°N;
   (d) in the Pacific Ocean and its dependent waters west of 150°W between 40°S and 20°N;
   (e) in the Indian Ocean and its dependent waters north of 40°S.

Classification of Areas and Divisions

9. (*a*) *Classification of Areas*
   Areas relating to Southern Hemisphere baleen whales except Bryde's whales are those waters between the ice-edge and the Equator and between the meridians of longitude listed in Table 1.
   (b) *Classification of Divisions*
   Divisions relating to Southern Hemisphere sperm whales are those waters between the ice-edge and the Equator and between the meridians of longitude listed in Table 3.
   (c) *Geographical boundaries in the North Atlantic*
   The geographical boundaries for the fin, minke and sei whale stocks in the North Atlantic are:

FIN WHALE STOCKS

NOVA SCOTIA
South and West of a line through:
47°N 54°W, 46°N 54°30'W,
46°N 42°W, 20°N 42°W.

NEWFOUNDLAND-LABRADOR
West of a line through:
75°N 73°30'W, 69°N 59°W, 61°N 59°W,
52°20'N 42°W, 46°N 42°W and
North of a line through:
46°N 42°W, 46°N 54°30'W, 47°N 54°W.

WEST GREENLAND
East of a line through:
75°N 73°30'W, 69°N 59°W,
61°N 59°W, 52°20'N 42°W,
and West of a line through
52°20'N 42°W, 59°N 42°W,
59°N 44°W, Kap Farvel.

---

*The Governments of Brazil, Iceland, Japan, Norway and the Union of Soviet Socialist Republics lodged objections to the second sentence of paragraph 6 within the prescribed period. For all other Contracting Governments this sentence came into force on 8 March 1982. Norway withdrew its objection on 9 July 1985 and Brazil on 8 January 1992. Iceland withdrew from the Convention with effect from 30 June 1992. The objections of Japan and the Russian Federation not having been withdrawn, this sentence is not binding upon these governments.

☼At its 54th Annual Meeting in 2002, the Commission agreed to continue this prohibition but did not discuss whether or not it should set a time when it should be reviewed again.

**The Government of Japan lodged an objection within the prescribed period to paragraph 7(*b*) to the extent that it applies to the Antarctic minke whale stocks. The Government of the Russian Federation also lodged an objection to paragraph 7(*b*) within the prescribed period but withdrew it on 26 October 1994. For all Contracting Governments except Japan paragraph 7(*b*) came into force on 6 December 1994.

+Paragraph 7(*b*) contains a provision for review of the Southern Ocean Sanctuary "ten years after its initial adoption". Paragraph 7(*b*) was adopted at the 46th (1994) Annual Meeting. The first review was completed in 2004, and the second in 2016.

EAST GREENLAND-ICELAND
East of a line through:
Kap Farvel (South Greenland),
59°N 44°W, 59°N 42°W, 20°N 42°W,
and West of a line through:
20°N 18°W, 60°N 18°W, 68°N 3°E,
74°N 3°E, and South of 74°N.

NORTH NORWAY
North and East of a line through:
74°N 22°W, 74°N 3°E, 68°N 3°E,
67°N 0°, 67°N 14°E.

WEST NORWAY-FAROE ISLANDS
South of a line through:
67°N 14°E, 67°N 0°, 60°N 18°W,
and North of a line through:
61°N 16°W, 61°N 0°, Thyborøn
(Western entrance to Limfjorden, Denmark).

SPAIN-PORTUGAL-BRITISH ISLES
South of a line through:
Thyborøn (Denmark), 61°N 0°, 61°N 16°W,
and East of a line through:
63°N 11°W, 60°N 18°W, 22°N 18°W.

MINKE WHALE STOCKS
CANADIAN EAST COAST
West of a line through:
75°N 73°30'W, 69°N 59°W, 61°N 59°W,
52°20'N 42°W, 20°N 42°W.

CENTRAL
East of a line through:
Kap Farvel (South Greenland),
59°N 44°W, 59°N 42°W, 20°N 42°W,
and West of a line through:
20°N 18°W, 60°N 18°W, 68°N 3°E,
74°N 3°E, and South of 74°N.

WEST GREENLAND
East of a line through:
75°N 73°30'W, 69°N 59°W, 61°N 59°W,
52°20'N 42°W, and
West of a line through:
52°20'N 42°W, 59°N 42°W,
59°N 44°W, Kap Farvel.

NORTHEASTERN
East of a line through:
20°N 18°W, 60°N 18°W, 68°N 3°E, 74°N 3°E,
and North of a line through:
74°N 3°E, 74°N 22°W.

SEI WHALE STOCKS
NOVA SCOTIA
South and West of a line through:
47°N 54°W, 46°N 54°30'W, 46°N 42°W,
20°N 42°W.

ICELAND-DENMARK STRAIT
East of a line through:
Kap Farvel (South Greenland),
59°N 44°W, 59°N 42°W, 20°N 42°W,
and West of a line through:
20°N 18°W, 60°N 18°W, 68°N 3°E,
74°N 3°E, and South of 74°N.

EASTERN
East of a line through:
20°N 18°W, 60°N 18°W, 68°N 3°E, 74°N 3°E,
and North of a line through:
74°N 3°E, 74°N 22°W.

(d) *Geographical boundaries in the North Pacific*
The geographical boundaries for the sperm, Bryde's and minke whale stocks in the North Pacific are:

SPERM WHALE STOCKS
WESTERN DIVISION
West of a line from the ice-edge south along the 180° meridian of longitude to 180°, 50°N, then east along the 50°N parallel of latitude to 160°W, 50°N, then south along the 160°W meridian of longitude to 160°W, 40°N, then east along the 40°N parallel of latitude to 150°W, 40°N, then south along the 150°W meridian of longitude to the Equator.

EASTERN DIVISION
East of the line described above.

BRYDE'S WHALE STOCKS
EAST CHINA SEA
West of the Ryukyu Island chain.

EASTERN
East of 160°W (excluding the Peruvian stock area).

WESTERN
West of 160°W (excluding the East China Sea stock area).

MINKE WHALE STOCKS
SEA OF JAPAN-YELLOW SEA-EAST CHINA SEA
West of a line through the Philippine Islands, Taiwan, Ryukyu Islands, Kyushu, Honshu, Hokkaido and Sakhalin Island, north of the Equator.

OKHOTSK SEA-WEST PACIFIC
East of the Sea of Japan-Yellow Sea- East China Sea stock and west of 180°, north of the Equator.

REMAINDER
East of the Okhotsk Sea-West Pacific stock, north of the Equator.

(e) *Geographical boundaries for Bryde's whale stocks in the Southern Hemisphere*

SOUTHERN INDIAN OCEAN
20°E to 130°E,
South of the Equator.

SOLOMON ISLANDS
150°E to 170°E,
20°S to the Equator.

PERUVIAN
110°W to the South American coast,
10°S to 10°N.

EASTERN SOUTH PACIFIC
150°W to 70°W,
South of the Equator (excluding the Peruvian stock area).

WESTERN SOUTH PACIFIC
130°E to 150°W,
South of the Equator (excluding the Solomon Islands stock area).

SOUTH ATLANTIC
70°W to 20°E,
South of the Equator (excluding the South African inshore stock area).

SOUTH AFRICAN INSHORE
South African coast west of 27°E and out to the 200 metre isobath.

Classification of Stocks

10. All stocks of whales shall be classified in one of three categories according to the advice of the Scientific Committee as follows:

(a) A Sustained Management Stock (SMS) is a stock which is not more than 10 per cent of Maximum Sustainable Yield (hereinafter referred to as MSY) stock level below MSY stock level, and not more than 20 per cent above that level; MSY being determined on the basis of the number of whales.

When a stock has remained at a stable level for a considerable period under a regime of approximately constant catches, it shall be classified as a Sustained Management Stock in the absence of any positive evidence that it should be otherwise classified.

Commercial whaling shall be permitted on Sustained Management Stocks according to the advice of the Scientific Committee. These stocks are listed in Tables 1, 2 and 3 of this Schedule.

For stocks at or above the MSY stock level, the permitted catch shall not exceed 90 per cent of the MSY. For stocks between the MSY stock level and 10 per cent below that level, the permitted catch shall not exceed the number of whales obtained by taking 90 per cent of the MSY and reducing that number by 10 per cent for every 1 per cent by which the stock falls short of the MSY stock level.

(b) An Initial Management Stock (IMS) is a stock more than 20 per cent of MSY stock level above MSY stock level. Commercial whaling shall be permitted on Initial Management Stocks according to the advice of the Scientific Committee as to measures necessary to bring the stocks to the MSY stock level and then optimum level in an efficient manner and without risk of reducing them below this level. The permitted catch for such stocks will not be more than 90 per cent of MSY as far as this is known, or, where it will be more appropriate, catching effort shall be limited to that which will take 90 per cent of MSY in a stock at MSY stock level.

In the absence of any positive evidence that a continuing higher percentage will not reduce the stock below the MSY stock level no more than 5 per cent of the estimated initial exploitable stock shall be taken in any one year. Exploitation should not commence until an estimate of stock size has been obtained which is satisfactory in the view of the Scientific Committee. Stocks classified as Initial Management Stock are listed in Tables 1, 2 and 3 of this Schedule.

(c) A Protection Stock (PS) is a stock which is below 10 per cent of MSY stock level below MSY stock level.

There shall be no commercial whaling on Protection Stocks. Stocks so classified are listed in Tables 1, 2 and 3 of this Schedule.

(d) Notwithstanding the other provisions of paragraph 10 there shall be a moratorium on the taking, killing or treating of whales, except minke whales, by factory ships or whale catchers attached to factory ships. This moratorium applies to sperm whales, killer whales and baleen whales, except minke whales.

(e) Notwithstanding the other provisions of paragraph 10, catch limits for the killing for commercial purposes of whales from all stocks for the 1986 coastal and the 1985/86 pelagic seasons and thereafter shall be zero. This provision will be kept under review, based upon the best scientific advice, and by 1990 at the latest the Commission will undertake a comprehensive assessment of the effects of this decision on whale stocks and consider modification of this provision and the establishment of other catch limits.*•#

---

*The Governments of Japan, Norway, Peru and the Union of Soviet Socialist Republics lodged objection to paragraph 10(*e*) within the prescribed period. For all other Contracting Governments this paragraph came into force on 3 February 1983. Peru withdrew its objection on 22 July 1983. The Government of Japan withdrew its objections with effect from 1 May 1987 with respect to commercial pelagic whaling; from 1 October 1987 with respect to commercial coastal whaling for minke and Bryde's whales; and from 1 April 1988 with respect to commercial coastal sperm whaling. The objections of Norway and the Russian Federation not having been withdrawn, the paragraph is not binding upon these Governments.

•Iceland's instrument of adherence to the International Convention for the Regulation of Whaling and the Protocol to the Convention deposited on 10 October 2002 states that Iceland 'adheres to the aforesaid Convention and Protocol with a reservation with respect to paragraph 10(*e*) of the Schedule attached to the Convention'. The instrument further states the following:

> 'Notwithstanding this, the Government of Iceland will not authorise whaling for commercial purposes by Icelandic vessels before 2006 and, thereafter, will not authorise such whaling while progress is being made in negotiations within the IWC on the RMS. This does not apply, however, in case of the so-called moratorium on whaling for commercial purposes, contained in paragraph 10(*e*) of the Schedule not being lifted within a reasonable time after the completion of the RMS. Under no circumstances will whaling for commercial purposes be authorised without a sound scientific basis and an effective management and enforcement scheme.'

#The Governments of Argentina, Australia, Brazil, Chile, Finland, France, Germany, Italy, Mexico, Monaco, the Netherlands, New Zealand, Peru, San Marino, Spain, Sweden, UK and the USA have lodged objections to Iceland's reservation to paragraph 10(*e*).

[1]Available to be taken by aborigines or a Contracting Government on behalf of aborigines pursuant to paragraph 13*(b)*2.

[2]Available to be struck by aborigines pursuant to paragraph 13*(b)*3. Catch limit for each of the years 2015, 2016, 2017 and 2018.

[+]The catch limits of zero introduced into Table 1 as editorial amendments as a result of the coming into effect of paragraph 10*(e)* are not binding upon the governments of the countries which lodged and have not withdrawn objections to the said paragraph.

*The Government of Norway presented objection to the classification of the Northeastern Atlantic stock of minke whales as a Protection Stock within the prescribed period. This classification came into force on 30 January 1986 but is not binding on the Government of Norway.

▲The Government of the Czech Republic lodged an objection within the prescribed period to the amendments to the Schedule arising from the 64th and 65th Meeting of the Commission.

Baleen Whale Catch Limits

11. The number of baleen whales taken in the Southern Hemisphere in the ***2016/2017*** pelagic season and the ***2017*** coastal season shall not exceed the limits shown in Tables 1 and 2.▲
12. The number of baleen whales taken in the North Pacific Ocean and dependent waters in ***2017*** and in the North Atlantic Ocean in ***2017*** shall not exceed the limits shown in Tables 1 and 2.▲
13. (*a*) Notwithstanding the provisions of paragraph 10, catch limits for aboriginal subsistence whaling to satisfy aboriginal subsistence need for the 1984 whaling season and each whaling season thereafter shall be established in accordance with the following principles:
    - (1) For stocks at or above MSY level, aboriginal subsistence catches shall be permitted so long as total removals do not exceed 90 per cent of MSY.
    - (2) For stocks below the MSY level but above a certain minimum level, aboriginal subsistence catches shall be permitted so long as they are set at levels which will allow whale stocks to move to the MSY level.[1]
    - (3) The above provisions will be kept under review, based upon the best scientific advice, and by 1990 at the latest the Commission will undertake a comprehensive assessment of the effects of these provisions on whale stocks and consider modification.
    - (4) For aboriginal whaling conducted under subparagraphs (*b*)(1), (*b*)(2), and (*b*)(3) of this paragraph, it is forbidden to strike, take or kill calves or any whale accompanied by a calf. For aboriginal whaling conducted under subparagraphs (*b*)(4) of this paragraph, it is forbidden to strike, take or kill suckling calves or female whales accompanied by calves.
    - (5) All aboriginal whaling shall be conducted under national legislation that accords with this paragraph.

    (b) Catch limits for aboriginal subsistence whaling are as follows:
    - (1) The taking of bowhead whales from the Bering-Chukchi-Beaufort Seas stock by aborigines is permitted, but only when the meat and products of such whales are to be used exclusively for local consumption by the aborigines and further provided that:
        - (i) For the years 2013, 2014, 2015, 2016 2017 and 2018, the number of bowhead whales landed shall not exceed 336. For each of these years the number of bowhead whales struck shall not exceed 67, except that any unused portion of a strike quota from any year (including 15 unused strikes from the 2008-2012 quota) shall be carried forward and added to the strike quotas of any subsequent years, provided that no more than 15 strikes shall be added to the strike quota for any one year.▲
        - (ii) This provision shall be reviewed annually by the Commission in light of the advice of the Scientific Committee.
    - (2) The taking of gray whales from the Eastern stock in the North Pacific is permitted, but only by aborigines or a Contracting Government on behalf of aborigines, and then only when the meat and products of such whales are to be used exclusively for local consumption by the aborigines.
        - (i) For the years 2013, 2014, 2015, 2016, 2017 and 2018, the number of gray whales taken in accordance with this sub-paragraph shall not exceed 744, provided that the number of gray whales taken in any one of the years 2013, 2014, 2015, 2016, 2017 and 2018 shall not exceed 140.▲
        - (ii) This provision shall be reviewed annually by the Commission in light of the advice of the Scientific Committee.
    - (3) The taking by aborigines of minke whales from the West Greenland and Central stocks and fin whales from the West Greenland stock and bowhead whales from the West Greenland feeding aggregation and humpback whales from the West Greenland feeding aggregation is permitted and then only when the meat and products are to be used exclusively for local consumption.
        - (i) The number of fin whales struck from the West Greenland stock in accordance with this sub-paragraph shall not exceed 19 in each of the years 2015, 2016, 2017 and 2018.
        - (ii) The number of minke whales struck from the Central stock in accordance with this sub-paragraph shall not exceed 12 in each of the years 2015, 2016, 2017, and 2018, except that any unused portion of the quota for each year shall be carried forward from that year and added to the quota of any subsequent years, provided that no more than 3 shall be added to the quota for any one year.
        - (iii) The number of minke whales struck from the West Greenland stock shall not exceed 164 in each of the years 2015, 2016, 2017 and 2018, except that any unused portion of the quota for each year shall be carried forward from that year and added to the strike quota of any of the subsequent years, provided

▲See footnote to Table 1.

[1]The Commission, on advice of the Scientific Committee, shall establish as far as possible (a) a minimum stock level for each stock below which whales shall not be taken, and (b) a rate of increase towards the MSY level for each stock. The Scientific Committee shall advise on a minimum stock level and on a range of rates of increase towards the MSY level under different catch regimes.

that no more than 15 strikes shall be added to the strike quota for any one year. This provision will be reviewed if new scientific data become available within the 4 year period and if necessary amended on basis of the advice of the Scientific Committee.

(iv) The number of bowhead whales struck off West Greenland in accordance with this sub-paragraph shall not exceed 2 in each of the years 2015, 2016, 2017 and 2018, except that any unused portion of the quota for each year shall be carried forward from that year and added to the quota of any subsequent years, provided that no more than 2 shall be added to the quota for any one year. This provision will be reviewed if new scientific data become available within the 4 year period and if necessary amended on basis of the advice of the Scientific Committee.

(v) The number of humpback whales struck off West Greenland in accordance with this sub-paragraph shall not exceed 10 in each of the years 2015, 2016, 2017 and 2018, except that any unused portion of the quota for each year shall be carried forward from that year and added to the strike quota of any of the subsequent years, provided that no more than 2 strikes shall be added to the strike quota for any one year. This provision will be reviewed if new scientific data become available within the remaining quota period and if necessary amended on the basis of the advice of the Scientific Committee.

(4) For the seasons 2013-2018 the number of humpback whales to be taken by the Bequians of St. Vincent and The Grenadines shall not exceed 24. The meat and products of such whales are to be used exclusively for local consumption in St. Vincent and The Grenadines.▲

14. It is forbidden to take or kill suckling calves or female whales accompanied by calves.

Baleen Whale Size Limits

15. (*a*) It is forbidden to take or kill any sei or Bryde's whales below 40 feet (12.2 metres) in length except that sei and Bryde's whales of not less than 35 feet (10.7 metres) may be taken for delivery to land stations, provided that the meat of such whales is to be used for local consumption as human or animal food.

(*b*) It is forbidden to take or kill any fin whales below 57 feet (17.4 metres) in length in the Southern Hemisphere, and it is forbidden to take or kill fin whales below 55 feet (16.8 metres) in the Northern Hemisphere; except that fin whales of not less than 55 feet (16.8 metres) may be taken in the Southern Hemisphere for delivery to land stations and fin whales of not less than 50 feet (15.2 metres) may be taken in the Northern Hemisphere for delivery to land stations, provided that, in each case the meat of such whales is to be used for local consumption as human or animal food.

Sperm Whale Catch Limits

16. Catch limits for sperm whales of both sexes shall be set at zero in the Southern Hemisphere for the 1981/82 pelagic season and 1982 coastal seasons and following seasons, and at zero in the Northern Hemisphere for the 1982 and following coastal seasons; except that the catch limits for the 1982 coastal season and following seasons in the Western Division of the North Pacific shall remain undetermined and subject to decision by the Commission following special or annual meetings of the Scientific Committee. These limits shall remain in force until such time as the Commission, on the basis of the scientific information which will be reviewed annually, decides otherwise in accordance with the procedures followed at that time by the Commission.

17. It is forbidden to take or kill suckling calves or female whales accompanied by calves.

Sperm Whale Size Limits

18. (*a*) It is forbidden to take or kill any sperm whales below 30 feet (9.2 metres) in length except in the North Atlantic Ocean where it is forbidden to take or kill any sperm whales below 35 feet (10.7 metres).

(b) It is forbidden to take or kill any sperm whale over 45 feet (13.7 metres) in length in the Southern Hemisphere north of 40° South Latitude during the months of October to January inclusive.

(c) It is forbidden to take or kill any sperm whale over 45 feet (13.7 metres) in length in the North Pacific Ocean and dependent waters south of 40° North Latitude during the months of March to June inclusive.

IV. TREATMENT

19. (*a*) It is forbidden to use a factory ship or a land station for the purpose of treating any whales which are classified as Protection Stocks in paragraph 10 or are taken in contravention of paragraphs 2, 3, 4, 5, 6, 7, 8, 11, 12, 14, 16 and 17 of this Schedule, whether or not taken by whale catchers under the jurisdiction of a Contracting Government.

(b) All other whales taken, except minke whales, shall be delivered to the factory ship or land station and all parts of such whales shall be processed by boiling or otherwise, except the internal organs, whale bone and flippers of all whales, the meat of sperm whales and parts of whales intended for human food or feeding animals. A Contracting Government may in less developed regions exceptionally permit treating of whales without use of land stations, provided that such whales are fully utilised in accordance with this paragraph.

(c) Complete treatment of the carcases of "dauhval" and of whales used as fenders will not be required in cases where the meat or bone of such whales is in bad condition.

▲See footnote to Table 1.

20. (*a*) The taking of whales for treatment by a factory ship shall be so regulated or restricted by the master or person in charge of the factory ship that no whale carcase (except of a whale used as a fender, which shall be processed as soon as is reasonably practicable) shall remain in the sea for a longer period than thirty-three hours from the time of killing to the time when it is hauled up for treatment.

(*b*) Whales taken by all whale catchers, whether for factory ships or land stations, shall be clearly marked so as to identify the catcher and to indicate the order of catching.

V. SUPERVISION AND CONTROL

21. (*a*) There shall be maintained on each factory ship at least two inspectors of whaling for the purpose of maintaining twenty-four hour inspection provided that at least one such inspector shall be maintained on each catcher functioning as a factory ship. These inspectors shall be appointed and paid by the Government having jurisdiction over the factory ship; provided that inspectors need not be appointed to ships which, apart from the storage of products, are used during the season solely for freezing or salting the meat and entrails of whales intended for human food or feeding animals.

(b) Adequate inspection shall be maintained at each land station. The inspectors serving at each land station shall be appointed and paid by the Government having jurisdiction over the land station.

(c) There shall be received such observers as the member countries may arrange to place on factory ships and land stations or groups of land stations of other member countries. The observers shall be appointed by the Commission acting through its Secretary and paid by the Government nominating them.

22. Gunners and crews of factory ships, land stations, and whale catchers, shall be engaged on such terms that their remuneration shall depend to a considerable extent upon such factors as the species, size and yield of whales and not merely upon the number of the whales taken. No bonus or other remuneration shall be paid to the gunners or crews of whale catchers in respect of the taking of lactating whales.

23. Whales must be measured when at rest on deck or platform after the hauling out wire and grasping device have been released, by means of a tape-measure made of a non-stretching material. The zero end of the tape-measure shall be attached to a spike or stable device to be positioned on the deck or platform abreast of one end of the whale. Alternatively the spike may be stuck into the tail fluke abreast of the apex of the notch. The tape-measure shall be held taut in a straight line parallel to the deck and the whale's body, and other than in exceptional circumstances along the whale's back, and read abreast of the other end of the whale. The ends of the whale for measurement purposes shall be the tip of the upper jaw, or in sperm whales the most forward part of the head, and the apex of the notch between the tail flukes.

Measurements shall be logged to the nearest foot or 0.1 metre. That is to say, any whale between 75 feet 6 inches and 76 feet 6 inches shall be logged as 76 feet, and any whale between 76 feet 6 inches and 77 feet 6 inches shall be logged as 77 feet. Similarly, any whale between 10.15 metres and 10.25 metres shall be logged as 10.2 metres, and any whale between 10.25 metres and 10.35 metres shall be logged as 10.3 metres. The measurement of any whale which falls on an exact half foot or 0.05 metre shall be logged at the next half foot or 0.05 metre, e.g. 76 feet 6 inches precisely shall be logged as 77 feet and 10.25 metres precisely shall be logged as 10.3 metres.

VI. INFORMATION REQUIRED

24. (*a*) All whale catchers operating in conjunction with a factory ship shall report by radio to the factory ship:
(1) the time when each whale is taken
(2) its species, and
(3) its marking effected pursuant to paragraph 20(*b*).

(b) The information specified in sub-paragraph (*a*) of this paragraph shall be entered immediately by a factory ship in a permanent record which shall be available at all times for examination by the whaling inspectors; and in addition there shall be entered in such permanent record the following information as soon as it becomes available:
(1) time of hauling up for treatment
(2) length, measured pursuant to paragraph 23
(3) sex
(4) if female, whether lactating
(5) length and sex of foetus, if present, and
(6) a full explanation of each infraction.

(c) A record similar to that described in sub-paragraph (*b*) of this paragraph shall be maintained by land stations, and all of the information mentioned in the said sub-paragraph shall be entered therein as soon as available.

(d) A record similar to that described in sub-paragraph (*b*) of this paragraph shall be maintained by "small-type whaling" operations conducted from shore or by pelagic fleets, and all of this information mentioned in the said sub-paragraph shall be entered therein as soon as available.

25. (*a*) All Contracting Governments shall report to the Commission for all whale catchers operating in conjunction with factory ships and land stations the following information:
(1) methods used to kill each whale, other than a harpoon, and in particular compressed air;
(2) number of whales struck but lost.

(b) A record similar to that described in sub-paragraph (a) of this paragraph shall be maintained by vessels engaged in "small-type whaling" operations and by native peoples taking species listed in paragraph 1, and all the information mentioned in the said sub-paragraph shall be entered therein as soon as available, and forwarded by Contracting Governments to the Commission.

26. (*a*) Notification shall be given in accordance with the provisions of Article VII of the Convention, within two days after the end of each calendar week, of data on the number of baleen whales

by species taken in any waters south of 40° South Latitude by all factory ships or whale catchers attached thereto under the jurisdiction of each Contracting Government, provided that when the number of each of these species taken is deemed by the Secretary to the International Whaling Commission to have reached 85 per cent of whatever total catch limit is imposed by the Commission notification shall be given as aforesaid at the end of each day of data on the number of each of these species taken.

(b) If it appears that the maximum catches of whales permitted by paragraph 11 may be reached before 7 April of any year, the Secretary to the International Whaling Commission shall determine, on the basis of the data provided, the date on which the maximum catch of each of these species shall be deemed to have been reached and shall notify the master of each factory ship and each Contracting Government of that date not less than four days in advance thereof. The taking or attempting to take baleen whales, so notified, by factory ships or whale catchers attached thereto shall be illegal in any waters south of 40° South Latitude after midnight of the date so determined.

(c) Notification shall be given in accordance with the provisions of Article VII of the Convention of each factory ship intending to engage in whaling operations in any waters south of 40° South Latitude.

27. Notification shall be given in accordance with the provisions of Article VII of the Convention with regard to all factory ships and catcher ships of the following statistical information:

(a) concerning the number of whales of each species taken, the number thereof lost, and the number treated at each factory ship or land station, and

(b) as to the aggregate amounts of oil of each grade and quantities of meal, fertiliser (guano), and other products derived from them, together with

(c) particulars with respect to each whale treated in the factory ship, land station or "small-type whaling" operations as to the date and approximate latitude and longitude of taking, the species and sex of the whale, its length and, if it contains a foetus, the length and sex, if ascertainable, of the foetus.

The data referred to in (*a*) and (*c*) above shall be verified at the time of the tally and there shall also be notification to the Commission of any information which may be collected or obtained concerning the calving grounds and migration of whales.

28. (*a*) Notification shall be given in accordance with the provisions of Article VII of the Convention with regard to all factory ships and catcher ships of the following statistical information:

(1) the name and gross tonnage of each factory ship,

(2) for each catcher ship attached to a factory ship or land station:

(i) the dates on which each is commissioned and ceases whaling for the season,

(ii) the number of days on which each is at sea on the whaling grounds each season,

(iii) the gross tonnage, horsepower, length and other characteristics of each; vessels used only as tow boats should be specified.

(3) A list of the land stations which were in operation during the period concerned, and the number of miles searched per day by aircraft, if any.

(*b*) The information required under paragraph (*a*)(2)(iii) should also be recorded together with the following information, in the log book format shown in Appendix A, and forwarded to the Commission:

(1) where possible the time spent each day on different components of the catching operation,

(2) any modifications of the measures in paragraphs (*a*)(2)(i)-(iii) or (*b*)(1) or data from other suitable indicators of fishing effort for "small-type whaling" operations.

29. (*a*) Where possible all factory ships and land stations shall collect from each whale taken and report on:

(1) both ovaries or the combined weight of both testes,

(2) at least one ear plug, or one tooth (preferably first mandibular).

(b) Where possible similar collections to those described in sub-paragraph (*a*) of this paragraph shall be undertaken and reported by "small-type whaling" operations conducted from shore or by pelagic fleets.

(c) All specimens collected under sub-paragraphs (*a*) and (*b*) shall be properly labelled with platform or other identification number of the whale and be appropriately preserved.

(d) Contracting Governments shall arrange for the analysis as soon as possible of the tissue samples and specimens collected under sub-paragraphs (a) and (*b*) and report to the Commission on the results of such analyses.

30. A Contracting Government shall provide the Secretary to the International Whaling Commission with proposed scientific permits before they are issued and in sufficient time to allow the Scientific Committee to review and comment on them. The proposed permits should specify:

(a) objectives of the research;

(b) number, sex, size and stock of the animals to be taken;

(c) opportunities for participation in the research by scientists of other nations; and

(d) possible effect on conservation of stock.

Proposed permits shall be reviewed and commented on by the Scientific Committee at Annual Meetings when possible. When permits would be granted prior to the next Annual Meeting, the Secretary shall send the proposed permits to members of the Scientific Committee by mail for their comment and review. Preliminary results of any research resulting from the permits should be made available at the next Annual Meeting of the Scientific Committee.

31. A Contracting Government shall transmit to the Commission copies of all its official laws and regulations relating to whales and whaling and changes in such laws and regulations.

INTERNATIONAL CONVENTION FOR THE REGULATION OF WHALING, 1946
SCHEDULE APPENDIX A

TITLE PAGE
(one logbook per catcher per season)

Catcher name…………………………………………… Year built…………………………………………

Attached to expedition/land station ………………………………………………………………………

Season…………………………………………………

Overall length…………………………………………… Wooden/steel hull………………………………

Gross tonnage……………………………………………

Type of engine..………………………………………… H.P. ………………………………………………

Maximum speed………………………………………… Average searching speed…………………………

Asdic set, make and model no.……………………………………………………………………………

Date of installation………………………………………

Make and size of cannon…………………………………………………………………………………

Type of first harpoon used……………………………… Explosive/electric/non-explosive

Type of killer harpoon used………………………………………………………………………………

Length and type of forerunner……………………………………………………………………………

Type of whaleline…………………………………………………………………………………………

Height of barrel above sea level…………………………

Speedboat used, Yes/No

Name of Captain…………………………………………………………………………………………

Number of years experience……………………………

Name of gunner……………………………………………………………………………………………

Number of years experience……………………………

Number of crew…………………………………………

INTERNATIONAL CONVENTION FOR THE REGULATION OF WHALING, 1946

DAILY RECORD SHEET TABLE 1

Date .... Catcher name .... Sheet No.............

Searching: Time started (or resumed) searching
*Time whales seen or reported to catcher
Whale species
Number seen and no. of groups
Position found
Name of catcher that found whales

Chasing: Time started chasing (or confirmed whales)
Time whale shot or chasing discontinued
Asdic used (Yes/No)

Handling: Time whale flagged or alongside for towing
Serial No. of catch

Towing: Time started picking up
Time finished picking up or started towing
Date and time delivered to factory

Resting: Time stopped (for drifting or resting)
Time finished drifting/resting
Time ceased operations

WEATHER CONDITIONS

	Time	Sea state	Wind force and direction	Visibility
Total searching time............................				
Total chasing time				
A) with asdic				
B) without asdic				
Total handling time				
Total towing time				
Total resting time				
Other time (e.g. bunkering, in port)				

Whales Seen (No. and No. of schools)

Blue..	Bryde's
Fin..	Minke
Humpback.......................................	Sperm ....
Right..	Others (specify)
Sei..	....
Signed...	....

*Time whales reported to catcher means the time when the catcher is told of the position of a school and starts to move towards it to chase it. .

SCHEDULE APPENDIX A

SCHOOLING REPORT TABLE 2

To be completed by pelagic expedition or coastal station for each sperm whale school chased. A separate form to be used each day.

Name of expedition or coastal station

Date Noon position of factory ship

Time School Found

Total Number of Whales in School

Number of Takeable Whales in School

Number of Whales Caught from School by each Catcher

Name of Catcher

Name of Catcher

Name of Catcher ....

Name of Catcher

Total Number Caught from School

Remarks:

Explanatory Notes

A. Fill in one column for each school chased with number of whales caught by each catcher taking part in the chase; if catchers chase the school but do not catch from it, enter O; for catchers in fleet which do not chase that school enter X.

B. A school on this form means a group of whales which are sufficiently close together that a catcher having completed handling one whale can start chasing another whale almost immediately without spending time searching. A solitary whale should be entered as a school of 1 whale.

C. A takeable whale is a whale of a size or kind which the catchers would take if possible. It does not necessarily include all whales above legal size, e.g. if catchers are concentrating on large whales only these would be counted as takeable.

D. 1nformation about catchers from other expeditions or companies operating on the same school should be recorded under Remarks.

SC/67B/REP/07 Rev1

Fifth Rangewide Workshop on the Status of North Pacific Gray Whales

IWC

INTERNATIONAL WHALING COMMISSION

Fifth Rangewide Workshop on the Status of North Pacific Gray Whales[1]

1. INTRODUCTORY ITEMS

1.1 Convenors' opening remarks
The Workshop was held at the Granite Canyon Laboratory (Big Sur, California) of the Southwest Fisheries Science Center from 28-31 March 2018. The list of participants is given as Annex A. Brownell welcomed the participants and explained the history of the facility, which has been used for almost five decades to census gray whales during their southbound migration. Donovan and Punt (co-convenors) noted that the primary tasks of the workshop were to review the results of the modelling work identified at the Fourth Workshop and SC67a, to examine the new proposed Makah Management Plan (submitted by the USA on gray whaling off Washington state and to update as possible (and develop a workplan for) updating the scientific components of the Conservation Management Plan (CMP) for western gray whales.

1.2 Election of Chair
Donovan and Punt were elected Chairs (Donovan chaired from the 28-30 March and Punt on 31 March).

1.3 Appointment of rapporteurs
Calambokidis, Cooke, Lang, Punt, Reeves, Scordino and Weller served as rapporteurs.

1.4 Adoption of Agenda
The Adopted agenda is given as Annex B.

1.5 Documents and data available
The documents available to the meeting are listed in Annex C. Annex D summarizes the terminology used to designate breeding stocks and feeding aggregations.

2. PROGRESS ON 'NON-MODELLING' RECOMMENDATIONS AND NEW DATA

2.1 Updated information from co-operative genetics studies
Bickham presented the results of a multi-authored study of SNPs using samples from approximately 50 whales feeding off Sakhalin Island ('western' gray whales) and approximately 100 whales from the Mexican wintering grounds (assumed 'eastern' gray whales); the full study was to be presented at SC67a. The methods used are described in DeWoody *et al.* (2017). Bickham stated that a finished version of the paper will be presented at the 2018 IWC SC meeting. The authors believe that the results will have implications for prioritising the various stock structure hypotheses being modelled in the Rangewide Review (see below).

Multiple duplicate biopsies were found within both the Sakhalin and Mexico sample sets, but none were shared between the two localities. SNP genotypes were also presented for two mitochondrial and two sex-linked loci (Zfx and Zfy). One of the sex-linked SNPs (ZFY_342) had an apparent fixed heterozygosity in the Mexican whales and thus only the second locus could be used for determining the sex of the whales. The Workshop noted that whilst there is no single explanation of this, one possibility is that there was a translocation (duplication) of the Y-linked SNP to the X or to an autosome.

Bickham also presented the results of the STRUCTURE analyses for the SNPs. In the cases with locality as a prior and without locality as a prior, $K = 2$ genomes (or populations) was the best solution; the plot with geography as a prior showed better differentiation with one predominating in the east (Mexico) and the other predominated in the west (Sakhalin). All eastern samples showed admixed ancestry (including some with predominantly the "western" genome) but the western samples showed a much higher proportion of admixture including individuals of nearly 'pure' eastern and western genomes. He also presented results for an analytical approach called Landscape and Ecological Associations (LEA)[2]. The LEA analysis also identified K = 2 genomes but with greater separation. In the Sakhalin sample set the western genome still predominated but there were both individuals with pure western and others with pure eastern genomes as well as admixed individuals. The more equal proportions

[1] Not all attendees have had a chance to comment on this final version although much of the report was agreed at the Workshop itself.

[2] http://membres-timc.imag.fr/Olivier.Francois/LEA/tutorial.htm

of western and eastern genomes in the Sakhalin samples was consistent with an Mxy estimate of genetic similarity (the Sakhalin sample set had a notably higher variance for genetic relatedness between paired samples than was observed in the Mexican sample set).

The authors of the working paper concluded that the Sakhalin population might be comprised of two types of individuals representing two breeding stocks (i.e., two different genomes), along with individuals of mixed ancestry (admixture). The proportions of the two genomes are vastly different in the two sample sets.

The Workshop **agreed** that incorporating photo-id data into the genetic results will greatly improve interpretation of stock structure and movements and **recommended** that the genetic dataset should be examined comparing whales seen only once off Sakhalin with those whales seen in multiple years.

Lang gave a brief update of her work on SNPs, using the next-generation sequencing approach ddRAD. She is analysing approximately 200 gray whales representing approximately equal sample sizes of PCFG (Pacific Coast Feeding Group), western gray whales, and Northern Feeding Group whales. She expects to present the results of at the 2019 gray whale *Implementation Review.*

The Workshop **welcomed** news from Bickham that a request to the government of Japan to obtain gray whale samples for genetics studies (including of the possible extant western breeding stock).

It was noted that the extent of mixing of gray whales in the past had probably fluctuated in response to changes in sea ice (glacial versus interglacial periods). Bickham responded that additional genome sequencing was planned and that the reconstruction of the historical demography of western and eastern gray whales is one goal of that study. Analyses may reveal associations with the climate cycles of the Pleistocene.

2.2 Updated information from photo-identification studies including consolidation of WGW catalogues

SC/MP/CMP/02 reviewed the results of long-term photo-identification studies conducted between 2002-2017 off northeast Sakhalin Island by the Joint Monitoring Program of two oil and gas companies[3]. The photo-identification catalogue resulting from this work contains 283 identified individual gray whales, including: (a) 175 whales that use the Sakhalin Island feeding area on a regular annual, (b) 27 occasionally-sighted whales (recorded at intervals greater than 3 years), and (c) 71 individuals that have been recorded only once. Forty-eight of the one-time visitors were recorded as calves, excluding the nine calves first identified in 2017. There are 29 identified mothers and 127 whales first identified as calves in the catalogue. Six mother-calf pairs were identified in 2017, along with three unpaired calves. Whale no. KOGW127 (aka “Agent”), was identified as a calf in 2005 and was first recorded as a mother in 2017 at the age of 12 years. Agent was satellite tagged in 2011 and her winter migration was tracked to the Gulf of Alaska before the transponder stopped working (Mate et al., 2015).

Drone-based photography was incorporated into the joint-programme field program in 2017. In most cases, the drone was used at an average distance of about 800 m from shore with a standard altitude of 8 meters. The range of the drone presently in use is 2.5 km from the shore. With the collection of aerial photographs from drones, a new body aspect (“back”) was added to the photo-identification catalogue. Also, a new supplemental catalogue of drone-collected video was created for 35 individuals.

The catalogues of the ENL-SEIC joint programme and the Russian Gray Whale Programme (previously the Russia-US programme) were last cross-matched using data available through 2011. At that time, the two Sakhalin photo-identification catalogues contained a total of 222 whales, of which 186 were common to both. Seventeen whales were found only in the Russian Gray Whale Programme catalogue and 19 only in the ENL-SEIC catalogue (IUCN, 2013). An updated catalogue comparison, under the auspices of the IWC, is being discussed as is the concept of a common shared catalogue and database.

In discussion, the Workshop **agreed** on the importance of the long-term nature of the research programmes being conducted off Sakhalin. The concept of a common catalogue and database was welcomed and several measures to ensure data compatibility were mentioned, including the important step to standardize reporting of effort and protocols used to designate calves versus yearlings. It was further mentioned that sighting histories of whales photo-identified off Kamchatka should be evaluated to determine patterns of annual occurrence. Finally, the availability of a shared catalogue and regular updating of such was highlighted with respect to the research component of the hunt management plan proposed for the Makah hunt.

2.3 Gray whales off Korea

SC/M18/CMP/04 reported the possible occurrence of a gray whale off Korea in 2015. Video footage of what appears to be a gray whale was uploaded on YouTube in 2015[4]. The whale was swimming near a port facility in

[3] Exxon Neftegas Limited (ENL) and Sakhalin Energy Investment Company (SEIC)

[4] https://www.youtube.com/watch?v=dJ4J7luGgcE

Samcheok, on the east coast of Korea. While the poor quality of the video prevented positive identification to species, some features of the whale suggest that it was a gray whale. Additional information is being sought to confirm the species identification. If this sighting was indeed of a gray whale, it would be the first record from Korea since 1977. The Workshop thanked D. Yasutaka Imai for alerting Kim to the existence of this video.

3. UPDATING SCIENTIFIC ASPECTS OF THE CMP

Donovan reported recent progress on the "Rangewide Review of the Status of North Pacific Gray Whales" and the 'Western Gray Whale Conservation Management Plan' (CMP). Since 2004, the IUCN and IWC have emphasized the need for a comprehensive international CMP to mitigate anthropogenic threats facing gray whales throughout their range in the western North Pacific. This CMP was initiated at an IUCN-convened international workshop in Tokyo in summer 2008 (IUCN 2009). A draft of the CMP was completed in 2010 (Brownell *et al.* 2010) and this was endorsed by both the IWC and IUCN. The first successes of the CMP included completion of a telemetry project conducted off Sakhalin and a Pacific-wide photo-identification catalogue comparison. The results of these projects showed that some of the whales sighted off Sakhalin in the summer migrate east, across the Pacific, reaching portions of the North American coast between British Columbia, Canada and the wintering lagoons off Baja California, Mexico. In light of this new information, the IWC has been engaged in the present rangewide review.

In support of the CMP initiative, in 2014 a 'Memorandum of Cooperation Concerning Conservation Measures for the Western Gray Whale Population' (the MoC), was signed by Japan, Russian Federation and the USA. In 2016, the memorandum was signed by Mexico and the Republic of Korea and Prof. Hidehiro Kato of the Tokyo University of Marine Science and Technology was appointed as coordinator of the memorandum. It is hoped that in time the other remaining range states will also sign the memorandum.

3.1 Review of existing sections

The Workshop noted that the work to complete the computing specifications, especially taking into account the new Makah Management Plan, meant that there was insufficient time to update the CMP sections, also recognising that this could best be completed after the modelling results became available, ideally at SC67b. Attention was drawn to the updated seasonal maps[5] and participants were asked to send any comments or suggestion for modification to Donovan and Reeves.

The Workshop **recommended** that the Scientific Committee considers establishing a small drafting group comprised of at least the national co-ordinators of the MoC, Reeves (IUCN) and Donovan be convened to meet intersessionally (e.g. at IUCN headquarters) to provide an updated version of the plan after SC67b.

3.2 Consideration of future stakeholder workshop

An important component of the CMP effort is the need for a stakeholder workshop (tentatively forecast to occur in 2019) that helps to finalize the CMP and develops a strategy for its implementation (IWC, 2017b). The workshop, which would be co-sponsored by IWC, IUCN and the signatories to the Memorandum of Cooperation, should be broad-based and include representatives of national and local governments, industry (e.g. oil and gas, fishing, shipping and tourism), IGOs and NGOs. Objectives of this meeting should include: (1) review and updating of the CMP taking into account any new scientific results from the rangewide workshops, (2) establish a stakeholder Steering Group to monitor CMP implementation, (3) arrange for a coordinator of the CMP and (4) establish a work plan and consider funding mechanisms to implement the actions of the plan. The IWC has a Voluntary Fund for Conservation, to which donations can be specifically directed towards the gray whale CMP and related work. It is expected, however, that after the first year of CMP implementation, range states will contribute the necessary funds to advance the conservation actions listed in the plan. The Workshop welcomed the support offered by IUCN with respect to organising the stakeholder workshop.

4 UPDATE ON MODELLING FRAMEWORK AND RUNS

4.1 Progress of modelling since SC67a including validation

4.1.1 General progress, including validation

Punt informed the Workshop that code implementing the specifications agreed at the 4th Rangewide Workshop and modified during SC67a had been written and used to condition the reference trials based on stock hypotheses 3a, 3e and 5a, along with the sensitivity tests that implement stock hypotheses 3b and 6b.

[5] https://iwc.int/western-gray-whale-cmp

Brandon summarized progress on validating the code implementing the operating model and the conditioning process. SC/M18/CMP/03 provides an update on code validation, including a brief overview of the code and input files, and a list of verification steps taken to date. The main focus of the validation process has been on the FORTRAN procedures necessary for the conditioning phase. Conditioning the operating model is the first and most computationally expensive phase of the Rangewide modelling effort because this code involves the bulk of calls to numerical methods to estimate parameters given model fits to the data. To this end, the conditioning code has been checked against the mathematical and statistical model specifications, to ensure that the procedures as implemented are consistent with the specifications (see Annex D for the specifications of the Rangewide model). Likewise, diagnostic output from the code has been checked against expected values. No errors in the coding were identified.

4.1.2 Modelling related to the proposed Makah management plan

Punt informed the Workshop that code implementing the Makah Management Plan (Annex X) had been developed and initial results presented to the March 2018 AWMP meeting. However, Brandon has yet to validate this code. The code implementing the Makah Management Plan needs to be validated prior to SC67b.

During the Workshop, the Makah Management Plan was clarified/updated as shown below.

(1) It was clarified that the hunt will be stopped if the PCFG 10-yr strike limit less number of PCFG-designated animals drops below 1 or if the PCFG 10-yr female strike limit less number of PCFG-designated females drops below 1. The initial implementation only stopped the hunt only when these differences were less or equal to zero.

(2) It was agreed to incorporate an 'unknown identity' component for landed whales because it may not be possible to obtain a useable photograph of landed as well as struck and lost whales (although at a lower probability).

(3) It was agreed to allowing for the fact that the amount that unidentified whales count towards the PCFG 10-year strike limit will be updated based on available data rather than always being assumed to be 0.4. The error associated with the estimate of the proportion of PCFG whales in even-year hunts needs to be accounted for (see Item 4.4.1).

4.2 Review of stock hypotheses

The Workshop reviewed how the three baseline stock hypotheses (3a, 3e and 5a) and the two stock hypotheses considered as tests of sensitivity (3b and 6b) had been implemented, noting that some of the 'limited' movements (light arrows in Annex E) had been omitted from the baseline hypotheses, but would be considered in tests of sensitivity (e.g. the PCFG in sub-area BSCS). The omission of the associated links was due to lack of mixing data to allow the links to be modelled. It was also noted that that there are no data (abundance estimates, mixing proportions, catches) for some of the sub-area (e.g. the OS sub-area), which implies that the results will be identical no matter how such regions are treated in the modelling.

The Workshop noted that the current implementation of hypothesis 5a did not include the WBS in the SKNK sub-area. This is because there was currently no basis to specify a mixing proportion for WBS vs WFG animals in the sub-area. Cooke provided abundance estimates by breeding stock / feeding group (see Item 4.3.1), which means that it is no longer necessary to specify mixing proportions for the SKNK sub-area.

The Workshop **agreed** that stock hypotheses 3a and 5a would form the references for the analyses as they appear to be most plausible, while trials would also be conducted for stock hypotheses 3b, 3c, 3e and 6b. Annex E shows the final stock hypotheses considered in the trials graphically, while Annex D, Table 2 shows the resulting mixing matrices. The γ values in Annex D, Table 2 indicate parameters that are estimated during the model fitting process.

4.2.1 Plausibility of stock hypothesis 6b

SC/M18/CMP/01 aimed to reopen discussion on the plausibility of the stock hypotheses previously considered as high priority for modelling, with special emphasis on stock hypothesis 6b. Stock hypothesis 6b assumes that the WBS has no fidelity to wintering ground and uses both wintering grounds in both Asia and Mexico. SC/M18/CMP/01 argued that this hypothesis was elevated to high priority due to discussions regarding the movements of humpback whales and the social aggregating hypothesis of Clapham and Zerbini (2015). This hypothesis involves humpback whales learning of new wintering grounds, likely through hearing other humpback whales, and temporarily immigrating. SC/M18/CMP/01 argued that this hypothesis does not apply well to gray whales because they are much quieter than humpback whales and there is a large distance between the distribution of WBS and eastern breeding stock whales (as portrayed by hypothesis 6b) preventing communication between whales. Furthermore, humpback whales and gray whales have very different breeding behaviour, with humpback whales aggregating on modified leks (Clapham and Zerbini 2015). There does not appear to be a functional benefit for WGW to justify shifting their migration to go to wintering grounds in Mexico instead of Asia given the extra 4,000 km of travel required (Villegas-Amtmann *et al*., 2015). Furthermore, it does not appear likely that the WBS used both wintering grounds without fidelity prior to commercial whaling given that whaling occurred off Japan and Korea during a period when the whales using the Mexican wintering grounds were depleted. Bickham et al. (2013) has also presented arguments based on genetics on why hypothesis 6b has low plausibility. SC/M18/CMP/01 also suggested that hypothesis 3e has low plausibility because it assumes that WBS whales occur in their historical feeding range but do not use the Piltun Lagoon area of Sakhalin Island, which has proved to be an important feeding area since the mid-1980s. It is more likely that if the WBS exists, that this breeding stock would spend at least some time feeding near Piltun Lagoon. SC/M18/CMP/01 concluded the trials based on stock hypotheses other than 3a and 5a should be sensitivity tests.

In discussion, it was noted that gray whales that feed off Sakhalin and traditionally used wintering grounds in the western North Pacific could be driven to occasionally use migratory routes and wintering areas in the Eastern North Pacific. While the Rangewide model does not explicitly account for breeding so does not incorporate information on when or where whales breed, this hypothesis could provide an explanation for the observations of Sakhalin whales in the eastern North Pacific. There is evidence showing that whales from the same feeding groups migrate together; both Sakhalin and PCFG whales have been photographically identified in the same groups and in localized areas while on migratory routes (Weller et al. 2012, Calambokidis and Perez 2017). This could provide a mechanism by which whales that feed together, but have traditionally used different wintering areas, could learn new migratory routes.

Although the possibility that gray whales use multiple wintering grounds could not be ruled out, the Workshop **agreed** that stock hypotheses 6b would be considered as a sensitivity test. It was also **agreed** that stock hypothesis 3e would be considered a sensitivity test.

4.3 Confirm final data sets

4.3.1 Removals (direct and incidental)

IWC (2018) referenced records of gray whale deaths from entanglement/entrapment, ship strike, and unknown causes in Japan from 1982 until the present (Nakamura *et al.*, 2017). A small group (Scordino, Reeves, Brownell) met to confirm and update what had been stated previously on removals in Japan (and elsewhere), recalling that the adult that 'died off Hokkaido in 1996' was killed deliberately (Brownell, 1999).

The Workshop **endorsed** the conclusions of the small group as summarised below.

(1) Of the six gray whales reported as beached in Japan between 1990 and 2016 but with cause of death undetermined, some proportion should be assumed to have died from either entanglement/entrapment or ship strike. The under-reporting factor (usually x4 but with sensitivities of x10 and x20; Annex D, tables 8 and 9) used in the model to convert observed mortality to true mortality in the case of bycatch and ship strike would account for this.

(2) There was no reason to believe there had been any change in fishing effort (e.g. set net fishing) in Japan between 1930 and 1982. Therefore, the removal rate from 1982 to the present should be extended back to 1930 for modelling purposes.

(3) Finally, with respect to commercial set gillnet fishing in California prior to 1981, as noted last year (IWC, 2018), a seabass fishery operated in northern Mexico and southern California prior to the 1980s (e.g. landing 412,000 pounds of black seabass and 873,000 pounds of white seabass in 1953; Marine Fisheries Branch, 1956). In fact, this fishery was active and overall fishing effort 'fairly constant' from before 1930 until the early 1980s (Vojkovich and Reed, 1983). There was no observer effort in this fishery before 1981, nor was an official stranding record of cetaceans maintained in California before that time. However, a coordinated reporting system for stranding was established in the early 1960s under the auspices of the American Society of Mammalogists, and stranded gray whales were regularly reported. For example, 24 dead gray whales were reported as stranded in California between 1960 and 1968, of which seven were confirmed or suspected of having been either entangled in fishing gear or struck by a ship; Brownell, 1971). A gray whale that stranded at Ocean Beach, California, on 19 February 1953 was missing its flukes and bore 'several gashes' on the body – all suggestive of an entanglement death (Robert Orr, pers. comm. to R. Brownell, April 1964).

At last year's workshop, it was assumed that set gillnet fishing effort for halibut in California declined linearly from 1982 to no effort in 1975. To model the effect of this assumption, it was decided to assign all records of gray whales recorded as injured or killed in halibut or other set gillnet fisheries to a single fishery and modelled separately from all other California fisheries. It was also decided to examine both a low case that assigned no deaths to set gillnet fisheries and a high case that considered all bycatch reports related to gillnet, set gillnet, net, and halibut fisheries in California as if they came from a single fishery (IWC, 2018). A recently found publication (Bureau of Commercial Fisheries, 1936) reported that both set gillnets and trammel nets were used in the 1930s in California for halibut and white seabass fishing. Based on this new information, the Workshop **agreed** to drop the assumption that fishing effort declined linearly to zero from 1982 to 1975 and therefore there was no reason to evaluate high and low scenarios as a way of accounting for bycatch in California prior to 1975.

Set gillnetting effort off California changed markedly in 1991 due to regulations passed in November 1990 intended to eliminate gillnet fishing within 3 n.miles of the mainland and within 1 n.mile of any offshore island in southern California by 1994 (Barlow *et al.*, 1994). To address this, a second set gillnet fishery was added to the model starting in 1991 and the set gillnet fishery described in the preceding paragraph was modelled as having ended in 1990.

Table 1

Abundance estimates (1+) for the WFG feeding aggregation and the western breeding stock

Year	Group	Hypothesis	Estimate	SD	CV
1995	WFG	3a/3c/3e/6b	75.1	3.8	0.051
1995	WBS	3b	25.8	7.3	0.282
1995	WFG	3b	75.5	3.3	0.043
1995	WBS	3e	30.0*	15.0	0.500
1995	WBS	5a	26.6	6.9	0.259
1995	WFG	5a	47.8	7.7	0.160
1995	WBS+WFG	5a	74.4	3.9	0.052
1995	WBS/(WBS+WFG)	5a	0.358	0.093	0.259
2015	WFG	3a/3c/3e/6b	199.8	5.4	0.027
2015	WBS	3b	63.8	15.8	0.248
2015	WFG	3b	198.9	5.7	0.029
2015	WBS	3e	30.0*	15.0	0.500
2015	WBS	5a	64.4	14.0	0.218
2015	WFG	5a	135.6	14.1	0.104
2015	WBS+WFG	5a	200.0	5.7	0.029
2015	WBS/(WBS+WFG)	5a	0.322	0.069	0.200

* Guestimate because the WBS cannot be distinguished given the available information.

4.3.2 Abundance estimates

There were no updates to the estimates of abundance for the PCFG or the ENP stock. New abundance estimates for western gray whales had been presented to the last WGWAP meeting (Cooke *et al*., 2017), which will also be presented to the SC67b. Estimates for the WFG were extracted at the Workshop that would correspond to the stock structure hypotheses listed in Annex E (table 1). The larger estimates for the WFG correspond to the hypothesis that all whales visiting SE Kamchatka and/or Sakhalin belong to the WFG, while the smaller ones correspond with the hypothesis that only whales that visit Sakhalin belong to the WFG (regardless of whether these individuals also visit Kamchatka).

For the hypotheses where a proportion of the WFG belongs to the western breeding stock (WBS), this proportion is highly uncertain (and could be zero) even though the estimate for the total WFG is reasonably precise. The estimates of the numbers of WFG animals in each of the two breeding stocks are, therefore, highly negatively correlated. In these cases, the multi-stock model uses as inputs the estimate of the total WFG and the estimated proportion of this that belongs to the WBS.

Table 2

Mixing proportions for use in the trials

Sub-area	Season	Stock / Feeding aggregation	Mixing proportion
EJPJ	All	WBS/NFG	0.33
SEA	Feeding	PCFG	0.57[1]
SEA	Migration	PCFG	0.1[2]
SEA	Migration	WGW	0.002[3]
BCNC	Feeding	PCFG	0.93
BCNC	Feeding	WGW	0
BCNC	Migration	PCFG	0.28
BCNC	Migration	WGW	0.002
CA	Feeding	PCFG	0.60
CA	Feeding	WGW	0
CA	Migration	PCFG	0.1
CA	Migration	WGW	0.002[3]

1: Not used in the conditioning as no bycatch is recorded for the SEA sub-area during the feeding season.
2: Assumed value owing to lack of data to estimate mixing proportions.
3: Set to the value calculated for BCNC by Moore and Weller 2013)

4.3.3 Mixing proportions
Table 2 lists the updated mixing proportions. The mixing proportion for the EJPJ sub-area is unchanged from that specified at the 4th Rangewide Workshop because none of whales encountered recently in this sub-area had adequate photographs to allow for matching (Table 3).

Table 3

Updated information on matches between whales encountered off Japan and those photographed off Sakhalin (D. Weller, SWFSC).

Date	Location and source	Conclusion
April 2016	Shizuoka, beached	no useable photos/no match
February 2017	Kanagawa, sighting	poor quality video only/no match
April 2017	Chiba, sighting	poor quality video only/no match
March 2017	Aogashima, sighting	no useable photos/no match
February 2018	Aogashima, sighting	no useable photos/no match

New mixing proportions were calculated for PCFG whales by sub-area for the winter/spring (migrating) and summer/fall (feeding) seasons (Table 4). The sub-regions of the BCNC region used for the analysis were northern Oregon, southern Washington, and northern Washington because they were thought to have the least chance of bias in calculated mixing proportions. Updated data through 2015 based on matches to the PCFG catalogue were used. There was considerable discussion about how to calculate the mixing rate for the Oregon-Washington outer coast area due to a dramatic change in proportion of PCFG whales in northern Washington from surveys in early April 2015. Those surveys identified a large number of whales in a previously poorly sampled area that had very few PCFG whales. Identifications in spring 2015 (heavily influenced by these April surveys) reduced the overall proportion of PCFG whales based on pooled proportions through 2015 to 24% (it had been 36% based on data through 2014). To provide a value less influenced by these two days of surveys, the proportions of PCFG whales were averaged over sub-region and month to compute an overall average of 28% (an average of the eight values presented in Table 4.

Table 4

Proportion of PCFG whales by region and month for cells with >10 IDs; complete through 2015 for OR-WA Jan to May (no Dec data)

Region	Jan	Feb	Mar	April	May
NWA	0.09		0.09	0.10	0.41
SWA			0.38	0.21	0.33
NOR					0.63

Mean of above cells for OR to WA: **Unweighted = 28%**, Pooled = 24%
Mean of above for just N WA: Unweighted = 17%, Pooled = 20%

The Workshop **agreed to** adopt 28% for the proportion of PCFG whales in the BCNC sub-area during the migrating season for the bulk of the trials, and that sensitivity would be evaluated to 17%. This value is obtained by restricting the analysis of mixing rates of PCFG whales during the winter/spring to just northern Washington where the hunt would occur (based on the unweighted average of the 4 months where there were at least 10 photo-IDs, table 4). Pooling all 622 photo-IDs for December to May would result in a rate of 20%, although this approach weights values towards periods with more photo-IDs.

Considering some of the uncertainty around the estimate for the portion of PCFG whales present in the spring off the Washington-Oregon coast and the variation by location, month, and year, the Workshop **agreed** the current best estimate of 28% to be +-20% (8-48%) for the true PCFG mixing rate. The rationale for the choice is that very different results would be obtained in different areas such as 1) the recently sampled zone north of Tatoosh Island in the early spring where migrating whales appear to gather in some years where recent efforts revealed almost no PCFG whales, compared to 2) areas along the Northern Washington Coast or for example in Barkley Sound that are feeding areas for PCFG whales and where their proportion compared to migrating whales would be highest.

4.4. Confirm final trial structure and conditioning

4.4.1 Changes to the trials specifications, including stock structure
Annex D lists the specifications for the model that will form the basis for drawing final conclusions regarding the implications of alternative stock structure hypotheses and of the implementation of the Makah management plan. The specifications (see also Annex D and Table 5 and 6) reflect changes to how the stock hypotheses are implemented as well as how the abundance estimates for the western Pacific are used in conditioning. The Workshop also agreed that the following additional changes will be made the trials specifications:

(1) the base-case survival rate for animals aged 1 and older would be assumed to be 0.98, which reflects the estimates obtained by Cooke (ref) and Punt and Wade (2012); the values used in previous trials was 0.95;

(2) the SET1 and SET2 fleets (set gillnets off California in the feeding and migration seasons) would be split between 1990 and 1991 given the changes in regulations in the associated fisheries that appear to have changed bycatch rates;
(3) the survey plan for the California counts were updated to reflect the current plan (two surveys in every five-year block); and
(4) the periods used to calculate average bycatch rates to infer bycatch prior to the establish of monitoring networks into the future as generally but the earliest and most recent five years, but a longer period is specification for sub-areas (e.g. EJPJ and SI) with limited data (Annex D, table 3)

Evaluation of the Makah Management Plan requires specification of the probability of photographing a landed or struck and lost whale, as well as the probability of correctly deciding that such a whale is from the PCFG or the WFG. In addition, it is necessary to specify the probability of striking and losing a whale and assigning a sex to an animal for which a match has been made. These probabilities are specified as follows:

(1) *Probability of obtaining a photograph of sufficient quality to allow it to be matched to the catalogue*. For struck and lost whales, this probability is estimated to be a 0.6 for winter/spring and 0.8 for summer/fall (due less favourable light and weather in winter/spring compared to summer/fall). For landed whales, it is estimated to be 0.9 for all seasons.
(2) *Probability of struck and lost*. The review of the Makah whale *SLA* concluded in 2013 was based on a value for this probability of 0.5, which was informed by two strikes that occurred during the Makah 1999 hunt in which one strike resulted in a landing and the other contacted the whale but did not penetrate the skin. The Workshop agreed to retain the assumption of a 50% struck and lost rate for hunts during the winter and spring. It was decided that hunts occurring during the summer and fall were much less likely to have struck and lost due to better weather conditions and more predictive movement behaviours of whales in the normal feeding depths of PCFG whales. The Workshop therefore agreed that the struck and lost rate for summer and fall hunts would be 0.1 and that sensitivity would be explored to a value of 0.5.
(3) *False positive rate for PCFG (i.e. probability of a non-PCFG being identified as from the PCFG given a good quality photograph*). The probability that a non-PCFG whale might be falsely identified as a PCFG whale is estimated to be 0.05. Normally, there is a near 100% confidence for matches that are identified to Cascadia's PCFG catalogue because these are double checked and photographs of poorer quality where there is some ambiguity are treated as Poor Quality and not used. The value of 0.05 is based on the assumption that a slightly different set of circumstances would exist for comparison of a whale struck or landed because there would be pressure to try to match regardless of the quality of the photograph and it would be hard to justify not reporting as a match something where there was a relatively high degree of confidence (i.e. 95% confident of the match to a PCFG whale).
(4) *False negative rate for PCFG* (i.e. *i.e. probability of a PCFG whale not being identified as such given a good quality photograph*). This probability is estimated to be 0.25 for a hunt in the winter/spring, and zero for a hunt in summer since all struck whales are assumed to be of the PCFG. This value of 0.25 accounts for several factors, including whales only seen in fewer in two years in the PCFG because of a combination of being young, not being photographed, and the one year lag in available catalogue. In addition, there could be a matcher error in missing a match due to things like changed markings.
(5) *False positive rate for WFG (i.e. probability of a non-WFG being identified as from the WFG given a good quality photograph*). This probability is estimated to be 0.01 based on the WFG catalogue being smaller and more well-known. Also, it is suspected that the matcher would likely only declare a match when there was a high level of confidence given the infrequent rate of these matches.
(6) *False negative rate for WFG* (i.e. *i.e. probability of a WFG whale not being identified as such given a good quality photograph*). On the assumption that calves and lactating mothers will not be hunted, the proportion of huntable WFG whales that would not be known as WFG whales if taken during the spring northward migration was estimated using the population model fit to the Sakhalin and Kamchatka photo-id data. An animal that has been seen off Sakhalin is assumed to be a WFG animal if seen or taken in the eastern North Pacific. An animal seen off eastern Kamchatka but not Sakhalin is not assumed to be a WFG animal, because it might be an NFG animal. The estimated proportion, averaged across the posterior distribution of the population trajectory, was 4-5% depending on the hypothesis. These estimates used data through 2011 only, that being the last season for which the catalogues were cross-matched. If only a single catalogue were used, the rate would be higher. The values used in the trials are: stock hypotheses 3a, 3c, 3e, and 6b: 0.041; stock hypothesis 3b: 0.040; stock hypothesis 5a: 0.049.
(7) *Probability of not assigning a sex to a struck and lost animal that has been identified to the PCFG.*
    a. This probability is estimated at 19% for the feeding season based on 81% of encounters of PCFG whales from June-Nov through 2015 for the Oregon and Washington outer coast having known sex. For those with known sex in this sample 58% were female and 42% male, but this could be

biased by some directed sampling toward females so the sex ratio should be treated as 50:50 in the management plan.

b. This probability is estimated at 27% for the migrating season based on 73% of encounters of PCFG whales from Dec-May through 2015 for the Oregon and Washington outer coast having known sex. For those with known sex in this sample 46% were female and 54% were male. This male-biased sex ratio is in the opposite direction of the bias from intentionally sampling females, which suggests males are actually more abundant and available in the spring off the Oregon and Washington outer coast likely as a result of females with calves migrating later and being less available in spring. Given the bias for trying to sample known females, it is likely that the sex ratio in spring is likely closer to 60:40 male:female. If hunters avoid taking mothers with calves it would further reduce the chances of taking a female.

Estimates of the proportion of PCFG whales used in the Makah management plan for assigning a struck unidentified whale in the winter/spring hunt are subject to uncertainty due to for example shifting proportions based on sampling differences and these should be considered subject to a bias (which depends on trials) that ranges from -0.1 to 0.1.

Table 5

Factors considered in the model scenarios. The bold values are the base-levels and the values in standard font form the basis for sensitivity analyses.

Factor	Levels
Model fitting related	
Stock hypothesis	**3a,** 3b, 3c, 3e, **5a,** 6b
$MSYR_{1+}$ (western)	As for WFG
$MSYR_{1+}$ (north)	**4.5%**, 5.5%, Estimated (common); estimate (separately)
$MSYR_{1+}$ (WFG)	**4.5%** Estimated (common); estimate (separately)
$MSYR_{1+}$ (PCFG)	2%, **4.5%**, 5.5%, Estimated (common); estimate (separately)
Mixing rate (migration season in BCBC	**0.28**, 0.17, 1.00
Immigration into the PCFG	0, 1, **2**, 4
Bycatches and ship strikes	Numbers dead + M/SI, **dead x 4**; dead x 10; dead x 20
Pulse migrations into the PCFG	10, **20**, 30
Projection-related	
Additional catch off Sakhalin (mature female)	0, 1
Catastrophic events	**None**, once in years 0 – 49, and once in years 50-99
Northern need in final year (from 150 in 2014)	**340**
Struck and lost rate	**(0.1; odd-years; 0.5 even years),** 0.5 all years
Future effort	**Constant**, Increase by 100% over 100 years
Probability of a photo (struck and lost whales)	**0.8; odd-years; 0.6 even years**
Probability of a photo (landed whales)	**0.9**
Probability of false positive rate PCFG	**0.05**, 0.1
Probability of false negative rate PCFG	**0.25**
Probability of false positive rate WFG	**0.01**
Probability of false negative rate WFG	**0.041 (stock hypotheses 3a, 3c, 3e, 6b);** 0.040 (stock hypothesis 3b); **0.049 (stock hypothesis 5a)**
Probability of a sex assignment given a PCFG match	**0.81**

4.4.2 Base-case trials and sensitivity tests

The 4th Rangewide workshop specified a series of trials. However, it had not been possible to implement all of these trials during the intersessional period. The Workshop reviewed the set of trials and made the following changes (trial numbers relate to revised numbering system):

(1) stock hypothesis 3e is now treated as a sensitivity test as it is a variant of stock hypothesis 5a (with no WBS animals in the SI sub-area);

(2) a new sensitivity test (18C) based on stock hypothesis 3c has been added as agreed at the 4th Rangewide workshop (IWC, 2018);

(3) the sensitivity test exploring a higher proportion of WBS whales in sub-area SI (3B) involves increasing the estimates of abundance for the WBS by 50% and correspondingly reducing the estimates of abundance for the WFG;

(4) the trials involving PCFG whales in the BSCS sub-area (12A/B) are based on assuming that all PCFG whales are in the BSCS sub-area. The assumption will be conservative given that most PCFG whales are located elsewhere when the aboriginal hunt off Chukotka occurs;

(5) the trials involving WFG whales in the BSCS sub-area (13A/B) are based on assuming that all WFG whales are in the BSCS sub-area. The assumption will be conservative given that most WFG whales are located elsewhere when the aboriginal hunt off Chukotka occurs;

(6) the trials exploring the sensitivity of how the California set gillnet catches were modelled (trials 14 and 15 in Table 8 of IWC (2018)) were dropped as the approach for modelling the SET1 and SET2 fleets was modified (see Item 4.3.1);

(7) the trials with MSYR estimated and a higher pulse were dropped as these trials are unlikely to be informative (trials 14A/B and 8A/B examine these factors individually);

(8) variants of trials 5A/B and 16A/B (trials 18A/B and 19A/B) that have net immigration of 1 to the PCFG were added because the assumption of zero immigration into the PCFG is unlikely given the results of Lang and Martien (2012);

(9) trials 7A/B and 16A/B exclude the PCFG abundance estimates for 1998-2002 as a low pulse would not allow the model to mimic these data – this change in model specifications mimics the adoption in the trials used to evaluate the *SLA* for a Makah hunt by IWC (2013) of a time-varying survey bias;

(10) trials 22A/B have been added to examine the future consequences of a catastrophic events in the NFG – these events occurs randomly once in the first 50 years and randomly once in the second 50 years, with a magnitude equivalent to that of the mortality event in 1999/2000; and

(11) trials 23A/B and 24A/B have been added to explore sensitivity to the struck and lost rate for a Makah hunt in the feeding season, and the false negative rate for a Makah hunt in summer.

Table 6

Final trial specifications

Trial	Description/stock hypothesis	PCFG or WFG in BSCS	$MSYR_{1+}$			PCFG		Bycatch	Condition?

4.4.3 Conditioning statistics

The Workshop reviewed the diagnostic plots for evaluating the conditioning developed for the trials specified at the 4th Rangewide Workshop. The Workshop **agreed** that the following plots should be produced for each trial and provided to the Intersessional Steering Group for review:

(1) The estimates of absolute abundance (with 90% sampling intervals) and the median, 50% and 90% intervals for the time-trajectory of the model estimates of 1+ population size.
(2) The time-trajectory of the model estimates of the number of mature females.
(3) The distributions (median, 50% and 90% intervals) for the generated mixing proportions and those for the model-predicted mixing proportions.
(4) The distribution for the net immigration rate from the NFG to the PCFG and the target value (black vertical bar).
(5) The estimates of average bycatch over the period for which reporting is considered adequate [Annex D, table 3] (with 90% sampling intervals) and the median, 50% and 90% intervals for the model-estimate of the average bycatch over the period.
(6) The distributions (median, 50% and 90% intervals) for the generated survival rates for PCFG whales and those for the model-predicted survival rates for PCFG whales.
(7) The time-trajectories of removals, including the recorded removals (adjusted for under-reporting) and the bycatch inferred for the years for which reporting is not considered adequate.

4.4.4 Projection scenarios

Previous projections for the Sakhalin population (J. Cooke in Reeves *et al.*, 2005) considered a scenario in which there is future bycatch of 1.5 mature females off Japan based on inferences from bycatch at that time. The Workshop noted that observed bycatch off Japan has declined since then. The Workshop **agreed** that a projection scenario with 1 mature female taken each year in the EJPJ sub-area should to be conducted.

In addition, the Workshop **agreed** that, if possible, projections should be conducted for the current Makah *SLA*, although it was recognised this may not be feasible to achieve before 67b.

The Workshop noted that care needs to be taken to compare the results from the previous *Implementation Review* with those based on the Rangewide review because the population structure hypotheses have changed and the Rangewide review has more fully accounted for bycatch and its uncertainty.

4.4.5 Performance statistics

4.4.5.1 TIME-TRAJECTORIES OF POPULATIONS

The results of the model fits and the projections will be summarized by time-trajectories of 1+ numbers of breeding stock / feeding group and by sub-area

4.4.5.2 MAKAH MANAGEMENT PLAN

The results of the projections to evaluate the performance of the Makah management plan will be based on the standard statistics used by the Committee to evaluate the performance of Strike Limit Algorithms

(1) D1. Final depletion of 1+ and mature female numbers by breeding stock / feeding group (median, lower 5th and upper 5th percentiles)
(2) D8. Rescaled final depletion: P_T/P_0 (1+ and mature female numbers by breeding stock / feeding group; median, lower 5th and upper 5th percentiles) where P_0 is number of 1+ / mature female animals had there been no future Makah hunts.
(3) D10. Relative increase. The ratio of the 1+ and mature population size after 10 and 100 years to that at the start of the projection period by breeding stock / feeding group (median, lower 5th and upper 5th percentiles)
(4) N9. Need satisfaction. The proportion of the total number of requested strikes that were taken over the first 10 years and the entire 100-year period (median, lower 5th and upper 5th percentiles).

Results are provided for both 10 and 100 years for the D10 and N9 statistics because (a) the Makah management plan current only operates for 10 years, and (b) previous evaluations of the performance of management procedures (RMP and AWMP) have considered performance over 100 years. Population-related statistics should be also be provided for the case there is no future Makah hunt (only bycatch and hunting off Chukotka).

5. WORKPLAN

Before / during 67b

(1) Update the code for the operating model (Punt)
(2) Validate any changes to the historical (conditioning) component of the operating model (Brandon)
(3) Conduct conditioning and distribution of conditioning diagnostics to the Steering Group (Punt)
(4) Review of the conditioning results (Steering Group)
(5) Code the revised Makah management plan and the associated testing code (Punt)
(6) Validate the revised Makah management plan and the associated testing code (Brandon)
(7) Conduct the projections and assemble the projection results (Punt)

After 67b

(1) Complete drafting of the CMP.

6. ADOPTION OF REPORT

The co-chairs thanked Brownell and his colleagues for the excellent and historic facilities provided at the laboratory in the beautiful setting of Granite Canyon (complete with gray whales migrating by). The report was adopted by email.

Annex B

Agenda

1. Introductory items
   - 1.1 Convenor's opening remarks
   - 1.2 Election of Chair
   - 1.3 Appointment of rapporteurs
   - 1.4 Adoption of Agenda
   - 1.5 Documents and data available
2. Progress on 'non-modelling' recommendations and new data
   - 2.1 Updated information from the co-operative genetics studies
   - 2.2 Updated information from photo-identification studies including consolidation of WGW catalogues
   - 2.3 Gray whales off Korea
3. Updating scientific aspects of the CMP
   - 3.1 Review of existing sections
   - 3.2 Consideration of future stakeholder workshop
   - 3.3
4. Update on modelling framework and runs
   - 4.1 Progress on modelling since SC/66b, including validation
     - 4.1.1 General progress, including validation
     - 4.1.2 Modelling related to the proposal Mkah management plan
   - 4.2 Review of stock hypothesis
   - 4.3 Confirm final data sets
     - 4.3.1 Removals (direct and incidental)
     - 4.3.2 Abundance estimates
     - 4.3.3 Mixing proportions
   - 4.4 Confirm final trial structure and conditioning
     - 4.4.1 Changes to the trial specifications, including stock structure
     - 4.4.2 Base-case trials and sensitivity tests
     - 4.4.3 Conditioning statistics
     - 4.4.4 Projection scenarios
     - 4.4.5 Performance statistics
5. Work plan
6. Adoption of Report

Annex D

Terminology Used with Respect to Stock Structure Hypotheses

Breeding stocks. There are up to two extant breeding stocks: Western (WBS) and Eastern (EBS).

*Feeding groups or aggregations**. There are up to three feeding groups or aggregations. There is dispersal between the PCFG and North Feeding Group (NFG), but the Western Feeding Group (WFG) is demographically independent of the other two feeding groups (i.e. there is no permanent movement of animals from the NFG or PCFG to the WFG).

	Feeding groups or aggregations	Abbreviation	Definition (may vary with hypothesis)
1	Western Feeding Group	WFG	Animals that feed regularly (define?) off Sakhalin Island* according to photo-identification data
2	Pacific Coast Feeding Group	PCFG	Animals that feed regularly (define?) in the PCFG area according to photo-identification data
3	North Feeding Group	NFG	Animals found in other feeding areas (and for which there is relatively little information including photo-ID)

* May need revising with regard to Southern Kamchatka animals given Justin's paper.

Sub-areas. The model includes 11 geographical sub-areas that are used to explain the movements of gray whales (breeding stocks and feeding groups) in the North Pacific and two 'latent sub-areas' used to link model predictions to observed indices of abundance.

	Sub-area	Abbreviation
1	Vietnam-South China Sea	VSC
2	Korea and western side of the Sea of Japan	KWJ
3	Eastern side of the Sea of Japan and the Pacific coast of Japan	EJPJ
4	Northeastern Sakhalin Island	SI
5	Southern Kamchatka and Northern Kuril Islands*	SKNK
6	Areas of the Okhotsk Sea not otherwise specified	OS
7	Northern Bering and Chukchi Sea	BSCS
8	Southeast Alaska	SEA
9	British Columbia to Northern California	BCNC
10	California	CA
11	Mexico	M
12	Latent sub-area	Calif-3
13	Latent sub-area	BC-BCA-3

* New at this workshop – replaces the old East Kamchatka and Kuril Islands to recognise the information from telemetry and photo-ID.

Annex E

Specifications of the rangewide model

A. **Basic concepts and stock structure**

The aim of the projections is to explore the population consequences of various scenarios regarding anthropogenic removals of gray whales, with a view to informing future conservation and management. The model distinguishes 'breeding stocks' and 'feeding aggregations'. Breeding stocks are demographically and genetically independent whereas feeding aggregations may be linked through dispersal of individuals[6], though perhaps at very low rates for some combinations of feeding aggregations. Each breeding stock / feeding aggregation is found in a set of sub-areas, each of which may have catches (commercial, aboriginal or incidental), proportions of breeding stock / feeding aggregation mixing[7] in those sub-areas, observed bycatch rates[8], estimates of survival rates, and indices of relative or absolute abundance. Removals may be specified to sets of months during the year for some sub-areas if the various feeding aggregations are not equally vulnerable to catches throughout the year for those sub-areas. The trials capture uncertainty regarding stock structure and MSYR, as well as uncertainty regarding bycatch and immigration.

The region concerned, the North Pacific, is divided into 11 sub-areas (Fig. 1). The model also includes several 'latent' sub-areas used to link model predictions to observed indices of abundance. These are denoted, WFG, WBS, WST, CA-3 and BCNC-3. There are up to two extant *breeding stocks* (Western and Eastern). The Eastern breeding stock consists of up to three *feeding aggregations* depending on the stock structure hypothesis: Western Feeding Group (WFG), Pacific Coast Feeding Group (PCFG) and North Feeding Group (NFG). There is dispersal between the PCFG and the NFG, but the WFG is demographically independent of the other two feeding aggregations (i.e. there is no *permanent* movement of animals from the NFG or PCFG to the WFG or vice-versa).

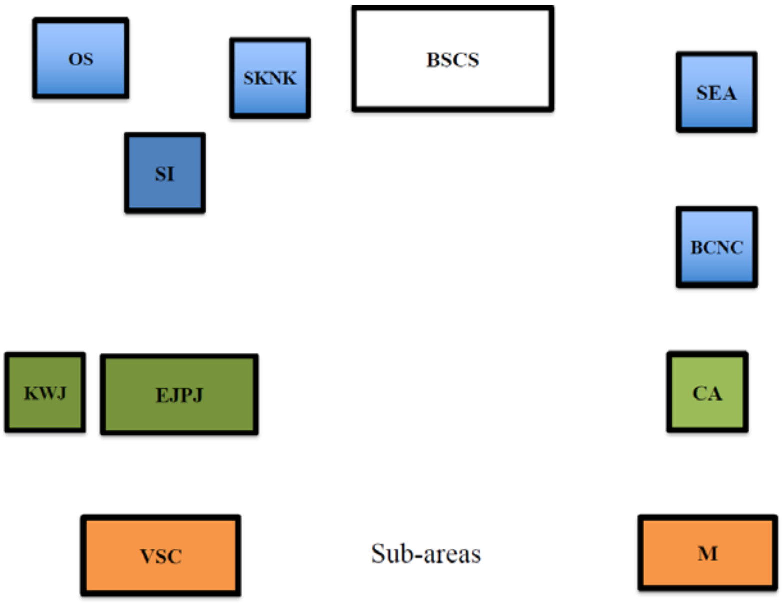

Fig. 1. The sub-areas in the model.

The trials consider five stock structure hypotheses

(1) *Hypothesis 3a.* Although two breeding stocks (Western and Eastern) may once have existed, the Western breeding stock is assumed to have been extirpated. Whales show matrilineal fidelity to feeding grounds, and the Eastern breeding stock includes three feeding aggregations: PCFG, NFG, and WFG.

[6] The term 'dispersal' is used here in the sense of 'effective dispersal', and refers to permanent movement of individuals among feeding aggregations. Such individuals become part of the feeding aggregation to which they move and contribute to future reproduction.

[7] Mixing is defined here as two feeding aggregations that overlap at some time on the feeding grounds, but do not exchange individuals.

[8] Bycatch is understood to include mortality or 'serious' injury from entanglement or entrapment in fishing gear (or debris) and ship strikes.

(2) *Hypothesis 3b*. Identical to hypothesis 3a, except that NFG whales do not feed off SKNK. In addition, a Western breeding stock exists that overwinters in VSC and feeds in the OS (but not SI) and SKNK. Thus, SKNK is used by both the WFG whales and the whales of the Western breeding stock.
(3) *Hypothesis 3c*. Identical to 3a, except that on occasion whales migrating between the Sakhalin feeding region and Mexico travel through the BSCS sub-area
(4) *Hypothesis 3e*. Identical to hypothesis 3a, except that the Western breeding stock is extant and feeds off both coasts of Japan and Korea and in the northern Okhotsk Sea west of the Kamchatka Peninsula. All of the whales feeding off Sakhalin overwinter in the eastern North Pacific
(5) *Hypothesis 5a*. Identical to hypothesis 3e except that the whales feeding off Sakhalin include both whales that are part of the extant Western breeding stock and remain in the western North Pacific year-round, and whales that are part of the Eastern breeding stock and migrate between Sakhalin and the eastern North Pacific
(6) *Hypothesis 6b*. This hypothesis assumes that the WFG does not exist, but that whales feeding in the SI sub-area represent an extant Western breeding stock that utilizes two wintering grounds (VSC and M). This hypothesis differs from hypothesis 5a, in that 1) all removals off China and Japan are assumed to be Western breeding stock animals, and 2) the abundance estimates for Sakhalin are assumed to relate only to the Western breeding stock.

B. **Basic dynamics**

The population dynamics are based on the standard age- and sex-structured model, which has formed the basis for the evaluation of *Strike Limit Algorithms* for eastern North Pacific gray whales, i.e.:

$$\begin{aligned}
N_{t+1,0}^{m/f,i,j} &= 0.5B_{t+1}^{i,j} && a=0\\
N_{t+1,a}^{m/f,i,j} &= (N_{t,a-1}^{m/f,i,j} + I_{t,a-1}^{m/f,i,j} - C_{t,a-1}^{m/f,i,j})\, S_{a-1}\, \tilde{S}_t^{i,j} && 1 \le a \le x-1 \quad \text{(B.1)}\\
N_{t+1,x}^{m/f,i,j} &= ((N_{t,x}^{m/f,i,j} + I_{t,x}^{m/f,i,j} - C_{t,x}^{m/f,i,j})S_x + (N_{t,x-1}^{m/f,i,j} + I_{t,x-1}^{m/f,i,j} - C_{t,x-1}^{m/f,i,j})\, S_{x-1})\, \tilde{S}_t^{i,j} && a=x
\end{aligned}$$

where $N_{t,a}^{m/f,i,f}$ is the number of males / females of age *a* in feeding aggregation *j* of breeding stock *i* at the start of year *t*; $C_{t,a}^{m/f,i,f}$ is the number of anthropogenic removals of males / females of age *a* in feeding aggregation *j* of breeding stock *i* during year *t* (whaling/incidental catches are assumed to take place in a pulse at the start of each year); S_a is the annual survival rate of animals of age *a* in the absence of catastrophic mortality events (assumed to be the same for males and females):

$$S_a = \begin{cases} S_0 & \text{if } a = 0 \\ S_{1+} & \text{if } 1 < a \end{cases} \qquad \text{(B.2)}$$

S_0 is the calf survival rate; S_{1+} is the survival rate for animals aged 1 and older; $\tilde{S}_t^{i,j}$ is the amount of catastrophic mortality (represented in the form of a survival rate) for feeding aggregation *j* of breeding stock *i* during year *t* (catastrophic events are assumed to occur at the end of the year after mortality due to anthropogenic removals, whaling and non-catastrophic natural causes and dispersal; in general $\tilde{S}_t^{i,j}$ =1, i.e. there is no catastrophic mortality); $B_{t+1}^{i,j}$ is the number of births to feeding aggregation *j* of breeding stock *i* during year *t*; $I_{t,a}^{s,m/f}$ is the net dispersal of female/male animals of age *a* into feeding aggregation *j* of breeding stock *i* during year *t*; and *x* is the maximum (lumped) age-class (all animals in this and the *x*-1 class are assumed to be recruited and to have reached the age of first parturition). *x* is taken to be 15.

C. **Births and density-dependence**

Density-dependence is assumed to be a function of numbers of animals aged 1 and older by feeding ground relative to the carrying capacity by feeding ground. The density-dependence component for feeding aggregation *j* of breeding stock *i* is the sum of the density-dependence components by feeding aggregation weighted by the proportion of animals from feeding aggregation *j* of breeding stock *i* that are found on each feeding ground, i.e.:

$$F(i,j,t) = \sum_A \psi^{A,i,j} \left(X^{A,i,j} (N_t^{1+,A} / K^{1+,A})^z \right) / \sum_A \psi^{A,i,j} X^{A,i,j} \qquad \text{(C.1)}$$

where z is the degree of compensation; $\psi^{A,i,j}$ indicates whether sub-area A impacts density-dependence for feeding aggregation j of breeding stock i, N_t^{1+A} is the number of 1+ animals on feeding ground A at the start of year t:

$$N_t^{1+,A} = \sum_i \sum_j X^{A,i,j} \sum_{a=1}^{x} (N_{t,a}^{m,i,j} + N_{t,a}^{f,i,j}) \tag{C.2}$$

K^{1+A} is the carrying capacity for feeding ground A:

$$K^{1+,A} = \sum_i \sum_j X^{A,i,j} \sum_{a=1}^{x} (N_{-\infty,a}^{m,i,j} + N_{-\infty,a}^{f,i,j}) \tag{C.3}$$

$X^{A,i,j}$ is the proportion of animals of feeding aggregation j of breeding stock i that are found in feeding ground A[9] (Tables 1 and 2).

The number of births at the start of year t for feeding aggregation j of breeding stock i, $B_t^{i,j}$, is given by:

$$B_t^{i,j} = b_t^{i,j} \, N_t^{f,i,j} \tag{C.4}$$

where $N_t^{f,i,j}$ is the number of mature females in feeding aggregation j of breeding stock i at the start of year t:

$$N_t^{f,i,j} = \sum_{a=a_m}^{x} N_{t,a}^{f} \tag{C.5}$$

a_m is the age-at-maturity (the convention of referring to the mature population is used here, although this actually refers to females that have reached the age of first parturition); $b_t^{i,j}$ is the probability of birth/calf survival for mature females:

$$b_t^{i,j} = \max(0, b_K\{1 + A^{i,j}(1 - F(I,j,t))\}) \tag{C.6}$$

b_K is the average number of live births per year per mature female at carrying capacity; and $A^{i,j}$ is the resilience parameter for feeding aggregation j of breeding stock i.

D. **Immigration (dispersal)**

The numbers dispersing into feeding aggregation j of breeding stock i, include contributions from pulse migration as well as diffusive dispersal:

$$I_{t,a}^{s,j,i} = I_{t,a}^{1,s,j,a} - I_{t,a}^{2,s,j,a} \tag{D.1a}$$

$$I_{t,a}^{1,s,j,i} = \sum_{k \neq j} \delta^{k,j,i} N_{t,a}^{s,i,k} \left(\frac{N_t^{f,i,k}}{N_{-\infty}^{f,i,k}}\right)^{\tilde{\lambda}} + \sum_{k \neq j} \Omega_y^{k,j,i} \frac{N_{t,a}^{s,i,k}}{\sum_{a=1}^{x} (N_{t,a}^{m,i,k} + N_{t,a}^{f,i,k})} \tag{D.1b}$$

$$I_{t,a}^{2,s,j,i} = \sum_{k \neq j} \delta^{j,k,i} N_{t,a}^{s,i,j} \left(\frac{N_t^{f,i,j}}{N_{-\infty}^{f,i,j}}\right)^{\tilde{\lambda}} + \sum_{k \neq j} \Omega_y^{j,k,i} \frac{N_{t,a}^{s,i,j}}{\sum_{a=1}^{x} (N_{t,a}^{m,i,j} + N_{t,a}^{f,i,j})} \tag{D.1c}$$

[9] It is usually the case that $\sum X^{A,i,j} = 1$. However, for gray whales, this is not necessarily the case because removals can take place in the various sub-areas at different times. What is then important is the relative values of the $X^{A,i,j}$ among feeding aggregations for a given feeding ground.

where $\delta^{k,j,i}$ is the rate of dispersal from feeding aggregation *k* to feeding aggregation *j* of breeding stock *i*; λ is a factor to allow for density-dependence in the dispersal rate (set to 2); and $\Omega_y^{k,j,i}$ is the number of animals that disperse in year *y* from feeding aggregation *k* to feeding aggregation *j* of breeding stock *i* in a pulse.

E. **Anthropogenic removals**

The catch by feeding aggregation, sex and age is the sum of the catch over fleet (see Table 3 for fleet definitions), i.e.:

$$C_{t,a}^{m/f,i,j} = \sum_k C_t^{m/f,k} \frac{\alpha_a^k X^{A_k,i,j} N_{t,a}^{m/f,i,j}}{\sum_{i,j,a} \alpha_a^k X^{A_k,i,j} N_{t,a}^{m/f,i,j}} \tag{E.1}$$

where $C_t^{m/f,k}$ is the catch of males/females by fleet *k* during year *t*; A_k is the sub-area in which fleet *k* operates; and α_a^k is the relative vulnerability of animals of age *a* to harvest by fleet *k*. The values for the catches by fleet and sex are either pre-specified (Table 4[10]) or computed using Equation E.2. for the years for which actual estimates are not available:

$$C_{t,a}^{m/f,k} = \lambda^k E_t^k \sum_{i,j,a,m/f} \alpha_a^k X^{A,i,j} N_{t,a}^{m/f,i,j} \tag{E.2}$$

where E_t^k is a measure of the effort by fleet *k* during year *t* (Table 5) and λ^k is the catchability coefficient for fleet *k*.

F. Initializing the parameter vector

The numbers at age in the pristine population are given by:

$$\begin{aligned} N_{-\infty,a}^{m/f,i,j} &= 0.5\, N_{-\infty,0}^{i,j} \prod_{a'=0}^{a-1} S_{a'} && \text{if } a < x \\ N_{-\infty,x}^{m/f,i,j} &= 0.5\, N_{-\infty,0}^{i,j} \prod_{a'=0}^{x-1} S_{a'} / (1-S_x) && \text{if } a = x \end{aligned} \tag{F.1}$$

The value for $N_{-\infty,0}^{i,j}$ is determined from the value for the pre-exploitation size of the 1+ component of feeding aggregation *j* of breeding stock *i* using the equation:

$$N_{-\infty,0}^{m,i,j} = K^{1+,i,j} / \left(\sum_{a=1}^{x-1} \left(\prod_{a'=0}^{a-1} S_{a'} \right) + \frac{1}{1-S_x} \prod_{a'=0}^{x-1} S_{a'} \right) \tag{F.2}$$

where $K^{1+,i,j}$ is the carrying capacity (in terms of the 1+ population size size) for feeding aggregation *j* of breeding stock *i*:

$$K_t^{1+,i,j} = \sum_{a=1}^{x} (N_{-\infty,a}^{m,i,j} + N_{-\infty,a}^{f,i,j}) \tag{F.3}$$

$N_{-\infty,a}^{m/f,i,j}$ is the number of animals of age *a* that would be in feeding aggregation *j* of breeding stock *i* in the pristine population.

The model is based on the assumption that the age-structure at the start of year τ is stable rather than that the population was at its pre-exploitation equilibrium size at some much earlier year. The determination of the age-structure at the start of year τ involves specifying the effective 'rate of increase', γ, that applies to each age-class. There are two components contributing to γ, one relating to the overall population rate of increase (γ^+) and the other to the exploitation rate due to all forms of anthropogenic removal. Under the assumption of knife-edge recruitment to the fishery at age a_r, only the γ^+ component (assumed to be zero following Punt and Butterworth

[10] The bycatches for 2016 are set equal to those for 2015 as data on bycatch for 2016 are not finalized at present.

[2002]) applies to ages a of a_r or less. The number of animals of age a at the start of year τ relative to the number of calves at that time, $N^*_{\tau,a}$, is therefore given by the equation:

$$N^*_{\tau,a} = \begin{cases} 1 & \text{if } a = 0 \\ N^*_{\tau,a-1}\, S_{a-1} & \text{if } a \le a_r \\ N^*_{\tau,a-1}\, S_{a-1}\,(1-\gamma) & \text{if } a_r < a < x \\ N^*_{\tau,x-1}\, S_{x-1}(1-\gamma)/(1-S_x\,(1-\gamma)) & \text{if } a = x \end{cases} \quad \text{(F.4)}$$

where B_τ is the number of calves in year τ and is derived directly from equations C.1 and C.6.

$$B_\tau = \left(1 - \left[1/(N^f_\tau b_K) - 1\right]/A\right)^{1/z} \frac{K^{1+}}{N^{1+,*}_\tau} \quad \text{(F.5)}$$

The effective rate of increase, γ, is selected so that if the population dynamics model is projected from year τ to a year Ψ, the size of the 1+ component of the population in a reference year Ψ equals a value, P_Ψ.

G. **Conditioning**

The parameters of the model are: (a) the carrying capacity of each stock, (b) the population size for each stock at the start of 1930 (expressed relative to carrying capacity), (c) MSYR by stock, (d) annual survival under 'normal' conditions, (e) maturity as a function of age, (f) the impact of the mortality event in the eastern Pacific in 1999 and 2000, (g) selectivity, (h) the rate of dispersal between the NFG and the PCFG, (i) the parameters of the mixing matrices, (j) the catchability coefficients that determine bycatch by fleet (Eqn E.2), and (k) the extent of additional variation for each abundance index. Some of these parameters are pre-specified:

(1) MSYR (except for trials 14, 15, and 17);
(2) Annual survival under 'normal' conditions (base-case 0.98);
(3) Maturity as a function of age (a logistic function of age, with an age-at-50%-first-parturition of 8 years and a minimum age-age-at-first parturition of 3 years); and
(4) Selectivity (Table 3).

Under the assumption that the estimates of abundance for a sub-area (Table 6) are log-normally distributed, the negative of the logarithm of the likelihood function is given by:

$$-\ell n L = \ell n\sqrt{\mathrm{Det}[V]} + 0.5\sum_k (\ell\,\mathrm{n}\,\underline{N}^{A,obs} - \ell\,\mathrm{n}\,\underline{N}^{A})[V^{-1}](\ell\,\mathrm{n}\,\underline{N}^{A,obs} - \ell\,\mathrm{n}\,\underline{N}^{A})^T \quad \text{(G.1)}$$

where $N_t^{A,\mathrm{obs}}$ is the survey estimate of abundance for sub-area A during year t; and V is the sum of the variance-covariance matrix for the abundance estimates plus an additional variance term (assumed to be independent of year). Note that the abundance estimates for the western areas (Table 6a) depend on the stock hypothesis under consideration.

The data on the proportion of each stock (Tables 6a and 7) in each sub-area are modelled under the assumption that the proportions are normally distributed, i.e.:

$$-\ell n L = \sum_i \sum_A \sum_t \tfrac{1}{2(\tau_t^{i,A})^2}(p_t^{i,A} - p_t^{i,A,\mathrm{obs}})^2 \quad \text{(G.2)}$$

where $p_t^{i,A}$ is the model-estimate of the proportion of the animals in sub-area A that are from feeding aggregation i of the Eastern breeding stock; $p_t^{i,A,\mathrm{obs}}$ is the observed proportion of animals in in sub-area A that are from feeding aggregation i of the Eastern breeding stock; and $\tau_t^{i,A}$ is the standard error of $p_t^{i,A,\mathrm{obs}}$.

The (non-zero) bycatches by sub-area for the first five years for which data are available are assumed to be log-normally distributed, and the model is fitted to the average bycatch by sub-area over a pre-specified set of years (the years for which detection and reporting of entanglements, ship strikes, and strandings in general was relatively good; Table 3), i.e.:

$$-\ell\text{n}L = \sum_A \frac{1}{2\sigma_{BC}^2}\left(\ell\text{n}C^{I,A,\text{obs}} - \ell\text{n}\hat{\hat{C}}^{I,A}\right)^2 \quad \text{(G.3)}$$

where $C^{I,A,\text{obs}}$ is the observed average annual bycatch from sub-area *A* over the pre-specified period, $\hat{\hat{C}}^{I,A}$ is the average over this period of the model-estimate of the bycatch from sub-area *A*, and σ_{BC} is the standard error of the logarithms of the observed bycatches.

A penalty is imposed on the average number of animals moving permanently from the NFG into the PCFG between 2001 and 2008, i.e.:

$$-\ell nL = \frac{1}{2\sigma_I^2}\left(\tilde{I} - \frac{\delta^{\text{m/f,north},West}}{8}\sum_{t=2001}^{2008}\sum_{s=m/f}\sum_{a=1}^{x} I_{t,a}^{s,\text{East,north}}\right)^2 \quad \text{(G.4)}$$

where $\tilde{I}$ is the pre-specified average number of immigrants into the PCFG from the NFG, and σ_I is a weighting factor.

The estimates of survival for PCFG whales (Calambokidis *et al.*, 2017) are assumed to be normally distributed, i.e.:

$$-\ell\text{n}L = \frac{1}{2\sigma_{S,1}^2}(S^{\text{obs},1} - \hat{S}^1)^2 + \frac{1}{2\sigma_{S,2}^2}(S^{\text{obs},2} - \hat{S}^2)^2 \quad \text{(G.5)}$$

where $S^{\text{obs},1} = 0.917$, $\sigma_{L,1} = 0.0142$, $S^{\text{obs},2} = 0.967$, $\sigma_{L,2} = 0.0066$, $\hat{S}_1$ is the estimate of post-first-year survival for whales that entered in 1998 or earlier, and $\hat{S}_2$ is the estimate of post-first-year survival for whales that entered in 1999 or later.

H. **Quantifying uncertainty using bootstrap**

A bootstrap procedure is used to quantify uncertainty for a given model specification. Each bootstrap replicate involves:

(1) Generating pseudo time-series of abundance estimates based on the assumption that the abundance estimates are log-normally distributed with means and variance-covariance matrices given by the observed abundance estimates and the reported variance-covariance matrices.

(2) Generating pseudo mixing proportions from beta distributions with means and CVs given by the observed means and CVs.

(3) Generating pseudo bycatch rates by sub-area from log-normal distributions with means of $C^{I,A,\text{obs}}$ and a log standard error of σ_{BC}.

(4) Generating a pseudo immigration rate from the NFG into the PCFG based on a normal distribution (truncated at zero) with mean $\tilde{I}$ and standard error σ_I.

(5) Generating pseudo survival rates from normal distributions.

I. Generation of Data

The actual historical estimates of absolute abundance (and their associated CVs) provided to the *Strike Limit Algorithms* are listed in Table 6. The future estimates of abundance for sub-areas WFG, WST, BCNC-3 and CA-3 (say sub-area *K*) are generated using the formula:

$$\hat{P} = PYw / P^*\beta^2 Yw \quad \text{(I.1)}$$

where *Y* is a lognormal random variable *Y*=e$^{\varepsilon}$ where $\varepsilon \sim N(0;\sigma_\varepsilon^2)$ and $\sigma_\varepsilon^2 = \ell n(1+\alpha^2)$; *w* is a Poisson random variable with $E(w) = \text{var}(w) = \mu = (P/P^*)/\beta^2$, *Y* and *w* are independent; *P* is the current total (1+) population size in survey area *K*:

$$P = P_t^K = \sum_i\sum_j\sum_g\sum_{a\ge1} N_{t,a}^{g,i,j} \quad \text{(I.2)}$$

P^* is the reference population level, and is equal to the total (1+) population size in the survey area prior to the commencement of exploitation in the sub-area for which an abundance estimate is to be generated. For consistency with the first-stage screening trials for a single stock (IWC, 1991, 1994), the ratio $\alpha^2 : \beta^2 = 0.12 : 0.025$, so that $CV^2(\hat{P}) = \tau(0.12 + 0.025P^* / P)$. If $\overline{CV}$ is the target CV then $\tau = \overline{CV}^2 / (0.12 + 0.025P_{\rm ref} / P^*)$ where $P_{\rm ref}$ is the population size in a reference year.

An estimate of the *CV* is generated for each estimate of abundance:

$$CV(\hat{P})^2_{\rm est} = \sigma^2 \chi^2 / n \qquad \text{(I.3)}$$

where $\sigma^2 = \ell n(1 + \alpha^2 + \beta^2 P^* / \hat{P})$, and χ is a random number from a Chi-square distribution with *n* degrees of freedom (where *n*=10 as used for NP minke trials; IWC, 2004).

J. Trials

The factors included in the trials are listed in Table 8 and the trials in Table 9.

K. Management options

The strike limits for the BSCS sub-area are based on the Gray Whale *SLA* (IWC, 2005). The strike limits for the BCNC sub-area based on the Makah Management Plan (Appendix 1) although sensitivity is explored using variant 1 agreed to in 2012 (IWC, 2013; Appendix 2).

Removals due to bycatch are based on the scenarios regarding future trends in effort. Table 8 lists the factors considered in the projections.

L. Output Statistics

The population-size statistics are produced for each breeding stock / feeding aggregation, while the removal-related statistics are for each sub-area.

I.1 Risk

D1. Final depletion: P_T/K (1+ and mature female numbers by breeding stock / feeding group (median, lower 5th and upper 5th percentiles)).

D2. Lowest depletion: $\min(P_t / K) : t = 0,1,...,T$.

D3. Plots of $\{P_{t[x]} : t = 0,1,..,T\}$ where $P_{t[x]}$ is the *x*th percentile of the distribution of P_i. Results are presented for *x* = 5, 50, and 95.

D8. Rescaled final depletion: P_T/P_0 (1+ and mature female numbers by breeding stock / feeding group; median, lower 5th and upper 5th percentiles) where P_0 is number of 1+ / mature female animals had there been no future Makah hunts.

D10. Relative increase. The ratio of the 1+ and mature population size after 10 and 100 years to that at the start of the projection period by breeding stock / feeding group (median, lower 5th and upper 5th percentiles)

I.2 Removal-related

N9. Need satisfaction. The proportion of the total number of requested strikes that were taken over the first 10 years and the entire 100-year period (median, lower 5th and upper 5th percentiles).

R1. Plots of strikes by year for simulations 1-100.

R2. Plots of landed whales by year for simulations 1-100.

R3. Plots of incidental catches by year for simulations 1-100 (median, lower 5th and upper 5th percentiles by year).

1992	1.197	2004	0.626		

Table 6a

Abundance estimates (1+) for the WFG feeding aggregation and the western breeding stock (J.G. Cooke, pers. commn)

Year	Group	Stock hypothesis	Estimate	SD	CV
1995	WFG	3a/3c/3e/6b	75.1	3.8	0.051
1995	WBS	3b	25.8	7.3	0.282
1995	WFG	3b	75.5	3.3	0.043
1995	WBS	3e	30.0*	15.0	0.500
1995	WBS	5a	26.6	6.9	0.259
1995	WFG	5a	47.8	7.7	0.160
1995	WBS+WFG	5a	74.4	3.9	0.052
1995	WBS/(WBS+WFG)	5a	0.358	0.093	0.259
2015	WFG	3a/3c/3e/6b	199.8	5.4	0.027
2015	WBS	3b	63.8	15.8	0.248
2015	WFG	3b	198.9	5.7	0.029
2015	WBS	3e	30.0*	15.0	0.500
2015	WBS	5a	64.4	14.0	0.218
2015	WFG	5a	135.6	14.1	0.104
2015	WBS+WFG	5a	200.0	5.7	0.029
2015	WBS/(WBS+WFG)	5a	0.322	0.069	0.200

* Guestimate because the WBS cannot be distinguished given the available information.

Table 6b

Estimates of absolute abundance (with associated standard errors) for the eastern North Pacific stock of gray whales based on shore counts (source: 1967/78-2006/07: Laake *et al*, 2012; 2006/07-2015/16: Durban *et al*, 2013, 2017). These estimates are assumed to pertain to the total number of gray whales.

Year	**Estimate**	**CV**	**Year**	**Estimate**	**CV**

Table 6c
Estimates of absolute abundance (with associated CVs) for the PCFG feeding aggregation based on mark-recapture analysis (source: Calambokidis et al., 2017).

Year	Estimate	CV	Year	Estimate	CV
1998	126	0.087	2009	208	0.101
1999	145	0.101	2010	200	0.095
2000	146	0.098	2011	205	0.078
2001	178	0.076	2012	217	0.052
2002	197	0.069	2013	235	0.059
2003	207	0.084	2014	238	0.080
2004	216	0.077	2015	243	0.078
2005	215	0.125			
2006	197	0.108			
2007	192	0.136			
2008	210	0.089			

Table 7
Data on mixing proportions (definite and likely matches / non-matches only) to be used when conditioning the models.

Sub-area	Season	Stock / Feeding aggregation	Mixing proportion (assumed SD)
EJPJ	All	WBS/NFG	0.33 (0.1)
SEA	Feeding	PCFG	0.57[1] (0.1)
SEA	Feeding	WFG	0
SEA	Migration	PCFG	0.1[2] (0.1)
SEA	Migration	WFG	0.002[3] (0.05)
BCNC	Feeding	PCFG	0.93 (0.1)
BCNC	Feeding	WFG	0
BCNC	Migration	PCFG	0.28 (0.1)
BCNC	Migration	WFG	0.002 (0.05)
CA	Feeding	PCFG	0.60 (0.1)
CA	Feeding	WFG	0
CA	Migration	PCFG	0.1 (0.05)
CA	Migration	WFG	0.002[3] (0.05)

1: Not used in the conditioning except for the sensitivity test based when the bycatch is based on M/SI as no dead bycatch is recorded for the SEA sub-area during the feeding season.
2: Assumed value owing to lack of data to estimate mixing proportions.
3: Set to the value calculated for BCNC by Moore and Weller (2013)

Table 8
Factors considered in the model scenarios. The bold values are the base-levels and the values in standard font form the basis for sensitivity analyses.

Factor	Levels
Model fitting related	
Stock hypothesis	**3a,** 3b, 3c, 3e, **5a,** 6b
$MSYR_{1+}$ (western)	As for WFG
$MSYR_{1+}$ (north)	**4.5%**, 5.5%, Estimated (common); estimate (separately)
$MSYR_{1+}$ (WFG)	**4.5%** Estimated (common); estimate (separately)
$MSYR_{1+}$ (PCFG)	2%, **4.5%**, 5.5%¸ Estimated (common); estimate (separately)
Mixing rate (migration season in BCBC	**0.28**, 0.17, 1.00
Immigration into the PCFG	0, 1, **2**, 4
Bycatches and ship strikes	Numbers dead + M/SI, **dead x 4**; dead x 10; dead x 20
Pulse migrations into the PCFG	10, **20**, 30
Projection-related	
Additional catch off Sakhalin (mature female)	0, 1
Catastrophic events	**None**, once in years 0 – 49, and once in years 50-99
Northern need in final year (from 150 in 2014)	**340**
Struck and lost rate	**(0.1; odd-years; 0.5 even years),** 0.5 all years
Future effort	**Constant**, Increase by 100% over 100 years
Probability of a photo (struck and lost whales)	**0.8; odd-years; 0.6 even years**
Probability of a photo (landed whales)	**0.9**
Probability of false positive rate PCFG	**0.05**, 0.1
Probability of false negative rate PCFG	**0.25**
Probability of false positive rate WFG	**0.01**
Probability of false negative rate WFG	**0.041 (stock hypotheses 3a, 3c, 3e, 6b);** 0.040 (stock hypothesis 3b); **0.049 (stock hypothesis 5a)**
Probability of a sex assignment given a PCFG match	**0.81**

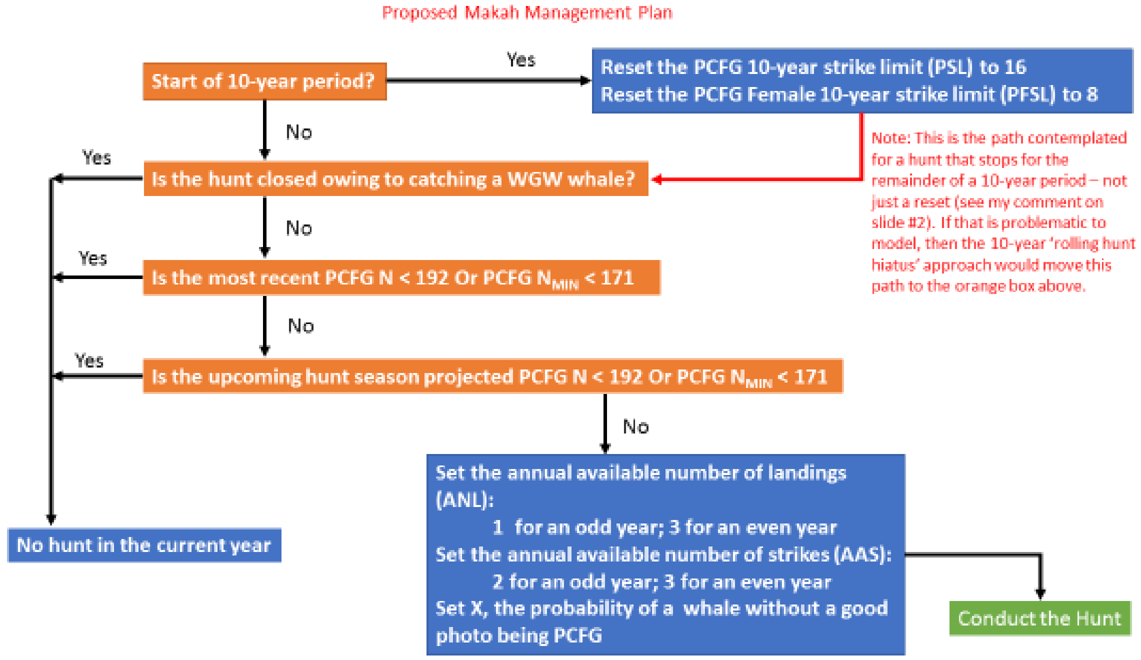
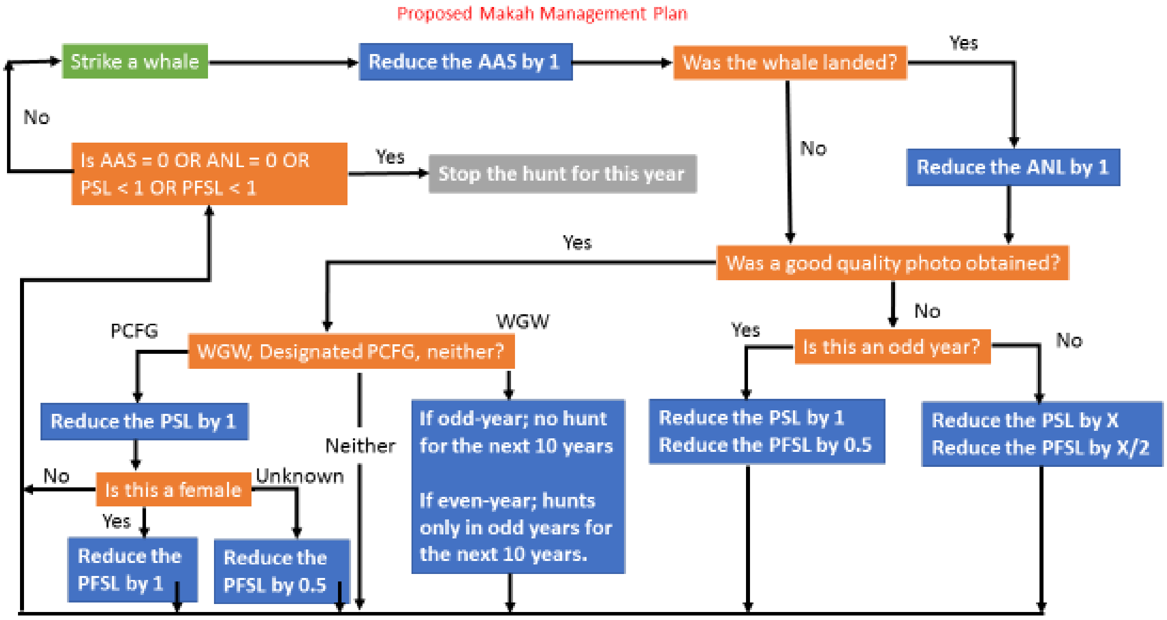
Appendix 1
OUTLINE OF THE MAKAH MANAGEMENT PLAN AND ITS IMPLEMENTATION IN TRIALS





Appendix 2
THE 'RESEARCH WITH VARIANT' (SLA VARIANT 1) OPTION (IWC, 2013).

This option operates as follows:

(1) Update the ABL (Allowable Bycatch Limit of PCFG whales) if this is the start of a new 6-year block as:

$$ABL = N_{MIN} * 0.5 * R_{MAX} * F_R$$

Where:

N_{MIN} is the log-normal 20th percentile of the most recent abundance estimate for the Oregon to Southern Vancouver (OR-SVI) sub-area of the PCFG. The abundance estimates for use in the ABL formula are generated as specified in Section I, except for allowance is made for a bias which differs among simulations but is constant over time between the estimates for OR-V and those for the PCFG, i.e. $\ell n B_A \sim N(-0.335, 0.112^2)$ (IWC, 2012).

R_{MAX} is equal to 0.04;

F_R is equal to 1.0.

(2) Strike an animal

(3) If the total number of struck animals equals the need of 7 stop the hunt.

(4) If the animal is struck-and lost:
   a. if the total number of struck and lost animals is 3, stop the hunt.
   b. go to step (2).

(5) If the animal is landed and is matched against the PCFG catalogue:
   a. add one to the number of whales counted towards the ABL
   b. if the ABL is reached; stop the hunt
   c. if the total number of landed whales equals 5; stop the hunt
   d. if the number of landed whales for the current six-year block equals 24; stop the hunt
   e. go to step (2).

(6) If the animal is landed and does not match any whale in the PCFG catalogue:
   a. if the total number of landed whales equals 5; stop the hunt
   b. if the number of landed whales for the current six-year block equals 24; stop the hunt
   c. go to step (2).

Annex E

Report of the Standing Working Group on Aboriginal Subsistence Whaling Management Procedures

Members: Donovan (Convenor), Allison, Aoki, Baba, Baird, Bell, Bickham, Brandão, Brandon, Brierley, Brownell, Burkhardt, Butterworth, Cubaynes, De Moor, DeMaster, Doniol-Valcroze, Double, Ferguson, Ferriss, Fortuna, Frey, Gallego, George, Givens, Haug, Hielscher, Holm, Hubbell, Iñíguez, Jaramillo-Legorreta, Johnson, Kitakado, Lang, Litovka, Lundquist, Mallette, Mckinlay, Morishita, Morita, Moronuki, Nelson, Palka, Pastene, Phillips,Punt, Reeves, R., Reeves, S., Ritter, Rodriguez-Fonseca, Rojas Bracho, Safonova, Scordino, Scott, Simmonds, Skaug, Slugina, Smith, Stachowitsch, Stimmelmayr, Suydam, Svoboda, Taylor, Terai, Thomas, Tiedemann, Víkingsson, Wade, Walløe, Walters, Weinrich, Weller, Wilberg, Witting, Zagrebelnyy, Zerbini, Zharikov.

1. INTRODUCTORY ITEMS

1.1 Convenor's opening remarks

Donovan welcomed the participants. The workload this year was immense. Two priority topics are: (1) work towards completion of the remaining *SLA*s for the Greenland hunts; and (2) developing a recommended Aboriginal Whaling Scheme. Both topics have been the subject of intense intersessional work including two workshops in Copenhagen in October 2017 and March 2018, as well as a small technical meeting in December at OSPAR headquarters in London. He stressed that this year, the Commission would be setting new catch/strike limits for all aboriginal subsistence hunts and therefore the third major topic is to provide advice on these. Finally, the SWG will try to complete the *Implementation Review* for Bering-Chukchi-Bering Sea (B-C-B) bowhead whales. He also reminded participants that we will need to provide a two-year workplan and budget.

Donovan noted that Cherry Allison was unable to attend the meeting in person this year and thanked her greatly for all the intersessional work undertaken as well as providing tremendous support from Cambridge. He also thanked Punt, de Moor, Brandão, Witting who have stepped up even more than usual with computing assistance.

He explained that the work of the intersessional Steering Group on developing *SLA*s for the Greenland hunts is ongoing and will continue during this meeting as the report of this group will assist greatly in discussing Item 2. Similarly, the intersessional group on the AWS is continuing and the group's final report will greatly facilitate discussions under Item 3.

1.2 Election of Chair and appointment of rapporteurs

Donovan and Brandon were named co-Chairs. Brandão, Brandon and Givens acted as rapporteurs with the assistance of the Chair.

1.3 Adoption of Agenda

The agenda was adopted. See Appendix 1.

1.4 Documents available

The documents available included SC/67b/AWMP01rev1, SC/67b/AWMP02-08, SC/67b/AWMP10, SC/67b/AWMP12, SC/67b/AWMP13rev1, SC/67b/AWMP14-19, SC/67b/AWMP20rev1, SC/67b/Rep06, and SC/67b/Rep07.

Donovan drew attention to the fact that Canadian scientists had submitted two papers (Frasier *et al.* (2015) [SC/67a/ForInfo31] and Doniol-Valcroze *et al.* (2015) [SC/67b/ForInfo32]) providing abundance estimates for Eastern Canadian-West Greenland bowhead whales. The SWG **greatly appreciated** these contributions.

2. *SLA* DEVELOPMENT

2.1 Fin whales (Greenland)

2.1.1 Review results of intersessional workshops – SC/67b/Rep06

Donovan presented SC/67b/Rep06 and provided an overview of progress made during two intersessional Workshops and the small working group meeting.

He reported that considerable progress was made in relation to the following|:

(a) updated abundance estimates (and see Item 5.6.2);
(b) finalisation of the trial structure;
(c) review and approval of conditioning;
(d) initial consideration of new *SLA*s and results.

2.1.2 Review post-Workshop progress

Most of the work undertaken after the final workshop involved *SLA* development. The final trial specifications are provided as Appendix 2. Table A.XX summarises the main factors considered in the *Evaluation Trials.*

SC/67b/AWMP13 developed a candidate *SLA* for West Greenland fin whales. The new fin whale trials have a large amount of variation in the point estimates of abundance, and the *SLA* takes an inverse variance weighted average of the last three estimates as an estimate of abundance. The strike limit is then calculated as a growth rate fraction of a lower percentile of the abundance measure, conditional on a trend modifier, a snap to need feature, and a protection level. This *SLA* is somewhat simpler than the earlier fin whale *SLA*s developed by Witting. Those fitted a straight line to the abundance estimates in order to obtain a measure of abundance and trend. However, these estimates were unreliable due to the highly variable abundance estimates of the trials. The *SLA* is proposed in three versions, where the D10 statistics for the 5th percentile of the 'Influx' trial F34-1 is tuned to 1.0, 0.9 and 0.8 for the medium (B) need envelope.

SC/67b/AWMP15 presented three potential *SLA*s for West Greenlandic fin whales that are based on a weighted-average interim *SLA* which uses all abundance estimates, but earlier abundance estimates are down-weighted compared to more recent ones. An adjustment to the multiplier of the abundance estimate in the interim *SLA* is applied which depends on the trend of the abundance indices. This approach allows for additional reduction of the *Strike Limit* if the time series of abundances shows a reasonably precise downward trend in abundance. Three candidate *SLA*s are tuned to achieve 1.0, 0.9 and 0.8 for the conservation statistic (D10, relative increase) at the lower 5th percentile for the Influx hypothesis trial GF34-1B with an $MSYR_{1+}$ of 1% and the middle need envelope (B) as suggested at the 2018 Workshop (SC/67b/Rep06). Dropping the D10 statistic to 0.8 for this trial improves need satisfaction by all other trials without sacrificing conservation performance (except for the Influx hypothesis trials at $MSYR_{1+}$= 1%). It was noted that these *SLA*s do not have a snap to need feature.

2.1.3 Review final results and performance

In total, seven potential *SLA*s (which include the 'Interim' *SLA* – a modified version of the *Interim SLA* that has been used to provide advice for the last two blocks) were reviewed. As in previous years, an initial examination of the full set of results was undertaken by a 'winnowing' group with the aim to focus the SWG to those aspects of the performance of the *SLA*s that needed to be discussed further. Initially, the focus was on projections of the lower 5th percentiles and medians for 1+ population abundance and 'Zeh' plots for various performance statistics. Focus was given to the exploration of the univariate performance statistics D1 (final depletion) and D10 at the lower 5th percentile. The desired performance for these statistics is to obtain a value of D10 greater or equal to one and for D1 to be above 0.6 (MSYL). In other words, satisfactory performance on the conservation criteria by an *SLA* is deemed if either the population is not at MSYL but it is increasing or the population is increasing/decreasing but is above MSYL.

Tables which highlighted which *SLA* was performing well or not relative to the 'best' performance amongst all the *SLA*s (including the 'Interim' *SLA*) were also examined to evaluate the performance of the proposed *SLA*s. Plots of depletion where examined as the conservation statistics are based on this rather than on population abundance numbers. Trials for which at least one of the proposed *SLA*s failed either the D1 or the D10 conservation statistics were highlighted for further investigation (5 trials). Looking at results on a single dimension was not helpful because the D10 statistic does not need to be at or above one if the population is above MSYL. Thus, further focus on the performance of the *SLA*s was placed rather on the joint statistic of D1 and D10 for these 5 trials.

The bivariate plots of the D1 and D10 statistics (see Fig. B.1 Appendix 3) were examined for all the proposed *SLA*s, with a focus on the simulation results in the quadrant in which D1 <0.6 and D10 <1. The counts of the simulations for all *SLA*s that fall in this quadrant were examined to see if this could help to distinguish the performance amongst the different *SLA*s. Examination of these plots concluded that for all the trials that had failed on at least one of the univariate conservation statistics, only trial F34-1C (a low MSYR, high need case for the Influx model) showed unacceptable conservation performance.

The SWG **agreed** that the proposed *SLA*s performed satisfactorily on the joint conservation statistics for the A and B (but not for C) need envelopes for all trials, and the selection between *SLA*s was narrowed down to those that had been tuned to obtain D10 of 0.8 for the more difficult Influx hypothesis trial F34-1B (B0.8 and L0.8). The focus on selecting amongst the *SLA*s should be on the *SLA* that meets need satisfaction best and that also achieves stability in the catches. 'Zeh' plots were examined for all trials, concentrating on the need satisfaction statistics, N9(20) the average need satisfaction over the first 20 years, N9(100) the average need satisfaction over the 100 years and N12 the mean downstep statistic, which is a modified average annual variability statistic.

It was noted that because of the present incorporation into the trial structure of the widely different 'Influx' and 'partial' hypotheses to explain the variability of the abundance estimates, the need satisfaction over 20 years is more appropriate to consider than over 100 years as it is likely that future *Implementation Reviews* may be able to remove one or other scenario.

After an examination of the full range of results, there was no obvious 'winner' between the two *SLA*s. Depending on the trials considered, and which statistic was examined, the different *SLA*s performed slightly differently but their performance overall was equivalent.

Following an approach originally adopted during the development of the *Bowhead SLA*, the SWG **agreed** that an *SLA* which sets the strike limit to the average of the values obtained by the two *SLA*s tuned to a D10 of 0.8 for the influx trial F34-1B (B0.8 and L0.8) would be preferable, providing performance was as good or better than either individual *SLA*; no snap to need for the averaged *SLA* has been applied. The results of the 'combined *SLA'* are summarised in Appendix 3.

2.1.4 Conclusions and recommendations
The SWG **agreed** that the *SLA* which sets the strike limit to the average of the values obtained by the two *SLA*s tuned to a D10 of 0.8 for the influx trial F34-1B (B0.8 and L0.8) performed satisfactorily in terms of conservation performance and that it was to be preferred over the individual proposed *SLA*s in terms of need satisfaction. The SWG **agreed** that this '*WG-fin SLA*' be used to provide management advice to the Commission on the subsistence hunt for West Greenland fin whales under need scenarios A and B. For the management advice see Item 5.6.

In conclusion, the SWG expressed its **great thanks** to the developers, Brandão and Witting for the vast amount of work put into the development process. It also expressed similar thanks to Allison and Punt for their extensive work developing the operating models and running the trials. It noted that final validation and archiving would be undertaken by Allison.

The SWG also concurred with the intersessional Workshop (SC/67b/Rep06, item 2.7) that one focus of the next *Implementation Review* would be to examine further stock structure in relation to the two hypotheses being considered at present, and especially the influx model which was developed in the context of low abundance estimates in some years rather than genetic information.

Attention: C-A, SC

The Committee ***draws attention*** *to the extensive work undertaken over recent years to develop an S*LA *for the West Greenland hunt for fin whales. In concluding this work, the Committee:*

(1) ***agrees*** *that the combined* SLA *(which sets the strike limit to the average of the values obtained by the two best SLAs considered) performed satisfactorily in terms of conservation performance and was to be preferred over the individual SLAs in terms of need satisfaction;*
(2) ***recommends*** *that this* 'WG-Fin SLA' *be used to provide management advice to the Commission on the subsistence hunt for West Greenland fin whales (provided the need request falls within need scenarios A and B);*
(3) ***expresses*** *its great thanks to the developers, Brandão and Witting for the vast amount of work put into the development process and to Allison and Punt for their extensive work developing the operating models and running the trials; and*
(4) ***agrees*** *that one focus of the next* Implementation Review *will be to examine further stock structure in relation to the two hypotheses being considered at present, and especially the 'influx' model which was developed in the context of low abundance estimates in some years, rather than being based upon genetic information.*

2.2 Common minke whales (Greenland)
2.2.1 Review results of intersessional workshops - SC/67b/Rep06
Donovan summarised report SC/67b/Rep06 and the intersessional progress made on common minke whales. He noted that enormous effort had been devoted to reviewing the new genetic information that had been provided in response to a recommendation at SC/67a. This had greatly assisted in developing the final stock structure hypotheses and mixing matrices to be considered in the trials. These extensive discussions can be found under items 3.3.1 and 3.3.2 of SC/67b/Rep04.

Finally, the Workshop **agreed** that instead of formally using the RMP to set catch limits by sub-area and year for each simulation, the RMP catch limits would be pre-specified based upon baseline hypothesis 1 trials (M01-1 and M01-4). This allows the trials to run more quickly and focus to be given on *SLA* development – the objective of this work. Details can be found in the full trials specification (Appendix 4).

2.2.2 Review post-Workshop progress
Considerable work was undertaken to finalise the list of trials, to ensure that the mixing matrices were correctly specified and to complete and agree conditioning. The final trial specifications are provided as Appendix 4.

Table 4.XX summarises the factors considered in the *Evaluation Trials.*

2.2.3 Candidate SLAs
SC/67b/AWMP14 developed a candidate *SLA* for common minke whales off West Greenland. It operates, like the fin whale *SLA* in SC/67b/AWMP13, on an inverse variance weighted average of the last three abundance estimates. The strike limit is calculated as a growth rate fraction of a lower percentile of the abundance measure, conditional on a snap to need feature, and a protection level. The *SLA* for common minke whales, however, does not include a trend modifier, as it is almost impossible to detect an underlying trend from the abundance data in West Greenland.

The *SLA* was tuned to have a 5th percentile of D10 of 0.80 for a flat need envelope of 164 on the most difficult *Evaluation Trial* (trial M04-1A, where there are two sub-stocks in the western North Atlantic, where the mixing between the Central and the Western stock, and the mixing between the putative western sub-stocks, are minimal, and where the MSYR is 1%). Conservation performance on all other measures was adequate for all trials with a flat need of 164, and the *SLA* produces an expected average need satisfaction of 99% (with a lower 5th percentile of 89%) for the first 20 years, and 89% (5th percentile of 61%) for the 100-year simulation period.

2.2.4 Consideration of results

The SWG **agreed** that conditioning of the *Evaluation Trials* had been completed satisfactorily. A summary of the results of the *Evaluation Trials* is provided in Appendix 5.

In determining satisfactory conservation and need performance when evaluating *SLA*s, the SWG considers the full range of results across all of the *Evaluation Trials* not simply the worst-case scenarios. The SWG **agreed** that conservation performance was satisfactory in all but one of the trials. This trial was a trial with low MSYR and two W-stocks and had been originally considered in the context of potential problems for the hunt to simulate possible local depletion in the hunting area rather than for conservation reasons. It was noted that genetic stock structure in the entire North Atlantic is subtle such that even a hypothesis of almost complete panmixia is not rejected by most of the analyses. Hence, differentiation among C and W is very low. This is even more true for substructure within the W stock (if there is any. Given that trials are conservative in so far to overrate isolation among stocks and the very subtle differentiation among stocks and sub-stocks in the North Atlantic, a single trial (which implements fully separate W1 and W2 sub-stocks for which evidence is weak) not meeting the D1/D10 criteria is not of conservation concern.

In developing this advice, the SWG noted that given the unforeseen situation with Secretariat computing, there had been insufficient time to consider the results of the *Robustness Trials* in the SWG. Such trials are not needed to determine an *SLA* but are examined to ensure that the selected *SLA* has no unforeseen properties in extreme trials. Given the importance of being able to provide the best management advice to the Commission, the SWG agreed that the Steering Group set up for *SLA* development should take responsibility to review the results of the *Robustness Trials* as soon as they become available and report to the Plenary session[1].

2.2.4 Conclusions and recommendations

Given the overall satisfactory performance in the *Evaluation Trials* with respect to meeting the Commission's conservation and management objectives for need envelope A (i.e. constant need over the simulation period), the SWG **agreed** to recommend this, the '*WG-common minke SLA'* to the Committee as the best way to provide management advice for the West Greenland hunt of common minke whales. The management advice developed using the *WG-common minke SLA* is provided under Item 5.5.

In accordance with the AWS (see Item 3), the first *Implementation Review* is scheduled for 2023. The SWG **agreed** that one focus of that review should be consideration of the results of analyses of genetic data using additional samples from Canada (as well as the additional samples that will become available from West Greenland and Iceland). To this end it **agrees** that planning for the *Implementation Review* should begin two years before the scheduled review. A small group comprising Tiedemann, Doniol-Valcroze, Witting and Víkingsson was established to facilitate issues related to obtaining samples.

In conclusion, the SWG expressed its **great thanks** to the developers, Brandão and Witting for the vast amount of work put into the development process. It also expressed similar **thanks** to Allison and Punt for their extensive work developing the operating models and running the trials. It noted that final validation/archiving would be undertaken by Allison.

Attention: C-A, SC

*The Committee **draws attention** to the extensive work undertaken over recent years to develop an* SLA *for the West Greenland hunt for common minke whales. In concluding this work, the Committee:*

(1) ***agrees*** *that the tested* SLA *which performed satisfactorily in terms of conservation performance;*
(2) ***agrees*** *that this 'WG-Common minke SLA' be used to provide management advice to the Commission on the subsistence hunt for West Greenland common minke whales provided the need request falls within need scenario A (i.e. does not exceed 164 annually);*
(3) ***expresses*** *its great thanks to the developers, Brandão and Witting for the vast amount of work put into the development process and to Allison and Punt for their extensive work developing the operating models and running the trials; and*
(4) ***agrees*** *that one focus of the next* Implementation Review *will be to examine further stock structure in relation to the two hypotheses being considered at present, should be consideration of the results of analyses of genetic data using additional samples from Canada (as well as the additional samples that will become available from West Greenland and Iceland); and*
(5) ***agree****s to establish an intersessional group to facilitate issues relating to samples.*

---

[1]Editor's note: this was completed and no problems were detected.

2.3 North Pacific gray whales (Makah whaling)

2.3.1 Management plan proposed by the US for Makah whaling

The Makah Indian Tribe has requested that the US National Marine Fisheries Service (NMFS) authorises a tribal hunt for Eastern North Pacific gray whales in the coastal portion of its 'usual and accustomed fishing area'. The Tribe intends to hunt gray whales from the ENP population, which currently numbers approximately 27,000 animals (Durban *et. al.*, 2017). In the management plan, NMFS has taken measures to restrict the number of PCFG whales that are struck or landed in a given 10-year period and to avoid, to the extent possible, striking or killing a Western North Pacific gray whale. The US government has requested that the Committee test this plan to ensure that it meets IWC conservation objectives. An overview of the hunt management plan and how it was operationalised in the coding of the *SLA* trials is provided in Appendix 1 of SC/67b/Rep/07.

2.3.2 Review intersessional progress including at the Rangewide Workshop - SC/67b/Rep07

Donovan summarised the report of the Fifth Rangewide Workshop on the Status of North Pacific Gray Whales (SC/67b/Rep07rev1). The Workshop was held at the Granite Canyon Laboratory, California of the Southwest Fisheries Science Center from 28-31 March 2018. The primary tasks of the Workshop were to: (a) review the results of the modelling work identified at the Fourth Workshop (IWC, 2018a) and SC/67a (IWC, 2018b); (b) examine the new proposed Makah Management Plan (submitted by the USA – described above and illustrated in the Workshop report under Annex E, Appendix 1) for gray whaling off Washington state; and (c) to update as possible (and develop a workplan for) the scientific components of the Conservation Management Plan (CMP) for western gray whales.

The major focus of the Workshop related to finalising the specifications for modelling to enable results to be available for SC/67b. A new component included the need to incorporate the recently developed Makah Management Plan (SC/67b/Rep07, Annex E, Appendix 1) into the modelling framework; the Plan is somewhat complex and the Workshop focus was on understanding the intended process and ensuring that it was parameterised in an appropriate way. A further key area was finalising the stock structure hypotheses to be given priority. After a review, the Workshop concluded that Hypotheses 3a and 5a would form the reference cases but that sensitivity trials would be conducted for Hypotheses 3b, 3c, 3e and 6b. The full specifications for these hypotheses are provided in SC/67b/Rep07 (Annex E, Appendix 1 and Annex F).

In summary, Hypothesis 3a assumes that whilst two breeding stocks (Western and Eastern) may once have existed, the Western breeding stock (WBS) is extirpated. Whales show matrilineal fidelity to feeding grounds, and the Eastern breeding stock includes three feeding aggregations: PCFG (Pacific Coast Feeding Group), NFG (Northern Feeding Group) and WFG (Western Feeding Group). Hypothesis 5a assumes that both breeding stocks are extant and that the WBS feeds off both coasts of Japan and Korea and in the northern Okhotsk Sea west of the Kamchatka Peninsula. Whales feeding off Sakhalin include both whales that are part of the extant WBS and remain in the western North Pacific year-round, and whales that are part of the Eastern breeding stock and migrate between Sakhalin and the eastern North Pacific (the WFG).

Another important component of the trials relates to bycatch. Considerable effort was put into capturing the uncertainty in past and future estimates of bycatch mortality based upon the available data. The base case for trials was that observed deaths due to bycatch account for only 25% of the true incidental human caused mortality. This fraction was based on a study of bottlenose dolphin stranding data off the coast of California (Carretta *et al*. 2016). Trials were also considered with higher rates of cryptic mortality, including scenarios where observations represent only 5% of true incidental human caused mortality.

Abundance estimates for the eastern North Pacific and the PCFG had been approved by the Committee last year (IWC, 2017). New estimates of abundance for western gray whales were provided by Cooke (SC/67B/ASI/02), and correspond with the various stock structure hypotheses for the western feeding group (WFG), WBS and WST (WFG + WBS). These estimates were reviewed and adopted by the SWG on ASI (Annex Q). Modifications were also made to the mixing matrices in the rangewide model based on the new estimates.

Each stock structure hypothesis was combined with multiple assumptions about other factors (e.g. bycatch rates) and this led to the development of 53 'trials' (see Table 6 of SC/67b/Rep07). Each trial was based on 100 simulations that reflect uncertainty in the estimated parameters of the model. Projections thus lead to a very large amount of model output that needed to be distilled to address questions such as the conservation performance of the new management plan for Makah whaling with respect to the stocks in question (in particular, the PCFG and the WFG). The Rangewide Workshop identified several plots and 'performance statistics' to summarise results from each trial (see Section 4.4.5 of SC/67b/Rep07 and Appendix 4).

Brandon presented an update on the code validation for the model. The first phase of code validation was completed prior to Fifth Rangewide Workshop. That effort focused on the code implementing the operating model and the conditioning process. A summary, including a brief overview of the code and input files was provided to the Workshop (SC/M18/CMP03). Like the first phase, the second phase of code validation involved checking the code against the mathematical and statistical model specifications. The focus of this validation phase was on three aspects of the code: (1) future projections and the updated US management plan concerning strike and landing limits for Makah whaling; (2) input files for the factors considered across conditioning trials and; (3) processing results across simulations into relevant performance statistics. Code validation was completed prior to the presentation of model results to the SWG.

The sub-committee on CMP reviewed and approved the conditioning results in the context of the full rangewide review. The SWG reviewed the model results with a focus on conservation performance of the management plan for Makah whaling. To aid in this evaluation, bivariate plots were generated for the lower 5th percentiles of the D1 and D10 performance statistics. Trials for which the D1 statistic is less the 0.6 after 100 years (i.e. the stock is not above its MSYL) and the D10 statistic after 100 years is not larger than 1 (i.e. the stock is not increasing towards MSYL) represent a scenario under which the management plan would not be expected to meet the conservation objectives for ASW (this is denoted by the gray quadrant in Fig X of Appendix 6). Several trials were identified in this category, but they corresponded with scenarios that were considered to have the low plausibility (e.g. bycatch mortality of ~ 20 PCFG whales per year). The SWG **agreed** that the performance of the management plan for Makah whaling was adequate to meet the Commission's conservation objectives for the PCFG, WFG and northern feeding group gray whales in the context of the proposed Makah hunt.

2.3.3. Conclusions and recommendations

The SWG **agreed** that the newly proposed hunt management plan for the Makah Tribe's gray whale hunt meets the IWC conservation objectives for PCFG, WFG, and ENP gray whales (see Appendix 6). Similar to its recommendations regarding the hunt plan evaluated during the last *Implementation Review* (IWC, 2012; 2013), the new hunt management plan is dependent on photo-identification studies to estimate PCFG abundance and the mixing proportions of PCFG whales available to the hunt (and bycatch in its range). The SWG's conclusions are dependent on the assumption that these studies will continue in the future.

Attention: C-A, SC

The Committee was asked by the USA to review a US Management Plan for a Makah hunt of gray whales off Washington State (the Committee had evaluated a previous plan in 2011 - IWC, 2011; 2012). The Committee conducted this work using the modelling framework developed for its rangewide review of gray whales (SC/67b/Rep07). In conclusion, the Committee:

(1) ***agrees*** *that the performance of the Management Plan was adequate to meet the Commission's conservation objectives for the Pacific Coast Feeding Group, Western Feeding Group and Northern Feeding Group gray whales;*
(2) ***notes*** *that the proposed management plan is dependent on photo-identification studies to estimate PCFG abundance and the mixing proportions of PCFG whales available to the hunt (and to bycatch in its range);*
(3) ***stresses*** *that its conclusions are dependent on the assumption that these studies will continue in the future; and*
(4) ***expresses*** *its great thanks to Punt, Brandon and Allison for their excellent work in developing and validating the testing framework and running the trials.*

2.4 West Greenland bowhead whales

2.4.1 Review results using 400 replicates

Following a previous examination of the precision with which estimates of the 5th percentiles of the performance statistics could be obtained as the number of replicates was increased; an agreement was made that 400 simulations should be used to determine the performance of the selected *SLA* for West Greenland bowhead whales. SC/O17/AWMP03 had showed projection plots for the 5th percentile and the median of the 1+ population for the baseline evaluation trials for this *SLA* based on 400 simulations. For comparison purposes, the projections for the *SLA* under 100 simulations were also shown. These show substantial variability between estimates of the 5th percentile of the distribution of population size.

Wilberg presented an analysis (Appendix 7) based on bootstrapping that was used to determine the effect of the number of simulations on the precision of the estimates of the 5th percentile of several performance measures. Projections for the selected *SLA* for West Greenland bowhead whales showed substantial differences in estimates of the 5th percentile of abundance based on 100 and 400 simulations. With only 100 simulations, the confidence intervals of the 5th percentile were quite wide, but 400 simulations led to a substantial improvement in precision. The investigation concluded that continuing to use 400 trials for the simulations appears to be sufficient to estimate the lower 5th percentile with a reasonable amount of precision.

2.4.2 Testing the Interim Allowance strategy

The SWG noted that the interim relief strategy (see Item 3) has not been examined for this *SLA* yet and **agreed** that this should be added to the workplan.

2.4.3 Conclusions and recommendations

It was agreed that continuing to use 400 replicates for the simulations is sufficient to estimate the lower 5th percentile with adequate precision.

3. ABORIGINAL WHALING MANAGEMENT SCHEME (AWS)

The Scientific Committee's Aboriginal Whaling Management Procedure (AWMP) applies stock-specific *Strike Limit Algorithms* (*SLA*s) to provide advice on aboriginal subsistence whaling (ASW) strike/catch limits.

ASW management (as part of an AWS, the aboriginal whaling scheme) incorporates several components, several of which have a scientific component:

(a) *Strike Limit Algorithms* (case-specific) used to provide advice on safe catch/strike limits;
(b) operational rules (generic to the extent possible) including carryover provisions, block quotas and interim relief allocations;
(c) Guidelines for *Implementation Reviews*; and
(d) Guidelines for data and analysis (e.g. guidelines for surveys, other data needs).

3.1 Review intersessional work
In 2017, the Scientific Committee appointed an intersessional correspondence group (Givens (Chair), Allison, Donovan, George, Scordino, Stachowitsch, Suydam, Tiedemann, Witting) to develop draft text regarding the scientific aspects of an Aboriginal Whaling Scheme. The starting place was a previous version agreed by the Scientific Committee (IWC, 2003). Two key components of a new draft AWS were the interim relief allowance and carryover provisions. The report of this group is SC/67b/AWMP21.

Donovan summarised the results from the intersessional workshops on the AWS. In addition to continuation of discussions on the extensive work of the intersessional group under Givens (see above), the Governments of Denmark and the USA had requested advice on the conservation implications of provisions that:

> '…allow for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit'.

This request was tested using the *Bowhead SLA* (applicable to the Bering-Chukchi-Beaufort Seas stock) and the *WG-Humpback SLA* (applicable to West Greenland) and three types of options were examined:

(1) baseline case - all strikes taken annually (i.e. no need for carryover);
(2) 'frontload' case - strikes taken as quickly as possible within block (+50% limit annually until the block limit is reached); and
(3) two alternative scenarios where carryover strikes are accrued for one or three blocks, followed by a period of carryover usage subject to the +50% limit.

The three-block scenario considered in (3) served as a direct test of the provision described in the request of USA and Denmark/Greenland. The Committee agreed that the Commission's conservation objectives were met for both *SLA*s for all of the options above and would also be met for a proposal carrying forward strikes from the previous two blocks.

Attention: CG-A

The Committee received a request from the USA and Denmark/Greenland (SC/67b/Rep06, Annex F, appendix) on the conservation implications of carryover provisions that:

> *'…allow for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit'.*

The Committee reviewed the request using its simulation frameworks and the two SLA*s available for stocks hunted by the USA and Greenland available at the time of the Workshop i.e. the* Bowhead SLA *(applicable to the Bering-Chukchi-Beaufort Seas stock) and the* WG-Humpback SLA *(applicable to West Greenland) and*

(1) ***agrees*** *that a carryover provision for up to 3-blocks meets Commission's conservation objectives; and*

(2) ***reiterates*** *its previous advice, applicable for all* SLA*s, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable; and*

(3) ***agrees*** *to evaluate the above request for the other Greenland* SLA*s at the 2019 Committee meeting.*

3.2 Review proposed updates to the AWS
The SWG considered a proposed update to the previous AWS based upon the work of the intersessional correspondence group. It considers carryover, block quotas, interim relief allocation, *Implementation Reviews* and Guidelines for surveys and data. The agreed text can be found as Appendix 8.

3.3 Conclusions and recommendations
The SWG **recommends** the AWS provided in Appendix 8 to the Committee. It notes that the Commission's AWS may include additional, non-scientific provisions.

Attention: C-R

The Committee has been working for some years to update the scientific components of an Aboriginal Whaling Scheme. It has completed this work and recommends the AWS provided in Annex E, appendix 8 to the Commission. It has sections on carryover, block quotas, interim relief allocation (and see Annex E, appendix 7), Implementation Reviews and guidelines for surveys and data. It notes that the Commission's AWS may include additional, non-scientific provisions.

---

4. *IMPLEMENTATION REVIEW* OF B-C-B BOWHEAD WHALES

From the Committee's Guidelines (*JCRM* 14 (*Suppl.*): 170-1), the primary objectives of an *Implementation Review* are to:

(1) review the available information (including biological data, abundance estimates and data relevant to stock structure issues) to ascertain whether the present situation is as expected (i.e. within the space tested during the development of a *Strike Limit Algorithm* (*SLA*)) and determine whether new simulation trials are required to ensure that the *SLA* still meets the Commission's objectives; and

(2) to review information required for the *SLA*, i.e. catch data and, when available at the time of the *Review*, new abundance estimates (note that this can also occur outside an *Implementation Review* at an Annual Meeting).

The *Bowhead SLA* was adopted in 2002 (*JCRM* 5 (*Suppl.*): 158) and there was an extensive *Implementation Review* completed in 2007 (*JCRM* 10 (*Suppl.*): 124) with a major focus on stock structure including three intersessional workshops. That included consideration of additional trials investigating management implications of assuming additional population structure even though these were considered of low plausibility. The Committee concluded that the *Bowhead SLA* remained the best tool to provide management advice. The next *Implementation Review* was completed in 2012 (*JCRM* 14 (*Suppl.*): 147); that concluded that there was no need to develop additional trials to those evaluated during the previous *Implementation Review* (IWC, 2008b).

In Committee discussions last year (IWC, 2018), it was agreed that at that time, there was no information that suggested that the situation for this stock was outside the tested parameter space. Given that, the Committee had agreed that it should be possible to complete the *Implementation Review* at the 2018 Annual Meeting. It established a Steering Group (Suydam [Convenor], Donovan, George) to prepare for the *Review* and Donovan confirmed that the Data Availability deadlines were met and that papers on the necessary topics were submitted. Donovan thanked the US colleagues for the extremely hard work that they have put in to providing the SWG with papers to facilitate this review.

Discussions within the SWG benefitted from the discussions within two other sub-committees, SD-DNA (Annex I) and ASI (Annex Q) and, as relevant, conclusions from those groups are briefly summarised under the agenda items below.

4.1 Stock structure: review new information

The Working Group on SD-DNA provided a summary of their discussions relevant to the *Implementation Review*. Genetic analyses (SC/67b/SDDNA01) confirmed that B-C-B bowheads and bowheads in the Sea of Okhotsk constitute two distinct stocks. There may be some weak distinction between B-C-B and EC-WG bowheads, but the majority of the evidence found no significant difference between these two populations. There is one known instance of interchange (from east to west), and one set of overlapping telemetry tracks, although those two whales returned to the populations from which they came. SC/67b/AWMP04 presented data from 64 satellite tagged whales, all but one of which followed the well-known counter-clockwise Bering-Beaufort-Chukchi circuit. The unusual track corresponded to a whale tagged in Utqiaġvik(Barrow) in autumn that migrated to the north coast of Chukotka the following spring, rather than swimming east into the Beaufort Sea. Considering the multiple lines of evidence as a whole, the Working Group on SDDNA had concluded that B-C-B bowheads constituted a single population, with no signs of substructure.

The SWG welcomed this information and thanked the hunters for their skill in making the tagging efforts efficient and successful. It **encouraged** continuation of these tagging studies. The SWG **agreed** that there was no need to consider any new *SLA* trials regarding stock structure, since the trials conducted in 2002 and 2007 already covered all plausible stock structure hypotheses.

Attention: SC

With respect to stock structure, considering the multiple lines of evidence, the Committee:

(1) agrees that BCB bowheads comprise a single population, with no signs of substructure;
(2) agrees that there was no need to consider any new SLA trials regarding stock structure, since the trials conducted in 2002 and 2007 already covered all plausible stock structure hypotheses;
(3) welcomes the telemetry information provided, thanks the hunters involved for their skill and assistance;
(4) encourages additional telemetry efforts; and
(5) agrees with the suggestions for future genetic studies in the Arctic provided under Item 11.

4.2 Abundance estimates: review new information

The Working Group on ASI (Annex Q) received new information about the 2011 B-C-B bowhead abundance from a long-term photo-identification capture-recapture study (SC/67b/AWMP01rev1). The estimated 1+ abundance was 27,133 (CV=0.217; 95% CI from 17,809 to 41,337). They concluded that this estimate could be classified as having been examined in detail and found to be suitable for providing management advice and for use in the *SLA*.

The SWG **welcomed** this information and noted that there was a completely independent 2011 abundance estimate from an ice-based survey (Givens *et al.*, 2016). This estimate is 16,820 (CV=0.052; 95% CI 15,176 to 18,643). It is not surprising that these two estimates differ because - in addition to random variability - the ice-based estimate does not count whales that are spatially or temporally excluded from the survey, whereas the photo-id dataset is more likely to contain false negative matches than false positive matches and this imbalance will tend to inflate the resulting abundance estimate.

There are thus two independent estimates for the same year considered suitable for use in the *SLA* (the ice-based estimate is already used). Discussion on how to consider such circumstances is provided under Items 3 and 5.

The Working Group on ASI (Annex Q) also received two reports on future B-C-B bowhead survey plans (SC/67b/AWMP12 and SC/67b/AWMP16). The first is for an ice-based survey in spring 2019, following methods used in earlier such surveys but not including an acoustic component. The availability of bowhead whales will be estimated from past acoustic data, as has been done with previously accepted estimates. The second survey is an August 2019 aerial line transect survey of unprecedented scope for B-C-B bowheads, covering the eastern edge of the Chukchi Sea and the entire Beaufort Sea (including Canadian waters) with most transects extending to the 200 m isobaths and some to the 2,000m isobaths. Detailed plans for the latter survey were presented in SC/67b/AWMP16, and were thoroughly discussed by the Working Group on ASI (see Annex Q).

The SWG thanked the authors for these papers, noting that their presentation is an accord with the AWS Guidelines (see Item 3) that 'plans for undertaking a survey/census should be submitted to the Scientific Committee in advance of their being carried out, although prior approval by the Committee is not required. This should normally be at the Annual Meeting before the survey/census is carried out'.

The SWG noted that the degree of precision to be achieved by the 2019 aerial survey is unknown and may be lower than for some other recent abundance estimates. The *Bowhead Evaluation and Robustness Trials* mainly specified CVs of 0.25 or less. If the new CV turns out to be higher than this, additional trials may be required at the next *Implementation Review*.

4.3 Biological parameters: review new information

The SWG received new information about length at sexual maturity and pregnancy rate (SC/67b/AWMP07). Studies of bowhead reproduction have been conducted by the North Slope Borough Department of Wildlife Management (Alaska) over the past 35 years, with the co-operation of Alaska Native hunters. Although low calf counts and few pregnant harvested females were a concern at the inception of the programme, the situation has improved markedly since then. For SC/67b/AWMP07, pregnancy rates were estimated from examinations of reproductively mature bowhead whales (*n*=208) landed during the Alaska Native subsistence harvest from 1976-2016. The estimated pregnancy rate was 0.317 (95% CI 0.251 to 0.385). This suggests an inter-birth interval of just over 3 years. Whales harvested in the autumn at Utqiaġvik (Barrow) and Kaktovik comprise the most reliable pregnancy dataset because pregnancies are easier to detect and whales are more carefully examined. From this restricted dataset (*n*=33), the pregnancy rate is estimated to be 0.394 (95% CI 0.211 to 0.553); which the authors considered is at the high end of what is plausible for this species.

Logistic regression was used to estimate length at maturity from a separate dataset (*n*=150) that included whale lengths. Length at maturity was defined, relative to an equally balanced set of mature and immature whales, as the length at which the estimated probability of maturity equals 0.5. Since the actual dataset is neither balanced nor representative, the authors introduced a correction calculation. The resulting length at maturity is estimated to be 13.65m (95% CI 13.29 to 13.94). The authors recognised that their data could be biased by sampling from harvested animals where hunter selectivity occurs and by the approximately 14-month gestation period of bowheads. The estimates are consistent with past investigations and suggest a reproductively robust population. The finding that pregnancy rates are stable or possibly increasing over the past 40 years is also consistent with the increase in population abundance seen over the same time span. Finally, the authors believe that there is no evidence in the reproductive data of density-regulated reproduction or the population approaching carrying capacity.

In discussion, the SWG noted that selectivity patterns in the bowhead harvest make some types of inference from such data difficult. In particular, there are several factors that may affect the determination of pregnancy rate and trends in pregnancy rate. The SWG concluded that it was not possible therefore, to conclude that there had been a long-term increase in pregnancy rate despite the statistically significant positive trend reported in the paper; the authors concurred. However, the SWG noted that the length-at-maturity analysis was specifically corrected for age selectivity in hunting so such concerns do not arise in that analysis.

The SWG welcomed information about the potential use of samples from baleen plates to examine hormone cycles and pregnancy. Since baleen provides up to 20 years of record, it may be possible to correlate reproductive information with other variables such as environmental factors. The SWG **encouraged** future work on this subject.

SC/67b/AWMP03 summarised sightings of bowhead whale calves in the western Beaufort Sea during July-October, 2012-17, from the Aerial Surveys of Arctic Marine Mammals (ASAMM) project. Overall, 76% of the calves recorded were first sighted only after the aircraft broke from the transect line to circle an adult whale sighting. Calves were detected during all months, although more calves were detected in autumn (September-October, 245 calves) than summer (July-August, 160 calves). Total number of calves sighted per year ranged from 22 in 2012 to 155 in 2017. The highest calf ratio (number of calves/number of whales) and sighting rate (number of calves/km of effort) occurred in 2017, although 2013 and 2016 were also high. Preliminary analysis of photo- identification data suggests that it is rare to see an individual calf more than once in a given year.

The SWG welcomed this information, recognising that that it relates to successful pregnancies and, if it can be collected and analysed to provide a calving rate/index representative of the population, can provide valuable information for future *Implementation Reviews*. In discussion, it was also noted that the ASAMM aerial survey data could potentially be useful as an independent index of calf production for comparative purposes with the pregnancy rates presented in SC/67b/AWMP07. The SWG **encouraged** the continuation of the ASAMM surveys and any future collaboration involving life history data from the harvest.

Attention: SC

With respect to biological parameter information, the Committee:

(1) welcomes the extensive information presented;
(2) encourages the continued collection of such data from the hunt;
(3) encourages the work on the baleen plate analyses to examine hormone levels and pregnancy;
(4) encourages continued aerial surveys under the ASAMM surveys and any future collaboration involving life history data from the harvest; and
(5) agrees that the information presented does not suggest the need to consider any new SLA trials regarding stock structure.

4.4 Removals: review new information

The SWG received updated information about the 2017 harvest (SC/67b/AWMP05) and long-term removals (SC/67b/AWMP06). The authors of SC/67b/AWMP05 reported that in 2017, 57 bowhead whales were struck resulting in 50 animals landed. The total landed for the hunt in 2017 was higher than the average over the past 10 years (2007-16 mean of landed=41.7; SD=6.7). Efficiency (no. landed/no. struck) in 2017 was 88%, which was also higher than the average for the past 10 years (mean of efficiency=75.2%; SD=6.5%). Of the landed whales, 28 were females and 22 were males. Based on total length (>13.4m in length) or pregnancy, 13 females were presumed mature. Six of those animals were examined and two were pregnant, one with a term foetus and another with a mid-term foetus, and one female was lactating. The fact that one third of the mature females were pregnant is consistent with past years.

SC/67b/AWMP06 provided a summary of bowhead whale catches in Alaska between 1974 and 2016. The authors pointed to the excellent cooperation and contribution of the whale hunters from the 11 villages that are members of the Alaska Eskimo Whaling Commission (AEWC). In total, 1,373 whales were landed. Over half (700) were landed in Barrow, while Shaktoolik and Little Diomede landed only one and two whales, respectively. Five of the 11 villages hunt only in the spring, two hunt only in the autumn whilst the remaining four have landed bowhead whales in both the spring and autumn/winter. Three of those villages (Gambell, Savoonga, and Wainwright) used to primarily hunt in the spring, but they now also hunt in the autumn or winter because changing ice conditions have made hunting more difficult in the spring. The efficiency of the hunt has improved over time. In the late 1970s, the efficiency averaged about 50% - because of improved hunting gear, communication, training and other factors, the efficiency now averages about 80%. Kaktovik and Nuiqsut hunt in the autumn in open water conditions and rarely have struck and lost whales. Some villages (Gambell, Savoonga, and Wainwright) on average land longer whales than others (Barrow and Point Hope). The length of landed whales within a season is correlated with the timing of the hunt. During spring, shorter whales tend to be landed earlier in the season while larger whales tend to be landed later. The opposite occurs in the autumn when larger whales tend to be landed earlier. The sex ratio of landed whales is even.

From 2013 to 2017, four bowhead whales (2 females and 2 males) were harvested near Chukotka, mainly in Anadyr Bay (SC/67b/AWMP20). The average length was 14.5m (minimum 13.0m, maximum 17.0m). Although the portion of the annual strike limit allocated to Russia under their bilateral agreement with the USA is five animals, the actual annual take is usually only 1-2 whales per year, and this has been the case since at least 2004.

The SWG thanked the authors of the provision of this information; catch and strike data are used in the *SLA* calculations (see Item 5.)

4.5 Other anthropogenic threats and health: review new information

New information about detection of carcasses in the eastern Chukchi and western Beaufort seas from the ASAMM project (2009-17, see summary under Item 3 above) was reported in SC/67b/AWMP02. A total of 27 bowhead whale carcasses (21 in the eastern Chukchi Sea) was detected, most in September but with the highest sighting rate in October. Survey effort does not account for the difference between the eastern Chukchi and western Beaufort study areas. A total of six carcasses, including all three of the calf/yearling carcasses sighted, showed signs of killer whale injuries; knowledge of killer whale behaviour and the location of the injuries on the whales, suggested to the authors that killer whale predation not scavenging was the cause of death. One carcass, with subsistence hunting gear (i.e., a line and float) attached, was observed in late October 2015. There were two struck and lost whales reported from about that same time; one at Barrow in late September and one in Wainwright in mid-October. Both of those whales were reported by the whaling captains to have likely died.

SC/67b/AWMP08 reported that during 2017, around 14% of landed whales carried injuries from line entanglement but none had ship strike injuries (consistent with 1990-2012 baselines). Two whales landed at Utqiaġvik (Barrow) in spring

2017 were carrying line associated with pot gear and had severe entanglement injuries such that veterinarians and the attending hunters thought that they were dying when captured.

The SWG **agreed** that whilst the present level of unintentional human induced mortality is too low to require new *Implementation* trials or incorporation into the *SLA* calculations, the situation should continue to be monitored and evaluated at the next *Implementation Review*. The SWG **welcomed** information that discussions between the AEWC and the Bering Sea Crabbers Association were ongoing, with the goal of limiting or reducing bowhead mortality attributable to their fishing gear.

The SWG **agreed** with the authors that the carcasses with killer whale injuries were probably a result of predation not scavenging. George expressed his opinion that killer whale/bowhead interactions have increased in the NE Chukchi Sea over the past 40 years. While beachcast gray whale calves killed by killer whales are commonly observed in Alaska along the NE Chukchi coast, dead bowhead calves (or subadults) were first seen only three years ago. There has also been an increase in observations of killer whale predation from ASAMM surveys and from hunters. In fact, a bowhead calf, probably killed by killer whales, was recovered by hunters northeast of Barrow; such a recovery has not happened before in the memory of native Alaskan hunters.

SC/67b/AWMP08 provided a comprehensive review of B-C-B bowhead health. The authors first noted that the strong, steady rate of population increase and the recent estimate of survival rate are possibly the best indicators that this population is healthy. A body condition index has shown a significant increase (fatter whales) over the period 1990-2012 but there is some evidence it has slowed or reduced in the last five years. This may reflect a density dependent effect of a population nearing carrying capacity, but further analysis is required. Post-mortem analyses indicate that whales caught in the spring migration are generally not feeding, while most (75-100%) in the autumn are. This is consistent with past findings and suggests that bowhead whale feeding habitat remains viable and productive.

General health information on landed bowhead whales was obtained from several major retrospective screening survey studies and from pathological analysis of 2017 post-mortem examinations. Key findings included: (i) declining body burden trend (blubber and muscle) in organic pollutants; (ii) limited detection of anthropogenic radionuclides (low levels in muscle); (iii) continued absence of major pathogens that could impact health; (iv) interannual variation of *Giardia* spp. with some suggestion of environmental marine contamination with human faeces; and (v) variable presence of marine biotoxins in faeces suggesting complex environmental drivers of harmful algae blooms in the Arctic. Pathological findings in 2017 were consistent with previous years e.g.: (i) low prevalence of fatty benign tumors in livers and gastric nodules associated with anisakis infection; and (ii) presence of kidney worm infection. Further work is underway on species characterisation of kidney worm specimens. The authors suggest that Arctic climate change (e.g., diminishing sea ice, increased sea surface temperature, opening of the Northwest Passage, range overlap with seasonal southern baleen whale migrants known to carry kidney worms, and prey shifts) may be setting the stage for an evolving host-parasite relationship in B-C-B bowhead whale stock.

The SWG **thanked** the authors for this valuable summary and **agreed** that nothing in the health analyses was cause for concern with respect to the continued application of the *Bowhead SLA*.

Attention: SC

With respect to threats and health to the B-C-B bowhead whales, the Committee:

(1) ***welcomes*** *the extensive information presented;*
(2) ***agrees*** *that whilst the present level of unintentional human induced mortality is too low to require new* Implementation *trials or incorporation into the* SLA *calculations, the situation should continue to be monitored and evaluated at the next* Implementation Review*;*
(3) ***agrees*** *that the health analyses give no cause for concern with respect to the continued application of the* Bowhead SLA*; and*
(4) ***encourages*** *that the excellent work on health-related issues continues.*

4.6 Conclusions and recommendations (and, if needed, workplan to complete *Review*)

The SWG **concluded** that no additional work was required to complete the *Implementation Review*. It further **concluded** that the range of hypotheses and parameter space already tested in *Bowhead SLA* trials was sufficient and therefore the *Bowhead SLA* could continue to be **recommended** to the Commission as the best way to provide management advice. This advice is presented under Item 5.3.

Attention: SC

With respect to the Implementation Review *of B-C-B bowhead whales, the Committee* ***concludes*** *that:*

(1) the Implementation Review *has been satisfactorily completed; and*
(2) the range of hypotheses and parameter space already tested in Bowhead SLA *trials was sufficient and therefore the* Bowhead SLA *remains the best way to provide management advice for this stock;*

In addition, it thanks the US scientists for the extremely hard work that they have put into providing comprehensive papers to facilitate this review

---

5. STOCKS SUBJECT TO ASW (NEW INFORMATION AND MANAGEMENT ADVICE)

The SWG noted that the Commission will be setting new catch/strike limits for at its 2018 biennial meeting in Brazil. It had received written or verbal requests for limits to be considered for each hunt as discussed below.

In addition, there had been a general request to the intersessional workshop from the USA and Denmark (SC/67b/Rep06, annex F, appendix) for advice on whether there would be a conservation issue if there was a one-time seven-year block followed by a return to six-year blocks to address logistical issues from a Commission perspective. The SWG **agreed** with the intersessional workshop that there are no conservation issues associated with this suggestion (and see the block quota section of the ASW Appendix).

5.1 Eastern Canada/West Greenland bowhead whales

5.1.1 New abundance information

Last year, the SWG had recommended that Canadian scientists attend the Committee to present the results of their work on abundance. It was very pleased that Doniol-Valcroze from Department of Fisheries and Oceans Canada and the primary author of the paper on aerial survey abundance estimate was present at the meeting.

The two relevant papers were first discussed by the Standing Working Group on ASI (see Annex Q for details). Doniol-Valcroze *et al.* (2015) provided a fully corrected estimate from the 2013 aerial survey of 6,446 bowheads (CV=0.26, 95% CI 3,722-11,200). The survey covered the major summering area for the Eastern Canada/West Greenland stock. The Working Group on ASI agreed that this was acceptable for management advice and for use within the AWMP. The other paper (ref) contained a genetic mark-recapture estimate that was considered preliminary at this stage.

The SWG **welcomed** this information and recalled that the *WG-Bowhead SLA* had been developed on the conservative assumption that the abundance estimates for the West Greenland area alone (1,274 whales in 2012 (CV=0.12)) represented the abundance of the whole stock, as it believed that it was not possible to assume that a non-member country would continue with regular surveys. Doniol-Valcroze advised the SWG that the present management strategy of Canada does involve obtaining regular abundance estimates. The SWG noted it would be pleased to receive such estimates from Canada being presented to the Committee in the future.

The SWG **welcomed** this information. It **agreed** that consideration of how to incorporate abundance estimates from Canada should be one focus of the next *Implementation Review.* It noted the regular collaboration of Canadian and Greenlandic scientists on other matters such as genetic sampling (*inter alia* for mark-recapture abundance estimation). It **encouraged** further collaboration between Canada, Greenland and the USA for the study of bowhead whales across their range and the presentation of these results at future Committee meetings.

In this regard, Witting reported that Greenland continues its biopsy sampling programme, with 60 biopsy samples collected in 2017. Bickham noted that many SNPs had been developed for B-C-B bowheads (SC/67b/SDDNA01) and that it would be productive for the same markers to be analysed for the Canadian samples since between-lab calibration is straightforward for SNPs and the increased statistical power would improve stock structure analyses, e.g. the ability to identify individual whales could provide information relevant to mixing proportions between areas.

5.1.2 New catch information

SC/67b/AWMP10 provided an update of recent Canadian takes made in the Inuit subsistence harvest of EC-WG bowhead whales. In the eastern Canadian Arctic, the maximum take is 7 bowhead whales per year according to domestic policy, with no carry-over of unused takes between years. Since 2015, five strikes were taken and four bowhead whales were successfully landed (one in 2015, two in 2016 and one in 2017).

The SWG **thanked** Canada for regularly providing catch information. It noted that the reported number of strikes was within the parameter space that was tested for the *WG-Bowhead SLA* and **encouraged** the continued collection of genetic samples from harvested whales.

Witting reported that West Greenland hunters struck no bowheads in 2017. There was one whale of 14.7m in length that died from entanglement in crab gear.

5.1.3 Management advice

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC/67 and no changes were requested for bowhead whales.

The SWG **agreed** that the *WG Bowhead SLA* remains the best available ways for management advice, and noted that this *SLA* had been developed under the conservative assumption that the number of bowhead whales estimated off West Greenland represented the total abundance between West Greenland and Eastern Canada. Based on the agreed 2012 estimate of abundance for West Greenland (1,274, CV=0.12), the catch of one whale in Canada in 2017, and using the agreed *WG-Bowhead SLA*, the SWG **repeated its advice** that an annual strike limit of two whales will not harm the stock and meets the Commissions conservation objectives.

Although the SWG had not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, Annex F, appendix) for this *SLA,* it **agreed,** based on *WG-bowhead SLA* testing thus far, that its previous advice that the interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next was acceptable.

Attention: C-A

A general request had been received from the USA and Denmark (SC/67b/Rep06, annex F, appendix) for advice on whether there would be a conservation issue if there was a one-time 7-year block followed by a return to 6-year blocks to address logistical issues related to the Commission.

The Committee ***agrees*** *there are no conservation issues associated with this suggestion (and see the block quota section of the ASW in Annex E, appendix 8).*

Attention: SC

The Committee greatly appreciated the presence of a Canadian scientist at its meeting. The Committee:

(1) ***welcomes*** *the provision of the abundance estimate for the Eastern Canada/West Greenland stock and (see Item 8.1.2) the regular provision of information on catch data by Canada;*
(2) ***welcomes*** *the attendance of Canadian scientists at its meetings;*
(3) ***agrees*** *that consideration of how to incorporate abundance estimates from Canada should be one focus of the next* Implementation Review *for this stock;*
(4) ***notes*** *the regular collaboration of Canadian and Greenlandic scientists on other matters such as genetic sampling (inter alia for mark-recapture abundance estimation); and*
(5) ***encourages*** *further collaboration between Canada, Greenland and the USA for the study of bowhead whales across their range and the presentation of these results at future Committee meetings.*

Attention: C-A
SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67 and no changes were requested for bowhead whales. The Committee therefore:
(1) ***agrees*** *that the* WG-Bowhead SLA *remains the best available way to provide management advice for the Greenland hunt;*
(2) ***notes*** *that this SLA had been developed under the conservative assumption that the number of bowhead whales estimated off West Greenland represented the total abundance between West Greenland and Eastern Canada;*
(3) based on the agreed 2012 estimate of abundance for West Greenland (1,274, CV=0.12), the catch of one whale in Canada in 2017, and using the agreed WG-Bowhead SLA*,* ***agrees*** *that an annual strike limit of two whales will not harm the stock and meets the Commissions conservation objectives; and*
(4) although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for the WG-Bowhead SLA*, reiterates its advice, applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next, is acceptable.*

5.2 North Pacific gray whales
The Russian Federation (SC/67b/AWMP17) had requested advice on the following provision:

> 'For the **seven** years 2019, 2020, 2021, 2022, 2023, 2024 and 2025, the number of gray whales taken in accordance with this sub-paragraph shall not exceed 980 (i.e. 140 per annum on average) provided that the number of gray whales taken in any one of the years 2019, 2020, 2021, 2022, 2023, 2024 and 2025 shall not exceed 140.'

5.2.1 New information (including catch data)
SC/67b/AWMP20 presented a comparison of gray whale catch data off Chukotka during: (i) the Soviet era (i.e. data from the catcher boat *Zvezdny*, from 1969-91); with (ii) recent data from 2013-17. The average length and weight of harvested whales in recent years is smaller than it was during the Soviet era. This discrepancy could be due to a difference in the selectivity patterns between the Soviet era industrial-sized catcher boat and the small boats used by native Chukotkans. The average annual number of whales was also higher during the Soviet era (150 *vs* 123). The annual biomass of removals in recent years is estimated to be one-third of that during the Soviet era. In recent years, most whales have been taken by the eastern and northeastern settlements of the Chukchi Peninsula – in the Bering Strait and east Chukchi Sea. Authors speculated that more mature whales migrate to the Arctic via the Bering Strait compared to those remaining in Anadyr Bay. Whales caught on Chukotka's Arctic coast were found to be statistically larger with a higher fat index than whales harvested on the eastern coast. Considering the 11% rise of native population in Chukotka since 2010 and also considering the drop in acquired whaling products comparing to 1980s-1990s, the authors concluded that the subsistence need of indigenous people is not satisfied.

Zharikov presented results of the 2017 whaling season in Chukotka. A total of 119 gray whales were struck in 2017 (37 males and 82 females). No whales were struck and lost, and no stinky (inedible) gray whales were taken. Similar whaling methods were employed as in recent years and the overall efficiency of the hunt was almost same as in 2016. It was noted that whale products are a large part of the local diet; there is also exchange with inland aborigines and use for non-nutritional purposes. A total of 615 gray whales have been taken in 2013-17 (SC/67b/AWMP17). Therefore only 105 strikes remain for 2018 under the current block quota, while the average annual take in recent years is 123 whales. The *SLA* trials performed in 2017 at the request of the Government of the Russian Federation (IWC, 2018) showed that a take of up to 136 whales per year by indigenous people of Chukotka will not harm the population. He noted that a possible overrun of 2013-18 quota by Chukotka native whalers was within this catch level and believed that such needs should be taken into account in the near future.

SC/67b/AWMP17 presented proposed text by the Russian Federation for amendments to Paragraph 13(b)(2) of the Schedule for gray whales. It was noted that a specific native diet has been documented. The consumption of relatively high amounts of proteins and fats is a necessary component of health and longevity in the native population of Chukotka. The importance of aboriginal whaling to the social, cultural and economic structure of Chukotka's coastal villages was also noted. Under the current block quota, the annual strike limit is 140 per year (including any strikes allocated to the Makah tribe). The proposed amendments would extend the duration of this block quota from six to seven years. Under the proposed seven-year block quota, the total number of strikes would be increased to 980 (140x7yrs). This provision would continue to be reviewed biannually by the Commission in light of the annual advice of the Scientific Committee.

5.2.2 Management advice

The SWG **agreed** that the *Gray Whale SLA* remains the best available way for management advice for this stock. It **advised** that an average annual strike limit of 140 whales will not harm the stock and meets the Commission's conservation objectives. It also noted that its previous advice that the interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next was acceptable. It also **advised** that the Makah Management Plan (Item 2.3) is in accord with the Commission's management objectives.

Attention: SC

In reviewing the results of new genetic analyses of gray whales in the North Pacific, the Committee ***agrees*** *that the genetic and photographic data for this species be combined to better assess stock structure-related questions. Given the potential for genomic data to aid in better evaluating the stock structure hypotheses currently under consideration for North Pacific gray whales, the Committee* ***encourages*** *the continuation of work to produce additional genomic data from sampled gray whales.*

Attention: C-A

The Russian Federation (SC/67b/AWMP/17) had requested advice on the following provision:

> *'For the seven years 2019, 2020, 2021, 2022, 2023, 2024 and 2025, the number of gray whales taken in accordance with this sub-paragraph shall not exceed 980 (i.e. 140 per annum on average) provided that the number of gray whales taken in any one of the years 2019, 2020, 2021, 2022, 2023, 2024 and 2025 shall not exceed 140.'*

The Committee therefore:

(1) ***agrees*** *that the* Gray Whale SLA *remains the best available way to provide management advice for the gray whale hunts;*
(2) ***advises*** *that an average annual strike limit of 140 whales will not harm the stock and meets the Commission's conservation objectives;*
(3) ***notes*** *that its previous advice that the interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next remains acceptable;*
(4) ***advises*** *that the Makah Management Plan (see Item 2.3) also is in accord with the Commission's management objectives.*

5.3 Bering-Chukchi-Beaufort Seas bowhead whale

5.3.1 New information

New information was considered as part of the *Implementation Review* discussed under Item 4.

The USA had indicated that it was proposing no changes to the present catch/strike limits although it may suggest changes to its carryover request in light of the advice received by the Committee as discussed at the intersessional Workshop (SC/67b/Rep06).

The SWG noted that there are now two independent estimates of abundance for this stock in 2011 (see Item 4). Recognising the need to formally consider the general question of how best to combine estimates in such cases as part of the workplan in the next biennium, the SWG noted that if they are combined as a weighted average by the inverse of their variances, there is little difference (it is slightly higher) between the combined estimate and that from the ice-based census estimate that is the approach used to obtain the other estimates used in the *SLA*. It therefore **agreed** to use the ice-based census estimate for 2011 survey (Givens *et al.*, 2016; 16,820, CV=0.052, 95% CI 15,176 to 18,643) as the most recent estimate of abundance for use in the *Bowhead SLA* this year.

5.3.2 Management advice
The SWG **agreed** that the *Bowhead SLA* remains the best available way for management advice for this stock. It **advised** that a continuation of the present average annual strike limit of 67 whales will not harm the stock and meets the Commission's conservation objectives.

The SWG also **advised** that provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit' has no conservation implications (see SC/67b/Rep04).

Attention: C-A

The USA indicated that it requested advice on the existing catch/strike limits. The Committee therefore:

(1) ***agrees*** *that the* Bowhead Whale SLA *remains the best available way to provide management advice for this stock;*
(2) ***advises*** *that a continuation of the present average annual strike limit of 67 whales will not harm the stock and meets the Commission's conservation objectives; and*
(3) ***advises*** *that provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit, has no conservation implications (see SC/67b/Rep04).*

5.4 Common minke whales off East Greenland
SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC/67. It requested advice on an annual take of 20 animals (it had previously been 12).

5.4.1 New information on catches
In the 2017 season, 9 common minke whales were landed in East Greenland, and one was struck and lost. Three of the landed whales were males, 6 were females, and genetic samples were obtained from 8 of the landed whales. One common minke whale died from entanglement in fishing gear. The SWG **encouraged** the continued collection of genetic samples and collaborative studies (see Item 5.1.1).

5.4.2 New information on abundance
The Working Group on ASI endorsed the 2015 aerial survey abundance estimate of 2,762 (CV=0.47; 95%CI 1,160-6,574). This is only a small part of the wider Western and Central stocks.

5.4.2 Management advice
The SWG noted that in the past its advice for the East Greenland hunt had been based upon the fact that the catch was a small proportion of the number of animals in the Central Stock. During the process to develop an *SLA* for common minke whales off West Greenland produced a simulation framework that produces a considerably more rigorous way to provide advice for this hunt, taking into account stock structure issues. In addition, there is for the first time a separate estimate of abundance for common minke whales off East Greenland alone (this is only a small part of the wider western and Central stocks from which the catches can be drawn). The results of the simulation trials that incorporated a continuing catch of 20 whales from East Greenland led to no conservation concerns (see Appendix 4). The SWG noted that a formal *SLA* for this hunt should be developed in the future.

Given the above information, the SWG **advised** that an annual strike limit of 20 whales for the next block will not harm the stock and meets the Commission's conservation objectives.

In response to a request for advice on the length of the season for the common minke whale hunts in SC/67b/AWMP19, the SWG **agreed** that changing the length of the season to 12 months had no conservation implications.

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on an annual take of 20 animals (it had previously been 12). It had also requested advice on any conservation implications of a 12-month hunting season for common minke whales.

The Committee therefore:

(1) ***notes*** *that in the past its advice for the East Greenland hunt had been based upon the fact that the catch was a small proportion of the number of animals in the Central Stock;*
(2) ***notes*** *the process to develop an* SLA *for common minke whales off West Greenland resulted in a simulation framework that produces a considerably more rigorous way to provide advice for this hunt than before, by taking into account stock structure issues;*
(3) ***notes*** *that the results of the simulation trials that incorporated a continuing catch of 20 whales from East Greenland gave rise to no conservation concerns;*
(4) ***notes*** *that the 2015 aerial survey abundance estimate of 2,762 (CV=0.47; 95%CI 1,160-6,574) is only a small part of the wider western and central stocks;*

(5) ***advises** that a continuation of the present average annual strike limit of 20 whales will not harm the stock and meets the Commission's conservation objectives;*
(6) ***advises** that changing the length of the season to 12 months had no conservation implications; and*
(7) ***agrees** that an* SLA *should be developed for this hunt in the future; and*
(8) ***encourages** the continued collection of samples for collaborative genetic analyses (and see Item 7.1.2.3).*

5.5 Common minke whales off West Greenland
SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC/67. It requested advice on annual strikes of 164 animals (i.e. no change).

5.5.1 New information on catches
In the 2017 season, 129 common minke whales were landed in West Greenland and four were struck and lost. Of the landed whales, there were 95 females, 33 males and one of unknown sex. Genetic samples were obtained from 104 of these common minke whales in 2017, and the SWG was pleased to note that samples were already part of the data used in the genetic analyses of common minke whales in the North Atlantic. The SWG **encouraged** the continued collection of samples and the collaborative approach of the genetic analysis.

5.5.2 New information on abundance
The Working Group on ASI endorsed the 2015 aerial survey abundance estimate of 5,095 (CV=0.46; 95%CI 2,171-11,961) as discussed in Annex Q.

5.5.3 Management advice
The SWG **agreed** that the new *WG-common minke SLA* (Item 2.2) is the best available way to provide management advice for this stock. It **advised** that an annual strike limit of 164 whales will not harm the stock and meets the Commission's conservation objectives. Although the SWG had not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, Annex F, appendix) for this new *SLA*, it **agreed,** based on *WG-common minke SLA* testing thus far, that its previous advice that the interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next was acceptable.

In response to a request for advice on the length of the season for the common minke whale hunts in SC/67b/AWMP19, the SWG **agreed** that changing the length of the season to 12 months had no conservation implications.

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 164 animals (i.e. no change). It had also requested advice on any conservation implications of a 12-month hunting season for common minke whales.

The Committee therefore:

(1) ***agrees** that the WG-Common minke SLA is the best available way to provide management advice for this stock under need scenario A;*
(2) ***advises** that a continuation of the present average annual strike limit of 164 whales will not harm the stock and meets the Commission's conservation objectives;*
(3) *although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for this SLA, reiterates its previous advice, applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable;*
(4) ***advises** that changing the length of the season to 12 months had no conservation implications; and*
(5) ***encourages** the continued collection of samples for collaborative genetic analyses (and see Item 7.1.2.3).*

5.6 Fin whales off West Greenland
SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC/67. It requested advice on annual strikes of 19 animals (i.e. no change).

5.6.1 New information on the catch
A total of seven fin whales (five females and two males) was landed, and one was struck and lost, off West Greenland during 2017. The SWG was pleased to note that genetic samples were obtained from five of these, and that the genetic samples are analysed together with the genetic samples from the hunt in Iceland. It **encouraged** the continued collection of samples and collaborative work on analyses.

5.6.2 New information on abundance
The Working Group on ASI endorsed the 2015 aerial survey abundance estimate of 2,215 (CV=0.41; 95%CI 1,017-4,823) as discussed in Annex Q.

5.6.3 Management advice

The SWG **agreed** that the new *WG-fin SLA* (Item 2.2) is the best available way to provide management advice for this stock. It **advised** that an annual strike limit of 19 whales will not harm the stock and meets the Commission's conservation objectives.

Although the SWG had not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, Annex F, appendix) for this new *SLA*, it **agreed,** based on *WG-fin SLA* testing thus far, that its previous advice that the interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next was acceptable.

In response to a request for advice on length limits for fin whales in SC/67b/AWMP19, the SWG **agreed** that removing the length limits had no conservation implications.

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC/67. It requested advice on annual strikes of 19 animals (i.e. no change). It also requested advice on whether there were any conservation implications of removing length limits (while retaining the prohibitions relating to calves.

The Committee therefore:

(1) *agrees that the* WG-Fin SLA *is the best available way to provide management advice for this stock;*
(2) *advises that a continuation of the present average annual strike limit of 19 whales will not harm the stock and meets the Commission's conservation objectives;*
(3) *although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for this SLA, reiterates its advice, applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable;*
(4) *advises that removing the length limits had no conservation implications; and*
(5) *encourages the continued collection of samples for collaborative genetic analyses (and see Item 7.1.1.3).*

5.7 Humpback whales off West Greenland

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC/67. It requested advice on annual strikes of 10 animals (i.e. no change).

5.7.1 New information on catches

A total of two (two females) humpback whales were landed and none were struck and lost in West Greenland during 2017. The SWG was pleased to learn that genetic samples were obtained from all the landed whales. The SWG again **emphasised** the importance of collecting genetic samples and photographs of the flukes from these whales.

The SWG noted that five humpback whales were observed entangled in fishing gear in West Greenland in 2017. Of these, one died, two became free and one was successfully disentangled by a disentanglement team. The remaining animal was alive and still entangled when it was last sighted.

The SWG noted that some bycaught whales had been included in the scenarios for the development of the *Humpback SLA.* If high levels continued, then this would need to be taken into account in any *Implementation Review.* It noted the IWC efforts with respect to disentanglement and prevention and **welcomed** the news that the Greenland authorities requested IWC disentanglement training that took place in 2016 and that they successfully disentangled one humpback whale.

5.7.2 New information on abundance

The Working Group on ASI endorsed the 2015 aerial survey abundance estimate of 993 (CV=0.46; 95%CI 434-2,272) as discussed in Annex Q.

5.7.3 Management advice

The SWG **agreed** that the *WG humpback SLA* remains the best available tool for management advice for this stock. It **advised** that a continuation of the present average annual strike limit of 10 whales will not harm the stock and meets the Commission's conservation objectives.

The SWG also **advised** that provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit' has no conservation implications (see SC/67b/Rep04).

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC/67. It requested advice on annual strikes of 10 animals (i.e. no change).

The Committee therefore:

(1) ***agrees** that the* WG-Humpback SLA *is the best available way to provide management advice for this stock;*

(2) ***advises*** *that a continuation of the present average annual strike limit of 10 whales will not harm the stock and meets the Commission's conservation objectives;*
(3) ***advises*** *that that provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit' has no conservation implications (see SC/67b/Rep04); and*
(4) ***encourages*** *the continued collection of samples and photographs for collaborative analyses.*

5.8 Humpback whales off St Vincent and The Grenadines

The alternate Commissioner for St Vincent and The Grenadines advised that no change to the present limits were envisaged.

5.8.1 New information on catch

It was reported that one humpback whale was struck and landed in 2017 by St Vincent and The Grenadines.

5.8.2 New information on abundance

Last year, the Committee had requested that the USA provide a new abundance estimate for the western North Atlantic based upon the available NOAA data (IWC, 2018). Clapham and Wade provided a progress report on this work with a focus on information on abundance estimates generated by the MONAH study, conducted in 2004 and 2005 on Silver Bank (a breeding ground in the West Indies) and in the Gulf of Maine feeding ground. The best estimate was judged to be a genotype-based two-year pooled feeding-to-breeding male-only Chapman estimate. This estimate was 6,156 (95% CI 4,344, 7,977), which when doubled (to account for females) equals 12,312. This was slightly higher than, although not significantly different from, the best estimate from the YONAH project from 1992/93, which was 10,400 (8,000, 13,600). The lack of strong population growth was unexpected given information on rates of increase from some other areas of the North Atlantic, and may reflect either a true rate of increase, unidentified sampling bias, and/or the idea that Silver Bank as a habitat has reached a maximum capacity. Given this, it was not clear whether the MONAH estimate is representative of the entire population, nor whether it can be applied to the southeastern Caribbean in the context of the St Vincent hunt. Four animals from the southeastern Caribbean have been linked to animals seen in the Gulf of Maine (one was caught in the hunt).

The SWG also noted the recent new abundance estimates of humpback whales in the North Atlantic including 993 (95% CI: 434-2,272) in West Greenland in 2015, 4,223 (95% CI: 1,845-9,666) in East Greenland in 2015 and Iceland-Faroes with 12,879 (95% CI 5,074; 26455) estimated from the 2007 ship survey

It has now been nearly two decades since the IWC has undertaken an In-Depth Assessment on North Atlantic humpback whales. The SWG **agreed** that it would be a valuable exercise to perform a North Atlantic Rangewide review of humpback whales, similar in scope to the Rangewide Review for North Pacific gray whales and taking into account recent work on stock structure including that of Stevick *et al.* (2018).

5.8.3 Management advice

The SWG noted that it did not have an approved abundance estimate for western North Atlantic since that in 1992. In accord with the advice provided in the AWS (see Appendix 8), it therefore considered the available evidence to see if was sufficient to provide safe management advice. Given the information above on recent abundance in the North Atlantic and the size of the requested catch/strikes (an average of four annually), the SWG **advised** that continuation of the present limits will not harm the stock.

The SWG also **repeats** its earlier advice that:

(1) the status and disposition of genetic samples collected from past harvested whales be determined and reported next year;
(2) photographs for photo-id (where possible) and genetic samples are collected from all whales landed in future hunts; and that
(3) the USA (NOAA, NMFS) provides an abundance estimate from the MONAH data as soon as possible for the Committee.

Attention: C-A

The alternate Commissioner for St Vincent and The Grenadines advised that no change to the present limits were envisaged. The Committee therefore:

(1) ***notes*** *that is does not have an approved abundance estimate for western North Atlantic since that in 1992;*
(2) ***notes*** *that in accord with the advice provided in the AWS (see Annex E, Appendix 8), it therefore considered the available evidence to see if was sufficient to provide safe management advice;*
(3) ***advises*** *that, given the information above on recent abundance in the North Atlantic combined with the size of the requested catch/strikes (an average of four annually), continuation of the present limits will not harm the stock;*

*The Committee also **reiterates** its previous advice that:*

(1) *the status and disposition of genetic samples collected from past harvested whales be determined and reported next year;*
(2) *photographs for photo-id (where possible) and genetic samples are collected from all whales landed in future hunts; and that*
(3) *the USA (NOAA, NMFS) provides an abundance estimate from the MONAH data as soon as possible for the Committee.*

6. WORKPLAN 2019-20 (INCLUDING WORKSHOPS AND INTERSESSIONAL GROUPS)

Table 1 summarises the work plan for work related to aboriginal subsistence whaling.

Simulation testing of interim relief allowances has been conducted for B-C-B bowheads and WG humpbacks (Appendix 8 under Item 3). Interim relief will be tested for eastern NP gray whales at the next *Implementation Review* for that stock. Testing for the remaining ASW stocks will be added to the future workplan of the Committee.

Table 1

Work plan for matters related to aboriginal subsistence whaling.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
(1) Annual review of catch/strike limits		Carry out		Carry out
(2) *Implementation Review*		Gray whales based upon rangewide review		West Greenland humpback whales
(3) *SLA*s		Consider development of an *SLA* for the hunt of common minke whales off East Greenland based on operational models developed for the West Greenland hunt		Adopt *SLA* if it is decided one is necessary
(5) Interim relief allowance testing	Run trials for gray whale hunts	Review results	Run trials for West Greenland common minke whales and fin whales	Review results
(6) Carryover (US/Denmark request)	Run trials for remaining Greenland hunts (West Greenland common minke whales, bowhead whales and fin whales	Review results		

7. BUDGETARY ITEMS 2019-20

The SWG has no budget requests for the next biennium.

8. ADOPTION OF REPORT

The Chair noted that this meeting represented the end of a long journey – with the adoption of the two new *SLA*s, the SWG had completed the development tasks it had been assigned by the Commission. He thanked all of the people who have made such a wonderful contribution over the years – the SWG has, in his view, achieved ground-breaking work over the last two decades in a spirit of great collaboration and co-operation, even when there were disagreements as inevitably there were. At this meeting, he thanked the rapporteurs, and especially John Brandon for their hard work. Primarily, though thanks were due to André Punt, Lars Witting and Anabela Brandão for their herculean efforts in developing and running trials and developing *SLA*s. However, greatest praise should go to Cherry Allison who under extremely difficult circumstances provided superb support from Cambridge. The whole SWG sends their thanks, support and best wishes.

AGENDA

1. INTRODUCTORY ITEMS
    - 1.1 Convenor's opening remarks
    - 1.2 Election of Chair and appointment of rapporteurs
    - 1.3 Adoption of Agenda
    - 1.4 Documents available
2. *SLA* DEVELOPMENT
    - 2.1 Fin whales (Greenland)
        - 2.1.1 Review results of intersessional Workshops
        - 2.1.2 Review post-Workshop progress
        - 2.1.3 Review final results and performance
        - 2.1.4 Conclusions and recommendations
    - 2.2 Common minke whales (Greenland)
        - 2.2.1 Review results of intersessional Workshops
        - 2.2.2 Review post-Workshop progress
        - 2.2.3 Review description of and results for candidate *SLA*s
        - 2.2.4 Conclusions and recommendations
    - 2.3 North Pacific gray whales (Makah management plan)
        - 2.3.1 Summarise the plan
        - 2.3.2 Review intersessional progress including at the Rangewide Workshop
        - 2.3.3. Conclusions and recommendations
    - 2.4 WG-bowhead whales
        - 2.4.1 Review results using 400 replicates
        - 2.3.2 Testing the Interim Allowance strategy
        - 2.3.3 Conclusions and recommendations
3. ABORIGINAL WHALING MANAGEMENT SCHEME (AWS)
    - 3.1 Review results of intersessional Workshops
    - 3.2 Review proposed updates to the AWS
    - 3.2 Conclusions and recommendations
4. IMPLEMENTATION REVIEW OF B-C-B BOWHEAD WHALES
    - 4.1 Stock structure: review new information (including advice from SD)
    - 4.2 Abundance estimates: review new information (including advice from ASI)
    - 4.3 Biological parameters: review new information
    - 4.4 Removals: review new information
    - 4.5 Other anthropogenic threats and health: review new information
    - 4.6 Conclusions and recommendations (and, if needed, workplan to complete *Review*)
5. STOCKS SUBJECT TO ASW (NEW INFORMATION AND MANAGEMENT ADVICE)
    - 5.1 Eastern Canada/West Greenland bowhead whales
    - 5.2 North Pacific gray whales
    - 5.3 Bering-Chukchi-Beaufort Seas bowhead whale
    - 5.4 Common minke whales off East Greenland
    - 5.5 Common minke whales off West Greenland
    - 5.6 Fin whales off West Greenland
    - 5.7 Humpback whales off West Greenland
    - 5.8 Humpback whales off St Vincent and The Grenadines
6. WORKPLAN 2019-20 (INCLUDING WORKSHOPS AND INTERSESSIONAL GROUPS)
7. BUDGETARY ITEMS 2019-20
8. ADOPTION OF REPORT

INTERIM RELIEF SCENARIOS

Appendix 8 specifies an interim relief provision for the Aboriginal Whaling Scheme. Under this provision, a survey is required at least every 10 years. If no survey is available after that time and third quota block has begun, the Committee has **endorsed** the use of an 'interim relief', namely a 'grace period' strike limit equal to the limit produced by the applicable Strike Limit Algorithm, without reduction, for a single block.

The 10-year survey interval requirement is complicated by the fact that there will usually be a delay between when the survey is conducted and when the resulting abundance estimate is agreed by the Committee, and because surveys, estimates and quota blocks need not be synchronised, as recognised in IWC (2003). For the sake of counting years, a survey is not considered to have occurred until the resulting abundance estimate is agreed. At that point, the 10-year time window is deemed to have begun in the year during which the survey was conducted. Then, ideally, the next survey would be conducted and the estimate approved within 10 years of the previous survey. However, other scenarios might occur. For example, the next survey might have occurred eight years after the previous one, but the corresponding abundance estimate not agreed until 13 years after the previous survey was conducted ('the 13th year'). In this case, a survey would be considered overdue during the 11th and 12th years. If the start of a new block occurred during that time, the grace period would be triggered and an interim relief provided. Otherwise, when the abundance estimate is agreed in the 13th year after the last survey was conducted, the fact that the survey actually took place eight years after the last agreed estimate would reset the clock so that the next deadline would be the 18th year, and a grace period would have been averted.

Tables 1 and 2 illustrate several scenarios about how strike limits might evolve with varying survey intervals and grace periods. In these tables, it is assumed for simplicity that the *Strike Limit Algorithm* would output a six-year block strike limit (SL) each time. For the sake of simplicity, carryover is ignored in these tables.

Five different scenarios (A-E) are shown in Tables 1 and 2. These tables cover more than four quota blocks (boxes), with surveys (Surv), abundance estimates (Est) and the establishment of block strike limits (SL) scheduled by year (Yr), The 'Clock' counts the number of years remaining before a survey will thereafter be overdue. Thus, when the clock set by the most recent estimate is negative, a survey is overdue and when a grace period quota is required an interim relief strike limit (IASL) is set.

Scenario A in Table 1 illustrates a situation with regular 8-year survey intervals and estimates two years later. Each strike limit is set using a timely survey; no surveys are overdue and no grace periods are required. Note that in year 13, a block strike limit is set using the survey from year 4. Although the more recent survey (year 12) has occurred, the corresponding abundance estimate has not yet been computed. Scenario B represents an unproblematic case with 10-year survey intervals.

Scenarios C and D illustrate cases where the grace period is invoked in year 13. In Scenario C, immediate revision of the interim relief strike limit (IASL) is assumed and an updated strike limit (USL) is computed. Scenario D presents the same schedule of surveys and estimates, but when the grace period is invoked, the IASL is retained for the entire block, with the year 12 survey first being used in year 19.

Scenario E illustrates that it is possible that surveys could be more than 10 years apart (in this case, 13 years) without triggering the grace period.

Tables 1 and 2

Example schedules of surveys, block strike limits and so forth. See the text for a detailed explanation.

Appendix 8

SCIENTIFIC ASPECTS OF AN ABORIGINAL WHALING SCHEME

The Scientific Committee's Aboriginal Whaling Management Procedure (AWMP) applies stock-specific *Strike Limit Algorithms* (*SLA*s) to provide advice on aboriginal subsistence whaling (ASW) strike/catch limits.

ASW management (as part of an AWS, the aboriginal whaling scheme) incorporates several components, several of which have a scientific component:

(a) *Strike Limit Algorithms* (case-specific) used to provide advice on safe catch/strike limits;
(b) operational rules (generic to the extent possible) including carryover provisions, block quotas and interim relief allocations;
(c) Guidelines for *Implementation Reviews*; and
(d) Guidelines for data and analysis (e.g. guidelines for surveys, other data needs)

The scientific components are considered below.

1. CARRYOVER

Carryover is a provision to enable (some) strikes not used in one year to be used in a subsequent year or years, in order to allow for the inevitable fluctuations in the success of hunts (e.g. due to environmental conditions and/or whale availability). Whilst providing flexibility, carryover does not allow hunts to take more than the total number of strikes agreed by the Commission. This flexibility may produce additional benefits for the local management of the hunt. The concept is not new and *ad hoc* provisions incorporating carryover have been included in the Schedule for many years (see the summary provided in *J. Cetacean Res. Manage* 19 (Suppl.), pp. 169-72). As general guidance, the Commission has (in 2001 and 2016), approved examination by the Committee of scenarios incorporating a 50% interannual variation within blocks and 50% allowance to the next block, noting that this did not imply any commitment by the Commission that these values would be used in the Schedule.

1.1 The Committee's role

The Scientific Committee's role is not to recommend a particular carryover approach (there are many possibilities e.g. see IWC *In Press*) but rather to provide advice on the conservation and need performance of carryover options when asked by the Commission or ASW countries. Formal evaluation of the performance of options (see Item 1.2) by the Committee will allow a more consistent approach to carryover across hunts. The Committee's evaluation began in the year 2000 as the Committee began to develop its first recommended components of an AWS (IWC, 2001).

1.2 Examining conservation performance

The Committee examines the conservation performance of options using the same simulation testing approach used to develop *SLA*s. This allows the Committee to provide guidance as to the acceptable limits within which carryover provisions can be developed. In requesting guidance on carryover provisions, at least the following information should be provided by ASW countries or the Commission:

(a) an initial start date for the provision (e.g. 2003, start of new block);
(b) an expiration period (unused strikes cannot be carried over indefinitely); and
(c) limits on use (e.g. the maximum number of strikes allowed in any one year).

1.3 Additional provision

The Committee's *Implementation Review* process (see section 4 below) includes the monitoring of carryover provisions. Should new information (e.g. abundance data) lead an *SLA* to indicate a severe decrease in the quota then this will trigger an appropriate review of the existing carryover provisions and any implications for conservation performance. If necessary, the review may lead the Committee to recommend changes in carryover provisions that may, for example, result in a 'reset' of the starting year or other amendments to carryover provisions.

1.4 Schedule language

The Committee advises that the incorporation of carryover provisions in the Schedule should avoid ambiguity. Rather than try to encode general provisions in the Schedule, the Committee offers to assist the Commission in by providing the actual numbers for each hunt in a new quota block, based upon agreed general provisions.

1.5 Example

An example of a response to a request for advice on a carryover option is given in (IWC, *In press*). The request from the USA and Denmark/Greenland was to

> '…allow for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit'.

This request was tested using the *Bowhead SLA* (applicable to the Bering-Chukchi-Beaufort Seas stock) and the *WG-Humpback SLA* (applicable to West Greenland) and three types of options were examined:

(1) baseline case - all strikes taken annually (i.e. no need for carryover);
(2) 'frontload' case - strikes taken as quickly as possible within block (+50% limit annually until the block limit is reached); and
(3) two alternative scenarios where carryover strikes are accrued for one or three blocks, followed by a period of carryover usage subject to the +50% limit.

The three-block scenario considered in (3) served as a direct test of the provision described in the request of USA and Denmark/Greenland. The Committee agreed that the Commission's conservation objectives were met for both *SLA*s for all of the options above and would also be met for a proposal carrying forward strikes from the previous two blocks.

2. BLOCK QUOTAS

The Committee has advised the Commission (in the context of moving to biennial meetings) that block quotas of up to 8 years are acceptable (IWC, 2013, p. 22), noting the requirement for abundance estimates every ten years (see Item 3).

3. INTERIM RELIEF

A variety of factors, including environmental conditions, beyond the control of the hunters may prevent the completion of a successful whale population abundance estimate. While recognizing such difficulties, the Committee notes that uncurtailed aboriginal whaling quotas cannot be continued indefinitely in the long-term absence of data. Therefore, the AWS must address what should be done in the event that efforts to obtain an agreed abundance estimate are unsuccessful after some time limit. For the purposes of applying AWMP *Strike Limit Algorithms*, the Committee has agreed that this limit is 10 years (IWC 2003; IWC, 2016a).

A third quota block begun after the 10-year limit has expired is termed a 'grace period' and the Committee has endorsed the use of an 'interim allowance', namely a grace period strike limit equal to the limit produced by the applicable *Strike Limit Algorithm*, without reduction, for a single block. This approach has been simulation tested for B-C-B bowheads and WG humpbacks to confirm that it meets the conservation and need satisfaction goals of the Commission (IWC, 2016a, pp.190-193; 2016b, pp. 471-484; IWC, 2017, p. 498) and the results are summarized in IWC (2017b; 2018 p. 159). It will be tested for eastern NP gray whales at the next *Implementation Review* for that stock. Testing for the remaining ASW stocks will be added to the future workplan of the Committee.

The 10-year survey interval requirement is complicated by the fact that (a) there will usually be a delay between when a survey is conducted and when the resulting abundance estimate is agreed by the Committee and (b) because surveys, estimates and quota blocks need not be synchronised, as recognised in IWC (2003). For the sake of counting years between surveys, a survey is not considered to have occurred until the resulting abundance estimate is agreed. At that point, the 10-year time window is deemed to have begun in the year during which the survey was conducted. Further details and examples are given in IWC (In press [SC 67b Annex E]).

The Committee recommends (IWC, 2003; 2006) that, during the grace period, a new strike limit is established immediately a new abundance estimate is agreed. this approach. However, it notes that if the Commission refrains from updating the strike limit until the grace period expires, this would not pose a conservation risk. If the strike limit is updated during a grace period block, the number of strikes taken to that point of the grace period should be subtracted from the updated quota, with the remainder being the strike limit for the rest of the grace period. Carryover is not affected.

The Committee emphasises that the interim allowance approach is intended to be applied only in the event that exceptional unforeseen circumstances had delayed obtaining an agreed abundance estimate beyond the end of the second quota block. It should not be interpreted as a routine approach for extending quotas for a third block without a concerted effort to obtain a successful survey prior to that time. Furthermore, the Committee would not recommend two consecutive interim allowances.

It is important to consider a scenario in which no acceptable abundance estimate is obtained by the end of the grace period. *SLA*s are not designed or intended to be applied if new abundance data are not forthcoming after such a long period. Given good faith efforts to obtain an abundance estimate, such a situation would probably have arisen from profound and unexpected environmental change (e.g. related to climate or a disaster such as a massive oil spill). Under such circumstances, an immediate *Implementation Review* (see Item 4.1.2) would probably have been initiated, irrespective of the timing of (un)successful surveys and quota blocks. As soon as it becomes apparent that an abundance estimate may not be obtained in time, researchers should immediately begin to develop alternative approaches to obtaining abundance estimates (or at least indices of abundance) that do not depend on the problematic circumstances. Nevertheless, if no abundance estimate is available the year before the end of the grace period, the Scientific Committee should immediately initiate an *Implementation Review*. The approach of the Committee in the absence of positive alternative evidence would be that the Committee could not provide advice on the quota using the *SLA* and the Commission should exercise great caution when agreeing any further strike limits. The level of caution will depend on the specifics of the situation.

4. *IMPLEMENTATION REVIEWS*

The concept of an *Implementation Review* is central to the functioning of the AWMP. The primary objectives of an *Implementation Review* are to:

(1) review the available information (including biological data, abundance estimates and data relevant to stock structure issues) to ascertain whether the present situation is as expected (i.e. within the space tested during the development of a *Strike Limit Algorithm* (*SLA*)) and determine whether new simulation trials are required to ensure that the *SLA* still meets the Commission's objectives; and

(2) to review information required for the *SLA*, i.e. catch data and, when available at the time of the *Review*, new abundance estimates (note that this can also occur outside an *Implementation Review* at an Annual Meeting).

4.1 Timing of *Implementation Reviews*

4.1.1 Regular Implementation Reviews

Implementation Reviews are undertaken regularly, normally every five to six years. This does not have to coincide with the renewal of catch/strike limits in the Commission. For logistical and resource reasons, only one major *Implementation Review* shall be undertaken at a time. The Committee shall begin planning for the *Review* at the Annual Meeting at least two years before the Annual Meeting at which the *Review* is expected to be finished. This is to enable the Committee to schedule additional work or Workshops if it believes that new information or analyses are likely to be presented that will necessitate the development of new simulation trials. Early planning will enhance the likelihood that the Committee will complete an *Implementation Review* on schedule. It is not expected that every *Implementation Review* will entail a large amount of work.

4.1.2 Special Implementation Reviews

In addition to regular *Implementation Reviews*, under exceptional circumstances the Committee may decide to call for special *Implementation Reviews,* should information be presented to suggest that this is necessary and especially if there is a possibility that the Commission's conservation objectives may not be met.

Calling such a *Review* does not necessarily mean revising the Committee's advice to the Commission, although it may do so. The Committee has not tried to compile a formal comprehensive list of what factors might trigger' such an early review, which implies unexpected/unpredictable factors. However, the following list is provided to give examples of some possible factors.

(1) Major mortality events (e.g. suggested by large numbers of stranded animals).
(2) Major changes in whale habitat (e.g. the occurrence of natural or anthropogenic disasters or changes, an oil spill, dramatic change in sea-ice, development of a major oil/gas field, etc.).
(3) Major ecological changes resulting in major long-term changes in habitat or biological parameters.
(4) A dramatically lower abundance estimate (although the SLA has been tested and found to be robust to large sudden drops in abundance, the Committee would review the potential causes of unexpected very low estimates).
(5) Information from the harvest and hunters (this might include very poor harvest results, reports of low abundance despite good conditions, reports of large numbers of unhealthy animals).
(6) Changes in biological parameters that may result in changes to management advice (e.g. reproduction, survivorship).
(7) If there are cases when need is not being satisfied, strong information that might narrow the plausibility range and allow an increase in block limits.

4.1.3 Outcomes of Implementation Reviews

There are a number of possible conclusions of *Implementation Reviews*:

(1) there is no need to run additional trials and that the existing *SLA* is acceptable;
(2) the results from the additional trials developed and run reveal that the existing *SLA* is acceptable;
(3) there is no need for any immediate additional trials or changes to management advice but work is identified that is required for consideration at the next *Implementation Review*; or
(4) the results of the additional trials require the development of a new (or modified and then retested) *SLA* in which case management advice will have to be reconsidered until that work is complete.

4.1.4 Data availability

Implementation Reviews fall under the Committee's Data Availability Agreement Procedure A (IWC, 2004). By the time of the Annual Meeting prior to that at which the *Implementation Review* is expected to be completed, the scientists from the country or countries undertaking the hunts, or others intending to submit relevant analyses, shall develop a document or documents that explains the data that will/could be used for the *Implementation Review*. Such a document will:

(a) outline the data that will be available, including by broad data type (e.g. sighting data, catch data, biological data): the years for which the data are available; the fields within the database; and the sample sizes;
(b) provide references to data collection and validation protocols and any associated information needed to understand the datasets or to explain gaps or limitations; and
(c) where available, provide references to documents and publications of previous analyses undertaken of data.

The data themselves shall be available in electronic format one month after the close of that Annual Meeting.

In the case of complex *Implementation Reviews* that may last more than one year and involve one or more workshops, new data can be submitted, provided that the data are described and made available at least nine months before the Annual Meeting at which the *Implementation Review* is expected to be completed.

4.1.5 Computer programs
Programs used in analyses submitted to the *Implementation Review* may be requested by the Committee, who may decide that the programmes need independent validation in accordance with its guidelines at the time. All *SLA* simulation testing and evaluation software shall be undertaken by the Secretariat using validated programmes.

5. GUIDELINES FOR SURVEYS

The Committee's general advice on surveys is applicable. Some more specific considerations are given below.

5.1 Survey/census methodology and design

Plans for undertaking a survey/census should be submitted to the Scientific Committee in advance of their being carried out, although prior approval by the Committee is not required. This should normally be at the Annual Meeting before the survey/census is carried out. Sufficient detail should be provided to allow the Committee to review the field and estimation methodology. Considerably more detail would be expected if novel methods are planned.

5.2 Committee oversight

Should it desire, the Scientific Committee may nominate one of its members to observe the survey/census to assess the scientific integrity of the process.

5.3 Data analysis and availability

Data to be used in the estimation of abundance will be made available to the Committee in accordance with Procedure A of the Data Availability Agreement (IWC, 2004). If new estimation methods are used in the data analysis, the Committee may require that computer programs (including documentation to allow such programs to be validated) be provided to the Secretariat for eventual validation.

5.4 Estimates to use in the *SLA*

The most recent estimate(s) accepted by the Committee for any year(s) should be incorporated in the *SLA* calculations. If there is more than one accepted estimate for a given year and the Committee agrees that the estimates are based on sufficiently independent data, then both estimates should be incorporated in the *SLA* calculations. If a revised estimate is obtained for a particular year, then the old one should be replaced before the *SLA* is next used.

6. GUIDELINES FOR DATA/SAMPLE COLLECTION

The Schedule states that data from each harvested animal should be collected and made available to the IWC. The following information should normally be provided for each harvest or individual whale as appropriate:

(1) species;
(2) number of animals;
(3) sex;
(4) season;
(5) location of catch (at least to the nearest village); and
(6) length of catch (to 0.1m).

The Committee recognises the importance of additional information, especially in the context of *Implementation Reviews* e.g. on reproductive status and health. It highlights the importance of collecting tissue samples for genetic studies in accordance with guidance provided by the Committee (e.g. *https://iwc.int/index.php?cID=60&cType=document*), especially in the context of stock structure issues. It notes that photo-identification data can be valuable for estimating biological parameters, assessing anthropogenic injuries, and encourages such research where possible. The value of traditional knowledge is also noted, and such information can also provide valuable input to conducting *Implementation Reviews*.

6.1 Revisions to the AWS

Revisions or additions to this AWS may be recommended by the Committee at any time, including during *Special Implementation Reviews*.

International Whaling Commission
Bled, Slovenia, 2018

Report of the Scientific Committee
Bled, Slovenia, 24 April - 6 May 2018

The meeting (SC/67b) was held at the Rikli Balance Hotel, Bled, Slovenia, from 24 April-06 May 2018 and was chaired by Caterina Fortuna. The next meeting of the Commission (IWC/67) will take place 4-14 September 2018. The list of participants is given as Annex A (about one-third of the Contracting Governments were represented by delegates).

1. INTRODUCTORY ITEMS

1.1 Chair's welcome and opening remarks

Fortuna welcomed the participants to the meeting. Although the meeting was not officially hosted by the Slovenian Government, she thanked it for welcoming them back and noted how pleased the Scientific Committee was to be once again in such a beautiful place. She thanked the IWC Secretariat staff for their hard work during the intersessional period, particularly Mark Tandy for organising the meeting under time pressure Stella Duff and Andrea Cooke for their assistance with meeting documents and Greg Donovan for all his support intersessionally. She thanked Sava Hotels for providing the meeting facilities and her Slovenian colleagues for helping meeting arrangements run smoothly. Fortuna also thanked the vice-Chair Robert Suydam, the Convenors (including those of intersessional groups) and Committee members for all their hard work since the last meeting.

Rebecca Lent, the new IWC Executive Secretary, welcomed participants to the meeting She noted this was her first IWC meeting, but already knew of its excellent global reputation and looked forward to attending many sessions. She noted her pleasure at joining the IWC at such an exciting time, with a busy year of meetings and several new initiatives. Two new coordinators have joined the Secretariat as part of the IWC work programmes endorsed by the Commission in 2016: Marguerite Tarzia as bycatch coordinator; and Karen Stockin as strandings coordinator. They will lead the Commission's work in these areas and will provide valuable input into the Scientific Committee's work.

Lent noted that the external "The IWC review – final report" (https://archive.iwc.int/?r=6890) undertaken as part of the IWC's Governance Review has recently become available and she noted that the Commission would welcome comments on it from the Scientific Committee, and that in particular, the Commission's Operational Effectiveness Working Group will take into consideration the comments from the Scientific Committee in making its recommendations to the Finance and Administration Committee; that Committee will then make recommendations to the Commission, which will determine the next steps in the governance review. Budget Management has become more challenging in recent years and there is much work to do to make sure the workplan of the Commission and all its subsidiary bodies is affordable going forward and into the long term. Finally, she thanked Scientific Committee members for their scientific input over the next two weeks and wished everyone a successful meeting.

The Committee was saddened to learn of the death of four scientists connected with the Scientific Committee:

(1) Greg Kaufman, a member of the Committee since 2006 and an active member of the sub-committee on whale watching and the Whale watching Working Group of the Conservation Committee;

(2) Doug Coughran, who although he did not attend Scientific Committee meetings, was a participant in numerous IWC workshops on entanglement and stranding response and was a charter member of both the IWC's entanglement and stranding expert (advisory) groups;

(3) Dale Rice, who although he has not attended IWC meetings in recent years, first represented the USA on the Scientific Committee as far back as 1960; and

(4) John Reynolds, who although not a member of the Scientific Committee, was a mentor to many Committee members.

The Committee paused in silence and respect for these scientists who had contributed directly and indirectly to the Committee's work and to whale conservation and management. Short obituaries can be found in Annex AA.

1.2 Appointment of rapporteurs

Donovan was appointed rapporteur with assistance from various members of the Committee as appropriate. Chairs of sub-committees and Working Groups appointed rapporteurs for their individual meetings.

1.3 Meeting procedures and time schedule

The Committee agreed to the meeting procedures and time schedule outlined by the Chair.

1.4 Establishment of sub-committees and Working Groups

The following pre-meetings were held:

(1) the Standing Working Group on Environmental Concerns held a pre-meeting on 'Cumulative Effects' from 22-23 April; and
(2) the sub-committee on Whale Watching held a pre-meeting on the IWC's 'Five Year Strategic Plan for Whale Watching' from 22-23 April.

Several sub-committees and Working Groups were established. Their reports were either made Annexes (see below) or subsumed into this report.

Annex D – Sub-Committee on the Revised Management Procedure;

Annex E – Standing Working Group on an Aboriginal Whaling Management Procedure;

Annex F – Sub-Committee on In-Depth Assessments;

Annex G – Sub-Committee on Other Northern Hemisphere Whale Stocks

Annex H – Sub-Committee on Other Southern Hemisphere Whale Stocks;

Annex I – Working Group on Stock Definition and DNA testing;

Annex J – Sub-Committee on Non-Deliberate Human-Induced Mortality of Cetaceans;

Annex K – Sub-Committee on Environmental Concerns;

Annex L – Standing Working Group on Ecosystem Modelling;

Annex M – Sub-Committee on Small Cetaceans;

Annex N – Sub-Committee on Whale Watching;

Annex O – Sub-Committee on Conservation Management Plans;

Annex P – Revised ‘Annex P’;

Annex Q – Standing Working Group on Abundance Estimates, Stock Status and International Cruises;

Annex R – *Ad hoc* working Group on Sanctuaries;

Annex S – *Ad hoc* Working Group on Photo-ID;

Annex T – Ad hoc Group on Global databases and repositories

Annex U – Statements on Special Permit discussions

Annex V – IWC-SORP – Southern Ocean Research Partnership

Annex W – Updated Rules of Procedure

Annex X – Comments on the ‘Governance Review’

Annex Y – Intersessional groups

Annex Z – Minority Statements on the Agenda

1.5 Computing arrangements
Donovan outlined the computing and printing facilities available for delegate use.

2. ADOPTION OF AGENDA

The adopted Agenda is given as Annex B. Statements on the Agenda are given as Annex Z.

3. REVIEW OF AVAILABLE DATA, DOCUMENTS AND REPORTS

3.1 Documents submitted
The documents available are listed in Annex C. As agreed at the 2012 Annual Meeting, primary papers were only available at the meeting in electronic format (IWC, 2013a, pp 78-79).

3.2 National Progress Reports on research
The National Progress Reports have their origin in Article VIII, Paragraph 3 of the Convention. All member nations are urged by the Commission to provide Progress Reports to the Scientific Committee following the most recent guidelines developed by the Scientific Committee and adopted by the Commission. The report is intended to provide (1) a concise summary of information available in member countries and (2) advice on where to find more detailed information if required. In addition, the IWC holds several specialist databases (including, catches, sightings, ship strikes, images – see Item 23).

As agreed at the 2013 Annual Meeting (IWC, 2014), all National Progress Reports were submitted electronically through the IWC National Progress Reports data portal. Encouragingly, 18 countries (Argentina, Australia, Brazil, Croatia, Denmark, France, Germany, Iceland, Italy, Japan, Korea, Mexico, New Zealand, Netherlands, Norway, Spain, UK and USA) submitted reports this year compared to 12 last year. Information was provided on bycatch, entanglement, ship strikes, direct and indirect takes, sampling, sightings and tracking studies.

Nearly all the recommendations identified by the Committee in 2017 (IWC, 2018c) have been implemented although further guidance is required on the appropriate level of aggregation for some records (e.g. strandings) to simplify and accelerate data entry without losing valuable resolution.

Although data entry this year was hampered due to problems with the IWC server, this generic issue has already been resolved by the IWC Secretariat. Several suggestions for improvements, including the removal of default values, can be See Annex T for full details.

Attention: C, CG, S, SC

Despite the technical issues of the portal, the eighteen Progress Reports submitted to SC67b was an improvement on the twelve submitted to SC67a. Nevertheless, this represents a small proportion of IWC member nations. The Committee ***reiterates*** *that National Progress Reports are required under the Convention and they represent a useful tool and* ***recommends*** *that Contracting Governments to submit them annually through the IWC data portal (http://portal.iwc.int).*

National Progress Reports include records of reported bycatch and ship strikes. The Committee ***agrees*** *that the data collected in these reports are not intended to replace in-depth studies and they should be considered and used with great caution. However, it also* ***agrees*** *the reports have value because much of these data would not otherwise be available and the reporting process can assist in supporting national compilation of cetacean data.*

To address in part several of the issues and challenges described above the Committee ***agrees*** *to:*

(1) develop a strategy with the Scientific Committee Chair and Secretariat to raise awareness of National Progress Reports and promote reporting by member nations;
(2) produce a short summary explaining the utility of National Progress Reports and suggest including this text in the circular to member nations calling for data submission;
(3) request the Secretariat to issue the first call for data submission in February and repeat the call a few weeks prior to the start of the SC meeting;
(4) develop text acknowledging the likely limitations of the reported data (subsequently this text will be included in all reports and data downloads;
(5) further explore approaches (using R markdown) to produce PDF- formatted national reports.

This work will be conducted by the GDR Steering Group intersessionally (see Annex Y).

3.3 Data collection, storage and manipulation

3.3.1 Catch data and other statistical material

Table 1 lists data received by the Secretariat since the 2017 meeting.

Table 1
List of data and programs received by the IWC Secretariat since the 2017 meeting.

Date	From	IWC ref.	Details
18/05/2017	St Vincent&G: J. Cruickshank-Howard	E128 Cat2016	Information from St Vincent and the Grenadines aboriginal hunt 2016-17
3-10 7/2017	S. Kromann and Y. Ivashchenko	E127 C	Individual catch data for Taiyo Gyogyo, Japan in 1943-44. Copy of data held at NMML Seattle
16/08/2017	Y. Ivashchenko	E127	Extra details of N. Pacific sei whale catches by the USSR 1963-71
16/02/2018	Japan: K. Matsuoka	CD103	2017 POWER sightings cruise data (except photographs)
16/02/2018	Japan: K. Matsuoka	CD104	2017 ICR North Pacific dedicated sighting survey data.
04/04/2018	Canada: S. Reinhart	E130 Cat2017	Details of the Canadian bowhead harvest for the 2015-7 seasons and some information on the 2018 quota
11/04/2018	Japan: K. Matsuoka	E131	Data from the 2017-18 NEWREP-A dedicated sighting survey
18/04/2018	Iceland: G. Vikingsson	E130 Cat2017	Individual records of minke whales caught by Iceland 2017 [there was no fin whale catch]
18/04/2018	Norway: N. Øien	E130 Cat2017	Individual minke records from the Norwegian 2017 commercial catch. Access restricted (specified 14-11-00).
19/04/2018	USA: R. Suydam	E130 Cat2017	Individual records from USA Alaska aboriginal bowhead hunt 2017
20/04/2018	Japan: H.Morita	E130 Cat2017	Individual data for Japan’s catch in 2017 in the N. Pacific (JARPN II) & 2017/8 in the Antarctic. (pdf format)

3.3.2 Progress of data coding projects and computing tasks

On behalf of Allison, Donovan reported that the 2017 catches and Japan coastal records in 1943-44 (data from NMML Seattle) have been added to the database. The changes agreed at the 2017 meeting, in particular to split out the catches taken *en route* to and from the Antarctic whaling grounds, have been implemented. Work on computing tasks with respect to work on the AWMP, RMP and in-depth assessments is reported under the relevant agenda items.

4. COOPERATION WITH OTHER ORGANISATIONS

Attention: C-A

The Committee ***stresses*** *the value of cooperation with other organisations when addressing the range of issues affecting cetacean conservation and management. In addition to the summaries below, co-operation is also discussed where relevant elsewhere in the agenda.*

4.1 African States Bordering the Atlantic Ocean (ATLAFCO)
There was no meeting of the Ministerial Conference of ATLAFCO during the intersessional period.

4.2 Arctic Council
4.2.1 PAME (Protection of the Arctic Marine Environment)
The PAME II-2017 meeting was held in Helsinki, Finland from 18-20 September 2017. No IWC observer attended the meeting. The Committee agrees that if possible an IWC observer should attend the next meeting of PAME.

4.3 Convention on Biological Diversity (CBD)
There was no meeting of the Conference of Parties during the intersessional period. The next meeting will take place 10-22 November 2018. The Committee agrees that if possible an IWC observer should attend the next meeting of CBD.

4.4 Convention for the Conservation of Antarctic Marine Living Resources (CCAMLR)
The 36th Meeting of the CCAMLR Scientific Committee was held 16 - 20 Oct 2017 October 2016 in Hobart, Australia. Although no IWC observer attended the meeting, co-operation with CCAMLR remains an important component of the IWC's work and is discussed further under Item 16.1.

4.5 Convention on the Conservation of Migratory Species (CMS)
4.5.1 Scientific Council
The Second Meeting of the Sessional Committee of the Scientific Council was held 10- 13 July 2017 in Bonn, Germany. No IWC observer attended the meeting.

4.5.2 Conference of Parties
The Conference of Parties met 23-28 October 2017 in Manila, Philippines. No IWC observer attended the meeting.

4.5.3 Agreement on Small Cetaceans of the Baltic and North Seas (ASCOBANS)
The report of the observer to ASCOBANS is given as SC/67b/COMM01E. The following key activities have occurred since the last IWC Scientific Committee meeting:

(1) first Joint Meeting of the 13th Meeting of the Jastarnia Group (Baltic Sea harbour porpoises) and the 6th Meeting of the North Sea Group;
(2) best-practice workshop on 'Fostering Inter-regional Cooperation on Underwater Noise Monitoring and Impact Assessments in waters around Europe, within the context of the European Marine Strategy Framework Directive';
(3) 23rd Meeting of the Advisory Committee; and
(4) 14th Meeting of the Jastarnia Group.

The key ongoing ASCOBANS activities are:

(1) work on the three harbour porpoise Action Plans (Baltic, Belt and North Seas)- in place since February 2018;
(2) web-accessed database on marine mammal stranding and necropsy in preparation (ZSL/IOZ leading), 2018-2020;
(3) preparation of an action plan for common dolphins; and
(4) implementing a change in the national reporting cycle from annual (on all topics) to a four-year cycle (selected topics each year) - the intention is that all the key ASCOBANS working groups and meetings align their agendas to home in on these issues in the respective years of reporting (e.g. covering 2017 in 2018).

The Action Points at the last Advisory Committee meeting included:

(1) preparing a discussion on prey depletion and changes in prey quality on the agenda of the 24th Meeting of the Advisory Committee;
(2) co-organisation of a workshop with ACCOBAMS on strandings and marine debris (the report has been made to the Scientific Committee);
(3) future focuses will include the white-beaked dolphin and the white-sided dolphin.
(4) a draft Action Plan for the Common Dolphin is due to be presented at the 24th Advisory Committee Meeting.

The Committee thanked Simmonds for his report and **agrees** that he should represent the Committee as an observer at the next ASCOBANS meeting.

4.5.4 Agreement on the Conservation of Cetaceans of the Black Sea, Mediterranean Sea and Contiguous Atlantic Area (ACCOBAMS)

MEETING OF PARTIES

There was no Meeting of the Parties (MoP) to ACCOBAMS during the intersessional period. Donovan will represent the Committee as an observer at the next ACCOBAMS MoP.

SCIENTIFIC COMMITTEE

There was no meeting of the ACCOBAMS Scientific Committee during the intersessional period. Donovan will represent the Committee at the next ACCOBAMS Scientific Committee meeting.

4.6 Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES)

No relevant meetings of CITES have taken place during the intersessional period.

4.7 Food and Agriculture Organisation of the United Nations (FAO)

There was no meeting of The Committee on Fisheries (COFI) during the intersessional period. The next meeting will take place in Rome, Italy 9-13 July 2018.

4.8 Inter-American Tropical Tuna Commission (IATTC)

The 92nd meeting of the Inter-American Tropical Tuna Commission (IATTC) was held in Mexico City, Mexico 24-28 July 2017. No observer attended IATTC meetings in the intersessional period.

4.8.1 Agreement on the International Dolphin Conservation Program (AIDCP)

No observer attended IADCP meetings in the intersessional period.

4.9 International Committee on Marine Mammal Protected Areas (ICMMPA)

There was no meeting of ICMMPA task force during the intersessional period. The 5th International Conference will be held from 8- 12 April 2019 in Greece. It will evaluate progress in meeting the ICMMPA's long-standing goal of bringing the MMPA community closer together. A primary goal is to focus on the challenges ahead towards achieving effective place-based protection and management for marine mammals. It will build on previous initiatives to advance our understanding of science, management, and effective biodiversity conservation in protected areas. It will also provide updates on plans for the worldwide Important Marine Mammal Area (IMMA) initiative (*marinemammalhabitat.org*). Rojas-Bracho will represent the Committee at this meeting.

4.10 International Council for the Exploration of the Sea (ICES)

The report of the IWC observer documenting the 2017 activities of ICES is given as SC/67b/COMM01A. The ICES Working Group on Marine Mammal Ecology (WGMME) reported on recent information on status of, and threats to, marine mammal populations and briefly reviewed current knowledge of effects of plastics and underwater noise. Criteria for assessment of abundance trends in offshore cetaceans in the context of the Marine Strategy Framework Directive (MSFD) were reviewed, modifying the proposed indicator (previously based solely on the rate of decline) to make specific reference to baseline values. The group also considered the outcomes of the 2016 SCANS III survey[1]. All three SCANS surveys have arisen from individual projects. WGMME recommended that the surveys be co-organised and coordinated by Member States as part of their routine monitoring and that the frequency is increased to once every six years to match the MSFD reporting cycle.

A Workshop on Predator-prey Interactions between Grey Seals and other marine mammals (WKPIGS) focused on predatory behaviour of grey seals towards other grey seals, harbour seals and harbour porpoises in European waters. The workshop aimed to consolidate pathological indicators of grey seal predation events, collate data on the prevalence and distribution and discuss methods to aid in detection of predation events and potential population level consequences of reported incidences. Cases of predation on harbour porpoises peaked in spring months. Reported incidence has increased over the last decade although it is not known if this represents a true increase in prevalence, an increase in seal numbers or an increase in effort/reporting.

Highlights from the 2017 ICES Working Group on Bycatch of Protected Species (WGBYC) included: review of ongoing bycatch mitigation research projects; presentations on interdisciplinary bycatch monitoring programs in the US Northwest Atlantic northeast region; collaborations with other ICES working groups; positive advancements on WGBYC database development working jointly with the ICES Data Centre; and progress on summarising bycatch for the Baltic Sea and Bay of Biscay/Iberia fisheries overviews.

Four cetacean species were reported as bycatch from the 2015 member state reports (common dolphins, white-beaked dolphin, bottlenose dolphin, and harbour porpoise). The WGBYC continues to highlight the inconsistent submission and content of annual reports provided by some member states and the shortcomings to accurately reflect the full magnitude of cetacean bycatch in European fisheries. WGBYC is preparing for the transition away from regular member state reports as the primary source of data on bycatch of cetaceans over to data coming through the ICES regional database.

[1] https://synergy.st-andrews.ac.uk/scans3/

The 2017 ICES Annual Science Conference (ASC) had no sessions devoted entirely to marine mammals. Nevertheless, some sessions had marine mammals included as an integral part - the most relevant sessions were: 'microbes to mammals: metabarcoding of the marine pelagic assemblage' and 'from iconic to overlooked species: how (electronic) tags improve our understanding of marine ecosystems and their inhabitants'.

More information is available from the ICES website *www.ices.dk.*

The Committee thanked Haug for his report and **agrees** that he should represent the Committee as an observer at the next ICES meeting.

4.11 International Maritime Organisation (IMO)

The report of the observer is given as SC/67b/COMM01D. At IWC66, the Commission endorsed recommendations of the IWC Conservation and Scientific Committees for continued engagement with the IMO, including submission of a paper to the IMO Marine Environment Protection Committee (MEPC) providing an update of recent information related to the extent and impacts of underwater noise from shipping. This paper was written by an intersessional group appointed at SC67a and submitted to the IMO MEPC 72 meeting 9-13 April 2018 (MEPC 72/Inf.9).

The ship strike section of the IWC website now contains a list of the measures that have been put in place globally through IMO or national regulations, to reduce ship strike risks to whales. These include Traffic Separation Schemes, Areas to be Avoided, Recommended Routes, voluntary and mandatory speed restrictions. New measures relevant to ship strikes include three recommendatory areas to be avoided (ATBA) encompassing King Island, Nunivak Island, and St. Lawrence Island in the Bering Sea proposed by the United States (NCSR 5/3/8). The proposal noted that King Island is a biologically important site to the gray whale, while St. Lawrence Island's ATBA would provide protection to bowhead whales, gray whales, and humpback whales. These areas were recommended for adoption (with a reduced size for the St. Lawrence ATBA) by the IMO Navigation, Communications and Search and Rescue sub-committee NCSR 5 in February 2018.

Members of the IWC Scientific Committee have attended IMO meetings in order to discuss how best to provide information on populations of marine mammals relevant to the marine mammal avoidance provisions of the IMO Polar Code. This is discussed further under Item 14.3.

The Committee thanked Ferris and Leaper for their report and **agrees** that they should represent the Committee at the next IMO meeting.

4.12 International Union for the Conservation of Nature (IUCN)

The report of the observers to IUCN is given as SC/67b/COMM01G. The IUCN Marine Mammal Protected Areas Task Force (*https://www.marinemammalhabitat.org*) held its 3rd regional workshop in Malaysia in March 2018 to identify, describe and map candidate areas for inclusion in the Important Marine Mammal Area (IMMA) e-Atlas (*marinemammalhabitat.org/imma-eatlas*). The 46 candidate IMMAs proposed by the workshop are currently undergoing independent review.

Cetaceans entries on the Red List are in the process of being updated. The first batch of updates covering 19 taxa was published on *redlist.org* in December 2017 and is summarised at *iucn-csg.org/index.php/page/3*. Most of the remaining mysticete species assessments and some subpopulation assessments, as well as around 10 more new assessments of small and medium-sized odontocetes, have been submitted for publication in the next Red List update in June 2018. Most of the remaining taxa are in the pipeline for publication in late 2018.

IUCN continues to convene the Western Gray Whale Advisory Panel (WGWAP), which provides advice to Sakhalin Energy Investment Company (SEIC) and other parties, especially on the mitigation of industrial and other impacts on the gray whales that feed each summer off Sakhalin Island, Russia. Details of the Panel's recent work are given in Annex O, Appendix 3.

Regular news items on activities by members of the IUCN SSC Cetacean Specialist Group are posted on the CSG website, *www.iucn-csg.org*.

4.13 North Atlantic Marine Mammal Commission (NAMMCO)

Scientific Committee

The report of the IWC observer at the 24th meeting of the NAMMCO Scientific Committee (NAMMCO-SC) is given as SC/67b/COMM01B. The NAMMCO-SC discussed a current joint project, 'Exploring marine mammal consumption relative to fisheries removal in the Nordic and the Barents Seas'. Preliminary results suggest that marine mammal consume around 15 million tons ± 50% of prey per year, predominantly targeting low and mid trophic level species (zooplankton and small pelagic fish). Fisheries remove around 4.3 million tons per year, targeting mid and top trophic levels (small pelagic fish and larger demersal and pelagic fish).

The NAMMCO By-Catch Working Group (BYCWG) met in May 2017. Methods used for collection of data and by-catch estimation were reviewed, and both the WG and the SC recommended methodological improvements to be implemented both in the data collection and the analysis before the bycatch estimates could be endorsed. Greenland is an atypical case because marine mammals that are caught, either directly or indirectly, are assumed to be reported as direct catch (with large whales being the exception where bycatch is reported as such). The primary concern is to ensure that any bycatch is included in the total number of removals to be used in population assessments.

The NAMMCO SC noted and appreciated that the IWC *Implementation Reviews* for North Atlantic fin whales and North Atlantic common minke whales are completed. The NAMMCO SC provided advice on sustainable catch levels fro these species in Icelandic waters (from 2018-2025) based upon application of the RMP. The NAMMCO SC also recommended that the *SLAs* that are developed in the IWC SC be used for advice for large whales in Greenland and provided advice on strike limits for West Greenland humpback whales for the 2019-24.

The NAMMCO SC received the results from an updated global review of monodontids and provided updated assessments and advice for white whales and narwhals in Greenland and Canada. It also received a new abundance estimate for bottlenose whales from the Faroese component of the 2007 T-NASS survey that was analysed together with data on deep diving species from the SCANS-II and CODA surveys. Sightings were mainly from the Faroese survey block.

Increased research on harbour porpoises in Norway is being driven by the concerns regarding bycatch. Bycaught harbour porpoises were collected in 2016 and 2017 by Norway for biological sampling, and a food-web model is being developed for the Vestfjord area close to Lofoten to study the role of the species in this area. An abundance estimate is now available from the SCANS-III survey which was extended from 62°N to include Vestfjorden, an area with high bycatch. Preliminary investigations using this new abundance estimate suggest that bycatch levels are within PBR.

NAMMCO's whale sighting surveys in the Northeast Atlantic in 2015 (NASS2015) included an intensive survey with the purpose of estimating the abundance of pilot whales around the Faroe Isles, an aerial survey of the coastal waters in East Greenland and a ship-based survey around Jan Mayen following methods developed for the Norwegian minke whale surveys. The next NASS survey should be in 2022-23. The NAMMCO SC strongly recommended that an attempt be made to conduct again a trans-Atlantic coordinated survey and charged the NAMMCO Secretariat to explore what are the present plans and how much flexibility they encompass.

Council
The report of the IWC observer at the 26th Annual Council meeting of NAMMCO held in Tromsø, Norway 7-8 March 2018 is given as SC/67b/COMM01C. Relevant items discussed at the Council meeting include the following:

(1) A newly established working group on bycatch, entanglements and live strandings has started its work and will gather information on the matter from other organisations and develop recommendations for NAMMCO. The focus is animal welfare associated to non-hunting related activities, and how NAMMCO can best contribute to addressing significant adverse impacts of by-catch, entanglement and live strandings on marine mammals; and

(2) The report of the Global Review of Monodontids (white whales and narwhals) reviewed the conservation status, threats, and data gaps for all stocks globally. The last review was in 1999.

The Committee thanked Moronuki for his report.

4.14 North Pacific Marine Science Organisation (PICES)
The report of the IWC observer at 2017 annual meeting of PICES is given as SC/67b/COMM01F.

The marine birds and mammals section (S-MBM) focussed on 'seasonal and climatic influences on prey consumption by marine birds, mammals and predatory fishes' Presentations were made on (1) significance of seasonal changes in prey consumption on energy budgets and ecosystem dynamics; (2) effects of changes in water temperature and other climatic variables on food requirements; (3) relationships between dietary shifts and population trends; (4) limits of plasticity in prey selection; and (5) how prey consumption of birds, mammals and predatory fishes is affected by the recent extreme climatic events. Overall, the collection of presented studies in this session contributed to the efforts of the S-MBM to estimate prey consumption of birds and mammals. They provided new methods to estimate prey consumption of marine mammals and gave insights into the existing databases of diets and population estimates that can be used to further this effort.

For 2018, the S-MBM will focus on 'diets, consumption and abundance of marine birds and mammals in the North Pacific'. Since the 2016 workshop, work on the agreed upon databases to estimate prey consumption has been initiated and will continue to be added to over the coming 12 months in anticipation of the 2018 workshop, when invited experts will review the compiled information. This process should result in near-complete databases of diets, abundances and energy requirements of marine birds and mammals in the North Pacific.

The 2018 annual meeting of the PICES will be held in Yokohama, Japan 25 October-4 November 2018. The Committee thanked Tamura for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next PICES meeting.

4.15 Protocol on Specially Protected Areas and Wildlife (SPAW) of the Cartagena Convention for the Wider Caribbean
No observer attended SPAW meetings in the intersessional period.

4.16 Pacific Region Environment Programme (SPREP)
No observer attended SPREP meetings in the intersessional period.

5. GENERAL ASSESSMENT ISSUES WITH A FOCUS ON THOSE RELATED TO THE REVISED MANAGEMENT PROCEDURE (RMP)

Several assessment topics apply not only to the Revised Management Procedure (RMP), but to the work of the Scientific Committee as whole. This item focuses on general assessment issues, such as: (1) the relationship between $MSYR_{mat}$ and $MSYR_{1+}$; (2) implications of RMP and AWMP simulation trials for consideration of 'status'; and (3) matters of relevance to special permits that involve RMP considerations including effects of catches upon stocks.

5.1 Evaluate the energetics-based model and the relationship between $MSYR_{1+}$ and $MSYR_{mat}$

MSYR is a key parameter in the *Implementation Simulation Trials* used to evaluate the conservation and catch performance of alternative RMP variants for specific species and regions. In recent years, the Committee has been reviewing progress on an individual based energetics model (IBEM) to provide insights into the relationship between $MSYR_{1+}$ and $MSYR_{mat}$. Two papers on the IBEM were reviewed by the Committee in SC/67b.

SC/67b/EM07 outlined enhancements to the IBEM since the last meeting. This included the ability to explicitly model the effects of feeding while on migration, which can have effects on the yield curve as well as MSYR and MSYL. The Committee discussed (Annex D, Item 2.1) several ways in which this model can potentially enhance understanding of the relationship between biological processes and MSYR.

SC/67/RMP01 reported on trials using the IBEM within the standard RMP testing framework. The results were consistent with the behaviour of the RMP *CLA* observed in less complex population models and will also provide a point of comparison for the emulator model for the IBEM currently under development. The Committee has previously agreed that a fully-developed emulator model could form the basis for future *Implementation Simulation Trials*.

Attention: SC

The Committee ***agrees*** *that work continue to develop an emulator model; assess whether it is possible to represent the trajectories from the IBEM using an emulator model; compare the yield curves from the IBEM with those from the emulator model; and develop guidelines for how to use an emulator model as the basis for a multi-stock, multi-area population dynamics model and how such a model could be conditioned given available data.*

5.2 Implications of ISTs for consideration of species' and populations' status

Last year, the Committee recommended that a set of *Implementation Simulation Trials* should be summarised using three statistics to provide information on status (IWC, 2018d). The Committee was advised that intersessional tasks toward that goal could not be completed prior to SC/67b due to computing workloads.

Attention: SC

The Committee ***agrees*** *that Allison should modify the control programs used for* Implementation Simulation Trials *to report the three measures of status agreed last year (IWC, 2018d). The RMP sub-committee, in conjunction with the Working Group on ASI, will review outcomes of the analyses at SC/68a. Punt and Donovan will develop draft updates to the Guidelines for* Implementations *and* Implementation Reviews *to reflect decisions on evaluation status of stocks for consideration at SC68a.*

5.3 General consideration of how to evaluate the effect of special permit catches on stocks and levels of information needed to show improved management performance

5.3.1 General issues

The Committee developed general guidelines on the levels of information needed to show improved management improvement, for proposals that identify this as an objective (Annex D; appendix 2). The guidelines are intended to assist proponents in proposal preparation and to facilitate the review process. It was stressed that these were guidelines not requirements. Proponents might request the establishment of an Advisory Group to provide comment on intersessional work, but this is not mandatory. An Advisory Group may most benefit nations which have not previously developed proposals or may be lacking analysts familiar with the modelling approaches commonly applied at the IWC.

Attention: SC

The Committee ***agrees*** *that the general guidelines on the levels of information needed to show improved management improvement, for proposals that identify this as an objective (Annex D; appendix 2), should be included as an Appendix to the Scientific Committee handbook.*

5.3.2 Specific issues
SC/67b/RMP03 provided draft specifications for RMP/IST type simulations to evaluate management procedures based on modified *CLA*s that use information on recruitment inferred from age data from Antarctic minke whales. This work originally arose from discussions of NEWREP-A and Recommendation 1 of the Panel Review of that proposal (and see Item 19). The Committee noted that SC/67b/RMP03 was a work-in-progress, and that several features of the operating models would need to be extended before final conclusions could be drawn. The author of SC/67b/RMP03 plans to continue this work and received several suggestions from the Committee to carry those efforts forward (Annex D, Item 2.3).

5.4 Work plan 2019-20
Details of work to be undertaken both before and during the 2019 Annual Meeting are given in Table 2.

Table 2

Work plan for general assessment matters with a focus on the RMP

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Item 5.1: Conduct work to evaluate the energetics-based model and hence the relationship between MSYR1+ and MSYRmat	(a) Continue to assess whether it is possible to represent the trajectories from the IBEM using the emulator model (Annex Y); (b) Compare the yield curves from the IBEM with those from the emulator model (Annex Y); and (c) Develop guidelines for how to use an emulator model as the basis for a multi-stock, multi-area population dynamics model and how such a model could be conditioned given available data (Annex Y).	Continue to work to evaluate the energetics-based model and hence the relationship between $MSYR_{1+}$ and $MSYR_{mat}$	Conduct follow-up analyses	Continue to work to evaluate the energetics-based model and hence the relationship between MSYR1+ and MSYRmat
Item 5.2: Implications of ISTs, for consideration of status	(a) Modify the control programs used for *Implementation Simulation Trials* to report the three measures of status (Allison) (b) Draft updates to the Guidelines for *Implementations* and *Implementation Reviews* to reflect decisions on evaluation status of stocks (Punt and Donovan)	Review the results of the projections Review the draft guidelines		
Item 5.3: levels of information needed to show improved management performance		Review progress implementing the suggested changes to the specifications of the model in SC/67b/RMP03 and any results.		

6. RMP – *IMPLEMENTATION*-RELATED MATTERS (RMP)

This agenda item includes the details of ongoing *Implementation Reviews* and preparation for new *Implementation Reviews*. For discussions related to the stock structure and abundance of these stocks, see also Items 11 and 12.

6.1 Completion of the *Implementation Review* of western North Pacific Bryde's whales
6.1.1 Report of the intersessional Workshop
The second intersessional Workshop on western North Pacific Bryde's whales was held in Tokyo from 14-16 February 2018 (SC/67b/Rep02). The objective was to facilitate completion of the *Implementation Review*. Much of the Workshop focussed on completing the final trial specifications, especially confirming the mixing matrices, updating the abundance estimates for the new sub-areas and confirming future sighting survey plans and whaling options. The Workshop reviewed preliminary conditioning results and agreed that they were satisfactory. It developed a workplan to try to ensure completion of the *Review* at SC/67b.

The Committee noted that the intersessional workshop had led to considerable progress towards completing the *Implementation Review*. It thanked Donovan for chairing the meeting, the Government of Japan for providing excellent facilities and all the participants for their contributions to the development of trial specifications and workplan.

The code and specifications for *Implementation Simulation Trials* were updated following the intersessional Workshop.

Attention: SC

The Committee ***agrees*** *to the updated trial specifications for the* Implementation Review *of western North Pacific Bryde's whales. These specifications are provided in Annex D, Appendix 3. It also* ***agrees*** *that conditioning has been achieved satisfactorily.*

6.1.2 Conclusions and recommendations

Once the trial specifications and conditioning had been agreed, the next step was to conduct projections under alternative RMP variants and survey plans. There was insufficient time during the meeting to complete all of the required projections and to check the associated calculations. Consequently, the remaining work will be completed intersessionally and reviewed and summarised by a Steering Group (Annex Y). This will occur well before SC/68a so that Japan has sufficient time to consider the results (e.g. with regard to its preferred survey options), prior to final conclusions being drawn. The Committee expects that this work can be completed before the end of 2018, but if complications arise conducting the projections, an extra day should be added to the 'First Intersessional Workshop for the western North Pacific minke whales' (see Item 6.2) to address outstanding issues.

Attention: SC

The Committee ***agrees*** *that the* Implementation Review *of western North Pacific Bryde's whales will be completed at SC/68a. Outstanding tasks will be completed intersessionally and the results reviewed and summarised by a Steering Group (Annex Y). This will occur well prior to SC/68a, and if complications arise then an extra day should be added to the First Intersessional Workshop for the western North Pacific minke whales (see Item 6.2) to address those issues.*

6.2 Start of the *Implementation Review* of western North Pacific common minke whales

6.2.1 Report of the intersessional Workshop

Donovan summarised the report of the preparatory Workshop for the Western North Pacific common minke whale *Implementation Review* (SC/67b/Rep05). Last year, the Committee recognised that the most difficult aspect of the last *Implementation Review* had been selecting, modelling and assigning plausibility to stock structure hypotheses. The objective of this Workshop was to begin to review work undertaken since the last *Implementation Review* and to develop, if necessary and possible, consensus advice on further analyses that will assist in the forthcoming *Implementation Review*. Stock structure discussions on common minke whales are detailed in Annex I, item 4.2.

This past lack of agreement with respect to the plausibility of existing stock structure hypotheses has, in part, revolved around how genetic analyses can be used to assign whales as part of the 'J' versus 'O' stocks. While some whales assign strongly to one of the two groups based on genetic data, the assignment of others is dependent on the assignment probability deemed sufficient to assign stock affinity. At the intersessional workshop (SC/67b/Rep05), the results of new stock structure-related analyses were reviewed by an advisory panel, and two recommendations were made with regard to additional genetic analyses needed to better understand stock structure. One of the recommended analyses involved evaluating the consistency of individual assignment probabilities when additional loci were genotyped. Progress with respect to that recommendation is discussed below.

The Workshop was also provided with an update to SC/67a/SCSP/13 that used information on the trend over time in the J:O stock ratio for common minke whale bycatches around Japan to draw various inferences, in particular about the value of the MSYR. The Workshop agreed that J:O stock ratios in bycatch will require attention when formulating stock distribution assumptions for the process of conditioning *IST*s in the coming *Implementation Review* and made some recommendations on how this could be achieved.

The Committee noted that the intersessional Workshop was held in an excellent spirit of co-operation among the participants and led to identification of additional data sets and analyses that should be taken forward. The Committee thanked Donovan for chairing the meeting, the Government of Japan for providing excellent facilities and all the participants for their contributions to progress the *Implementation Review*.

6.2.2 Progress since the intersessional Workshop

SC67b/SDDNA06 presented the results of the recommended analysis from the Workshop (see Item 6.2.1) and the Committee confirmed that the workshop's recommendation for this analysis had been properly completed.

Attention: SC

The Committee reviewed new results of genetic analyses that were recommended at the intersessional workshop (SC/67b/Rep05) to better evaluate the use of genetic data to assign stock affinity in North Pacific common minke whales. The Committee:

(1) ***agrees*** *that future analyses should incorporate a range of assignment thresholds to encompass uncertainty;*
(2) ***supports*** *the additional genetic analyses described in Annex I Appendix 5 relating to the second recommendation of the intersessional workshop and agrees that they should be performed prior to the next intersessional workshop; and*
(3) ***encourages*** *the inclusion of non-genetic biological data to inform stock structure where possible.*

SC/67b/RMP/02 aimed at suggesting a plausible range for $MSYR_{1+}$ for the western North Pacific common minke whales, and the relative plausibility of two stock structure hypotheses. The Committee thanked Kitakado for the updated analysis, which implemented some of the recommendations from the intersessional Workshop. Details of this paper and associated discussion can be found in Appendix D, Item 3.2.2. The Committee also discussed the analysis of genetic data conducted since the intersessional workshop (Annex I, Item 4.5).

Attention: SC, CG-A

The Committee ***agrees*** *that:*

(a) it is necessary to update the mixing matrices in the trial specifications to be more consistent with observed genetic and bycatch data, also taking into account sensitivity to alternative methods of genetic assignment to stock;
(b) whether it is possible to use the bycatch data to assign plausibility ranks to $MSYR_{1+}$ values and stock structure hypotheses depends on assumptions regarding trends in fishing effort spatially and temporally; and
(c) trials would need to consider different assumptions regarding the use of J:O bycatch ratios, including that these data do not provide information on $MSYR_{1+}$ and the plausibility of stock structure hypotheses because of possible differential distributional changes by stock.

The Committee therefore ***agrees*** *that scientists from Japan and Korea should provide data on the amount, location and timing (seasonal and annual) of fishing effort and bycatch to the First Intersessional Workshop (see item 6.2.3).*

6.2.3 Preparation for the First Intersessional Workshop

The Committee began preparations for the First Intersessional Workshop on the *Implementation Review* of western North Pacific common minke whales. It re-established the Steering Group (Annex Y) to organise this Workshop.

In accordance with the Committee's *'Requirements and Guidelines for Implementations and Implementation Reviews'* (IWC, 2012b), the primary objectives of the First Intersessional Workshop will be to: (a) consider plausible hypotheses and eliminate any hypotheses that are inconsistent with the data); (b) examine more detailed information in expected whaling operations, including options or suggested modifications to the pattern of those operations; (c) review the small geographical areas ('sub-areas') that will be used in specifying the stock structure hypotheses and operational pattern; and (d) specify the data and methods for conditioning the trials that will be carried out before the next annual meeting. An initial annotated agenda for the Workshop, highlighting the associated data and analysis requirements can be found in Annex D, appendix 5.

6.3 Workplan 2019-20

Details of work to be undertaken both before and during the 2019 Annual Meeting are given in Table 3.

Table 3

Work plan for RMP (*Implementation*-related matters)

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Item 6.1: Western North Pacific Bryde's whales	Finalise the projections and the application of the criteria for evaluating which RMP variants are acceptable, borderline, and unacceptable	Complete the *Implementation Review*		
Item 6.2: Western North Pacific minke whales	(a) conduct the First Intersessional Workshop; (b) code the resulting trials and condition the trials	Conduct the work required for the First Annual Meeting	Conduct the Second Intersessional Workshop	Conduct the work required for the Second Annual Meeting

7. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT PROCEDURE (AWMP)

This item continues to be discussed as a result of Resolution 1994-4 of the Commission (IWC, 1995), which has been strengthened by Resolution 2014-1 (IWC, 2016a). The report of the Standing Working Group (SWG) on the development of an aboriginal whaling management procedure (AWMP) is given as Annex E. The Committee's deliberations, as reported below, are largely a summary of that Annex, and the interested reader is referred to it for a more detailed discussion. The primary issues at this year's meeting comprised: (1) finalising the development of *SLA*s (*Strike Limit Algorithms*) for Greenlandic hunts, with a focus on fin and common minke whales; (2) finalising the work on the scientific components of the AWS (Aboriginal Subsistence Whaling Management Scheme); (4) completion of the *Implementation Review* for Bering-Chukchi-Beaufort Seas stock of bowhead whales; and (3) providing management advice for aboriginal hunts (see Item 8).

Considerable progress on items (1) and (2) was made because of intense intersessional work including two workshops in Copenhagen in October 2017 and March 2018, as well as a small technical meeting in December 2018 at OSPAR headquarters in London.

7.1. *SLA* development for the Greenland hunts

7.1.1 Fin whales

SC/67b/Rep06 incorporated the discussions of the two intersessional Workshops and the small working group meeting. Considerable progress was made in relation to (a) updated abundance estimates; (b) finalisation of the trial structure; (c) review and approval of conditioning; and (d) initial consideration of new *Strike Limit Algorithms* (*SLA*s) and results.

The Committee thanked Donovan, the Workshop chair and the participants for the excellent progress made.

The final trial specifications for the West Greenland fin whales are provided in Annex E (Appendix 2).

Table 4 below summarises the main factors considered in the *Evaluation Trials.* The most influential involve different stock structure hypotheses, different productivity rates (MSYR) and different 'need' envelopes (need envelopes incorporate scenarios where need remains constant at the present level for 100 years (termed A), where it increases linearly to twice the present level over the 100-year simulation period (termed B) and where it increases linearly to three times the present level over the 100-year period (termed C).

Table 4

Summary of the key factors considered in the fin whale trials

Factor
Stock structure hypotheses
Mixing matrices
MSYR rate
Survey bias
Need envelope

7.1.1.1 CANDIDATE *SLA*S

The Committee received two papers with candidate *SLA*s, SC/67b/AWMP13 and SC/67b/AWMP15. The general properties of the three *SLA*s presented in SC/67b/AWMP13 involve taking an inverse variance weighted average of the last three estimates as an estimate of abundance and calculating the strike limit as a growth rate fraction of a lower percentile of the abundance (conditional on a trend modifier), a snap to need feature and a protection level. The three variants relate to how they are 'tuned' (the trade-off balance between conservation and need).

The three *SLA*s presented in SC/67b/AWMP15 are based on a weighted-average interim *SLA* which uses all abundance estimates, but where the earlier ones are down-weighted. An adjustment to the multiplier of the abundance estimate in the interim *SLA* is applied which depends on the trend of the abundance indices. The three variants relate to how they are 'tuned' (the trade-off balance between conservation and need).

7.1.1.2 REVIEW FINAL RESULTS AND PERFORMANCE

In total, seven potential *SLA*s (which include the 'Interim' *SLA* – a modified version of the *Interim SLA* used to provide advice previously by the Committee until the final *SLA*s had been developed) were considered. The full range of conservation and need statistics were reviewed for the *Evaluation Trials*[2], noting that the initial focus is on meeting the Commission's conservation objectives. Those candidate *SLA*s that meet these are then evaluated on their ability to meet need satisfaction. In summary, conservation performance is deemed satisfactory if either the population is not at MSYL but it is increasing towards it or the population is above MSYL (in which case it may be increasing or decreasing towards MSYL). These concepts are captured in the 'D1' and 'D10' statistics (defined fully in Annex E, table 2) and can be visualised in bivariate plots given in Annex E.

The Committee agreed that the proposed *SLA*s had performed satisfactorily on the joint conservation statistics for the A and B (but not for the C) need envelopes for all trials. The focus was then to evaluate the need satisfaction performance over 20 and 100 years and consider stability in catch levels. This performance was captured by examining three statistics:

[2] The Committee also examines the results of *Robustness Trials* to ensure that the *SLA* does not exhibit unusual behaviour in more extreme trials.

N9(20) the average need satisfaction over the first 20 years, N9(100) the average need satisfaction over the 100 years and N12 the mean down step statistic (these are also defined fully in Annex E, table 2). They can be visualised in 'Zeh' plots (e.g. see Annex E).

Given the present incorporation into the trial structure of two widely different stock structure hypotheses ('influx' and 'partial'- see Annex E, appendix 2) to explain the variability of the abundance estimates, the need satisfaction over 20 years was given more weight in the evaluation as it is likely that future *Implementation Reviews* may be able to remove one or other scenario.

After an examination of the full range of results, there was no obvious 'winner' between two of the *SLA*s (one from each developer). Depending on the trials considered, and which statistic was examined, they performed slightly differently but their performance overall was equivalent.

Following an approach originally adopted during the development of the *Bowhead SLA*, it was decided that an *SLA* which sets the strike limit to the average of the values obtained by the two *SLA*s[3] would be preferable, providing performance was as good or better than either individual *SLA*; no 'snap to need' for the averaged *SLA* has been applied. The results of the 'combined *SLA'* are summarised in Annex E, appendix 3[4].

7.1.1.3 CONCLUSIONS AND RECOMMENDATIONS

The management advice developed using this *SLA* is given under Item 8. 6.

Attention: C-A, SC

The Committee ***draws attention*** *to the extensive work undertaken over recent years to develop an* SLA *for the West Greenland hunt for fin whales. In concluding this work, the Committee:*

(1) ***agrees*** *that the combined* SLA *(which sets the strike limit to the average of the values obtained by the two best* SLAs *considered) performed satisfactorily in terms of conservation performance and was to be preferred over the individual SLAs in terms of need satisfaction;*
(2) ***recommends*** *that this* 'WG-Fin SLA' *be used to provide management advice to the Commission on the subsistence hunt for West Greenland fin whales (provided the need request falls within need scenarios A and B);*
(3) ***expresses*** *its great thanks to the developers, Brandão and Witting for the vast amount of work put into the development process and to Allison and Punt for their extensive work developing the operating models and running the trials; and*
(4) ***agrees*** *that one focus of the next* Implementation Review *will be to examine further stock structure in relation to the two hypotheses being considered at present, and especially the 'influx' model which was developed in the context of low abundance estimates in some years, rather than being based upon genetic information.*

7.1.2 Common minke whales (Greenland)

SC/67b/Rep06 incorporated the discussions of the two intersessional Workshops and a small working group meeting. Considerable progress was made in relation to (a) updated abundance estimates; (b) finalisation of the trial structure; (c) conditioning; and (d) initial consideration of new *Strike Limit Algorithms* (*SLA*s) and results.

The Committee thanked Donovan, the Workshop chair and the participants for the excellent progress made.

The final trial specifications for the West Greenland common minke whales are provided in Annex E (appendix 4).

Table 5 below summarises the main factors considered in the *Evaluation Trials* for common minke whales. The most influential involve different stock structure hypotheses, different productivity rates (MSYR) and different 'need' envelopes (see discussion under Item 7.1.1), where it increases linearly to twice the present level over the 100-year simulation period (termed B) and where it increases linearly to three times the present level over the 100-year period (termed C).

Considerable work was undertaken to finalise the list of trials, to ensure that the mixing matrices were correctly specified and to complete and agree conditioning. The final trial specifications are provided in Annex E, Appendix 4.

Table 5

Summary of the key factors considered in the common minke whale trials

Factor
Stock structure hypotheses
Mixing matrices
MSYR rate
Survey bias
Need envelope

[3] tuned to a D10 of 0.8 for the influx trial F34-1B

[4] Final validation and archiving of results will be undertaken by Allison in Cambridge.

7.1.2.1 CANDIDATE *SLAS*
SC/67b/AWMP14 developed a candidate *SLA* for common minke whales off West Greenland similar to that used for fin whales in SC/67b/AWMP13. It operates on an inverse variance weighed average of the last three abundance estimates. The strike limit is calculated as a growth rate fraction of a lower percentile of the abundance measure, conditional on a 'snap to need' feature, and a protection level. It does not include a trend modifier.

It was tuned to have a 5th percentile of D10 of 0.80 for need envelope A for the most difficult *Evaluation Trial* (trial M04-1A – see Annex E, appendix 4), where there are two sub-stocks in the western North Atlantic in which the mixing between the Central and the Western stock, and mixing between the putative western sub-stocks, is minimal, and where the MSYR is 1%).

7.1.2.2 CONSIDERATION OF RESULTS
Conditioning of the *Evaluation Trials* was completed satisfactorily and a summary of the results of the is provided in Annex E (appendix 5[5]). Annex E, fig. 3 provides the bivariate plot.

In determining satisfactory conservation and need performance when evaluating *SLA*s, the Committee considers the full range of results across all the *Evaluation Trials*, not simply the worst-case scenarios. Conservation performance was satisfactory for all but the most extreme trial (trial M04-1A) where it was slightly below for the lower 5th percentile. This trial had low MSYR and two W-stocks; it had been originally considered in the context of investigating potential problems for the hunt to simulate possible local depletion in the hunting area rather than for conservation reasons. Genetic stock structure in the entire North Atlantic is subtle such that even an hypothesis of almost complete panmixia is not rejected by most of the analyses and thus differentiation among 'C' and 'W' is very low. This is even more true for substructure within the W stock (if, indeed, there is any). Given that trials are conservative in so far as they overrate isolation among stocks, and the very subtle differentiation among stocks and sub-stocks in the North Atlantic, a single trial (which implements two fully separate W sub-stocks, for which there is little evidence) not meeting the D1/D10 criteria is not of conservation concern.

The SWG (Annex E, item 2.2.3) had noted that given the unforeseen situation with Secretariat computing, there had been insufficient time for it to consider the results of the *Robustness Trials* during its meeting. Such trials are not needed to determine an *SLA* but are examined to ensure that the selected *SLA* has no unforeseen properties in extreme trials. These were subsequently run prior to the plenary discussions and the results showed no unexpected properties.

7.1.2.3 CONCLUSIONS AND RECOMMENDATIONS
The management advice developed using the *WG-common minke SLA* is provided under Item 8.5.

Attention: C-A, SC

The Committee ***draws attention*** *to the extensive work undertaken over recent years to develop an* SLA *for the West Greenland hunt for common minke whales. In concluding this work, the Committee:*

(1) ***agrees*** *that the tested* SLA *which performed satisfactorily in terms of conservation performance;*
(2) ***agrees*** *that this 'WG-Common minke SLA' be used to provide management advice to the Commission on the subsistence hunt for West Greenland common minke whales provided the need request falls within need scenario A (i.e. does not exceed 164 annually);*
(3) ***expresses*** *its great thanks to the developers, Brandão and Witting for the vast amount of work put into the development process and to Allison and Punt for their extensive work developing the operating models and running the trials; and*
(4) ***agrees*** *that one focus of the next* Implementation Review *will be to examine further stock structure in relation to the two hypotheses being considered at present, should be consideration of the results of analyses of genetic data using additional samples from Canada (as well as the additional samples that will become available from West Greenland and Iceland); and*
(5) ***agree****s to establish an intersessional advisory group (Annex Y) to facilitate issues relating to samples.*

7.1.3 North Pacific gray whales (Makah whaling)
7.1.3.1 MANAGEMENT PLAN PROPOSED BY THE U.S. FOR MAKAH WHALING
The Makah Indian Tribe has requested that the U.S. National Marine Fisheries Service (NMFS) authorise a tribal hunt for Eastern North Pacific (ENP) gray whales in the coastal portion of its 'usual and accustomed fishing area' in Washington State. The Tribe intends to hunt gray whales from the ENP population, which currently numbers approximately 27,000 animals (Durban *et al.*, 2017). However, at certain times of the year there is a possibility that the hunt may take animals from the PCFG (Pacific Coast Feeding Group) and/or the WNFG (Western North Pacific Feeding Group). In an updated management plan – known as the Makah Management Plan (the Committee had approved an earlier plan for this hunt in 2012 (IWC, 2013), NMFS has taken measures to restrict the number of PCFG whales that are struck or landed in a given 10-year period and to avoid, to the extent possible, striking or killing a WNFG gray whale. The Government of the USA requested the Committee to test this plan to ensure that it meets IWC conservation objectives.

[5] Final validation and archiving of results will be undertaken by Allison in Cambridge.

This task was begun at the Fifth Rangewide Workshop on the Status of North Pacific Gray Whales (SC/67b/Rep07) from 28-31 March 2018. The major focus of the Workshop related to finalising the specifications for modelling, to enable results to be available for SC67b including incorporation of the Makah Management Plan (SC/67b/Rep07, Annex E, appendix 1) into the modelling framework. The factors taken into account in the trials are given in Table 6.

Table 6

Summary of the main factors considered in the Makah gray whale trials

Factor	
Model fitting related	Projection-related
Stock hypothesis	Additional catch off Sakhalin
MSYR	Catastrophic events
Mixing rate	Northern need in final year
Immigration into the PCFG	Struck and lost rate
Bycatches and ship strikes	Future effort
Pulse migrations into the PCFG	Factors related to obtaining and matching photographs

At the present meeting, the focus was on the conservation performance of the Makah Management Plan. Performance was evaluated in the same manner as described for the evaluation of the *SLA*s for West Greenland fin and common minke whales (see Items 6.1 and 6.2). The results can be found in Annex E (appendix 6). The only scenarios under which the plan might not perform adequately were considered to have low plausibility (e.g. a bycatch mortality of ~ 20 PCFG whales per year). Annex E, fig. 4 shows the bivariate plot.

7.1.3.2 CONCLUSIONS AND RECOMMENDATIONS

The management advice relating to the Makah Management Plan is provided under Item 8.2.

Attention: C-A, SC

The Committee reviewed a US Management Plan for a Makah hunt of gray whales off Washington State (the Committee had evaluated a previous plan in 2011 - IWC, 2011; 2012), using the modelling framework developed for its rangewide review of gray whales (SC/67b/Rep07). In conclusion, the Committee:

(1) ***agrees*** *that the performance of the Management Plan was adequate to meet the Commission's conservation objectives for the Pacific Coast Feeding Group, Western Feeding Group and Northern Feeding Group gray whales;*
(2) ***notes*** *that the proposed management plan is dependent on photo-identification studies to estimate PCFG abundance and the mixing proportions of PCFG whales available to the hunt (and to bycatch in its range);*
(3) ***stresses*** *that its conclusions are dependent on the assumption that these studies will continue in the future; and*
(4) ***expresses*** *its* ***great thanks*** *to Punt, Brandon and Allison for their excellent work in developing and validating the testing framework and running the trials.*

7.1.4 Conclusions on AWMP work

The Chair of the SWG on the AWMP, Donovan, noted that this meeting represented the end of a long journey – with the adoption of the two new *SLA*s, the SWG and the Committee has completed the development tasks it had been assigned by the Commission, originally in Resolution 1994-1. It was an immense task but a great pleasure to work with such dedicated and talented people. He thanked all of the scientists who have made such a wonderful contribution to this work over the years and especially Geof Givens, Kjartan Magnússon (sadly no longer with us), Eva Dereksdóttir, Lars Witting, Anabela Brandão, Doug Butterworth, Cherry Allison and André Punt – the SWG has, in his view, achieved ground-breaking work over the last two decades in a spirit of great collaboration and co-operation, even when there were disagreements, as inevitably there were. He also thanked the hunters and their representatives who had made major contributions in terms of not only data provision but also advice on the AWS (see Item 7.2). The Committee **concurred** that this was an excellent example of what the Scientific Committee could achieve with international collaboration. Finally, they **thanked** Donovan for his dedicated, good humoured and impartial leading of such a major piece of complex work over such a long period - this work has been central to the Committee's role in providing the best scientific advice to the Commission on aboriginal subsistence whaling hunts, bringing together conservation needs and the needs of the hunters.

7.2 Aboriginal Whaling Scheme (AWS)

7.2.1 Introduction

The Scientific Committee's Aboriginal Whaling Management Procedure (AWMP) applies stock-specific *Strike Limit Algorithms* (*SLA*s) to provide advice on aboriginal subsistence whaling (ASW) strike/catch limits.

ASW management (as part of an AWS, the aboriginal whaling scheme) incorporates several components, several of which have a scientific component:

(1) *Strike Limit Algorithms* (case-specific) used to provide advice on safe catch/strike limits;

(2) operational rules (generic to the extent possible) including carryover provisions, block quotas and interim relief allocations;
(3) Guidelines for *Implementation Reviews*; and
(4) Guidelines for data and analysis (e.g. guidelines for surveys, other data needs).

Considerable work on updating the AWS since the version presented (but not accepted by) to the Commission in 2002 (IWC, 2003) was undertaken by an intersessional correspondence group (SC/67b/AWMP 21) and at the intersessional workshops (SC/67b/Rep04).

7.2.2 Carryover request from the Governments of USA and Denmark/Greenland
The Governments of USA and Denmark/Greenland (SC/67b/Rep06, Annex F, appendix) had requested advice at the March intersessional Workshop on the conservation implications of carryover provisions allowed for a carryover provision that allowed use of unused strikes from the previous three blocks, provided that the number used in any year did not exceed 50% of the annual strike limit.

This request was tested on the two *SLA*s available for stocks hunted by the USA and Greenland at the time of the Workshop i.e. the *Bowhead SLA* (applicable to the Bering-Chukchi-Beaufort Seas stock) and the *WG-Humpback SLA* (applicable to West Greenland).

Three types of options were examined:

(1) baseline case - all strikes taken annually (i.e. no need for carryover);
(2) 'frontload' case - strikes taken as quickly as possible within block (+50% limit annually until the block limit is reached); and
(3) Two alternative scenarios where carryover strikes are accrued for one or three blocks, followed by a period of carryover usage subject to the +50% limit.

The three-block scenario considered in (3) served as a direct test of the provision described in the request of USA and Denmark/Greenland.

Attention: CG-A

The Committee received a request from the USA and Denmark/Greenland (SC/67b/Rep06, Annex F, appendix) on the conservation implications of carryover provisions that
'…allow for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit'.
The Committee reviewed the request using its simulation frameworks and the two SLA*s available for stocks hunted by the USA and Greenland available at the time of the Workshop i.e. the* Bowhead SLA *(applicable to the Bering-Chukchi-Beaufort Seas stock) and the* WG-Humpback SLA *(applicable to West Greenland) and*

(1) ***agrees*** *that a carryover provision for up to 3-blocks meets Commission's conservation objectives; and*
(2) ***reiterates*** *its previous advice, applicable for all* SLA*s, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable; and*
(3) ***agrees*** *to evaluate the above request for the other Greenland* SLA*s at the 2019 Committee meeting.*

7.2.3 Review proposed updates to the AWS
The proposed update to the previous AWS is provided in Annex E, appendix 8. It has sections on carryover, block quotas, interim relief allocation (and see Annex E, appendix 7), *Implementation Reviews* and guidelines for surveys and data.

7.2.4 Conclusions and recommendations

Attention: C-R

The Committee has been working for some years to update the scientific components of an Aboriginal Whaling Scheme. It has completed this work and ***recommends*** *the AWS provided in Annex E, appendix 8 to the Commission. It has sections on carryover, block quotas, interim relief allocation (and see Annex E, appendix 7), Implementation Reviews and guidelines for surveys and data. It* ***notes*** *that the Commission's AWS may include additional, non-scientific provisions.*

7.3 *Implementation Review* of BCB bowhead whales
According to the Committee's guidelines, the primary objectives of an *Implementation Review* are to:

(1) review the available information (including biological data, abundance estimates and data relevant to stock structure issues) to ascertain whether the present situation is as expected (i.e. within the space tested during the development of a *Strike Limit Algorithm* (*SLA*)) and determine whether new simulation trials are required to ensure that the *SLA* still meets the Commission's objectives; and
(2) to review information required for the *SLA*, i.e. catch data and, when available at the time of the *Review*, new abundance estimates (note that this can also occur outside an *Implementation Review* at an Annual Meeting).

The *Bowhead SLA* was adopted in 2002 (IWC, 2003, p.158) and there was an extensive *Implementation Review* completed in 2007 (IWC, 2008a, p.124) with a major focus on stock structure including three intersessional workshops. That included consideration of additional trials investigating management implications of assuming additional population structure even though these were considered of low plausibility. The Committee concluded that the *Bowhead SLA* remained the best tool to provide management advice. The next *Implementation Review* was completed in 2012 (IWC, 2013b, p.147); that concluded that there was no need to develop additional trials to those evaluated during the previous *Implementation Review* (IWC, 2008c).

The primary review was undertaken by the SWG on the AWMP (Annex E, Item 4) but the review benefitted from discussions within two other groups, SD-DNA (Annex I, Item X) and ASI (Annex Q, Item Y).

7.3.1 Stock structure: review new information
A full discussion of the work on stock structure can be found in Annex E (item 4.1) and Annex I. New information considered included genetic analyses (SC/67b/SDDNA 01) and telemetry results (SC/67b/AWMP04). SC67b/SDDNA01provided information on genetic analyses using samples from the BCB, Canadian and Okhotsk Sea stocks of bowhead whales. Within the BCB stock, no significant differences were identified in temporal or spatial comparisons, and age-related structure was not detected in comparisons between groups of large (old) versus small (young) whales. While comparisons of the BCB stock with the Okhotsk Sea stock revealed significant differences, there were only small, and in most cases statistically insignificant, differences between BCB and Canadian stocks. While this pattern could be related to historical connectivity between the two stocks, it could also, or additionally, be driven by some degree of contemporary gene flow.

Attention: SC

With respect to stock structure, considering the multiple lines of evidence, the Committee:

(1) ***agrees*** *that BCB bowheads comprise a single population, with no signs of substructure;*
(2) ***agrees*** *that there was no need to consider any new SLA trials regarding stock structure, since the trials conducted in 2002 and 2007 already covered all plausible stock structure hypotheses;*
(3) ***welcomes*** *the telemetry information provided, thanks the hunters involved for their skill and assistance;*
(4) ***encourages*** *additional telemetry efforts; and*
(5) ***agrees*** *with the suggestions for future genetic studies in the Arctic provided under Item 11.*

7.3.2 Abundance estimates: review new information
A new abundance estimate (SC/67b/AWMP) has been accepted for the year 2011 from a long-term photo-id capture-recapture study (27,133, CV=0.217; 95% CI from 17,809 to 41,337) that it has been agreed is suitable for providing management advice and for use in the *SLA* (Annex Q). The previously accepted, completely independent, 2011 abundance estimate from the ice-based survey (Givens *et al.*, 2016) is also acceptable for use in the *SLA* and has already been used in that regard (16,820, CV=0.052; 95% CI 15,176 to 18,643).

There are thus two independent estimates for the same year considered suitable for use in the *SLA* and this is considered under Item 8.3.

The Committee also discussed plans for future surveys (SC/67b/AWMP 12 and AWMP 16) in Annex Q (item 3.1.1.1). These plans are in accord with the AWS Guidelines that 'plans for undertaking a survey/census should be submitted to the Scientific Committee in advance of their being carried out, although prior approval by the Committee is not required.

7.3.3 Biological parameters: review new information
New and extensive information on biological parameters was received as discussed Annex E (item 4.3). These covered such matters: length at sexual maturity and pregnancy rate from hunted animals (SC/67b/AWMP 07); the potential use of samples from baleen plates to examine hormone cycles and pregnancy; and information on calves from aerial surveys (SC/67b/AWMP03).

Attention: SC

With respect to biological parameter information, the Committee:
(1) ***welcomes*** *the extensive information presented;*
(2) ***encourages*** *the continued collection of such data from the hunt;*
(3) ***encourages*** *the work on the baleen plate analyses to examine hormone levels and pregnancy;*
(4) ***encourages*** *continued aerial surveys under the ASAMM surveys and any future collaboration involving life history data from the harvest; and*
(5) ***agrees*** *that the information presented does not suggest the need to consider any new SLA trials regarding stock structure.*

7.3.4 Removals: review new information
The Committee received updated information about the 2017 harvest (SC/67b/AWMP 05) and long-term removals (SC/67b/AWMP 06). In 2017, 57 bowhead whales were struck resulting in 50 animals landed. The total landed for the hunt in 2017 was higher than the average over the past 10 years (2007-2016 mean of landed =41.7; SD=6.7). Efficiency (number landed / number struck) in 2017 was 88%, which was also higher than the average for the past 10 years (mean of efficiency=75.2%; SD=6.5%).

The Committee also received SC/67b/AWMP06 that provided a summary of bowhead whale catches in Alaska between 1974 and 2016. The authors pointed to the excellent cooperation and contribution of the whale hunters from the 11 villages that are members of the Alaska Eskimo Whaling Commission (AEWC). This information is discussed in Annex E (item 4.4).

From 2013 to 2017, four bowhead whales (2 females and 2 males) were harvested near Chukotka, mainly in Anadyr Bay (SC/67b/AWMP20). The average length was 14.5m (minimum 13.0m, maximum 17.0m). Although the portion of the annual strike limit allocated to Russia under their bilateral agreement with the USA is 5 animals, the actual annual take is usually only 1-2 whales per year, and this has been the case since at least 2004.

The Committee thanked the authors of the provision of this information, noting that catch and strike data are used in the *SLA* calculations (see Item 8.3).

7.3.5 Other anthropogenic threats and health: review new information
The Committee received extensive information related to threats and health ranging from entanglement, predation and health (body condition, pathology and parasite loads). The discussion of this can be found in Annex E (item 4.5).

Attention: SC

With respect to threats and health to the BCB bowhead whales, the Committee:
(1) ***welcomes*** *the extensive information presented;*
(2) ***agrees*** *that whilst the present level of unintentional human induced mortality is too low to require new Implementation trials or incorporation into the SLA calculations, the situation should continue to be monitored and evaluated at the next Implementation Review;*
(3) ***agrees*** *that the health analyses give no cause for concern with respect to the continued application of the Bowhead SLA; and*
(4) ***encourages*** *that the excellent work on health-related issues continues.*

7.3.6 Conclusions and recommendations (and, if needed, workplan to complete Review)

Attention: SC

With respect to the Implementation review of BCB bowhead whales, the Committee ***concludes*** *that:*
(1) the Implementation Review has been satisfactorily completed; and
(2) the range of hypotheses and parameter space already tested in Bowhead SLA trials was sufficient and therefore the Bowhead SLA remains the best way to provide management advice for this stock;
In addition, it ***thanks*** *the US scientists for the extremely hard work that they have put into providing comprehensive papers to facilitate this review.*

8. STOCKS SUBJECT TO ABORIGINAL SUBSISTENCE WHALING (NEW INFORMATION AND MANAGEMENT ADVICE)

The Committee noted that the Commission will be setting new catch/strike limits for at its 2018 biennial meeting in Brazil. It had received written or verbal requests for limits to be considered for each hunt as discussed below.

Attention: C-A

A general request had been received from the USA and Denmark (SC/67b/Rep06, annex F, appendix) for advice on whether there would be a conservation issue if there was a one-time 7-year block followed by a return to 6-year blocks to address logistical issues related to the Commission.

The Committee ***agrees*** *there are no conservation issues associated with this suggestion (and see the block quota section of the ASW in Annex E, appendix 8).*

8.1 Eastern Canada/West Greenland bowhead whales

8.1.1 New abundance information

Last year, the Committee had recommended that Canadian scientists attend the Committee to present the results of their work on abundance. It was very pleased that Doniol-Valcroze from Department of Fisheries and Oceans Canada, and the primary author of the paper on the 2013 aerial survey abundance estimate, was present at the meeting.

The Committee accepted, for the provision of management advice and use in an *SLA* (see Annex Q for details), the fully corrected abundance estimate (Doniol-Valcroze *et al.*, 2015) from a 2013 aerial survey of 6,446 bowheads (CV=0.26, 95% CI 3,722-11,200). The survey covered the major summering area for the Eastern Canada/West Greenland (EC/WG) stock.

The Committee recalled that the *WG-Bowhead SLA* had been developed on the conservative assumption that the abundance estimates for the West Greenland area alone (1,274 whales in 2012 (CV=0.12)) represented the abundance of the whole stock, as it believed that it was not possible to assume that a non-member country would continue with regular surveys. Doniol-Valcroze advised the Committee that the present management strategy of Canada does involves obtaining regular abundance estimates. The Committee noted it would be pleased to receive such estimates from Canada being presented to the Committee in the future.

Attention: SC

The Committee greatly appreciated the presence of a Canadian scientist at its meeting. The Committee:
(1) ***welcomes*** *the provision of the abundance estimate for the Eastern Canada/West Greenland stock and (see Item 8.1.2) the regular provision of information on catch data by Canada;*
(2) ***welcomes*** *the attendance of Canadian scientists at its meetings;*
(3) ***agrees*** *that consideration of how to incorporate abundance estimates from Canada should be one focus of the next Implementation Review for this stock;*
(4) ***notes*** *the regular collaboration of Canadian and Greenlandic scientists on other matters such as genetic sampling (inter alia for mark-recapture abundance estimation); and*
(5) ***encourages*** *further collaboration between Canada, Greenland and the USA for the study of bowhead whales across their range and the presentation of these results at future Committee meetings.*

8.1.2 New catch information

SC/67B/AWMP/10 provided an update of recent Canadian takes made in the Inuit subsistence harvest of the EC-WG bowhead whale stock. In the eastern Canadian Arctic, the maximum allowed take is 7 bowhead whales per year according to domestic policy, with no carry-over of unused takes between years. Since 2015, 5 strikes were taken and 4 bowhead whales were successfully landed (1 in 2015, 2 in 2016 and 1 in 2017). Witting reported that West Greenland hunters struck no bowheads in 2017. There was one 14.7m whale that died from entanglement in crab gear.

The Committee notes that the reported number of strikes was within the parameter space that was tested for the *WG-Bowhead SLA*, and encourages the continued collection of genetic samples from harvested whales.

8.1.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67 and no changes were requested for bowhead whales. The Committee therefore:

(1) ***agrees*** *that the WG-Bowhead SLA remains the best available way to provide management advice for the Greenland hunt;*
(2) ***notes*** *that this SLA had been developed under the conservative assumption that the number of bowhead whales estimated off West Greenland represented the total abundance between West Greenland and Eastern Canada;*
(3) based on the agreed 2012 estimate of abundance for West Greenland (1,274, CV=0.12), the catch of one whale in Canada in 2017, and using the agreed WG-Bowhead SLA, ***agrees*** *that an annual strike limit of two whales will not harm the stock and meets the Commissions conservation objectives; and*
(4) although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for the WG-Bowhead SLA, ***reiterates*** *its advice, applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next, is acceptable.*

8.2 North Pacific gray whales

8.2.1 New information (including catch data)

The Committee received considerable new information on the hunt off Chukotka as discussed in Annex E (item 5.2). In 2017, a total of 119 gray whales were struck in 2017 (37 males and 82 females). No whales were struck and lost, and no stinky (inedible) gray whales were taken. Similar whaling methods were employed as in recent years and the overall efficiency of the hunt was almost same as in 2016.

In advance of the gray whale *Implementation Review* that is scheduled to begin in 2019, the Committee reviewed new information regarding the stock structure of gray whales in the North Pacific (SC67b/SDDNA02 and SC67b/SDDNA03) – for details see Annex I. The results were based on whole genome sequence data from three individuals (one sampled off Barrow, Alaska and two sampled off Sakhalin Island, Russia) and SNP genotype data generated from larger sample sets representing whales sampled off Sakhalin and in the Mexican lagoons.

Attention: SC

In reviewing the results of new genetic analyses of gray whales in the North Pacific, the Committee ***agrees*** *that the genetic and photographic data for this species be combined to better assess stock structure-related questions. Given the potential for genomic data to aid in better evaluating the stock structure hypotheses currently under consideration for North Pacific gray whales, the Committee* ***encourages*** *the continuation of work to produce additional genomic data from sampled gray whales.*

8.2.2 Management advice

Attention: C-A

The Russian Federation (SC/67b/AWMP/17) had requested advice on the following provision:

'For the seven years 2019, 2020, 2021, 2022, 2023, 2024 and 2025, the number of gray whales taken in accordance with this sub-paragraph shall not exceed 980 (i.e. 140 per annum on average) provided that the number of gray whales taken in any one of the years 2019, 2020, 2021, 2022, 2023, 2024 and 2025 shall not exceed 140.'

The Committee therefore:
(1) ***agrees*** *that the* Gray Whale SLA *remains the best available way to provide management advice for the gray whale hunts;*
(2) ***advises*** *that an average annual strike limit of 140 whales will not harm the stock and meets the Commission's conservation objectives;*
(3) ***notes*** *that its previous advice that the interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next remains acceptable;*
(4) ***advises*** *that the Makah Management Plan (see Item 2.3) also is in accord with the Commission's management objectives.*

8.3 Bering-Chukchi-Beaufort Seas bowhead whales

8.3.1 New information

New information (on abundance and catches) was considered as part of the *Implementation Review* discussed under Item 7.3.

The USA had indicated that it was proposing no changes to the present catch/strike limits although it may suggest changes to its carryover request in light of the advice received by the Committee as discussed at the intersessional workshop (SC/67b/Rep06).

The Committee noted that there are now two independent estimates of abundance for this stock in 2011 (see Item 7.3.1). Recognising the need to formally consider the general question of how best to combine estimates in such cases as part of the workplan in the next biennium, the Committee noted that if they are combined as a weighted average by the inverse of their variances, there is little difference (it is slightly higher) between the combined estimate and that from the ice-based census estimate; the ice-based approach has been the method used for the other estimates used in the *SLA*. Therefore, the ice-based census estimate for 2011 (16,820, CV=0.052; 95% CI 15,176 to 18,643) is considered the most recent estimate of abundance for use in the *Bowhead SLA* this year.

8.3.2 Management advice

Attention: C-A

The USA indicated that it requested advice on the existing catch/strike limits. The Committee therefore:

(1) ***agrees*** *that the* Bowhead Whale SLA *remains the best available way to provide management advice for this stock;*
(2) ***advises*** *that a continuation of the present average annual strike limit of 67 whales will not harm the stock and meets the Commission's conservation objectives; and*
(3) ***advises*** *that provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit, has no conservation implications (see SC/67b/Rep04).*

8.4 Common minke whales off East Greenland

8.4.1 New information on catches

In the 2017 season, nine common minke whales (3 males and 6 females) were landed in East Greenland, and one was struck and lost. Genetic samples were obtained from 8 of the landed whales. One common minke whale died from entanglement in fishing gear.

8.4.1 New information on abundance
The Committee endorsed the 2015 aerial survey abundance estimate of 2,762 (CV=0.47; 95%CI 1,160-6,574). This is only a small part of the wider Western and Central stocks from which catches may occur.

8.4.2 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on an annual take of 20 animals (it had previously been 12). It had also requested advice on any conservation implications of a 12-month hunting season for common minke whales.

The Committee therefore:

*(1) **notes** that in the past its advice for the East Greenland hunt had been based upon the fact that the catch was a small proportion of the number of animals in the Central Stock;*
*(2) **notes** the process to develop an* SLA *for common minke whales off West Greenland resulted in a simulation framework that produces a considerably more rigorous way to provide advice for this hunt than before, by taking into account stock structure issues;*
*(3) **notes** that the results of the simulation trials that incorporated a continuing catch of 20 whales from East Greenland gave rise to no conservation concerns;*
*(4) **notes** that the 2015 aerial survey abundance estimate of 2,762 (CV=0.47; 95%CI 1,160-6,574) is only a small part of the wider western and central stocks;*
*(5) **advises** that a continuation of the present average annual strike limit of 20 whales will not harm the stock and meets the Commission's conservation objectives;*
*(6) **advises** that changing the length of the season to 12 months had no conservation implications; and*
*(7) **agrees** that an* SLA *should be developed for this hunt in the future; and*
*(8) **encourages** the continued collection of samples fro collaborative genetic analyses (and see Item 7.1.2.3).*

8.5 Common minke whales off West Greenland
8.5.1 New information on catches
In the 2017 season, 129 common minke whales were landed in West Greenland and four were struck and lost. Of the landed whales, there were 95 females, 33 males and one of unknown sex. Genetic samples were obtained from 104 whales, and the Committee was pleased to note that samples were already part of the data used in the genetic analyses of common minke whales in the North Atlantic. The Committee **encourages** the continued collection of samples and the collaborative approach of the genetic analysis.

8.5.2 New information on abundance
The Committee endorsed the 2015 aerial survey abundance estimate of 5,095 (CV0.46; 95%CI 2,171-11,961) as discussed in Annex Q.

8.5.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 164 animals (i.e. no change). It had also requested advice on any conservation implications of a 12-month hunting season for common minke whales.
The Committee therefore:

*(1) **agrees** that the WG-Common minke SLA is the best available way to provide management advice for this stock under need scenario A;*
*(2) **advises** that a continuation of the present average annual strike limit of 164 whales will not harm the stock and meets the Commission's conservation objectives;*
*(3) although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for this SLA, **reiterates** its previous advice**,** applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable;*
*(4) **advises** that changing the length of the season to 12 months had no conservation implications; and*
*(5) **encourages** the continued collection of samples for collaborative genetic analyses (and see Item 7.1.2.3).*

8.6 Fin whales off West Greenland
SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 19 animals (i.e. no change).

8.6.1 New information on the catch
A total of seven fin whales (5 females and 2 males) was landed, and one was struck and lost, off West Greenland during 2017. The Committee was pleased to note that genetic samples were obtained from five of these, and that the genetic samples are analysed together with the genetic samples from the hunt in Iceland.

8.6.2 New information on abundance
The Committee endorsed the 2015 aerial survey abundance estimate of 2,215 (CV=0.41; 95%CI 1,017-4,823) for use in providing management advice and in the *SLA* as discussed in Annex Q (Item Y).

8.6.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 19 animals (i.e. no change). It also requested advice on whether there were any conservation implications of removing length limits (while retaining the prohibitions relating to calves.
The Committee therefore:

(1) ***agrees*** *that the WG-Fin SLA is the best available way to provide management advice for this stock;*
(2) ***advises*** *that a continuation of the present average annual strike limit of 19 whales will not harm the stock and meets the Commission's conservation objectives; and*
(3) although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for this SLA, ***reiterates*** *its advice, applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable;*
(4) ***advises*** *that removing the length limits had no conservation implications; and*
(5) ***encourages*** *the continued collection of samples for collaborative genetic analyses (and see Item 7.1.1.3).*

8.7 Humpback whales off West Greenland
8.7.1 New information on catches
A total of two (both female) humpback whales were landed and none were struck and lost in West Greenland during 2017. Genetic samples were obtained from all the landed whales. The importance of collecting genetic samples and photographs of the flukes from these whales is emphasised.

Five humpback whales were observed entangled in fishing gear in West Greenland in 2017. Of these, one died, two became free and one was successfully disentangled by a disentanglement team. The remaining animal was alive and still entangled when it was last sighted.

Inclusion of bycaught whales had been incorporated into the scenarios for the development of the *Humpback SLA*. If high levels continued, then this will need to be taken into account in any *Implementation Review*. The Committee noted the IWC efforts with respect to disentanglement and prevention and welcomed the news that the Greenland authorities requested IWC disentanglement training that took place in 2016 and that they successfully disentangled one humpback whale.

8.7.2 New information on abundance
The Committee endorsed the 2015 aerial survey abundance estimate of 993 (CV=0.46; 95%CI 434-2,272) as discussed in Annex Q (Item Y) for use in the provision of management advice and in the SLA.

8.7.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 10 animals (i.e. no change).
The Committee therefore:
(1) ***agrees*** *that the* WG-Humpback SLA *is the best available way to provide management advice for this stock;*
(2) ***advises*** *that a continuation of the present average annual strike limit of 10 whales will not harm the stock and meets the Commission's conservation objectives;*
(3) ***advises*** *that that provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit' has no conservation implications (see SC/67b/Rep04); and*
(4) ***encourages*** *the continued collection of samples and photographs for collaborative analyses.*

8.8 Humpback whales off St. Vincent and The Grenadines
The alternate Commissioner for St Vincent and the Grenadines advised that no change to the present limits were envisaged.

8.8.1 New information on catch
It was reported that one humpback whale was struck and landed in 2017 by St. Vincent and The Grenadines.

8.8.2 New information on abundance

Last year, the Committee had requested that the USA provide a new abundance estimate for the western North Atlantic based upon the available NOAA data. A progress report on this work was provided with a focus on information on abundance estimates generated by the MONAH study, conducted in 2004 and 2005 on Silver Bank (a breeding ground in the West Indies) and in the Gulf of Maine feeding ground. The best estimate around 12,300, similar to the Committee endorsed best estimate from the YONAH project from 1992/93, which was 10,400 (8,000, 13,600). The lack of strong population growth was unexpected given information on rates of increase from some other areas of the North Atlantic, and may reflect either a true rate of increase, unidentified sampling bias, and/or the idea that Silver Bank as a habitat has reached maximum capacity. It is not clear whether the MONAH estimate is representative of the entire population, nor the extent to which the full estimate can be applied to the southeastern Caribbean in the context of the St Vincent hunt. However, four animals from the Gulf of Maine have been linked to animals seen in the southeastern Caribbean (including one that was caught in the hunt).

The Committee also noted several endorsed recent abundance estimates of humpback whales in parts of the North Atlantic including: 993 (95% CI: 434-2,272) in West Greenland in 2015; 4,223 (95% CI: 1,845-9,666) in East Greenland in 2015; and 12,879 (95% CI 5,074; 26,455) in the Iceland-Faroes region in 2007.

It has now been nearly two decades since the IWC has done an In-Depth Assessment on North Atlantic humpback whales. The Committee **agrees** that it would be a valuable exercise to perform a North Atlantic Rangewide review of humpback whales, similar in scope to the Rangewide Review for North Pacific gray whales and taking into account recent work on stock structure including that of Stevick *et al.* (2018).

8.8.3 Management advice

Attention: C-A

The alternate Commissioner for St Vincent and the Grenadines advised that no change to the present limits were envisaged. The Committee therefore:

*(1) **notes** that is does not have an approved abundance estimate for western North Atlantic since that in 1992;*
*(2) **notes** that in accord with the advice provided in the AWS (see Annex E, Appendix 8), it therefore considered the available evidence to see if was sufficient to provide safe management advice;*
*(3) **advises** that, given the information above on recent abundance in the North Atlantic combined with the size of the requested catch/strikes (an average of four annually), continuation of the present limits will not harm the stock;*

*The Committee also **reiterates** its previous advice that:*

(1) the status and disposition of genetic samples collected from past harvested whales be determined and reported next year;
(2) photographs for photo-id (where possible) and genetic samples are collected from all whales landed in future hunts; and that
(3) the USA (NOAA, NMFS) provides an abundance estimate from the MONAH data as soon as possible for the Committee.

8.9 Workplan 2019-20

Table 7 summarises the work plan for work related to aboriginal subsistence whaling. The Committee also established an Intersessional Correspondence Group to work on ASW related issues (Annex Y).

Table 7

Work plan for matters related to aboriginal subsistence whaling

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
(1) Annual review of catch/strike limits		Carry out		Carry out
(2) *Implementation Review*		Gray whales based upon rangewide review		West Greenland humpback whales
(3) *SLA*s		Consider development of an *SLA* for the hunt of common minke whales off East Greenland based on operational models developed for the West Greenland hunt		Adopt *SLA* if it is decided one is necessary
(5) Interim relief allowance testing	Run trials for gray whale hunts	Review results	Run trials for West Greenland common minke whales and fin whales	Review results
(6) Carryover (US/Denmark request)	Run trials for remaining Greenland hunts (West Greenland common minke whales, bowhead whales and fin whales	Review results		

9. WHALE STOCKS NOT SUBJECT TO DIRECTED TAKES

9.1 In-depth Assessments

Donovan gave a presentation explaining a streamlined procedure hereby the Committee, via its sub-groups, can undertake Comprehensive Assessment (traditionally the first time an assessment is undertaken for a particular species/ocean basin) or an in-depth assessment (assessments subsequent to a comprehensive assessment). This can be found as SC/67B/GEN04 and is summarised in Fig. 1. The objective is to provide a consistent approach (including methods) that initially focusses on ensuring that sufficient data are available to undertake an assessment (the pre-assessment approach that will normally be undertaken at annual meetings) and then follows this with a concentrated effort (ideally two workshops and two annual meetings, with no new data) to complete the assessment. The objective is to provide Commission with robust information on present status. This involves identifying:

(1) if populations are recovering, recovered or if there is cause for concern;

(2) factors that may be or are affecting status so that conservation and management needs can be determined; and

(3) information gaps and ways to address these in order to reduce uncertainty at the next assessment.

9.1.1 Comprehensive Assessment of North Pacific humpback whales

Work towards a Comprehensive Assessment of North Pacific humpback whales began in 2016, and included an intersessional workshop held in April 2017 (IWC, 2018b). After the 2017 Committee meeting, an intersessional steering group continued preparing the input data and assessment model (IA/67b/IA03). The assessment model is a simplified age-aggregated model of the breeding and feeding grounds. The development of the input data (stock structure, abundance, catches, and life history parameters) continued during the year but given the slower than initially expected progress, particularly with respect to narrowing down the number of stock structure hypotheses, the steering group had agreed that it was premature to hold the anticipated workshop prior to SC67b.

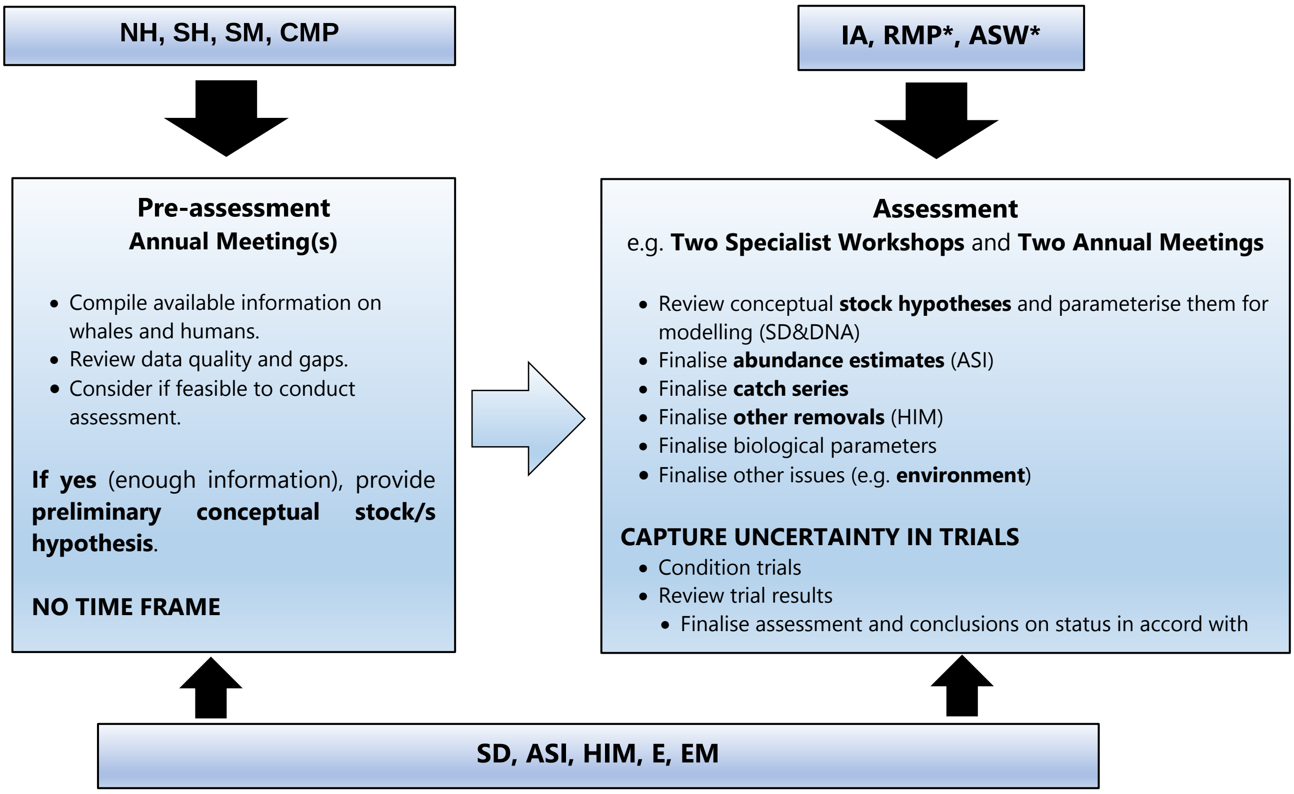

Fig. 1. Schematic of the approach to conduct assessments within the Scientific Committee. Acronyms refer to sub-groups. Normally the final assessment will take place in the sub-committee on in-depth assessments but for stocks subject to direct catches it may occur in the context of the RMP or AWMP sub-groups as appropriate.

Work continued at this meeting and the detailed discussions can be found in Annex F (item 4). The subdivisions of the North Pacific humpback whale feeding and breeding grounds in Annex F (fig. 1) are broadly consistent with existing data; identified uncertainties will be addressed in the assessment by evaluating four scenarios with different numbers of feeding and breeding grounds. This work will be greatly assisted by undertaking comparisons of humpback whale photographs from the Pacific obtained after the conclusion of the photographic component of the SPLASH (Structure of Populations, Levels of Abundance and Status of Humpback Whales) programme in 2005 (e.g. see Calambokidis *et al.*, 2008).

The general underlying structure of the assessment model has been developed but before the model can be run the input data (e.g. catches and abundance estimates) need to be updated and allocated for each stock structure hypotheses and mixing matrices developed and parameterised.

Attention: SC, G

The Committee is undertaking a Comprehensive Assessment of North Pacific humpback whales. To complete this assessment the Committee ***agrees*** *that:*

(1) a large-scale matching effort of post-2005 photo-identifications should be undertaken (see Annex F, item 4 for methods); and
(2) this matching effort will (a) help clarify the connections among the feeding/breeding areas within the North Pacific; and (b) assist in developing updated abundance estimates where appropriate.
The Committee ***stresses*** *that to obtain the most robust assessment and thus conservation advice, all available data should be included in the matching effort. Therefore, the Committee* ***strongly encourages*** *all catalogue holders to participate in this exercise, after the appropriate data sharing agreements are made.*

The Committee also ***welcomes*** *the provision of new abundance estimates (e.g. those from the IWC-POWER surveys and from local areas in Japan), noting that they will also need to be adjusted for the various stock structure hypotheses.*

The Committee ***agrees*** *that the next assessment workshop should take place at a time prior to SC68b when the intersessional Steering Group (Annex Y) decides sufficient progress has been made.*

9.1.2 Comprehensive Assessment of North Pacific sei whales
The Committee began what was called an in-depth assessment of North Pacific sei whales in 2015 (IWC, 2016c) but, in keeping with the discussion under Item 9.1 will now be termed a Comprehensive Assessment for consistency. Work has focussed since then on finalising the stock structure hypotheses (two have been agreed for use in the assessment - a single-stock hypothesis and a five-stock hypothesis), developing an appropriate population model and finalising the model inputs in accordance with these hypotheses (including catches, mark-recovery locations, abundance estimates, estimates of mixing between sub-areas, and life history parameters).

Considerable progress was made with this work intersessionally and at this meeting as discussed in Annex H, item 3.

Attention SC, G

The Scientific Committee intends to complete the Comprehensive Assessment of North Pacific sei whales within the next biennial period. It notes the progress made at this meeting with respect to stock structure, abundance estimates, marking data, catch history, life history parameters and the assessment model. To complete this work, the Committee ***agrees*** *to:*

(a) the work undertaken to finalise input data for the assessment (Annex F, appendices 2-7);
(b) support the modelling work identified in Annex F; and
(c) re-establish the intersessional steering group to oversee the assessment.

In addition, the Committee ***encourages*** *telemetry work in waters outside the 'pelagic' sub-area to assist in quantifying the movement patterns of animals.*

9.1.3 In-depth Assessment of Indo-Pacific Antarctic minke whales
An intersessional correspondence group under Murase completed its task to finalise a document synthesising the results of the 2001 - 2014 in-depth assessment of an eastern Indian stock (I-stock) and a western South Pacific stock (P-stock) of Antarctic minke whales distributed between 35°E and 145°W.

The Committee **commends** the authors for completing this paper and submitting it to the *Journal of Cetacean Research and Management.* As the paper has just entered the review process, the intersessional correspondence group (Annex X) has been re-established to see the paper through to publication.

9.1.4 Workplan 2019-20
The work plan for Comprehensive and in-depth assessments for the next biennium is provided in Table 8.

Table 8

Work plan for in-depth assessments

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting (SC/68b)
In-depth Assessment of Indo-Pacific Antarctic minke whales	Complete review of paper submitted for publication	-	-	-
Comprehensive Assessment of North Pacific sei whales	Re-establish the ISG (Annex Y) to further data preparation and development of the assessment model	Review progress of intersessional work and continue the assessment	Finalise preparation of assessment	Review progress of intersessional work and finalise the assessment
Comprehensive Assessment of North Pacific humpback whales	Re-establish the ISG (Annex Y) to further data preparation, development of the assessment model and hold a Workshop	Review progress of intersessional work and continue the assessment	Finalise /continue preparation of assessment	Review progress of intersessional work and continue/finalise the assessment

9.2 Evaluation for potential new Comprehensive or In-Depth Assessments

9.2.1 North Pacific blue whales

The Committee welcomed the report of an intersessional group that had been determining the data that are available on items required to carry out a Comprehensive Assessment of blue whales in the North Pacific. The status of the eastern North Pacific population is well known and a stock assessment was reviewed and accepted by the Committee in 2016 (Monnahan and Branch, 2015). However, information from the central and western North Pacific is sparser. Information presented at this meeting concerned stock structure, catch history, biological parameters, photo-identification, Discovery marks and sighting surveys. Details can be found in Annex G (item 6.1).

Several papers and datasets were discussed including: the use of blue whale sounds to identify stocks; morphological data; genetic data; sightings data (SC/67b/IA02; SC/67b/SCSP06; SC/67b/SCSP07; SC/67b/NH08).

Attention: SC

*The Committee **agrees** the following priorities to progress the pre-assessment:*

(1) obtain abundance estimates from the IWC-POWER surveys;
(2) obtain abundance estimates from the JARPN and JARPNII surveys;
(3) analyse and compare genetic samples from ENP, IWC-POWER and ICR biopsy samples to determine stock structure throughout the North Pacific;
(4) compare photo-identification data from POWER, JARPN/JARPNII and other ENP catalogues;
(5) Review new acoustic locations and information and conduct fine-scale analysis of song features for central Pacific blue whale calls, with particular focus on calls around Japan;
(6) Obtain better life history parameters (especially age at sexual maturity and calving interval) from the Cascadia Research Collective, the Mingan Island Cetacean Study Research Station and the CICIMAR-IPN photo-ID dataset;

*With respect to (3), the Committee **requests** the collection of about 20 biopsy samples if possible during the NEWREP-NP surveys in the western North Pacific to improve the power to evaluate stock structure and **encourages** genetic analysis of the existing Japanese samples.*

*With respect to (5), the Committee **requests** a reanalysis of recordings from the Northern Mariana Islands (Saipan and Tinian) collected by the Pacific Islands Fisheries Science Center to look for the presence or absence of the new song type recorded from Japan. It also **encourages** passive acoustic data collection during surveys (e.g. IWC-POWER, university/training cruises) from the region of high blue whale density southeast of the Kamchatka Peninsula to determine the song type produced by animals in that region.*

*The Committee **agrees** that the intersessional correspondence group continue to review data needed for an assessment of North Pacific blue whales be reappointed under Branch (Annex Y).*

9.2.2 Non-Antarctic Southern Hemisphere blue whales

9.2.2.1 SOUTHERN HEMISPHERE POPULATION STRUCTURE

The Committee is currently preparing for a Comprehensive Assessment of pygmy blue whales. For this reason, it continues to gather information on population structure (see Item 3.1, IWC, 2018a). This year, the web-based pygmy blue whale song library funded by the IWC will be launched (SC/67b/SH12). This will enable researchers to compare their acoustic recordings with validated song archetypes and greatly assist the determination of Southern Hemisphere blue whale distribution patterns and stock structure. Photo-ID and genetic evidence support the idea that each distinct pygmy blue whale song represents a geographically and genetically distinct population of pygmy blue whales around the Southern Hemisphere. A full description of the discussion of the use of songs in this pre-assessment is given in Annex H (item 3.1), including comparison with genetic and photo-identification data. The Committee also received information from whale bones and notes that further analysis of blue whale bones from old whaling land stations will be helpful to establish the past distribution of these stocks.

Assessments require catches to be allocated to populations and in 2016 the Committee funded an examination of regional catches to assign them to each putative population (Item 5.1, IWC, 2017a). The results of this work are provided in SC/67b/SH23 and discussed in Annex H (item 3.1). Total pygmy blue whale catches were estimated at 12,184 with totals for each population of 1,228 (Northern Indian Ocean), 6,889 (South West Indian Ocean), 3,646 (South East Indian Ocean) and 421 (South West Pacific Ocean).

The Committee also discussed an intersessional effort to identify and standardise genetic markers used in Southern Hemisphere blue whale research (only four loci were common across all research laboratories) and received a progress report (SC/67b/PH04) on matching within the Southern Hemisphere Blue Whale Catalogue, which has been supported by funding from the Committee (Item 10.2.2, IWC, 2017a). This helps understanding of blue whale movements between regions, and allows estimation of regional abundance. The catalogue is currently being migrated to IWC servers (and see Item 23.2.3.2).

Attention: SC, G

In order to progress its work towards an assessment of pygmy blue whales, the Committee:

(1) ***agrees*** *that further work is needed to identify high and base case catch scenarios for pygmy blue whales;*
(2) ***encourages*** *deployment of more acoustic recorders in the southern Indian Ocean;*
(3) ***agrees*** *that further population modelling is needed to assess pygmy blue whale populations;*
(4) ***strongly encourages*** *blue whale research groups to publish the metadata associated with their sequences in order that levels of sample overlap can be established and datasets compared;*
(5) ***agrees*** *that the Southern Hemisphere Blue Whale Catalogue should be continued to help understand blue whale movements, with a priority focus on matching photographs within regions to measure regional abundance of pygmy blue whales.*

9.2.2.2 INDONESIA/AUSTRALIA BLUE WHALES

The Australian blue whale photo-ID catalogue data have now nearly all been uploaded and matched within the Southern Hemisphere Blue Whale Catalogue, at which point quality control analysis can begin. This will allow the potential for using these data for mark recapture abundance estimation to be assessed. The Scientific Committee was informed that mark-resighting data from the Perth Canyon (Australia) will be analysed intersessionally, to provide a new estimate of Australian blue whale abundance which assist in a future assessment of this population.

Attention: SC, G

The Committee ***encourages*** *analysis to provide an estimate of Australian blue whale abundance using mark-resighting data.*

9.2.2.3 MADAGASCAR BLUE WHALES

The Committee was informed that passive acoustic monitoring of blue whales in the Mozambique Channel detected both South West Indian Ocean (SWIO) and Antarctic blue whale song types, as well as fin and Antarctic minke whales (SC/67b/SH14). In addition, SC/67b/SH24 reported an unidentified blue whale song off Oman. A full discussion of the results of these papers can be found in Annex I (item 3.3.2).

This new information means that the blue whale catch allocations for the Indian Ocean, currently only ascribed to a single ‘NIO’ population in the Northern Indian Ocean, will need revision to take this new acoustic pattern into account.

Attention: SC, G

The Committee notes that the distribution and population isolation of blue whales is poorly understood in the northern and western Indian Ocean. The Committee therefore:

(1) ***strongly encourages*** *further acoustic work in the western Indian Ocean and Arabian sea to better understand the distribution, seasonality and overlap of blue whale calls;*
(2) ***strongly encourages*** *the collection and analysis of available tissue samples for analysis of genetic population structure in this region to assist with characterising these populations; and*
(3) ***agrees*** *that catch allocations of blue whales be revised to include the new blue whale song in the northwest Indian Ocean as a potential distinct ‘stock’.*

9.2.2.4 NEW ZEALAND BLUE WHALES

Three papers were presented on blue whales off New Zealand (see Annex H, item 3.3.4 for a full discussion).

SC/67b/SH09 reported a recent study of blue whale movement and habitat use in the Taranaki region of New Zealand in which two animals were tagged. However, due to the small sample size and La Niña conditions, it is uncertain how representative these movements are for blue whales in New Zealand waters.

SC/67b/SH05 summarised a multi-disciplinary study included acoustics, genetics and photo-identification in the same area, and provided a conservative estimate of blue whale population abundance (see Annex Q, item 3.1.1.9), to consider if this estimate can be used in the upcoming regional assessments of pygmy blue whales. SC/67b/SH04 reported projects underway to assist regional conservation management, including a description of fine-scale habitat use during summer months in the South Taranaki Bight, and response to local acoustic disturbance.

Attention: SC, G

With respect to information on blue whales off New Zealand, the Committee:

(1) ***welcomes*** *the work being undertaken to understand abundance and connectivity, which will contribute towards the pygmy blue whale population assessments; and*
(2) ***agrees*** *that New Zealand photo-identifications should be combined with others within the Southern Hemisphere Blue Whale Catalogue to provide the fullest possible assessment of regional abundance and connectivity*

9.2.2.5 SOUTHEAST PACIFIC BLUE WHALES
The Committee received two papers relevant to blue whales off Chile and the full discussion can be found in Annex H (item 3.3.1). SC/67b/SH03 presented a morphometric analysis of Chilean blue whales which reinforces the argument that Chilean blue whales should be considered a separate sub-species from the Antarctic and pygmy forms. (Bedrinana-Romano *et al.*, 2018) reported distribution modelling of blue whales using Chilean Northern Patagonia waters. Preliminary delimitations of possible blue whale conservation areas in this region overlap with highly used vessel navigation routes and areas allocated for aquaculture. The Committee was also informed that predictions of southeast Pacific blue whale habitat following Redfern *et al.,* (2017) will be completed intersessionally.

Attention: SC, G

In view of the recent identification of movements of Chilean blue whales into the South Atlantic and ongoing questions about the distribution of this population, the Committee:

(1) ***encourages*** *further satellite tracking and surveys (including collection of photo-ID and genetic data) to assess the population limits, habitat use and abundance and sub-species identity of blue whales in Chile;*
(2) ***encourages*** *compilation of morphometric data available for northeast Pacific blue whales and comparison with Chilean data, to assess morphological differentiation of these whales in the eastern Pacific and evaluate sub-species identity; and*
(3) ***welcomes*** *plans for further photo-ID catalogue matching within this region to assist with regional abundance estimation.*

9.2.2.6 WORK PLAN
The work plan for all Southern Hemisphere blue whales is given in Table 9.

9.2.3 Antarctic blue whales (Areas III and IV)
Undertaking a regional population assessment of Antarctic blue whales is challenging due to the scarcity of whales and logistical challenges. The Committee received new information this year on sightings, abundance and genetic studies.

SC/67b/SH08 presents a preliminary estimate of abundance (the first using photo-ID data) and this is discussed in Annex Q (see item 3.1.19) where suggestions were made to refine the analyses. Reports from two 2017/18 NEWREP-A summer cruises included sightings of blue whales and information on biopsy sampling (SC/67b/SP08 and SC/67b/ASI07). An IWC-SORP Southern Ocean blue whale-focussed cruise is planned for January to March 2019 (140°E-175°W), which intends to describe krill swarms in relation to blue whale density and distribution (SC/67b/SH07).

With respect to genetic work, IWC-SORP funded work on blue whale bones to compare past and current genetic diversity levels is reported in SC/67b/SH02 and discussed in Annex I (item 4.4.2). The Committee was also updated about ongoing work to analyse a collection of 1,626 baleen plates (roughly 50:50 blue and fin whales) from the Japanese whaling in the 1940s and held at the Smithsonian Natural History Museum, USA. A pilot study has established that mitochondrial DNA can be sequenced from these plates. Further analyses including of stable isotope and hormone levels are planned for these samples.

Attention: SC, G

The Committee ***welcomes*** *the progress being made towards being able to undertake am in-depth assessment of Antarctic blue whales. The Committee:*

(1) ***encourages*** *further work to update the abundance estimate for Antarctic blue whales following Committee recommendations;*

*(2) **strongly encourages** continued opportunistic photo-ID data collection in the Antarctic to assist with developing estimates of population abundance for this subspecies; and*
*(3) **encourages** continued collection and analysis of bone and baleen from historical Antarctic commercial whaling samples and sites to evaluate loss of genetic diversity and shifts in population structure.*

9.2.3.1 WORK PLAN

The work plan for all Southern Hemisphere blue whales is given in Table 9.

Table 9.

Workplan for Southern Hemisphere Antarctic and pygmy blue whales

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Antarctic blue whales				
Catalogue matching	Catalogue matching of photo-IDs (Annex Y)	Report	Catalogue matching (opportunistically collected photos)	Report
Abundance estimation	Mark recapture modelling work to update SC/67b/SH08 Annex Y	Report		
Photo-ID outreach material	Create photo-ID information booklets for distribution via IAATO operators	Report		
SH non-Antarctic blue whales				
Population assessment	Improve catch separation model, explore alternative catch allocation models (Annex Y)	Report	Population assessment. Analyse minimum and extrapolated recovery status of all populations for which abundance is available	Report
Catalogue matching	Catalogue matching of photo-IDs within southeast and central east Pacific (Annex Y)	Report	Catalogue matching (opportunistic photos from citizen scientists and collaborators) if funds are available	Report
Blue whale song library	Finish implementation of blue whale song library (Annex Y)	Report		
Australian abundance estimate	Analyse Perth Canyon abundance using mark recapture data (Annex Y)	Report		

9.2.4 Southern Hemisphere fin whales

9.2.4.1 POPULATION STRUCTURE

As part of its pre-assessment work, the Committee is gathering information on Southern Hemisphere fin whales in order to: (1) clarify the subspecies status of these whales (currently two Southern Hemisphere subspecies are recognized, Committee on Taxonomy, 2017); and (2) measure population differentiation around the Southern Hemisphere to establish whether any distinct populations exist.

A summary of available data on Southern Hemisphere fin whale structure was presented in SC/67b/SH15 and is discussed in detail in Annex H (item 4.1). The only evidence for any structure comes from acoustics. A genetic study from the southeast Pacific (SC/67b/SH13) found high local diversity in Chile, with no significant differentiation from the other Southern Hemisphere datasets. The Committee noted however that genetic differentiation can be difficult to detect when diversity levels are high and genetic differentiation is low (see Annex H, item 4.1).

Attention: SC, G, S

Knowledge of population structure is essential to future efforts to assess Southern Hemisphere fin whales. To determine the differentiation and potential sub-species structure among fin whales the Committee:

*(1) **agrees** that analysis of concurrently collected acoustic recordings of fin whales, to assess song variation around the Southern Hemisphere, is a priority;*
*(2) **agrees** that a review of all Discovery mark data published on fin whales to assess population connectivity patterns should be carried out; and*

(3) ***requests*** *that the Secretariat provide a letter of support for a study examining the evidence for* B. physalus patachonica*, which requires access to the holotype for this species from the Bernardino Rivadavia Natural Sciences Museum in Buenos Aires***.**

The Committee also ***encourages:***

(1) *analysis of fin whale distribution and geographic aggregations using all available catches;*
(2) *strategic biopsy sampling and analysis to measure the genetic differentiation of fin whales around the Southern Hemisphere;*
(3) *further biopsy sampling and sequencing of multiple nuclear loci to establish Chilean fin whale differentiation patterns, with co-collection of photo-IDs and body length measurements to establish population identity;*
(4) *satellite telemetry to discern seasonal movements; and*
(5) *photo-identification to understand site fidelity and residency patterns and linkages between high- and low-latitude grounds.*

9.2.4.2 DISTRIBUTION AND ABUNDANCE

The Committee welcomed a review of the available metadata on Southern Hemisphere fin whales (SC/67b/SH19), compiling data from dedicated and opportunistic surveys, moored acoustic recorders, sonobuoy surveys, photo-identifications, satellite tagging and biopsy sampling. The Committee also welcomed a summary of recent work by the Brazilian Antarctic Program to conduct dedicated fin whale research using sighting surveys, photo-ID, biopsy sampling and telemetry.

Reports from two 2017/18 NEWREP-A summer cruises included sightings of fin whales and information on biopsy sampling (SC/67b/SP08 and SC/67b/ASI07). A new abundance estimate for fin whales using sightings data from the third IDCR-SOWER circumpolar survey is expected to be available for review at next year's meeting.

SC/67b/14 provided information on the presence of fin whales in the Mozambique Channel and a new lower-latitude song. Details of the discussions can be found in Annex H (item 4.2).

The Committee was also informed that an analysis has suggested that Antarctic fin whales are sufficiently well marked to enable to use in photo-ID projects (SC/67b/PH01) and this is discussed in Annex S (item 4.1).

Attention: SC, G, CG-A

With respect to obtaining information on the distribution, movements and abundance of Southern Hemisphere fin whales for use in a future assessment, the Committee:

(1) ***encourages*** *a meta-analysis of the Antarctic Peninsula and Scotia Sea sightings data, to measure recent fin whale distribution, density and habitat use;*
(2) ***strongly encourages*** *continued work by the Brazilian Antarctic Program towards the understanding of fin whale population structure, movements and habitat use*
(3) ***agrees*** *that a new abundance estimate for fin whales from the IWC IDCR/SOWER programme should be presented for review at next year's meeting,*
(4) ***welcomes*** *news that fin whales can be used in photo-ID studies, and* ***encourages*** *further photo-ID data collection at high latitudes.*

9.2.4.3 WORK PLAN

The work plan for Southern Hemisphere fin whales is given in Table 10.

Table 10

Work plan for Southern Hemisphere fin whales

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Fin whale acoustic structure	Review fin whale call patterns across Southern Hemisphere, investigate call variation (Annex Y)	Report	Complete review of fin whale call patterns (Annex Y)	Report
Discovery marks	Review available Discovery mark data on fin whales (Pastene and Jackson)	Report		
Catch maps	Update fin whale catch model to include Soviet catch data (de la Mare)	Report		

9.2.5 North Atlantic sei whales

The Committee welcomed information on two separate habitat-based density modelling efforts, using visual survey data to produce seasonal abundance estimates for sei whales from the purported 'Nova Scotia' stock, ranging from Nova Scotia to the southeastern USA (SC/67b/NH07). There was also some consideration of passive acoustic and strandings data from the US eastern seaboard. No new data are available from around Iceland or Norway, partially due to difference in timing between surveys and species' arrival in regional waters. This information was discussed in Annex G (item 6.2). An intersessional correspondence group (Annex Y) will compile additional information this species in the North Atlantic and the Committee looks forward to a further update on reanalysis of historical data, particularly related to stock structure and strandings, next year.

9.2.6 North Atlantic right whales

Since 2016, the Committee has recommended a comprehensive update on North Atlantic right whales. SC/67b/NH05 summarised the information on the status of the North Atlantic right whale. This population has been slowly declining since 2010 and the abundance at the end of 2015 was estimated to be around 460 individuals (Pace *et al.*, 2017[6]). Of particular concern is the lower annual survival rate of females than males and poor recent calving (five in 2016/17 and none so far in the 2017/18 calving season). The observed number of dead whales in 2017 was 17 whales, several showing signs of death from fishing gear or blunt force trauma. These clearly represent minimum numbers and there was some discussion as to whether it was possible to scale minimum observed mortalities to an overall estimate but several confounding factors preventing this were identified (see Annex F, item 6.3 and Annex J, item 2.1.2).

Due to the increased 2017 Canadian interactions in the Gulf of St. Lawrence, on 19 April 2018 the Government of Canada implemented mitigation measures to reduce future interactions (DFO, 2018), including: closing a large part of the Gulf of St. Lawrence snow crab fishery on 30 June; creating a dynamic 15-day fishing closure; introducing a 10 knot speed restriction when any single right whale sighting in any area is detected; putting in place mandatory gear marking and reporting of any lost gear; minimising the allowable amount of floating line at surface; and using vessel monitoring systems that reports the boats position every 5 minutes.

A substantial increase in collaboration and data sharing between the US and Canada has occurred as a result of these mortalities.

Attention: C-A, CC

The Committee reiterates its serious concern over the status of the western North Atlantic stock of right whales as it is probably the only viable population of this species, for which entanglements and ship strikes have long been identified as key threats.

This year, the Committee:
(1) ***recognises*** *that entanglements have now replaced ship strikes as the primary cause of deaths (Kraus et al. 2016);*
(2) ***reiterates*** *its recommendation for the USA to submit a comprehensive update on the status of North Atlantic right whales (IWC, 2017:40) including an update of the Pace* et al. *abundance estimate, prior to the 2019 meeting;*
(3) ***stresses*** *that this update will allow time for explanations or additional analyses to be undertaken before the proposed 2019 Workshop on the Comparative Biology, Health, Status and Future of North Atlantic Right Whales: Insights from Comparative with other Balaenid Populations (including bowheads);*
(4) ***encourages*** *updates from the US Large Whale Take Reduction Team (ALWTRT) on progress of the Whale Safe Rope and Gear Marking Feasibility Subgroups; and*
(5) ***requests*** *that the Commission asks the IWC Executive Secretary to write to the U.S. National Marine Fisheries Service (NMFS) and the Canadian Department of Fisheries and Oceans, informing them of the Committee's serious concerns over the declining population trend of this species, and stressing that,* ***as a matter of absolute urgency****, every effort be made to reduce human induced mortality in the population to zero.*

9.2.7 North Pacific right whales

The Committee received a report of a dead right whale caught in a set net off Izu, Japan in 2018 (SC/67b/NH06) – the first in a set net since one in Korea in 2015 (Kim *et al.*, 2015).

The Committee welcomed information on a single sighting off Hokkaido (and a biopsy sample) from a Japanese national cruise (SC/67b/ASI10). It also welcomed information on North Pacific right whales from the visual, acoustic and biopsy sampling components of the 2017 IWC-POWER cruise in the eastern part of the Bering Sea. A total of 9 schools and 18 individuals (including 2 duplicate schools of 3 individuals) of right whales were sighted with photo-identification of 12 individuals and biopsy samples from 3 individuals. Discussion of these sightings can be found in Annex G (item 6.4).

In response to a recommendation made last year (IWC, 2018c), US and Japanese scientists presented the results of new genetic analyses of right whales in the North Pacific. Comparison of whales sampled in the eastern and western North Pacific revealed statistically significant differentiation based on mtDNA data, supporting presumed separation of the two stocks based on gaps in the spatial distribution of sightings (and also see discussion in Annex I, item 4.3).

[6] Any revised estimate from the Pace *et al.* 2017 paper will be reviewed by the ASI sub-committee during SC68a.

Attention: SC

The results of new genetic analyses support the recognition of separate stocks of right whales in the eastern and western North Pacific. Given the importance of this work and the precarious situation of this species, especially in the eastern North Pacific, the Committee ***encourages*** *the publication of this information as soon as possible.*

9.2.8 Workplan 2019-20
The Committee agreed to the two-year workplan in Table 11.

9. 3 New information and workplan for other northern stocks *(NH)*

9.3.1 North Pacific fin whales
The Committee received new information on studies of North Pacific fin whales. New sightings of fin whales were reported in the papers (SC/67b/ASI12, SC/67b/ASI10, SC/67b/SCSP06) during the POWER cruise in the Bering Sea and the two surveys in the western North Pacific (Areas 7, 8 & 9). Over 260 schools found, many individuals were photo-identified and biopsy samples were obtained from 28 whales.

9.3.2 Omura's whale
The Committee welcomed the new information on this species (SC/67b/NH09) from the west coast of Madagascar, supporting the current understanding that the population is resident and non-migratory with strong site fidelity. Likely threats to the Madagascar population include entanglement in local fisheries, impacts from oil and gas exploration, and most imminent the risk of coastal water contamination from a recently initiated mining operation for Rare Earth Elements. Future work should include a long-term latitudinal study that incorporates multiple methodologies to investigate all aspects of the species biology and conservation threats to the population.

Kim and colleagues reported on the first confirmed documentation of Omura's whale in the waters of South Korea. Two of six large baleen whales bycaught were confirmed by genetic analysis to be Omura's whale. This bycatch reinforces the concept that this coastal species is vulnerable to anthropogenic impacts, especially entanglement in fishing gear.

Attention: SC, G

The Committee notes that little information is available to assess the status of Omura's whale. The Committee:

(1) ***recognises*** *the significant contribution the research efforts off Madagascar have made to the understanding of this species and* ***encourages*** *this work to be continued and expanded into the future; and*
(2) ***encourages*** *identification of study sites that are suitable for long-term comparative study on Omura's whales in other parts of its range (e.g. New Caledonia, Komodo Islands, Indonesia, and the Bohol Sea, Philippines).*

Table 11

Workplan for other Northern Hemisphere stocks

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
North Pacific blue whales	Data collection and review with focus on catches and stock structure	Review especially stock structure	Develop proposal for stock structure	Agree stock structure hypotheses
North Atlantic sei whales	Review distribution, strandings, sightings and stock structure	Review new information for assessment	Develop proposal for stock structure	Agree stock structure hypotheses
North Atlantic right whales		Review status and mortality data		Review status and mortality data
North Pacific right whales		Review new information for assessment		Review new information for assessment
North Atlantic humpback whales		Consider information for new assessment		Develop plans for new assesssment
Gulf of Mexico Bryde's whale		Review new information on mortality		Review new information on mortality
All other stocks		Review new information		

9.3.3 North Atlantic Bryde's whales
SC/67b/ASI01 presented sightings collected during recent coastal surveys off Guinea, Sierra Leone and Liberia in March 2018. During this survey, two groups of five individual Bryde's whales were observed.

The Committee welcomed this information and **encourages** future surveys in this region.

9.3.4 North Atlantic blue whales
The Committee welcomed new information from the USA on blue whales in the North Atlantic including recent sightings, serious injuries or mortalities, seasonal occurrence based on acoustics. Lesage *et al.* (2018) provides an extensive summary of recent data collected in Canadian waters. This is discussed in Annex G (item 7.6) where it was noted that multiple new datasets (including from passive acoustic monitoring) have been recently collected and may provide more information on blue whale distribution in North Atlantic waters

Attention: SC, G

The Committee notes that there has been a recent increase in information available on North Atlantic blue whales. The Committee:

(1) ***draws attention to*** *the lack of data on interchange between blue whales in the eastern and western North Atlantic and* ***recommends*** *that U.S., Canadian and Icelandic colleagues conduct a new comparison of blue whale photo-identification catalogues and present this information at SC/68a; and*
(2) ***encourages*** *Canadian colleagues to generate a new population abundance estimate as soon as feasible, and looks forward to updates on new passive acoustic and visual sightings data SC/68a.*

9.3.5 North Atlantic humpback whales
The Committee received new information (NOAA, 2018b) on humpback mortalities along the US coast (vessel strikes and entanglements were noted as the primary causes of anthropogenic mortality). An 'Unusual Mortality Event' was declared by the USA for humpback whales in April 2017. This is discussed further in Annex G (item 7.7. New abundance estimates for parts of the North Atlantic are discussed in Annex Q (item 3.1.1.3) and presented in Item 12.1. Consideration of the need for a new in-depth assessment of North Pacific humpback whales is given in Annex E (item 5.8.2) and Item 8.7.3.

9.3.6 North Atlantic bowhead whales not subject to aboriginal subsistence whaling
No new information was available to the Committee.

9.3.7 North Pacific bowhead whales not subject to aboriginal subsistence whaling
No new information was available to the Committee.

9.3.8 North Pacific sperm whales
Three papers (SC/67b/ASI10,12 and SC/67b/SCSP06) provided new information of sperm whale occurrence and distribution was collected during 2017 in the western North Pacific, eastern Bering Sea. An intersessional correspondence group to examine possible ways to assess sperm whales has been reappointed (Annex Y)

9.3.9 Gulf of Mexico Bryde's whales
9.3.9.1 NEW INFORMATION
The Committee received an update on activities related to monitoring and new research plans for the critically endangered Gulf of Mexico sub-species of Bryde's whale. The Southeast Fisheries Science Center undertook a shipboard survey in the northern Gulf of Mexico in 2017, including known habitat of the Gulf of Mexico Bryde's whale. Passive acoustic data were collected in historic habitat of the central and western Gulf from June 2016 to June 2017. The In the USA, there is legislation that provides funds to restore and protect ecosystems of the Gulf of Mexico following the Deepwater Horizon oil spill (2010); this work will include research on the Gulf of Mexico Bryde's whale.

Attention: SC, G

The Committee ***agrees*** *that the NOAA scientists working with this sub-species should present results from shipboard and acoustic data analyses to the IWC at the 2019 Scientific Committee meeting and looks forward to receiving a report from the Workshop held in conjunction with the initiation of research associated with funds to restore and protect ecosystems of the Gulf of Mexico following the Deepwater Horizon oil spill.*

The Committee also ***encourages*** *U.S. and Mexican scientists to collaborate in efforts to determine whether any of these whales occur in Mexican waters (e.g. Bay of Campeche) where a major oil spill of three million barrels occurred in 1979. This should include consideration of the use o9f passive acoustics as well as visual surveys focusing on areas of habitat similar to that found in the core known range in the north-eastern Gulf. It was further noted that passive acoustic data or specimen records from the northern coast of Cuba would be useful to determine potential occurrence of this subspecies in that region.*

9.3.9.2 CONSERVATION ADVICE

Attention: CG-R, S
The small population size, known human related mortality, restricted range and low genetic diversity place the Gulf of Mexico sub-species of Bryde's whale (added to the Critically Endangered category of the IUCN Red List in 2017) at significant risk of extinction. The Committee ***reiterates*** *its previous* ***recommendations*** *that US authorities:*

(1) make full and immediate use of available legal and regulatory instruments to provide the greatest possible level of protection to these whales and their habitat;
ensure that seismic surveys and associated activities that degrade acoustic habitat are excluded from the region of the eastern Gulf of Mexico inhabited by these whales, including an appropriate geographic buffer against acoustic impacts from activities in the Central Planning Area and active leases in the Eastern Planning Area;
(2) characterise the degree of overlap between the whales' currently known preferred habitat and ship traffic, and immediately implement appropriate measures to reduce the risk of ship strikes (e.g. re-routing, speed restrictions);
(3) based on the known distribution of these whales and overlap with certain fisheries, improve understanding of potential for interaction with fishing gear, and expand and implement appropriate measures, such as area closures, to reduce the risk of entanglement throughout their range;
(4) develop and implement restoration projects (with funds from the Deepwater Horizon oil spill settlement) for these whales and their habitat as a priority and ensure that a robust monitoring and adaptive management plan is in place to evaluate the effectiveness of all restoration efforts;
(5) design and conduct research programmes (sighting surveys, acoustic monitoring, genetic mark-recapture, photoidentification if feasible, satellite tagging if feasible, health studies if feasible) to further investigate these whales' distribution, movements, habitat use, health, survival and fecundity - this should include efforts to better document the whales' total geographic range and to document causes of mortality through necropsies when carcasses are reported; and
(6) *ensure that information about core known habitat and movements in the Gulf of Mexico is transmitted to the U.S. Coast Guard, shipping industry trade organizations, and Gulf of Mexico port authorities (e.g. in Tampa, Florida) for their consideration to mitigate ship-strike risk.*

In addition, the Committee ***reiterates*** *its recommendation that the IWC Secretariat (i) communicate the above concerns and recommendations to range state authorities and (b) specifically explore in collaboration with the International Maritime Organization the feasibility of providing internationally recognized forms of protection to these whales (e.g. designation of an Area to be Avoided) that would reduce the risk of ship strike and help mitigate degradation of acoustic habitat by ship noise.*

9.3.10 Other stocks - Northern Indian Ocean sperm whales
No new information was available to the Committee.

9.3.11 Workplan 2019-20
The Committee agreed to the two-year workplan in Table 11.

9.4 New information and workplan for other Southern stocks
9.4.1 Southern Hemisphere humpback whales
9.4.2.1 BREEDING STOCK D
The assessment of the Breeding Stocks D (West Australia), E1 (East Australia) and Oceania was completed in 2014 (IWC, 2015a), but there were substantial associated problems in obtaining a reliable estimate of absolute abundance for Breeding Stock D. See Annex H (IWC, 2017a; 2018a) for a detailed discussion of these issues. Last year (IWC, 2018c), the Committee had agreed that efforts should focus on designing and implementing a new 'survey' (perhaps using new approaches such as drones), and recommended that prior to implementation, an assessment of the feasibility of such a 'survey', focusing in particular on the study conducted by du Fresne *et al.*, (2014), is conducted.

Attention: SC, G, CG-R

The Committee ***agrees*** *that obtaining a reliable estimate of absolute abundance for humpback whale Breeding Stock D (west Australia) is a priority for any future in-depth assessment. The Committee* ***reiterates*** *its recommendation that an evaluation of abundance survey feasibility be carried out for this population, focusing in particular on the study conducted by du Fresne et al. (2014), with a view to implementing a new survey of this population in the future.*

9.4.2.2 WORK PLAN
The work plan for Southern Hemisphere humpback whales is given in Table 12.

Table 12.
Work plan for Southern Hemisphere humpback whales

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Survey feasibility	Reanalyse pilot study to assess feasibility of future West Australia surveys (Kelly)	Receive report		

9.4.3 Southern Hemisphere right whales not the subject of CMPs

The Committee would like to progress regional population assessments for southern right whales (Item 10.8.1.5, IWC, 2017b) This requires a good understanding of population structure, abundance, trend and past exploitation levels. It was agreed that Australia should be the highest priority region for the next assessment (Item 9, IWC, 2018a).

9.4.3.1 SOUTH AFRICA

SC/67a/SH01 provided the results of the 2017 survey of southern right whales flown along the coast of South Africa, part of a long-term monitoring programme since 1979. Since 2015 there has been a marked decline in the presence of unaccompanied adults and cow-calf pairs for unknown reasons (see discussion in Annex S, item 5.1.3). Photo-ID analyses indicated an increasing occurrence of apparent 4- and 5-year calving intervals since 2014. SC/67b/SH22 applied a life history model to photo-ID data collected from 1979 to 2017. They showed that a model variant which allows the probability of a resting female remaining in the resting phase (rather than having a calf) to vary through time provided a better fit to the data than a time-invariant model. They calculate an annual population growth rate of 6.5% and measure first year survival at 0.852, with subsequent annual survival of 0.988.

Attention: SC, G, C-A, CG-A

*The Committee is **concerned** that the future of the exemplary long-term monitoring programme of right whales in South African waters remains uncertain. The Committee therefore **reiterates** that it:*

*(1) **strongly recommends** continuation of the survey;*
*(2) **requests** the Commission to urge South Africa to do all it can to ensure the long-term future of this vital monitoring programme; and*
*(3) **encourages** South African scientists to investigate the offshore movements and locations of southern right whales with future surveys.*

9.4.3.2 AUSTRALIA

The Committee was informed about the latest of a series of aerial surveys conducted in South and West Australia in 2017. The 2017 counts were the highest yet in the series and an exponential increase of ~6% per year remains a good description of the data. Funding has been obtained for the next three years of surveys. The Committee was also informed about: (a) a 26-year cliff-top study conducted at the Head of the Great Australian Bight (south Australia) on right whale population trends and identifications (Charlton *et al.*, In prep); and (b) an aerial survey in southeast Australia where small numbers of whales have been sighted (Watson *et al.*, 2015). Right whales in southeast Australia are genetically and geographically distinct from the large population in south/southwest Australia (e.g., Carroll *et al.*, In press).

The Committee was advised that the Australian Government has recently allocated funds towards a two-year project that will provide an abundance estimate for Australia's two southern right whale populations. It will investigate life history characteristics as well as connectivity between breeding areas on the eastern, southern and western coasts of Australia.

Attention: SC, G, CC, CG-A

*The Committee **recognises** the value of the Australian long-term right whale monitoring programmes to understand right whale population trends and dynamics, and **recommends** that this monitoring continues.*
*In regard to right whales in southeast Australia, the Committee **reiterates** concerns expressed in 2017 that abundance remains low despite this area having been a significant historic calving ground. The Committee therefore:*

(1) recommends an assessment of the likely effects of fish farms and other developments in hindering population recovery in this region; and
(2) encourages further work to estimate the abundance of the southeast Australia population.

9.4.3.3 NEW ZEALAND

The Committee welcomed information that surveys will be conducted in the Auckland Islands in 2020/21 to estimate abundance (updating the last estimate from 2009), to assess trend and population age structure, as well as changes in genetic diversity of right whales using this calving ground.

9.4.3.4 FEEDING GROUNDS

The Committee welcomed the results of a visual and acoustic survey of southern right whales off South Georgia/Islas (SC/67b/SH20). SC/67b/SH06 used genotypic markers to assess re-sight rates and sex ratios from biopsy samples (*n*=157) collected during 14 summer surveys in Antarctic Area IV. A preliminary abundance estimate was calculated using these data and further mark recapture analyses will be conducted intersessionally to provide an abundance estimate for review at next year's meeting. To further investigate linkages it was suggested that these high latitude data be compared the western Australia stock to investigate what population component is using this high latitude area.

Attention: SC

The Committee ***encourages*** *further mark recapture analysis of the genotype data of the 14-year dataset collected in the high latitudes of Area IV, to estimate the abundance of southern right whales in this feeding area and* ***agrees*** *that this will be considered at next year's meeting.*

9.4.3.5 PROGRESS TOWARDS POPULATION ASSESSMENT

This year, the Committee reviewed newly available information on population structuring of southern right whales around the Southern Hemisphere (Carroll *et al.*, In press) which further confirms the genetic differentiation of regional calving grounds off Argentina, South Africa, New Zealand and Australia, showing limited migratory movements between these areas (see Annex H, item 5.1,).

The Committee was provided with updates on trends and distribution for calving grounds off South Africa and off south and southwest Australia. Recent published data on population size and trend for calving grounds across the Southern Hemisphere were summarised in Annex H (table 2); this will be reviewed at next year's meeting. Given the trends in abundance and calving rates reported this year (Items 9.4.3.1 and 9.4.3.2), integration of these analyses in a common modelling framework was suggested as a useful way to evaluate common patterns and changes in demography and investigate the relative importance of environmental drivers in determining these patterns.

Another important aspect of population assessment is to update the pre-modern catch series for southern right whales, to better reflect patterns of regional exploitation. The Committee was informed that substantial new data are available on offshore whaling patterns and extent, particularly from American and British voyage logbooks (see Annex H, item 5.2,), which are likely to increase regional catch estimates and provide revised estimates of the numbers of whales struck but lost at sea by the different fisheries.

Attention: SC, G

To better understand patterns of right whale population dynamics around the Southern Hemisphere, and further the work on updated assessments, the Committee:

(1) ***agrees*** *that analysis of three southern right whale calving grounds (Head of the Bight and southwest Australia, southwest Atlantic and south Africa) should be undertaken using the same life-history model, to estimate regional demographic parameters and investigate commonalities in the population dynamics of these populations; and*
(2) ***supports*** *the compilation of new data on pre-modern right whale catches, and the organisation of a workshop to investigate regional right whale catches and rates of whales struck but lost by fisheries, in order to proceed toward regional population assessments.*

9.4.3.6 WORK PLAN AND BUDGET REQUESTS FOR 2019-2020

The work plan for southern right whales not the subject of a CMP is given in Table 13.

Table 13.

Workplan for southern right whales that are not the subject of a CMP

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Southern right whales	Examine southern right whale demographic parameters across multiple calving grounds using a common modelling framework	Review progress		Complete comparison
Southern right whales	Plan right whale catch series workshop	Progress update	Organise catch series workshop	Workshop report

10. STOCKS THAT ARE OR HAVE BEEN SUGGESTED TO BE THE SUBJECT OF CONSERVATION MANAGEMENT PLANS (CMPs)

10.1 Stocks with existing CMPs

This item covers stocks (with a focus on progress with scientific work and information) that are either: (1) the subject of existing CMPs; or (2) are high priority candidates for a CMP. It also considers stocks that have previously been considered as potential CMPs, recognising that the Commission has stressed the need for Range States to support any IWC CMPs.

10.1.1 SE Pacific southern right whales

10.1.1.1 NEW INFORMATION

The Committee received information on advances with respect to sightings (SC/67b/CMP20) and acoustic monitoring (SC/67b/CMP08; SC/67b/CMP18) of the critically endangered population of SE Pacific southern right whales. This information is discussed in detail in Annex O (item 2.1.1). Four confirmed observations were made off Chile in 2017 (three opportunistic sightings and one entangled carcass) and there was another, as yet unconfirmed sighting involving adults and calves. Analysis to date of acoustic data collected off the southwestern tip of Isla de Chiloe in 2012 has provided valuable new information about call parameters and patterns.

10.1.1.2 PROGRESS WITH THE CMP

The Committee received information on progress in implementing priority actions of the CMP (SC/67b/CMP20) as discussed in Annex O (item 2.1.1.2).

This progress includes:

(1) deployment of Passive Acoustic Monitoring (PAM) devices along the coast of Chile and Peru (SC/67b/CMP18) in two locations that will also be used as the focus of educational and capacity-building activities in communities near the monitoring sites;
(2) additional capacity-building and awareness efforts (including posters, press releases and social media) including advice on how fishermen and the public can provide information to the national sighting network; and
(3) additional training towards increasing the capacity of range states to respond to entanglements.

Attention: SC, CC

The Committee ***reiterates*** *the importance of the CMP for the conservation of this critically endangered population of southern right whales in the southeastern Pacific,* ***welcomes*** *the progress being made in its implementation by Chile and Peru. It therefore:*

(1) ***commends*** *the scientific work and international co-operation being undertaken for the PAM project and looks forward to receiving the results of the acoustic studies such that future sighting surveys will be more informed and baseline information on the location of breeding grounds will be available; and*

(2) ***advises*** *that satellite imagery be explored as an additional means to inform the design of sighting surveys because it is likely that line-transect surveys would not successfully identify whales in some areas even if they were present.*

10.1.2 Southwestern Atlantic southern right whales

10.1.2.1 NEW INFORMATION

The Committee was pleased to receive a considerable amount of new information on the southwest Atlantic population of southern right whales; this is fully discussed in Annex O (item 2.1.2.1).

With respect to abundance, SC/67b/CMP/05 suggested that although the population has continued to increase, the rate may have been slowing, perhaps as a consequence of changes in distribution due to density-dependence processes (SC/67b/CMP02).

The Committee has for some time been focussing on the die off at Peninsula Valdes (e.g. IWC, 2011; 2015) and the excellent work of the Southern Right Whale Health Monitoring Program. New and updated information was presented this year on strandings and investigations related to health including examination of levels of stress hormones in baleen and kelp gull attacks (SC/67b/CMP04) and nutritional condition (SC/67b/CMP03). This work is ongoing.

Information was received on telemetry studies (one animal in 2016 and 8 in 2017) as part of an ongoing long-term study to understand the migratory routes and destinations of southern right whales wintering off the coast of Argentina (SC/67b/CMP17. Tracks reveal that these animals are found across a vast extent of the South Atlantic and each season visit multiple potential feeding areas.

The Committee also received the report of a land-based survey of whales near Miramar on the southwest coast of the Buenos Aires Province, Argentina, where there has been a recent expansion of right whales into the region where they have been seen from May to October with peaks in August and September (SC/67b/CMP21).

Attention: SC, G

The Committee ***reiterates*** *the importance of continued monitoring of the southwestern Atlantic population of southern right whales and research into threats that it may face. The Committee therefore:*

(1) ***commends*** *the work being undertaken on understanding the mortality events and* ***encourages*** *its continuation;*
(2) ***encourages*** *the researchers working on stress hormones in baleen to increase their sample size, consider suggestions for additional studies provided in Annex O (item 2.1.2.1) and present a full report to the Committee when it becomes available;*
(3) ***commends*** *the telemetry work,* ***encourages*** *its expansion and draws attention to additional analyses that could be addressed using the telemetry data suggested in Annex O (item 2.1.2.1).*

10.1.2.2 PROGRESS WITH THE CMP

The overall objective of the southern right whale CMP is to protect their habitat and minimise anthropogenic threats to maximise the likelihood that the population will recover to healthy levels and recolonise its historical range. The Committee was pleased to receive information on progress with the actions of the CMP from Argentina (SC/67b/CMP14), including the work described under Item 10.1.2.2, and Brazil (Annex O, appendix 2). Work in Brazil includes long-term monitoring via sightings and strandings networks, mitigation of entanglements and the development of a management plan for whalewatching (see Annex O, item 2.1.2.2).

Attention: SC, CC

The Committee ***reiterates*** *the importance of the CMP for the conservation of the southwestern Atlantic population of southern right whales. The Committee therefore:*

(1) ***welcomes*** *the progress being made in the implementation of the CMP reported by Argentina and Brazil and supports its continuation;*
(2) ***encourages*** *the continued co-operation and collaboration amongst range states towards implementing the CMP and addressing mortality evens in this population; and*
(3) recognising the report of a ship-struck southwestern Atlantic southern right whale in the range of the southeastern Pacific (Estrecho de Magallanes), ***encourages*** *co-operation with those involved in the southeastern Pacific CMP to facilitate a regional assessment; and*
(4) ***encourages*** *the research work identified under Item 10.1.2.1.*

10.1.3 North Pacific gray whales

10.1.3.1 RANGEWIDE ASSESSMENT

Donovan summarised the report of the Fifth Rangewide Workshop on the Status of North Pacific Gray Whales (SC/67b/Rep07) held at the Granite Canyon Laboratory, California of the Southwest Fisheries Science Center from 28-31 March 2018. The primary tasks of the workshop were to (a) review the results of the modelling work identified at the fourth rangewide workshop (IWC, 2018a) and the 2017 Scientific Committee meeting (IWC, 2018b), (b) examine the new proposed Makah Management Plan (submitted by the USA – given as Annex E, Appendix 1) for gray whaling off Washington state and (c) to update as possible, and develop a workplan for, updating the scientific components of the Conservation Management Plan (CMP) for western gray whales.

A full discussion of the workshop can be found in Annex O (item 2.1.3.1). The Workshop finalised its work on (a) prioritising stock structure hypotheses, (b) finalising inputs for the modelling work especially related to bycatch; and (c) incorporating the Makah Management Plan (SC/67b/Rep07, Annex E, Appendix 1) into the modelling framework.

Two stock structure hypotheses (3a and 5a) were given priority whilst others were used in sensitivity tests. In summary, Hypothesis 3a assumes that whilst two breeding stocks (Western and Eastern) may once have existed, the Western breeding stock is extirpated. Whales show matrilineal fidelity to feeding grounds, and the Eastern breeding stock includes three feeding aggregations: Pacific Coast Feeding Group (PCFG), Northern Feeding Group (NFG), and the Western Feeding Group. Hypothesis 5a assumes that both breeding stocks are extant and that the Western breeding stock feeds off both coasts of Japan and Korea and in the northern Okhotsk Sea west of the Kamchatka Peninsula. Whales feeding off Sakhalin include both whales that are part of the extant Western breeding stock and remain in the western North Pacific year-round, and whales that are part of the Eastern breeding stock and migrate between Sakhalin and the eastern North Pacific.

In discussion of the report and intersessional progress, the Committee thanked Donovan, Punt and the participants for the progress made, approved the conditioning results developed after the workshop, noted the preliminary results from the modelling and agreed a strategy for obtaining conservation advice (see recommendation below under Item 10.3). The management implications of the results for the Makah Management Plan are found under Item 7.1.3.

10.1.3.2 REGIONAL STUDIES

The Committee was pleased to receive recent information from long-term studies in the breeding lagoons of Mexico (SC/67b/CMP09) as discussed in Annex O (item 2.1.3.1.1).

The Committee received several updates on work undertaken in the Russian Federation (see Annex O, item 2.1.3.2). It welcomed the annual update of activities from the IUCN Western Gray Whale Advisory Panel (see Annex O, appendix 3) which highlighted work to develop a monitoring and mitigation plan for a 2018 seismic survey being undertaken near the feeding grounds off Sakhalin Island, Russia and issues related to fishing gear. SC/67b/CMP07 updated findings from the long-term monitoring programme carried out by the Russian Gray Whale Project off Sakhalin Island, Russia. The research programme run in the same area by two oil companies was presented in SC/67b/ASI04 and discussed in Annex S (item 4.2).

The recent status of conservation and research on gray whales in Japan was reported in SC/67b/CMP12. During May 2017-April 2018, no anthropogenic mortalities were reported from the adjacent waters off Japan, while two opportunistic sightings of gray whales were made near Aogashima Island in May 2017 and February 2018.

Finally, SC/67b/CMP11 reported on the possible occurrence of a gray whale off the east coast of Korea; work is continuing to try to confirm the species identification; if confirmed it will be the first record in these waters in over 40 years.

Attention: CG-R, SC, G

The Committee ***reiterates*** *the importance of long-term monitoring of gray whales,* ***recommends*** *that range states support such work and* ***welcomes*** *the information provided this year. In particular, the Committee:*

(1) ***commends*** *the work in the breeding lagoons and urges its continuation;*
(2) ***encourages*** *an additional calf-count survey for Punta Banda to address apparent differences in numbers of calves observed in the lagoons with counts from California;*
(3) ***reiterates its concern*** *at the risk of whales becoming entangled in gear placed by the salmon trap-net fishery off Sakhalin Island, recognises that disentanglement training has occurred but* ***recommends*** *that measures to be taken to reduce risk;*
(4) ***encourages*** *continued genetic analyses to assist in stock structure discussions especially related to a western breeding stock;*
(5) ***welcomes*** *the continued provision of information from Japan and* ***encourages*** *researchers to continue to collect as much information on sightings as possible, including, if feasible, attempting to obtain biopsy samples; and*
(6) ***welcomes*** *the information from Korea and the willingness of researchers to investigate sightings from social media as a form of 'citizen science', which can be especially valuable for areas where occurrence is very rare animals in areas with little to no information on critically endangered species.*

10.1.3.3 PROGRESS WITH THE CMP

As noted above, one of the objectives of the fifth rangewide workshop was to progress work with updating the scientific components of the original IWC/IUCN CMP in the light of the results of the rangewide review. Although some work was undertaken, there was insufficient time at the workshop to complete this although a workplan to achieve it was suggested (see SC/67b/Rep07). The Committee concurred with this view and this is incorporated into the workplan below.

Another important component of the CMP effort is the need for a stakeholder workshop (tentatively forecast to occur in 2019) to finalise the CMP and develops a strategy for its implementation. The plan is for a workshop, co-sponsored by IWC, IUCN and the signatories to the Memorandum of Cooperation, to: (1) review and updating of the CMP; (2) establishing a stakeholder Steering Group to monitor CMP implementation, (3) arrange for a coordinator of the CMP and (4) establish a work plan and consider funding mechanisms to implement the actions of the plan.

Attention: C-A, CG-R, CC, SC

The Committee ***reiterates*** *the importance of the CMP for the conservation of western gray whales. The Committee therefore:*

(1) ***recognises*** *the tremendous work undertaken in the rangewide assessment and the value of the modelling framework developed;*
(2) ***agrees*** *that the next part of the process is to develop conservation-related questions and to use the framework to address these with a view to examining results at SC68a;*
(3) ***agrees*** *that a small group meeting (see Item 27) attended by at least the national co-ordinators of the Memorandum of Co-operation on gray whales, Reeves, Punt and Donovan be held to: (a) draft an update to the CMP; and (b) identify conservation-related questions to be addressed by the modelling framework and to present results at SC68a;*
(4) ***requests*** *those signatories to the Memorandum of Co-operation on western gray whales who have not yet named a national co-ordinator to do so promptly; and*
(5) ***supports*** *the holding of a stakeholder workshop in 2019 co-sponsored by the IWC, IUCN and the states that have signed the Memorandum of Co-operation and* ***welcomes*** *the valuable assistance of IUCN in organising the workshop.*

10.1.4 Franciscana

10.1.4.1 NEW INFORMATION

The Committee received valuable new information on franciscana at this meeting related to fisheries and bycatch from five localities in North Espírito Santo State, Brazil (SC/67b/SM30) – bycatches of Guiana dolphins was also reported. Additional information was presented assessing fisheries that operate in Fisheries Management Area (FMA) Ib for their compliance with Brazilian ordinance (IN) 12 (e.g. with respect to gill-net regulations and no-take zones) and risk of bycatch (SC/67b/SM05) – compliance was limited and enforcement poor. Both projects were funded by the IWC Small Cetacean Fund and the Government of Italy. This information is discussed in Annex O (item 2.1.4.1) and a related recommendation is given under Item 10.4.2.2.

10.1.4.2 PROGRESS WITH THE CMP

The overall objective of the CMP, submitted by Argentina, Brazil and Uruguay (IWC/66/CC11) and adopted in 2016, is to protect franciscana habitat and minimise anthropogenic threats, especially bycatch. It includes seven high priority actions, ranging from public awareness and capacity building through research to mitigation. Coordination with Uruguay to implement the CMP in this area will be initiated during a workshop that will take place in May 2018 with the main stakeholders (SC/67b/CMP16). The CMP is funded by the IWC CMP Voluntary Funds and the World Wildlife Fund.

Attention: CG-R

The Committee ***emphasises*** *the importance of the CMP for the conservation of franciscana in the waters of Argentina, Uruguay and Brazil. The Committee therefore:*

(1) ***stresses*** *the value of the actions included in the CMP towards future assessments of the status of franciscana, which is imperative for determining the effectiveness of conservation efforts;*
(2) ***recommends*** *that research be undertaken to estimate the abundance of franciscana dolphin off Buenos Aires province, Argentina; and*
(3) ***recommends*** *that additional research be undertaken to determine the effectiveness of management measures, such as that described in SC/67b/SM05 for other ports (e.g. Macaé, Tamoios (Cabo Frio) and Armação dos Búzios – the fishery in Tamoios coincides with a high diversity of marine megafauna).*

The Committee established an intersessional correspondence group that will help co-ordinate the presentation of CMP projects for this species across sub-committees at SC/68a (Annex Y).

10.2 Progress with identified priorities

10.2.1 Humpback whales in the northern Indian Ocean including the Arabian Sea

10.2.1.1 NEW INFORMATION

The Committee received several papers that improved knowledge of Arabian Sea humpback whales and a full discussion can be found in Annex O (item 2.2.1). It welcomed the information on the progress of work being undertaken by the Arabian Sea Whale Network (ASWN) formed in 2015 (SC/67b/CMP10). The ASWN is an informal collaboration of researchers, consultants and conservation and governmental organisations interested in the conservation of whales in the Northern Indian Ocean. A primary goal of the ASWN is to promote and foster research and collaboration in previously unsurveyed parts of the Arabian Sea humpback whales' suspected range, as well as in Oman where surveys have been conducted since 2000. Work has focused on collecting data on whale distribution and status (including through increased awareness and an observer programme – described in SC/67b/CMP15)), the introduction and implementation of a regional online data platform (SC/67b/PH03) and providing updates on research activities in Oman, India, Pakistan and Sri Lanka (SC/67b/INFO07). Two marine protected areas have been established in Pakistan (Astola Island and Indus Canyon).

Madhusudhana *et al.* (2018) reported on and compared humpback whale songs recorded off India, Oman, Reunion Island and Comoros Islands in the southwest Indian Ocean. The results highlighted (a) the distinct nature of the Arabian Sea population and (b) that SW Indian Ocean whales may move into the Arabian Sea more commonly than previously thought.

SC/67b/CMP13 reported on a humpback whale tagged off Oman that moved to the southern tip of India and back again - the first recorded movement of a whale across the Arabian Sea. Four additional satellite tags were deployed where the whales remained over the continental shelf of central and southern Oman.

Attention: G, SC

The Committee ***welcomes*** *the new information from the region on this critically endangered population and* ***commends*** *the researchers for their initiatives and collaborative efforts. In light of the information presented, the Committee:*

(1) ***encourages*** *the collection of genetic information which would be helpful for identifying stock structures within the area;*
(2) ***recommends*** *future use of unoccupied aerial systems to (i) measure whale health, (ii) develop long-term health metrics, (iii) compare body condition to stock C in the Southern Hemisphere, which is the presumed 'source' population for whales in the Arabian Sea and (iv) assess for evidence of anthropogenic threats;*
(3) ***commends*** *the use of fishing crew as observers and* ***advises*** *that the crew-based observer programme continue, recognising that it is not clear if the timing of the sightings reflects the seasonal distribution of whales or the seasonal nature of fishing effort and* ***encourages*** *future research to tease apart timing of the distributions using targeted surveys;*
(4) ***advises*** *that capacity building for local scientists be continued such that surveys can be deployed in suspected areas of humpback whale distribution and data can be gathered for future assessments;*
(5) ***advises*** *the continuation of monitoring songs of Arabian Sea humpback whales and that additional data sets be acquired comparison purposes, particularly from the southwest Indian Ocean, if they exist, to further (i) detect the movement of southwestern Indian Ocean animals in Boreal winter, (ii) document potential diffusion of southwestern Indian Ocean song, (iii) provide a long-term data set for the comparison of songs across Oman, Pakistan and India to assess continuity of whales in the Arabian Sea and (iv) evaluate the unprecedented temporal stasis of song in the Arabian Sea; and*
(6) ***agrees*** *that an intersessional correspondence group (Annex Y) be formed to review the methods used for the preliminary estimates of abundance, in order to increase their robustness by taking into account the non-random survey approach that violates some key assumptions of mark-recapture models.*

10.2.1.2 PROGRESS WITH INTERNATIONAL CO-OPERATION AND REGIONAL MEASURES SUCH AS CMPS

A Concerted Action for Arabian Sea humpback whales under the Convention on Migratory Species (CMS; SC/67b/INFO06) was drafted and passed with wide support from Arabian Sea range states at the CMS COP in October 2017. It is hoped that this Concerted Action can be implemented in conjunction with a CMP as a means to translate current research and conservation efforts and plans into concrete, government-supported conservation measures in Arabian Sea humpback whale range states.

Attention: *C-A, S*

The Committee ***reiterates*** *its serious concern about the status of the endangered Arabian Sea humpback whale population and the anthropogenic threats it faces. It therefore:*

(1) ***commends*** *efforts to develop the Concerted Action under the CMS, noting that it covers many of the elements required for a CMP;*
(2) ***stresses*** *the value of regional initiatives and* ***encourages*** *range states to explore future sources of collaboration; and*
(3) ***encourages*** *continued efforts between range states and Secretariats to work toward a joint CMS-IWC CMP.*

10.2.2 Mediterranean fin whales

The ACCOBAMS Meeting of Parties has endorsed the development of a CMP, ideally jointly with the IWC, for fin whales in the Mediterranean Sea. A small group will meet in the summer of 2018 to draft an outline for a CMP that can be presented at SC/68a. ACCOBAMS is also considering the development of CMPs for other species in the region.

10.2.3 South American River Dolphins

Advice was sought regarding the development of a CMP for South American river dolphins, which currently have several actions plans endorsed by various range states.

Attention: CG-A

The Committee ***advises*** *that the applicable range states work towards developing a draft CMP for presentation at SC/68a.*

10.3 Workplan 2019-20

The workplan on matters related to stocks that are or might be the subject of CMPs is given as Table 14.

Table 14

Summary of the work plan on conservation management plans.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Southeast Pacific right whales	.	Review progress with scientific aspects of the CMP		Review progress with scientific aspects of the CMP
Southwestern Atlantic right whales		Review progress with scientific aspects of the CMP		Review progress with scientific aspects of the CMP
Gray whales	Hold workshop on scientific aspects of CMP and use of modelling framework.	Review results and provide advice on scientific aspects of CMP	Stakeholder workshop	Review scientific aspects of results of stakeholder workshop
Franciscana		Pre-assessment for in-depth review		Continue pre-assessment and develop plan for in-depth assessment
Humpback whales in Northern Indian Ocean	Intersessional email group (Annex Y) on abundance estimates	Review new information and progress towards CMP		Review new information and progress towards CMP
Mediterranean fin whales	Develop outline draft	Review draft and progress towards CMP		Review progress towards CMP
South American river dolphins		Review new information and progress towards CMP		Review new information and progress towards CMP

11. STOCK DEFINITION AND DNA TESTING

This agenda item merges two previously separate sub-groups, the Working Group on Stock Definition and the Working Group on DNA. During SC67b, the Stock Definition and DNA Testing Working Group assessed genetic methods used for species, stock and individual identification, including matters associated with the maintenance of DNA registers (see 11.1); continued to develop and update guidelines for preparation and analysis of genetic data within the IWC context (see 11.2); and provided the Committee with feedback and recommendations concerning stock structure related methods and analyses (see 11.4), including those relevant to other sub-committees (see 11.3). The Report of the Working Group is given as Annex I.

11.1 DNA testing

This item has been considered since 2000 in response to a Commission Resolution (IWC, 2000).

11.1.1 Genetic methods for species, stocks and individual identification

The Committee received two papers relating to the use of genetic methods for species, stock and individual identification. The first paper (Carroll *et al.*, 2018) provided a review of how technological advances, particularly those associated with the development of high throughput sequencing (HTS) technology, can aid in genetic monitoring. Of particular interest to the Committee was discussion of targeted capture approaches that allow for microsatellite genotyping via HTS (e.g. De Barba *et al.*, 2017). Much of the past genetic work has relied on generating microsatellite datasets, including the work to maintain DNA registries of bycaught or direct catches (see Items 11.1.2 and 11.1.3). These 'legacy' datasets may include microsatellite genotypes for thousands of individuals. While technical challenges exist, microsatellite genotyping via HTS could 'bridge the gap' by maintaining the utility of these legacy datasets while also taking advantage of the newer HTS approaches.

The second paper (Baker *et al.*, In press) presented the results of a study confirming the potential to detect environmental DNA (eDNA) in seawater collected from the wake of killer whales. This is a new approach for detecting and identifying cetacean species, including those that may be elusive to study using other methods. Although eDNA has been more broadly used to detect the occurrence of species in an area (i.e. DNA barcoding), it could provide sequence data useful for stock-level identifications of cetaceans under certain circumstances (e.g., when a single animal is present). It was noted, however, that its utility in addressing questions requiring individual identification via multi-locus genotyping is, at least currently, limited for scenarios in which the water sample could contain DNA from multiple individuals.

Attention: SC

The Committee ***welcomes*** *the opportunity to review papers that take advantage of technological advances to improve the ability to detect and identify species, stocks, and individual cetaceans. It* ***encourages*** *the submission of similar papers in the future and recognises the relevance of these techniques to the Committee's work.*

11.1.2 'Amendments' of sequences deposited in GenBank

While *GenBank*[7] is an important scientific resource, it is an uncurated database of DNA sequences and thus contains sequences that are misidentified or have other annotation problems. While retaining the 'raw data' represented in *GenBank* is valuable, less-experienced users may be unaware that additional sequence validation may be needed when incorporating *GenBank* sequences into a study. The Committee has agreed (IWC, 2018c, p. 228) that its revised DNA quality guidelines will contain a section discussing the precautions that should be taken when including GenBank sequences in a study. This text has been drafted and will be incorporated into the revised guidelines (see Item 11.2).

11.1.3 Collection and archiving of tissue samples from catches and bycatches and
11.1.4 Reference databases and standards for diagnostic DNA registries

The Committee previously endorsed a new standard format for the updates of national DNA registers to assist with the review of such updates (IWC, 2012a, p. 53), and the new format has worked well in recent years. This year, the update of the DNA registers by Japan, Norway and Iceland were based again on this new format. Details are given in Annex I (appendices 2-4) for each country, covering the period up to and including 2017. Almost all samples in the three registries have been analysed for microsatellites, and work on unanalysed samples is continuing. Almost all samples in the registries of Japan and Iceland have also been analysed for mtDNA.

During last year's discussion of the Norwegian minke whale DNA register (IWC, 2018c, p. 228-229), the Committee was informed that mtDNA analysis on Norwegian samples had been discontinued and that microsatellite typing would eventually be replaced by SNP analysis. The Committee had expressed concern regarding the comparability of the DNA registers in the future. This year, the Committee noted that Norway had discontinued mtDNA typing of samples and substituted it with SNP genotyping.

Attention: CG-A

The Committee ***expresses appreciation*** *to Japan, Norway and Iceland for providing updates to their DNA registries using the standard format agreed in 2011 and providing the detailed information contained in their DNA registries.*

11.2 Guidelines and methods for genetic studies and DNA data quality

Two sets of guidelines have been developed for reference in the Committee's discussions of stock structure. The most recent version of the guidelines for genetic data analyses are in press with the Commission's *Journal of Cetacean*

[7] https://www.ncbi.nlm.nih.gov/genbank/

Research & Management. The DNA data quality guidelines address DNA validation and systematic quality control in genetic studies, and are currently available as a 'living document' on the IWC website[8]. In recent years, it has become common for the Committee to review papers using data derived from Next Generation Sequencing (NGS) approaches, including SNPs, to address stock structure questions (see Item 11.3).

Attention: SC

The Committee ***emphasises*** *the importance of keeping its guidelines related to genetic data quality and analyses up to date. It therefore:*

(1) ***reiterates*** *the need to update these guidelines to incorporate the discussion of data quality measures used for Next Generation Sequencing data; and*
(2) ***agrees*** *to continue the intersessional correspondence group (Annex Y) to review revised sections of the DNA data quality guidelines that apply to data generated from next generation sequencing platforms, including SNPs and whole genome sequencing, with the goal of posting an updated version of the guidelines on the website next year.*

11.3 Provide advice on stock structure to other sub-groups
The Working Group on Stock Definition and DNA also has the task of discussing high-priority stock related papers from other sub-committees and working groups to provide them with stock structure related feedback and recommendations. These discussions often refer to the genetic analysis guidelines and genetic data quality documents.

The discussions (see Annex I for details) are summarised under the relevant stock agenda items in this report. Two, more general issues arose from discussions of Southern Hemisphere stocks and North Atlantic common minke whales. These are considered below.

11.3.1. Southern Hemisphere whale stocks and use of samples
The Committee reviewed the results of genetic analyses of Southern Hemisphere whale stocks, including Southern Hemisphere blue, fin, right and sei whales. These results highlighted the value of existing collections of tissue samples to address stock structure questions.

Attention: SC

In reviewing the results of stock structure analyses of Southern Hemisphere whale stocks, the Committee expresses ***concern*** *regarding the depletion of tissue samples in existing collections (including those collected during the IWC SOWER surveys, although the Steering Group does take this into account when reviewing requests). Given recent advances in high throughput sequencing technology, the Committee* ***agrees*** *that an intersessional correspondence group (Annex Y) should be formed to provide recommendations on genomic approaches to maximise the utility of these samples for future studies.*

11.3.2. North Atlantic common minke whales
The Committee reviewed the results of genetic analyses pertaining to the stock structure of North Atlantic minke whales (SC/67b/Rep06). The analyses presented involved the use of a new approach to evaluate stock mixing proportions by (1) identifying a 'reference' year in which mixing of stocks was considered low based on a lack of heterogeneity in genetic characteristics estimated for each area, and (2) using principal component analysis of the genetic data to assign stock affinities in the non-reference years based on proximity to mean values in the reference year.

Attention: SC, C-A

The Committee reviewed the use of a new approach that used ordination analyses of genetic data to assign stock mixing proportions. Recognising that this new approach requires making certain assumptions about the data, the Committee:

(1) ***agrees*** *that the inference of mixing rates was informative for AWMP/RMP simulation trials in the absence of empirical data; and*
(2) ***encourages*** *the attempt to use genetic data to estimate mixing rates in the context of other IWC-related tasks.*

11.4 New statistical and genetic issues relating to stock definition
11.4.1. Simulation tools for spatial structuring
TOSSM was developed with the intent of testing the performance of genetic analytical methods in a management context using simulated genetic datasets (Martien *et al.*, 2009), and more recently the TOSSM dataset generation model has been used to create simulated datasets to allow the plausibility of different stock structure hypotheses to be tested (Archer *et al.*, 2010; Lang and Martien, 2012). The Working Group noted that while TOSSM has been particularly valuable in

[8] http://iwc.int/scientific-committee-handbook#ten

informing the interpretation of results of stock structure related analyses, it has not been broadly used within the IWC Scientific Committee for this purpose.

In recent years, a wide-range of software packages have become available for producing simulated datasets that can be used for statistical inference and/or validating statistical methods (Hoban, 2014, and see ; IWC, 2017c p.44), and in 2016 the Committee agreed to expand this item (formerly specific to TOSSM) to include a broader range of tools (IWC, 2016c p.44).

Attention: SC

*The Committee noted that while simulation-based approaches have been particularly valuable in informing the interpretation of results of stock structure-related analyses, they have not been broadly utilized within the Committee for this purpose. The Committee **agrees**:*

(1) to continue an intersessional review via an email correspondence group (Annex Y) of the available simulation tools and their potential utility to the Committee; and
(2) to consider bringing in invited expertise to present an overview of the applicability of such approaches in order to expedite progress on this agenda item.

11.4.2. Terminology
Defining and standardising the terminology used to discuss 'stock issues' remains a long-standing objective of the Working Group, in order to help the Committee report on these issues according to a common reference of terms (IWC, 2014 p.287-8). At SC67b, the status of the existing draft glossary on key terms related to stock definition was revisited.

Attention: SC

*The Committee **agrees** to establish an intersessional correspondence group (Annex Y) to revisit terminology with specific reference to the implications of inferred stock structure in other sub-committees, particularly those that deal with large whale assessments, and suggest revisions where appropriate for consideration at SC68a.*

11.4.3. Close-kin mark-recapture
An overview of the close-kin mark-recapture (CKMR) approach (Bravington *et al.*, 2016) was presented to the Committee last year (IWC, 2018c p.40). CKMR uses multi-locus genotyping to find close relatives among tissue samples from dead and/or live animals; the number of kin-pairs found, and their pattern in time and space, can be embedded in a statistical mark-recapture framework to infer absolute abundance, parameters like survival rate, and stock structure. No papers applying the CKMR approach were reviewed by Committee this year, although the value of integrating data from epigenetic aging (see 11.4.4) into CKMR was noted.

Attention: SC, G

*Given that close-kin mark-recapture has multiple applications that fall within the Committee's scope of work, the Committee **encourages** the submission of papers using this approach in the future.*

11.4.4. Epigenetic ageing
Information on estimated age of individuals can be used in many aspects of the Committee's work, including (1) discriminating between the parent and offspring among genetically identified parent-offspring pairs, which can inform both assessment of stock structure as well as genetic mark-recapture estimates of abundance (e.g. CKMR); and (2) integrating age information into the population modelling exercises integral to assessment work (e.g. on RMP implementation). Recently, epigenetic (DNA-methylation) ageing has been successfully used to estimate age in humpback whales (Polanowski *et al.*, 2014). This year, the Committee invited Jarman, the lead scientist on the humpback whale work, to give an overview presentation to the Committee. This session was organised as a special evening session in order to enable participation across sub-committees and Working Groups. He covered issues specific to age estimation in cetaceans, including how DNA methylation-based age estimation are likely to perform in cetaceans and what current and near-future prospects there are for this class of methods (see Annex I, item 5.5).

The Committee also reviewed the results of a study to evaluate the feasibility of using the DNA-methylation technique to estimate age in Antarctic minke whales (SC/67b/SDDNA04). This study was initiated in response to a recommendation made during the Expert Panel review of the NEWREP-A proposal (SC66A/REP06, p17). DNA-methylation rates were examined for seven methylation sites (CpG sites) within three genes, and regressions of each CpG methylation site against age determined by earplug were conducted. When all sites were incorporated, the assay predicted age from skin samples with a standard deviation of about 8.9 years. While some sites showed age-related effects, others did not show such correlation. Thus, using only those loci that appear to have an age-related effect might reveal a stronger relationship between methylation rates and age.

During the discussion (Annex I, item 5.5) it was noted that the humpback whale age assay, which used the same sites, reports a precision of 2.99 years, measured as the average of the absolute values of the differences between known and estimated ages (Polanowski *et al.*, 2014). During the presentation, the precision as measured by the standard deviation for absolute age prediction was reported as 4.8 years. That was a preliminary study demonstrating the fundamental feasibility of this approach, and is not as accurate or precise as tests developed for humans and mice based on analysis of many more CpG sites. While precision is expected to improve with the inclusion of more CpG sites, the maximum precision possible for any DNA methylation-based age estimator is likely limited by the imperfect relationship between chronological age and biological age. To date, that precision has ranged from 3.9% in humpback whales (Polanowski *et al.*, 2014 assuming a 95-year lifespan), to 3.2% of lifespan in humans (e.g. Horvath, 2013) and 1.7% of lifespan in mice (Stubbs *et al.*, 2017). These observations indicate that the SD and 95% CI for age estimation described in Polanowski *et al.* (2014) and in SC67b/SDDNA04 could be substantially improved before an inherent limit is reached. These precision estimates adhere to age determination in individual specimens. Hence, averaged age estimates over cohort will improve over larger sample sizes and may be more precise.

The Committee noted that the implications of this upper limit on precision in estimating age for individuals would need to be evaluated in the context of the specific application for which the age data were being used. For example, although additional precision is helpful, CKMR studies may be informed by relatively crude estimates of age allowing the parent to be discriminated from the offspring (i.e. ordinal age).

Attention: SC

The Committee welcomed the results of the study to evaluate the feasibility of using epigenetic techniques to estimate age in Antarctic minke whales and ***agrees****:*

(1) that the current set of loci did not provide sufficient precision for use in the population dynamics modelling exercise recommended for NEWREP-A; and
(2) that identification of additional sites with an age-related DNA-methylation pattern is encouraged, as it would likely allow more precise estimates of age to be made in the future; and
(3) given that there is an upper limit to the degree of precision that can be achieved using this technique, the utility of epigenetic age estimation to the Committee should be further evaluated by the sub-committees concerned with regard to the degree of precision needed for the specific application of interest.

11.5 Workplan 2019-20

The details of the workplan are given in Table 15.

Table 15

Workplan on topics related to genetics.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
3.1 DNA quality guidelines	Intersessional group (Annex Y) to review recent revisions to the DNA quality guidelines that pertain to data produced using NGS approaches.	Report and finalise updated guidelines		
4.4.2 Recommendations to avoid sample depletion	Intersessional email group to provide recommendations on genomic approaches to maximize the utility of tissue samples that are in danger of becoming depleted in the future.	Report and provide advice		
4.5 North Pacific minke whale stock structure	Perform genetic analyses detailed in Appendix 5; report results at intersessional workshop on the North Pacific minke whale IR.	Review results and provide advice		
5.1 Simulations	Intersessional email group to review software packages and evaluate utility to the Committee.	Report	Continue as needed	Report (if needed)
5.3 Terminology	Intersessional email group to continue discussions of the use of stock structure-related terms within the Committee.	Report	Continue as needed	Report (if needed)

12. CETACEAN ABUNDANCE ESTIMATES, STOCK STATUS

The Committee received new information from the Standing Working Group on Abundance Estimates, Status and International Cruises (ASI) that had been established (IWC, 2017c, p. 94) to formally review and agree on the status of the abundance estimates submitted to the Scientific Committee across all of the Committee's sub-committees and working groups. It also assists the Committee and the Secretariat in developing a biennial document reporting to the Commission on the abundance and status of whale stocks.

12.1 Summary of abundance estimates and update of IWC consolidated table

Appendix 3 of Annex Q provides detailed information about abundance estimates agreed by the Committee, including estimates received prior to and during 2017, as well as ones evaluated this year. The Secretariat maintains a consolidated table.

Broadly, cetacean abundance estimates are usually obtained in one of three ways. Line transect surveys require observers on ships or aircraft to detect animals while the observers are traveling on paths traversing the survey area. Statistical methods are used to estimate how many animals were not seen, usually by evaluating how detection deteriorates as sighting distance increases and by extrapolating to survey areas beyond visual detection distance. Mark-recapture studies require multiple attempts to 'capture' individuals that are mixing between attempts. For cetaceans, individual animals are usually identified - and hence 'captured'- on the basis of matching photographs of whale markings, or by genetic analysis of biopsy samples of live animals. Statistical methods are used to estimate how many animals were never captured, based on information about the probability of capture, which is inferred from instances when the animal was sometimes captured and sometimes not. Population model based abundance estimates use information from a variety of sources to build a mathematical model of how a population changes over time. Important data and parameters in such models include survival rates, productivity rates, and previous abundance estimates. By fitting (and possibly projecting) this model, an estimate of current abundance is achieved.

Many sophisticated abundance estimation methods are hybrids or extensions of these basic approaches.

This year, the Committee **endorses** the following:

(1) a photo-id mark-recapture estimate of 2011 abundance for Bering-Chukchi-Beaufort Seas bowhead whales;
(2) an aerial line transect estimate of 2013 abundance of East Canada / West Greenland bowhead whales;
(3) aerial line transect estimates of 2015 abundance of East Greenland and West Greenland North Atlantic humpback whales;
(4) ship-based line transect abundance estimates of North Atlantic humpback whales in Iceland/Faroe Islands in 2007 and 2015;
(5) aerial line transect abundance estimates of East Greenland (2015) and West Greenland (2007 and 2015) North Atlantic minke whales;
(6) ship-based line transect abundance estimates of North Pacific Bryde's whales for several areas and time periods;
(7) aerial line transect abundance estimates of East Greenland (2015) and West Greenland (2005, 2007 and 2015) North Atlantic fin whales; and
(8) genetic mark-recapture abundance estimates for Maui's dolphins in New Zealand for several years.

Table 16 summarises key information about the **agreed** abundance estimates. Full details are given in Annex Q (item 3 and appendix 3).

Attention: SC, S, C-A

Abundance estimates are a key parameter in determining status. The Committee:

(1) ***endorses*** the new abundance estimates *presented in Annex Q, Appendix 3 for inclusion in the IWC Table of Accepted Abundance Estimates;*
(2) ***agrees*** *that they should be incorporated into that table and uploaded to the IWC website; and*
(3) ***agrees*** *that the table should continue to be updated intersessionally by the Steering Group (Annex Y).*

12.2 Process to review abundance estimates

Abundance estimates are needed to assess the status of cetacean populations and are used extensively by the Committee, including for providing management advice. These estimates are often computed by standard, but technically advanced methods. In addition, because of the high scientific standards found within the Committee's work, it is not uncommon for the Committee to receive estimates of abundance computed using novel methods and non-standard software/code. The review of these estimates can be complex and time consuming. At last year's meeting, the Committee noted that adequate time is needed to review abundance estimates and agreed that a process to facilitate the review of these estimates be developed (IWC, 2018c). In addition, the Committee noted that reviews would benefit if minimum requirements for the presentation of abundance estimates are established.

Table 16

Abundance estimates, CVs and 95% confidence intervals for estimates agreed at the 2018 meeting.

Whale and Region	Year	Estimate	CV	95% Confidence Interval
North Pacific Bryde's whales				
Area 1W	1995	12,149	0.41	5,579-26,454
	2000	6,894	0.47	2,872-16,549
	2011	25,158	0.38	12,202-51,872
Area 1E	1995	15,695	0.42	7,079-34,801
	2000	19,200	0.56	6,929-53,204
	2011	9,315	0.33	4,957-17-505
Area 2	1995	4,340	0.45	1,876-10,039
	2000	6,083	0.61	2,030-18,229
	2014	6,491	0.36	3,254-12,950
North Atlantic common minke whales				
East Greenland	2015	2,762	0.47	1,160-6,574
West Greenland	2007	9,066	0.39	4,333-18,973
	2015	5,095	0.46	2,171-11,961
North Atlantic fin whales				
East Greenland	2015	6,440	0.26	3,901-10,632
West Greenland	2005	9,800	0.62	3,228-29,751
	2007	15,957	0.72	4,531-56,202
	2015	2,215	0.41	1,017-4,823
North Atlantic humpback whales				
East Greenland	2015	4,223	0.44	1,845-9,666

This year, the Committee developed a process to improve the review of abundance estimates, including a prioritisation of the estimates according to the timeline they need to be used by the Committee. This process is described in detail in Annex Q, item 2.1. In addition, minimum requirements to present abundance estimates for review by the Committee were established. Details are given in item 2.2 of Annex Q.

The Committee noted that validation may be needed before estimates computed using novel methods and non-standard software are used to provide management advice (Annex Q, item 2.3). The Committee also noted the need to consider how estimates of abundance from population models are reviewed before they are included in the Table of Accepted Abundance Estimates (Annex Q, item 2.4).

Attention: SC, S

The Committee ***reiterates*** *the importance of using high quality, fully reviewed abundance estimates for its work. To achieve this the Committee* ***agrees****:*

(1) to adopt the process to improve the review of abundance estimates given in Annex Q (item 2.1);
(2) the minimum requirements for the presentation of estimates for review by the Committee given in Annex Q (item 2.2);
(3) to host a pre-meeting before next year's meeting (SC68a) to develop (a) a process to validate abundance estimates computed with non-standard methods, noting the value of simulated datasets in this process; (b) a process to review estimates of abundance computed with population models is needed.

12.3 Methodological issues

12.3.1 Model-based abundance estimates (and amendments to RMP guidelines)

The Committee noted that there was a need for RMP guidelines to be modified in order to incorporate spatial modelling approaches to estimate abundance.

Attention: SC

The Committee noted that whilst much progress has been made with respect to considering model-based estimates (IWC, 2016c), the 'Requirements and Guidelines for Conducting Surveys and Analysing Data within the Revised Management Scheme' need to be modified. The Committee ***agrees*** *that an intersessional steering group (Annex Y) will develop instructions and select a candidate to modify the Guidelines.*

12.3.2 Review new survey techniques/equipment

The Committee received information on the use of unmanned aircraft vehicles (UAVs) to improve estimation of abundance of river dolphins in the Amazon. Details are provided in Annex Q, item 5.

Attention: SC, G

*The Committee **looks forward** to receiving information on new survey technologies used to improve estimates of abundance of cetaceans.*

12.4 Consideration of the status of stocks

The Committee noted that further consideration on how to report status of cetacean stocks is needed.

Attention: SC

*The Committee **recognises** the need to further consider how to report status of stocks to the Commission in a consistent manner and **agrees** to address this topic at a pre-meeting to be held prior to next year's SC meeting (SC68A).*

12.5 Workplan 2019-20

The Committee **agrees** to the workplan given in Table 167

Table 17

Workplan on abundance estimates and status.

Topic	Intersessional 2018-19	SC68a	Intersessional 2019-20	SC68b
Review of Abundance Estimates	Review estimates identified at SC67B (New Zealand Blue Whales, Arabian Sea humpback whales) – Annex Y	Review intersessional progress and estimates available at SC68A	Review estimates identified at SC68A	Review intersessional progress and estimates available at SC68A
Upload the estimates accepted at the annual meeting to the IWC website and continue to update the IWC Abundance Table	Update the table with estimates accepted at SC67B (Annex Y)		Update the table with estimates accepted at SC67B	
Review and provide advice on plans for future surveys		Receive, review and provide feedback to research plans to conduct abundance estimates		Receive, review and provide feedback to research plans to conduct abundance estimates
Pre-meeting to consider: (a) validation of non-standard software and methods, (b) estimates of abundance computed from population models and (c) Status of populations	Meeting Preparation	Review of progress		
Amend the RMP Guidelines to consider abundance estimates computed with model-based methods.	Identify a candidate to update the RMP Guidelines (Annex Y)	Review an updated document of the Guidelines		
Develop simulation software to evaluate methods for abundance estimates		Review Progress		

13. BYCATCH AND ENTANGLEMENTS

13.1 Review new estimates of entanglement rates, risks and mortality (large whales)

The Committee received three papers relating to the bycatch of large whales. SC/67b/HIM03 provided information on stranded humpback whales stranded along the southeastern coast of Brazil in 2016 and 2017 including records of entanglements over the São Paulo coast. SC/67b/HIM09 focussed on ten baleen whale populations for which bycatch appears to be a component of substantial conservation problems and the authors categorised priorities for action. SC/67b/AWMP08 provided information on Bering-Chukchi-Beaufort Seas stock of bowhead whales. Discussion can be found in Annex J (item 2.1).

13.2 Reporting of entanglements and bycatch in National progress reports

Reports of large whale bycatch are summarised in Annex J (item 2.4) and the issue of partial reporting discussed. Issues related to reporting and progress reports is given under Item 3.2.

13.3 Mitigation measures for preventing large whale entanglement

Mattila, the IWC's technical advisor for reducing unintended human impacts, reported on relevant activities under the entanglement initiative. Details can be found in Annex J (item 2.5). Since last year's meeting, IWC entanglement trainings have been conducted in Sakhalin (Russia), Arica (Chile), Sortland (Norway) and Bahía Solan (Colombia). This brings the total number of trainees in this initiative to 1,130 from 27 countries. In addition, two apprentices were hosted this year, one from Chile and one from Oman. Mattila also presented the IWC's work with entanglement in two workshops at the Society for Marine Mammalogy Biennial conference (2017). The Committee thanked Mattila for his exemplary work in coordinating the Global Whale Entanglement Response Network.

13.4 Review proposal for global entanglement database

The Committee considered progress with the development of a dedicated entanglement database. This will be considered further at the June 2018 meeting of the Global Whale Entanglement Response Network (see Annex J, item 2.3).

13.5 Estimation of rates of bycatch, risks of, and mortality for small cetaceans

13.5.1 Small cetacean bycatches in Peru

The Committee received a report (SC/67b/HIM01) summarising monitoring efforts of beach-cast cetaceans in 11 locations along the Peruvian coast from 2000-2017. Full discussion can be found in Annex J (item 2.1.2) that showed clear evidence of continued high bycatch rates and some intentional takes. Burmeister's porpoises accounted for 66% of the specimens and the low proportion (25%) of dusky dolphins contrasted with 1985-1990 statistics, when dusky dolphins accounted for three quarters of all cetacean captures. This reiterated prior concerns (Van Waerebeek, 1994) about a persistent long-term trend of a significant decline in prevalence of Peruvian dusky dolphin in catch and stranding records.

The observed high mortality levels in Burmeister's porpoise are a serious concern, and action is needed to avoid the same critical situation as with the closely related vaquita. Burmeister's porpoise is already included in a preliminary list for potential Conservation Management Plan development (Genov *et al.*, 2015), and dusky dolphin could potentially also be included. The Committee reiterated recommendations from 2008 regarding bycatch monitoring programmes and mitigation efforts in these fisheries (IWC, 2009, p. 323).

Attention: C-A, CC

*The Committee **draws the attention** of the Commission to its **serious concern** over the high mortality levels from bycatches in Peru and especially those of the Burmeister's porpoise and dusky dolphin. It **stresses** that action is needed to avoid the same critical situation for Burmeister's porpoise as with the closely related vaquita. In this regard the Committee:*

*(1) **reiterates** its advice (IWC, 2009, p. 323) on bycatch monitoring and mitigation in these fisheries;*
*(2) **reiterates** that the Burmeister's porpoise is a potential candidate for a Conservation Management plan;*
*(3) **highlights** opportunities to focus on the bycatch of small cetaceans in Peru through the new IWC Bycatch Mitigation Initiative and **recommends** that they are considered as a potential pilot project; and*
*(4) **offers its assistance** to the Government of Peru; and*
*(5) **requests** that the Commission, through the Secretariat, transmits the Committee's concern and offer of assistance to the Government of Peru.*

13.5.2 Franciscana bycatch in Brazil

Considerable information was provided on the Santos Basin Beach Monitoring Project required by the Brazilian authorities for licensing oil and gas production and transport (see Annex J, item 2.1.2). This provided information *inter alia* on stranded franciscana. From October 2015 to September 2017, 1,123 carcasses were recorded stranded in the area and interactions with fishing gear was reported for over 85% of necropsied individuals with signs of human activities.

Attention: CG-A

*The Committee **draws attention** to the fact that the franciscana remains under strong pressure from human activities, especially bycatch, in Brazilian waters despite fishing net regulations established by the government. The Committee:*

*(1) **advises** that the existing regulation on gillnets, implemented in 2012, is either not being effectively enforced or is not effective in reducing bycatch; and therefore*
*(2) **recommends** the need for this to be investigated further by the Brazilian authorities.*

13.5.3 Estimating bycatch from strandings data

Estimates of common dolphin mortality in the Bay of Biscay based on strandings data (Peltier *et al.*, 2016) had been discussed at SC67a. SC/67B/HIM/05 and SC/67B/HIM/08 provided further analyses related to using stranding data to make inferences about small cetacean mortality. An intersessional group was established at SC67a to provide advice on consistent ways to estimate bycatch across both large and small cetaceans, and specifically, to review the methods applied in Peltier *et al.* (2016) focused on small cetaceans. Discussion of the report of the intersessional group and some additional related papers (SC/67b/ HIM05 and SC/67b/HIM08) can be found in Annex J (item 2.1.2).

In discussion of other ways to estimate bycatch, the Committee noted that Bartholomew *et al.* (2018) had concluded that Remote Electronic Monitoring can provide a time- and cost-effective method to monitor target catch in small-scale fisheries and can be used to overcome some of the challenges of observer coverage. This requires consideration by the Committee.

Attention: CG-A, SC, G

With respect to methods for obtaining bycatch estimates the Committee:

*(1) **agrees** with the recommendations of its intersessional group regarding (a) uncertainties in bycatch estimates derived from strandings; (b) the use of bycatch estimates derived from strandings; and (c) assessing whether strandings can identify gaps in observer coverage;*
*(2) **notes** the importance of observer programmes, including electronic monitoring, and the limitations of stranding information for determining the type of fishing gear implicated in a bycatch event, or in determining reliable bycatch estimates;*
*(3) **recognises** that in small scale fisheries (a) observer programmes are particularly complicated, given the small size of vessels and (b) electronic monitoring may not capture the animals falling from the net during hauling*
*(4) **advises** that a robust evaluation of the effectiveness of bycatch mitigation measures requires a combination of monitoring measures, including well-designed and effectively implemented observer programmes, electronic monitoring and stranding programmes;*
*(5) **advises** that the above advice is relevant to the situation of the franciscana in Brazil; and*
*(6) **agrees** that given the increased use of Remote Electronic Monitoring techniques and the rapid development of camera and associated electronic technology, these techniques should be a focus topic at SC68a.*

13.6 Scientific aspects of mitigation measures

13.6.1 The IWC Bycatch Mitigation Initiative

The Committee considered the outcomes of an assessment on the potential work areas for the new IWC Bycatch Mitigation Initiative (SC/67b/HIM12). This resulted in several recommendations for the Committee in relation to potential work areas, including:

(1) identification of priority fisheries/sites/species/populations to be considered for pilot projects based on conservation need and the establishment of bycatch baselines for relevant cetacean populations where mitigation is to be trialled;
(2) leading in communicating the need for increased research on mitigation measures/management approaches for cetaceans to the broader scientific community;
(3) annually reviewing mitigation measure tables;
(4) providing technical assistance to the coordinator and the expert panel in the development of scientific trials/monitoring programmes to evaluate mitigation measures; and
(5) collaborating with researchers identifying fishing effort using vessel monitoring and tracking systems and assessing bycatch risk, with a focus on small scale fisheries.

With respect to the identification of priorities, five criteria for the selection of pilot projects were identified:

(1) urgency of conservation situation driven by bycatch or concern over situations with little or no data on bycatch, but suspected overlap between high risk fishing gears and vulnerable cetacean species;
(2) enabling conditions necessary for success;
(3) scope for IWC to contribute (e.g. enhanced international cooperation);
(4) ability to monitor effectiveness of mitigation actions; and
(5) potential for the project to contribute to mitigation of bycatch in other areas.

A list of information sources (including SOCER) was created at the meeting to assist Tarzia, the new BMI coordinator, to identify potential projects, after which she will consult with the expert panel to apply the above criteria, including contact with any of the governments involved, to select the projects for review by the initiative's Standing Working Group which can be presented to the Commission. The Committee suggested that identified fisheries in the Republic of Congo, Peru, Ecuador, Pakistan and India appear to fulfil many of the criteria and are locations where past or present IWC work is being carried out which is relevant to bycatch.

Attention: C-R, SC, CC

The Committee discussed the strategic assessment of the Bycatch Mitigation Initiative (BMI) and the role of the Committee. The Committee:

(1) ***welcomes*** *the progress made thus far under the BMI, including the Strategic Assessment;*
(2) ***thanks*** *Tarzia for the excellent work she has carried out since her appointment as co-ordinator;*
(3) ***agrees*** *to incorporate in its workplan the five work areas listed in its report under Item 13.6.1 and also consideration of 'rapid bycatch and risk assessment' tools;*
(4) ***agrees*** *to the criteria listed in its report under Item 13.6.1 when identifying priority fisheries/sites/species/populations; and*
(5) ***recommends*** *to the Commission that the BMI continues and is supported, including the provision of ongoing support for the BMI coordinator.*

13.6.2 Collaboration with FAO

FAO held an Expert Workshop on Means and Methods for Reducing Marine Mammal Mortality in Fishing and Aquaculture Operations in March 2018 which had been attended by several members of the Committee. The workshop report contained a review of mitigation measures and a decision tree providing guidance on choosing a bycatch mitigation pathway. The IWC Executive Secretary and BMI Coordinator will attend the FAO Committee on Fisheries (COFI) meeting in July 2018 where the report will be reviewed.

Attention: C-R, S

The Committee ***welcomes*** *the efforts of the FAO to consider cetacean bycatch and* ***recommends*** *that the IWC Secretariat continues to collaborate with the FAO on this issue.*

13.7 New information on cetacean bycatch in the Western, Central and Northern Indian Ocean

Last year (IWC, 2018c, p. 46), the Committee had recommended that in light of the scope and scale of cetacean bycatch in the Western, Central and Northern Indian Ocean and the considerable data gaps associated with intensive and extensive gillnet fisheries, the topic be included in the work plan for this meeting and the Secretariat establish communications on the issue with the Indian Ocean Tuna Commission (IOTC). SC/67B/HIM/07 provided updated information on this topic, as discussed in Annex J (item 2.7). The IWC's Executive Secretary provided an update on engagement with the IOTC, including a recent teleconference with the IOTC Executive Secretary.

Attention: C-A, CC, SC

With respect to bycatches of cetaceans in the Indian Ocean, the Committee:

(1) ***reiterates*** *its willingness to collaborate with the IOTC on this issue; and*
(2) ***encourages*** *the Secretariat to continue to work with the IOTC Secretariat.*

13.8 Workplan 2019-20

The Committee's workplan on bycatch and entanglement is given in Table 18.

14. SHIP STRIKES

14.1 Review estimates of rates of ship strikes, risk of ship strikes and mortality

The Committee received information on a pilot study to better characterise ship strikes in Southeastern Alaska (see Annex J, item 3.1) and looks forward to further updates on this work.

14.1.1 Review progress on ship strike database

The IWC continues to develop a global database of ship strike incidents as discussed in Annex J (item 3.1.1). The primary task is ongoing review of previously reported records by two data coordinators in conjunction with a data review group (SC/67b/HIM11). It is expected that the review process for all historical records will be completed in the next biennium.

Attention: C-R, S

The Committee ***reiterates*** *the importance of the global ship strikes database to its work. It therefore:*

(1) ***welcomes*** *the work undertaken thus far;*
(2) ***recommends*** *the continuation of this work including (a) that of the co-ordinators and Data Review Group on the review of historical records and (b) the Secretariat on upload tools.*

Table 18

Workplan on bycatch and entanglement related issues.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Bycatch Mitigation Initiative		Review aspects relevant to Committee and respond to requests for advice		Review aspects relevant to Committee and respond to requests for advice
Rates and risks		Review new estimates of entanglement rates, risks and mortality		Review new estimates of entanglement rates, risks and mortality
Mitigation		Review new information on mitigation		
Inferences from strandings	Consider new information and issues that need to be addressed at SC68a	Review new information		
Rapid risk assessment		Consideration of 'rapid risk assessment' tools and outputs		
Electronic monitoring		Consideration of remote electronic monitoring and vessel tracking		
Mitigation measures tables		Develop table of mitigation measures for small cetaceans and update table for large whales from 2017 if needed.		
Global disentanglement database	Discussion at GWERN workshop	Review Progress	Advance database development if considered feasible	Review Progress
Collaboration with FAO	Secretariat attend COFI meeting	Review FAO outputs on bycatch	Continue collaboration	Continue to review
Encouraging innovative research on mitigation	BMI through existing networks, at conferences, workshops and with students – all members of Committee with relevant expertise	Review progress		

14.2 Mitigation of ship strikes in high risk areas

The Pelagos Sanctuary in the Mediterranean is a recognised high risk area for ship strikes to fin and sperm whales. In France, the REPCET reporting system became mandatory on 1 July 2017 for French passenger, cargo vessels (SC/67b/HIM04). As discussed in Annex J (item 3.2.1), 'alerting' systems such as REPCET require a trained observer and a subsequent avoidance action of some sort by the vessel in order to be a considered as a mitigation tool.

The Committee had previously agreed that the available data supported a proposal to IMO to move the shipping lanes off the southern coast of Sri Lanka to reduce the risks of ship strikes to Northern Indian Ocean blue whales. In 2017, major shipping organisations represented at IMO also wrote to the Sri Lankan government requesting the routing change to reduce ship strike risks and improve maritime safety. So far, there has been no response from Sri Lanka.

The Hellenic Trench west of Greece is also an identified high risk area for sperm whales and in 2015 (IWC, 2016d), the Committee recommended that interested parties (including Greece, ACCOBAMS and the shipping industry) move forward with Greece in order to develop a proposal for routing measures.

The IUCN Marine Mammal Protected Areas Task Force process for identifying Important Marine Mammal Areas (IMMAs) may assist in identifying high risk areas for ship strikes. The Committee and the IWC's Ship Strike Standing Working Group have previously encouraged cooperation on this between the IUCN Task Force and the IWC.

Attention: C-A, CC, SC, G

The Committee has continued its work on identifying high risk areas for ship strikes and potential mitigation measures. In this regard the Committee:

(1) ***recommends*** *continued work to develop and evaluate mitigation measures, such as speed restrictions, that might be associated with the designation of a Particularly Sensitive Sea Area (PSSA) in the Pelagos Sanctuary area;*
(2) ***reiterates*** *its previous recommendations on the importance of evaluating the efficacy of the REPCET system for reducing the risk of ship strikes;*
(3) ***requests*** *the Commission, via the Secretariat, to remind the authorities in Sri Lanka of its previous offer of assistance from the IWC on this issue;*
(4) ***requests*** *the Commission via the Secretariat, to follow up on previous correspondence on the ship strike risks to sperm whales off Greece;*
(5) ***agrees*** *to support a workshop to evaluate how the data and process used to identify IMMAs can assist the IWC to identify areas of high risk for ship strikes; and*
(6) ***agrees*** *to continue ongoing IWC engagement with the process to identify IMMAs, including consideration of their utility to address other threats.*

14.3 Co-operation with IMO Secretariat and relevant IMO committees
The Committee has long recognised the importance of co-operation with IMO on matters related to shipping including ship strikes.

Attention: C-R, S

*The Scientific Committee **reiterates** the importance of cooperation with IMO and:*

*(1) **welcomes** the ongoing co-operation the Secretariat has maintained with IMO and its Secretariat on ship strike issues, including meetings during IMO MEPC 72; and*
*(2) **recommends** that this dialogue continue.*

14.4 Work Plan
The Committee's work plan on matters related to ship strikes is given as Table 19.

Table 19

Workplan on matters related to ship strikes

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Rates and risks		Review estimates of rates of ship strikes, risk of ship strikes and mortality		Review estimates of rates of ship strikes, risk of ship strikes and mortality
Mitigation		Review new information on mitigation		
Advice on routing measures related to ship strike risk	Provide advice as required (Annex Y)	Review advice	Provide advice as required (Annex Y)	Review advice
Follow up on previous contacts offering IWC assistance regarding high risk areas	Secretariat to contact Sri Lankan and Greek authorities	Review progress on identified high risk areas in IWC Ship Strike Strategic Plan		
Continued co-operation with IMO	Secretariat to maintain dialogue with IMO Secretariat. Attend relevant IMO meetings.	Review cooperation		
Ship strike database	Continue ongoing data entry into Ship Strike Database and validation of records	Review progress against specific deliverables and time line	Continue ongoing data entry into Ship Strike Database and validation of records	Review progress against specific deliverables and time line
Provision of AIS data	Secretariat to develop MOU with Marine Traffic for provision of data	Consider best way to handle requests for data through the MOU		
Use of IMMAs to identify high risk areas for ship strikes	Hold workshop to evaluate how the data and process used to identify IMMAs can assist the IWC to identify areas of high risk for ship strikes.	Review workshop report		

15. ENVIRONMENTAL CONCERNS
The Commission and the Scientific Committee have increasingly taken an interest in the environmental threats to cetaceans. In 1993, the Commission adopted a resolution on research on the environment and whale stocks and on the preservation of the marine environment, IWC Resolution 1993-12 (e.g. IWC, 1996; 1997; 1998; 1999; 2010). As a result, the Committee formalised its work by establishing a Standing Working Group that has met every year subsequently. This year, it has been established as a sub-committee and its report can be found in Annex K.

15.1 Pollution 2020
15.1.1 Review on intersessional progress on the Pollution 2020 initiative
The individual based model to investigate the effects of pollutants on cetacean populations (SPOC) has been finalised. A peer-reviewed paper detailing the model and applying it to a number of case studies has been published in *Environmental Pollution* (Hall *et al.*, 2018) and the model's R code is available through the repository associated with the paper. The web-based, user-friendly version is now available through the Sea Mammal Research Unit, University of St Andrews server (*http://www.smru.st-andrews.ac.uk/reports/*) and a link will be added to the IWC webpages on the Chemical Pollution page. There are new data on the combined effects of persistent organic pollutants (POPs) on the immune system of killer whales (Desforges *et al.*, 2017) and this will be integrated into the model in the next year.

As noted in Annex K (item 2.1), the contaminant mapping tool will be completed next year, with the inclusion of the data on the concentrations of mercury in cetacean tissues by time and region. This online resource that will be made available through the IWC website and will be updated with new information identified in the SOCER annual reviews.

Research to estimate how long it is likely to take for POPs in the blubber of cetaceans to observably decline, following a reduction in environmental levels, will be completed next year.

Attention: SC

The Committee ***agrees*** *that the Pollution 2020 initiative should be completed and presented at SC/68a. It also* ***encourages*** *a paper to be presented at SC/68a summarising the potential mitigation measures for reducing exposure of cetaceans to polychlorinated biphenyls (PCBs) in particular and persistent organic pollutants (POPs) in general.*

15.1.2 Report on mercury in cetaceans

The impact of mercury exposure is still an issue of concern for cetaceans. SC/67b/E08, reviewed mercury in cetaceans, in response to Commission Resolution 2016-4, 'Resolution on Minamata Convention'. The paper (see discussion in Annex K, item 2.2) highlights continued global exposure and potential effect of mercury on cetaceans. Although cetaceans have a unique detoxifying mechanism which may protect them from the health effects of organic mercury, the resulting mercuric-selenide complexes may cause adverse effects in individuals experiencing other physiological and metabolic challenges. Research into identifying the toxic thresholds for mercury in cetaceans is still required.

The Committee also received several papers presenting information on mercury in cetaceans including river dolphins (SC/67b/E06), humpback whales (SC/67b/E09) and gray whales off Chukotka (SC/67b/E03). The Committee highlighted the need for standardisation in reporting units. It also discussed preferred tissues for mercury analyses. Discussion of these papers can be found in Annex K (item 2.2)

Attention: SC, CG-R

The Committee continued to work on mercury in cetaceans in response to Resolution 2016-4. It therefore:

(1) ***encourages*** *the continued provision of information on mercury and cetaceans;*
(2) ***encourages*** *researchers presenting such information to report concentrations on both wet and dry weight bases; and*
(3) ***recommends*** *that Contracting Governments support the continued monitoring of mercury in cetaceans, as this is required in order to assess the medium- and long-term impact of the Minamata Convention.*

15.1.3 Impact of heavy fuel oils on cetaceans

There is a paucity of information on the impacts of heavy fuel oils on cetacean health (Annex K, item 2.3). However, some new information comparing the occurrence of cancer and elevated PAH levels in St Lawrence Estuary white whales with similar cancers in the local human population, was highlighted. In addition, behavioural changes in white whales in the White Sea following exposure to oil have been observed.

Attention: CG-A, SC, G

The Committee:

(a) ***reiterates*** *the need to estimate the risk and impact of oil spills, particularly to cetaceans in the Arctic;*
(b) ***notes*** *that heavy fuel oil could pose an environmental threat in many regions due to its high viscosity and chemical composition;*
(c) ***notes*** *that heavy fuel oil poses a special threat in the Arctic due to difficulties in recovery and potential impacts of some recovery measures (e.g. dispersant use and in situ burning); and*
(d) ***encourages*** *the collection of baseline data for cetaceans, including standardisation of measures.*

15.1.4 Other pollution issues

Understanding the effects of oil dispersants and dispersed oil on cetaceans is a gap in our current knowledge. To address this need, the Coastal Response Research Center (CRRC) in the USA has co-ordinated a discussion among scientists with dispersant research expertise, as well as those with Arctic expertise, to determine the state-of-science regarding dispersants or dispersed oil, as it applies to Arctic waters. The Committee looks forward to the publication of the final report.

Attention: CG-A, SC, G

The Committee ***draws attention to*** *the lack of data the effects of oil dispersants and dispersed oil on cetaceans. It therefore:*

*(1) **encourages** Contracting Governments to support research on the effects of dispersants or dispersed oil to the Arctic and other ecosystems; and*
*(2) **requests** that the results of such research be brought forward to future meetings of the Scientific Committee.*

15.2 Cumulative effects

The Committee welcomed the summary of the Cumulative Effects Workshop (see Annex K, item 3) and looked forward to receiving the report. Overall, the Workshop found that there is considerable uncertainty in addressing this topic and thus in developing assessments and management advice.

The Scientific Committee also received a report on a workshop entitled 'Towards understanding the overlap of selected threats and Important Marine Mammal Areas (IMMAs) across the Mediterranean Sea', which was held jointly by the IUCN Joint Species Survival Commission/World Commission on Protected Areas (SSC/WCPA) Marine Mammal Protected Areas Task Force (the 'Task Force') and by the Agreement on Conservation of Cetaceans of the Black Sea, Mediterranean Sea and contiguous Atlantic area (ACCOBAMS). The workshop provided the opportunity to support the ongoing effort to map specific threats to cetaceans in the ACCOBAMS area by overlaying the Mediterranean IMMAs with the available area-explicit information on shipping and seismic surveys, thereby giving preliminary indications of new Cetacean Critical Habitats in the ACCOBAMS area and facilitating the implementation of conservation actions at the regional level.

Attention: SC, G

*The Committee **recognises** the importance of understanding cumulative effects of threats on populations of cetaceans, as well as its complexity. It therefore:*

*(1) **concurs** with the Cumulative Effects Workshop recommendations (see Annex K, item 3) to improve our knowledge and enable quantitative assessments;*
*(2) **highlights** the recommendation that consideration needs to be given to 'developing a widely applicable approach for providing precautionary advice for populations in which cumulative effects are of concern';*
*(3) **agrees** to establish cumulative effects as a standing item on its agenda;*
*(4) **notes** the work on Important Marine Mammal Areas (IMMAs) and **encourages** additional efforts to identify the relevant threats in these, in order assist with the management of cumulative effects;*
*(5) **endorses** the results of the recent IUCN/ACCOBAMS workshop entitled 'Towards understanding the overlap of selected threats and Important Marine Mammal Areas (IMMAs) across the Mediterranean Sea';*
*(6) **encourages** that such an effort – aimed at overlaying different sources of threat and pressure on existing Important Marine Mammal Areas (IMMAs) – be continued and carried out in more detail in the other marine regions where IMMAs have already been identified; and*
*(7) **offers** its assistance in such assessments.*

15.3 Strandings and mortality events

15.3.1 Update on the IWC Strandings Initiative

The IWC strandings initiative was agreed by the Commission at its 2016 meeting (IWC, 2017d) and details can be found in Annex K (item 4.1). It noted that the rescue and welfare aspects of live strandings will be addressed by the Strandings Initiative but that this aspect is not within the purview of the Committee.

Attention: C-R, S, SC

*The Committee **reiterates** the importance of the IWC Strandings Initiative. It therefore:*

*(1) **welcomes** the excellent progress that has been made in the Strandings Initiative and the appointment of Sandro Mazzariol (Italy) as the Chair of the Strandings Expert Panel and Karen Stockin (New Zealand) as the Stranding Coordinator;*
*(2) **recommends** that the Commission (a) endorses the Strandings Initiative governance structure in Annex K (appendix 2) and (b) endorses the continuation of the Strandings Coordinator position for another two years (until IWC68) subject to available funding and requests the Secretariat make the necessary arrangements;*
*(3) **recommends** that the Strandings Initiative Steering Committee and Expert Panel, with the support of the Secretariat, should explore the best ways to gather information on strandings events and what basic data about these events should be recorded, focussing on what is useful for the Committee and the Commission;*
*(4) **agrees** that a phased approach to this, starting with an initial pilot project, will assist in this endeavour; and*
*(5) **agrees** that criteria for allocating funds for emergency responses should be developed by the Steering Committee and the Expert Panel and should be presented to the Committee at SC/68a.*

15.3.2 New information on unusual mortality events

Cetacean morbillivirus continues to be a major disease issue for cetaceans and a cause of unusual mortality events in dolphins in and around the Atlantic. Focus this year was on an outbreak of cetacean morbillivirus in the South Atlantic Ocean (SC/67b/E14) that is discussed in Annex K (item 4.2).

Attention: CG-R, SC

*The Committee **commends** the impressive rapid and comprehensive response to the cetacean morbillivirus outbreak in Brazilian Guiana dolphins. It therefore:*

*(1) **encourages** further work on the longer-term impact of the outbreak and the investigation of the occurrence and impact of this disease in cetaceans across different geographical areas;*
*(2) **draws attention to** the large number of animals that died during the outbreak (particularly mature females) and the historical high levels of human impacts affecting Guiana dolphins in Rio de Janeiro state, such as bycatch, chemical and noise pollution;*
*(3) **recommends** that immediate actions should be taken to protect affected populations in order to increase the chances of population recoveries;*
*(4) **draws attention to** the increase in Guiana dolphin deaths reported in Sao Paulo and Espirito Santo states in the weeks following the onset of the cetacean morbillivirus outbreak in Rio de Janeiro; and*
*(5) **encourages** the monitoring of the virus presence in neighbouring coastal dolphin populations, particularly species and populations in which immunosuppressive conditions or cumulative threats are identified.*

15.4 Noise

The Committee welcomed an update on international efforts addressing anthropogenic noise and their impacts on cetaceans, particularly regarding the appropriate assessment and protection of acoustic habitat quality as discussed in Annex K (item 5), and commended IWC engagement with organisations such as IMO and the UN.

Guidelines developed by the Convention on Migratory Species (CMS) Secretariat, also on behalf of the ASCOBANS and ACCOBAMS Secretariats, for Environmental Impact Assessments for noise-generating offshore industries were presented to the Scientific Committee. These guidelines had been endorsed through CMS Resolution 12.14 on Adverse Impacts of Anthropogenic Noise on Cetaceans and Other Migratory Species, and provide a pathway to implementing the Best Available Techniques (BAT) and Best Environmental Practice (BEP).

The Committee also considered the results of a study utilising modelling approaches to evaluate relative levels of communication masking for four baleen whale species in the Stellwagen Bank National Marine Sanctuary, in Massachusetts Bay, USA Cholewiak *et al.* (In press).

Attention: SC, G, CG-A

Recalling its previous recommendations on noise and the importance of addressing its impacts on cetaceans, the Committee:

*(1) **welcomes** and **draws attention** to the Convention on Migratory Species Family Guidelines on Environmental Impact Assessments for Marine Noise-Generating Activities (https://www.cms.int/en/guidelines/cms-family-guidelines-EIAs-marine-noise), noting that these guidelines will help improve global standards for environmental impact assessments;*
*(2) **recommends** that levels of anthropogenic noise and its effects on marine species be explicitly considered in the management of marine protected areas;*
*(3) **welcomes** the information received on using marine soundscape planning strategies to reduce interference between hydroacoustic instrumentation (e.g. echosounders and airgun arrays) and marine mammals, and **encourages** work to further develop this approach;*
*(4) **recognises** the commonalities identified among the concurrent efforts of multiple international bodies to develop national guidance on noise strategies, and **encourages** continuing efforts to identify synergies and develop priorities for actions to reduce exposure of cetaceans to anthropogenic noise;*
*(5) **welcomes** the work on modelling cetacean communication space, and **encourages** scientists engaged in the development of modelling techniques that address multiple anthropogenic impacts, such as noise and entanglement in fishing gear to bring these forward to the Scientific Committee;*
*(6) **agrees** that a pre-meeting on noise be organised for SC/68b and that an intersessional steering group be convened (Annex Y) to develop the agenda for that pre-meeting.*

15.5 State of the Cetacean Environment Report – SOCER

The Scientific Committee **thanks** the editors of the State of the Cetacean Environment Report (SOCER) for their work and commended them on compiling this information on the Mediterranean and Black Seas. Next year's region will be the Atlantic Ocean. The Scientific Committee would welcome input from the members for information on this region. A 5-year global compendium is being produced in cooperation with the Secretariat that will receive a dedicated webpage on the IWC website in time for presentation to the 2018 Commission meeting.

15.6 Update on other standing topics

15.6.1 Marine debris[litter]

The Committee received and discussed a number of papers relating to several aspects of marine debris as discussed under Annex K (item 7.1). Exposure to marine debris and microplastics in cetaceans is now widespread and common. However the impacts on cetacean health and populations is not fully understood.

Attention: C-A, SC

The Committee ***draws attention*** *to the fact that marine debris remains a threat, and that in particular, exposure to plastics (including microplastics) is a rapidly emerging area of concern.* It therefore:

(1) ***agrees*** *that an intersessional workshop on Marine Debris should take place, preferably to coincide with the World Conference on the Biology of Marine Mammals in Barcelona in December 2019.*

15.6.2 Climate change

Climate change was highlighted at SC/67a as being an overarching issue that is important to various topics, and that where relevant its impact should be discussed in conjunction with that topic (see discussion in Annex K, item 7.2). Notwithstanding that, the Committee may want to initiate a specific activity related to climate change in future (see intersessional correspondence group in Annex Y).

Attention: C-A, CG-A, SC

The Committee ***draws attention*** *to the fact that climate change remains a threat that interacts with other threats and stressors impacting cetacean populations.*

15.6.3 Cetacean diseases of concern

Monitoring health and disease agents in large whales in the Arctic is continuing to provide important information on changing patterns in prevalence, environmental status, and potential impacts. In addition, morbillivirus and Brucella continue to be important pathogens causing disease and increased mortality in cetaceans in the Atlantic.

Remote methods for assessing health and condition using visual and aerial photography (e.g. SC/67b/CMP13), is a major rapidly developing field, due to the widespread availability and reduced cost of unmanned aerial vehicles (UAVs). Standardisation efforts (e.g. see Annex S) for measuring body condition using UAVs for photogrammetry, and for collecting blow samples, should progress to ensure this useful tool can provide comparable data across studies, taking into account the differences between the various platforms available. Cross-validation with current methods for assessing body condition from visual health assessments is essential.

Attention: SC

The Committee ***agrees*** *to hold a focussed session next year (SC/68a) on our current understanding of the pathology and epidemiology of morbillivirus and* Brucella *and the potential for identifying and understanding the cumulative effects of exposure to other immunosuppressive stressors in cetaceans.*

15.7 Progress on previous recommendations

15.7.1 Pollution

The SC/67a recommendations were to (a) make the effect of contaminants on cetacean populations (SPOC) model available to the public; (b) review mercury in cetaceans; and (c) include new data into the contaminant mapping tool. These have all been completed.

15.7.2 Cumulative effects

As recommended last year, a workshop on understanding the cumulative effects of multiple stressors was held as a pre-meeting to SC/67b.

15.7.3 Diseases of concern

The Committee noted that the content on the Cetacean Diseases of Concern (CDoC) website will now be utilised and merged with the Strandings Initiative for the development of their training and outreach materials.

Whilst the recommended quarterly CDoC updates remain of interest to the Committee, a means of progressing this on a voluntary basis has not yet been identified although efforts to find such assistance are ongoing.

15.7.4 Strandings

The Strandings Initiative has progressed as recommended at SC/67a and a full progress report can be found in Annex K, Appendix 2.

15.7.5 Noise
In response to a previous recommendation, that Committee has received the recently developed seismic survey guidelines by the New Zealand government, a link to the technical working group reports created during the NZ seismic guidelines review is now available (*http://www.doc.govt.nz/our-work/seismic-surveys-code-of-conduct/work-of-the-technical-working-groups/*). However, these guidelines have not yet been discussed by the Committee.

As recommended and noted earlier under Item 15.5, the intersessional group assisted in the development of a summary of the IWC recommendations relevant to shipping noise for presentation to the International Maritime Organization's Marine Environment Protection Committee in 2018.

15.7.6 Thanks
The Committee would like to thank Teri Rowles for her exceptional support and hard work as Chair of the sub-committee on environmental concerns over recent years. Her extensive knowledge, expertise and guidance has been most appreciated and will be missed.

15.8 Workplan 2019-20
The Committee's workplan on environmental concerns is given as Table 20.

Table 20

Work plan for matters related to environmental concerns (for more details see Annex K, Appendix 4).

Item	SC68a	SC68b
Pollution 2020 (including oil spills)	If new information	Primary topic (including oil spills and mercury), summary report to Commission
Cetacean diseases of concern (incl. HAB toxins)	Primary topic	Primary topic
Strandings	If new information	Primary topic
Noise		Noise focus session
Marine litter	Pre-meeting on litter and plastics focus session	If new information
Cumulative impacts	If new information	If new information
Emerging issues	If new information	If new information
SOCER	Receive report	Receive report
Climate change	Over-arching topic	Over-arching topic

16. ECOSYSTEM MODELLING

The report of the Working Group on Ecosystem Modelling is given as Annex L. This group was first convened in 2007 (IWC, 2008b). It is tasked with informing the Committee on relevant aspects of the nature and extent of the ecological relationships between whales and the ecosystems in which they live.

Each year, that Working Group reviews new work on a variety of issues falling under three areas:

(1) reviewing ecosystem modelling efforts undertaken outside the IWC;
(2) exploring how ecosystem models can contribute to developing scenarios for simulation testing of the RMP; and
(3) reviewing other issues relevant to ecosystem modelling within the Committee.

16.1 Cooperation with CCAMLR on multi-species modelling

The Committee has been considering plans for joint workshops with CCAMLR on ecosystem modelling for some time (e.g. see IWC, 2017c, p.56), although this has not yet happened, the Committee remains interested.

Attention: SC

*The Committee **reiterates** its interest in holding joint workshops with CCAMLR. It **agrees:***

(1) that a two-year delay in the occurrence of the workshop will provide the opportunity to pursue and complete the relevant work with input from CCAMLR as needed; and
(2) that collaboration between SC-IWC/SC CCAMLR should be on going, and that the revised plan for the workshops (IWC, 2018e) be implemented.

16.2 Applications of species distribution models (SDMs) and ensemble averaging

The Committee had agreed in 2015 to review the application of species distribution modelling (SDM) and associated techniques as they pertain to the goals of the Committee and to develop good practice guidelines and recommendations. While the review has occurred (IWC, 2016b), there has been no significant progress in the intersessional correspondence group set up to develop the guidelines.

Attention: SC

The Committee ***reiterates*** *the importance of developing good practice guidelines and recommendations for species distribution modelling and* ***agrees*** *that this should be pursued by an intersessional correspondence group (Annex Y) with a view to reviewing and adopting guidelines within the next biennium.*

16.3 MODELLING OF COMPETITION AMONG WHALES

16.3.1 Individual-based energetic models
Enhancements to an individual-based energetics model (IBEM) were presented to the Committee (SC/67b/EM07). These included the explicit modelling of feeding on migration, individual dives and searching for prey schools. Results showed that carrying capacity and productivity were sensitive to the level of food available during migration, making it important that ecosystem models to cover the entire migratory range of the species. This is an important contribution to the determination of species' function response, which can play a pivotal role in ecosystem modelling. This approach is also discussed under Item 5.1.

16.3.2 Modelling of relationship between whales and prey
The Committee reviewed three papers relevant to modelling of the relationships between whales and prey, SC/67b/EM04, SC/67b/EM06 and de la Mare *et al.* (*in press*). The discussion of these can be found in Annex L (item 3.2).

16.3.3 Modelling of competition among baleen whales
The Committee noted that multi-species individual based energetic models (IBEM) such as those described under Items 16.3.1 and 16.3.2 could be used to model direct and indirect competition of different whale species in the same environment, and that relevant modelling work was nearing completion.

16.3.4 Stable isotope analyses
The Committee received preliminary results of the analysis of stable carbon (δ13C) and nitrogen isotope ratios (δ15N)) on samples from the edge of baleen plates in Antarctic minke whales (SC/67b/SP09). The details can be found in Annex L (item 3.5).

16.4 Standing topics

16.4.1 Effects of long-term environmental variability on whale populations
How long-term environmental variability might affect stock assessments is of particular interest to the Committee. Given the need for a literature review on the subject to facilitate discussions, an intersessional correspondence group (Annex Y) has been established.

16.4.2 Update on body condition analyses for the Antarctic minke whales
For several years, the Committee has been discussing whether there has been a statistically significant (5% level) decline in the blubber thickness and fat weight of Antarctic minke whales over the course of the JARPA surveys. In 2014, the Committee had agreed that there had been such a decline (IWC, 2015b). Since then, scientists from Australia, Japan and Norway have presented a series of models both supporting and challenging this conclusion. There has been collaboration over this period and significant development in the types of models used. In addition, there have been in-depth discussions regarding the proper handling of data, the explanatory variables to be included in the analysis and the appropriateness of various statistical methods.

New analyses were presented this year and detailed discussions can be found in Annex L, item 2. This year the debate focused on three points; (1) the use of a new variable of primary interest (the 'accumulated blubber thickness in each feeding season); (2) the use of FIC and (3) the appropriate handling of the data.

Attention: SC, G

The Committee has been discussing whether there has been a statistically significant (5% level) decline in the blubber thickness and fat weight of Antarctic minke whales over the course of the JARPA surveys for several years. In conclusion, the Committee ***agrees****:*

(1) that, for the data set considered as a whole, all approaches result in point estimates reflecting a decline when fit to a linear trend in time;
(2) however, the extent of the decline estimated differs amongst the methods, and is not statistically significant at the 5% level for all approaches;
(3) for some approaches, when the data are disaggregated by gender and/or area, some point estimates of trend are not negative;
(4) there are some indications of temporal variation that is more complex than linear.

In addition, the Committee:

(1) ***encourages*** *the authors to publish the results of their study in peer-reviewed journals; and*
(2) ***agrees*** *that this matter will not be considered during the forthcoming biennium.*

In discussion of the above, Norwegian scientists stated that since an error in parts of the Australian scientists' calculations has recently been acknowledged by them, and parts of the Australian scientists' conclusion and appendix had recently been withdrawn, the overall position regarding the blubber thickness and fat weight analyses now became as follows. There are no new analyses from the Australian scientists on the five response variables which have been considered and discussed in the Committee from 2011 to 2017. The results presented this year by the Norwegian scientists (SC/67b/EM02), which took into account some of the queries from the Australian scientists from last year, confirmed results presented by the Norwegian scientists earlier. Thus, the conclusions by the Committee in 2014 and 2017 on these variables remain valid. For this meeting the Australian scientists had presented analyses related to a new difficult dependent variable 'increase in blubber thickness during summer feeding in Antarctic waters' estimated from the blubber thickness at position BT11. The conclusion above about variables with a non-significant decline now pertains to the new variables only (points (2) and (3) above). The Norwegian scientists' position is that the conclusion drawn above was heavily influenced by the results of the calculations subsequently withdrawn, so that parts of those conclusion are no longer valid.

In response, the Australian scientists stated that results of some calculations carried out earlier were withdrawn because of a previously unidentified problem with a standard statistical package failing to converge on a solution without giving an error message. Subsequent collaborative checking with the Norwegian scientists led to the discovery of this problem. Withdrawing this calculation (which the Australian scientists had carried out to illustrate a property of the Norwegian scientists' methods) had no effect on the main results which the Australian scientists had presented in SC/67b/EM03. Nor did this retraction affect the results of analyses the Australian scientists had presented in 2017 showing non-significant trends in fat weight and blubber thickness (De La Mare *et al.*, 2017a; 2017b). The Australian scientists held the view that the assertion by the Norwegian scientists that "There are no new analyses from the Australian scientists on the five response variables which have been considered and discussed in the SC from 2011 to 2017" was not correct; the Australian scientists had provided full results of fitting models to BT11 in SC/67b/EM03. The main results in SC/67b/EM03 were based on differences between early- and late-season predictions from models with BT11 as the dependent variable. This difference was a simple measure of feeding in Antarctica. The earlier conclusion should not be materially affected by withdrawing the Australian scientists' compromised demonstration in relation to the Norwegian scientists' methods.

16.4.3 Review the information on krill distribution and abundance by NEWREP-A

The Committee received the results of the krill and oceanographic surveys during the third NEWREP-A survey in Area V-E and VI-W (SC/67b/EM05). Discussion of this information can be found in Annex L (item 6.1).

16.4.4 Ecosystem functioning

Resolution 2016-3 tasked the Committee with investigating the contribution of cetaceans to ecosystem functions. Last year, the Committee noted that its focus would be on scientific aspects of the issue and it established an intersessional correspondence group to progress this work. Progress made by that group, including development of a final terms of reference, can be found in Annex L, item 6.2. The Committee notes that the Conservation Committee will focus on the conservation and social science aspects of this issue.

It was noted that there is broad interest in understanding the role of cetaceans in ecosystem functions, and that the Committee's expertise relates to the scientific aspects of the issue. Given the broad international interest, it is suggested that the Committee work in collaboration with interested parties (e.g. CMS, CCAMLR, SCAR and SCOR) to share information and avoid the duplication of work.

C-A, CC, SC

Commission Resolution 2016-3 tasked the Committee with investigating the contribution of cetaceans to ecosystem functions. The Committee notes that the Conservation Committee will focus on the conservation and social science aspects of this issue. In responding to the Resolution 2016-3, the Committee ***advises*** *the Commission that with respect to the scientific aspects on the contribution of cetaceans to ecosystem functioning:*

(1) it is unlikely that the ultimate goal of reliably determining the contribution of cetaceans to ecosystem functioning could be achieved in under a decade, given the complexity of the issue and the data gaps; and
(2) a more immediate and achievable goal is the carrying out of a gap analysis to identify knowledge gaps and to develop a plan to address them.

To further this work, the Committee ***agrees****:*

(1) to hold a workshop to (a) define short- and medium-term objectives to be addressed and (b) to identify what further research is required in order to begin initial modelling of the contribution of cetaceans to ecosystem function; and
(2) that the Secretariat in conjunction with the Steering Group (Annex Y) should contact CMS to determine their interest in participating in such a workshop.

16.6 Workplan 2019-20

The Committee's work plan on ecosystem modelling is provided in Table 21.

Japan referred to its statement on the adoption of the Agenda (Annex Z) and considered that several of the items for the proposed workshop (Item 16.4.4 and Item (7) in Table 1) are outside the competence of IWC. Therefore, it cannot support the proposed workshop or associated funding from the Committee's budget.

Table 21

Summary of the two-year work plan on matters related to ecosystem modelling

Item	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting (SC/68b)
(1) Ecosystem modelling in the Antarctic Ocean	Continue further analyses.	Review results of further analyses	Continue further analyses.	Review results of further analyses
(2) Application of species distribution models (SDMs)	Intersessional group activity (Annex Y)	Review progress		
(3) Effect of long-term environmental variability on whale populations	Continue further analyses. Intersessional group activity (Annex Y)	Review results of further analyses. Review progress	Continue further analyses	Review results of further analyses
(4) Further investigation of individual-based energetic models	Continue further analyses	Review results of further analyses	Continue further analyses	Review results of further analyses
(5) Modelling of competition among whales	Continue further analyses	Review results of further analyses	Continue further analyses	Review results of further analyses
(6) Update of any exercises on krill distribution and abundance	Conduct NEWREP-A krill survey and an international cooperative krill survey. Conduct simulation analyses to resolve issues on survey design.	Review results of survey and analyses.	Conduct NEWREP-A krill survey. Conduct analysis of data taken by the international survey.	Review results of survey and analyses.
(7) Cetaceans & Ecosystem Functioning: a gap analysis workshop or pre-meeting	Review relevant scientific studies before the workshop in addition to preparation of workshop (Annex Y).	Review outcomes of workshop and develop clear work plans with priorities.	Continue analyses	Review results of analyses.

17. SMALL CETACEANS

The report of the Committee on Small Cetaceans is given as Annex M.

17.1 Overview of taxonomy, distribution and abundance for *Inia* and *Sotalia*

In this assessment, two species and two sub species of dolphins were considered, some of which have several common names. In addition, a new species has been proposed but has not yet been recognised (Table 22).

Table 22

Summary of names used in the description of *Inia* and *Sotalia*

Scientific name	Common Name
Inia geoffrensis	boto, Amazon River dolphin
I. g. boliviensis	Bolivian bufeo
I. g. geoffrensis	Common boto
I. araguaiensis	Araguaian boto
(proposed species)	(from the Tocantins and Araguaia basins)
Sotalia fluviatilis	tucuxi, delphín gris, bufeo negro
Sotalia guianensis	Guiana Dolphin

The river and estuarine dolphins of South America are subject to various threats from habitat degradation, competition with fisheries, bycatch and direct exploitation. A major threat to river dolphins in South America is population fragmentation, altered habitat productivity and regulation of natural river flow as a result of dam construction. The cumulative impacts from this type of infrastructure at the macrobasin scale exacerbate the threats to river dolphins and their habitat in the Amazon and Orinoco basins. It was estimated that more than 50% of the range of Araguaian *Inia* is affected by damming.

Two genera were discussed in depth, *Inia* and *Sotalia*, from the vast and convoluted systems within the Amazon, Orinoco, Tocantins and Araguaia River basins. In the case of *Sotalia*, two species are recognised: *Sotalia guianensis* (marine) and *Sotalia fluviatilis*, (freshwater) in the Amazon basin. *S. guianensis* in the Orinoco basin likely represents an independent population unit as it is isolated from other coastal populations. Two intersessional workshops have been proposed that aim to elucidate the status of *S. guianensis* and it is that divisions within this genus will be clearer on the completion of this work in 2020. The taxonomoy of *Inia* has a complex history and at this time, one species and two sub species are recognised: *Inia geoffrensis*, the Amazon river dolphin, *I. g. boliviensis*, the Bolivian bufeo, and *I. g. geoffrensis*, the common boto. There is a third putative subspecies, *I. g. humboldtiana*, in the Orinoco basin of Venezuela and Colombia. The information currently available suggests that *I. g. boliviensis* should be elevated to species level and that *I. g. humboldtiana* should be recognised. Another new species, *I. araguaiensis*, has been proposed for the dolphins that inhabit the Tocantins and Araguaia basins of central Brazil as this area is geologically and hydrologically separate from the Amazon basin.

Attention: SC, G

Given the incomplete resolution of Inia *taxonomy, the importance of clarifying and solidifying recognition (or elevation to species) of the* Inia *subspecies found in different river basins, the possibility that in such complex habitats localised specialisation is likely, and the need to focus attention on the conservation of demographically independent populations, the Committee* ***encourages*** *support for efforts to resolve* Inia *spp. taxonomy in light of the significant and diverse threats affecting the populations inhabiting the Amazon-Orinoco-Tocantins/Araguaia drainages.*

17.1.1 Inia

For *Inia*, there are estimates of abundance for some rivers, however, there is little information on population trends. It was suggested that new technologies, such as Unmanned Aerial Vehicles (UAV), may help to better refine population survey techniques. From telemetry studies and two long term studies some information on population parameters is available. In particular, the Committee commends an ongoing telemetry study as it begins to address some of the most important scientific questions concerning *Inia* ecology, habitat use, behaviour and, particularly movements.

In addition, and central to IUCN assessments, a generation time for *Inia* has been calculated as 24.8 years from a long-term mark and recapture study. Given the estimated rate of population decline, this equates to a loss of 82% per generation and in excess of 99% over three generations. Such values are well above the threshold for a Red List assessment of a species as Critically Endangered. Concern was also expressed at the high rate of mortality of <1 year calves in one study site, where examined carcasses show evidence of both deliberate killing and net entanglement.

The information presented on population parameters were based on direct observations in a very small geographic area of the Amazon and therefore, a very small proportion of the total range of *I. geoffrensis.* As such, extrapolation to the whole region would be unwarranted, nonetheless these results and their implications for population decline are alarming.

Attention: CG-A, G

The Committee ***draws attention*** *to declines in Inia numbers documented in two study areas and the lack of abundance surveys in most parts of its range. The Committee therefore* ***encourages*** *the collection of data, calculation of abundance estimates and undertaking of analyses to estimate population trends for* Inia *throughout its range, for use in assessments of the status of the species, subspecies, and regionally isolated populations.*

17.1.2 Sotalia

Sotalia fluviatilis, known as tucuxi (Brazil) delphín gris (Colombia) or bufeo negro (Peru and Ecuador) is restricted to the Amazon basin in Ecuador, Peru, Colombia and Brazil and has a more limited distribution than *Inia*. *Sotalia guianensis*, the Guiana dolphin, occurs mainly in nearshore and estuarine waters of the Atlantic from southern Brazil, along the coast of Central America, to Nicaragua and possibly Honduras. Small populations in Lake Maracaibo and in the lower reaches of the Orinoco River, Venezuela, were highlighted as being heavily impacted.

In the Mamirauá Reserve, Brazil, the population of *S. fluviatis*, has shown a precipitous decline in abundance over a 22-year study period. Using the average observed decline of 7.4% per year, and, from literature, a generation time estimate of 15.6 years, the Mamirauá population trend equates to a 97% reduction over 3 generations, qualifying this population as Critically Endangered under IUCN Red List criteria. Unlike *Inia*, which is heavily exploited for use as bait in the piractaninga fishery, the primary driver of the decline in Sotalia in this region is gillnet entanglement.

17.1.3 Threats shared by dolphins in the Amazon and Orinoco River systems and Lake Maracaibo

Throughout the range of both genera, illegal hunting was highlighted as a transnational problem, making it difficult to create and enforce effective conservation measures. This issue is severe for *Inia* throughout its range and, for *Sotalia* in the Orinoco River and particularly in Lake Maracaibo, Venezuela.

Attention: C-A, G, CC

The Committee ***draws attention to*** *the serious situation reported for Lake Maracaibo in Venezuela, where both directed takes and oil pollution are thought to be having serious impacts on populations of* S. guianensis. *The Committee* therefore ***recommends*** *that NGOs and researchers focus on documenting the threats to* Sotalia *and work with local communities to mitigate the impacts on these dolphin populations.*

In addition to direct exploitation, there are numerous other threats to both species throughout their habitat in South America: the recent increase in deforestation effects their prey species, as there is no deposition of seeds and fruits into the rivers to support productivity and sustain fish stocks; hydropower developments and channel dredging affects flows regimes, the connectivity of rivers, the migrations of fish and can fragment dolphin populations, as has already occurred in the Tocantins River basin; heavy metals, such as mercury, have been measured in high concentrations in dolphin tissues; negative interactions with fisheries, in addition to directed takes for use as bait and food, also include bycatch, deliberate poisoning and 'control' killing.

Attention: CG-A, G, CC

The Committee ***draws attention to*** *the multiple threats associated with development, habitat degradation and fragmentation, and pollutants facing river dolphins in the Amazon, Orinoco and Tocantins basins. It therefore:*

(1) ***advises*** *the Brazilian, Bolivian and Peruvian Governments, as they carry out their reviews of proposed construction of new dams for hydroelectric energy production, to explicitly consider the potential impacts on river dolphins (e.g. isolation, loss of genetic diversity, habitat degradation;*
(2) ***discourages*** *water pumping in the Araguaia-Tocantins river basin for agricultural use as such a practice causes dramatic decreases in water levels in rivers, thereby increasing the probability that dolphin populations will be extirpated;*
*(3) e****ncourages*** *range states of the Amazon basin and its tributaries to support and carry out baseline research into the impacts of the development of commercial waterways in the Amazon (hydrovias) and their potential impacts on dolphin populations and habitats, including but not limited to the ecological impacts of dredging, noise pollution, channelisation by embankments, altered sediment suspension and transfer, and changes in turbidity, light, oxygen availability and primary productivity, and (b) work to minimize or at least mitigate these impacts;*
*(4) e****ncourages*** *(a) a review of the status of dolphins trapped within dammed stretches of the Tocantins and Madeira rivers and (b) evaluation of possible relocation (translocation) of animals when environmental conditions create a high likelihood that they cannot continue to survive in this severely compromised habitat; and*
*(5) e****ncourages*** *the review of the effects and the scale of contaminant and heavy metal (e.g. mercury) pollution on river dolphins in key areas of the Amazon (Japura/Caquetá, Içá/Putumayo, in Brazil and Colombia) and Orinoco (Venezuela) basins.*

17.2 *Tursiops* populations occurring in estuarine areas in southern Brazil

Discussion focused on two populations of Lahille's bottlenose dolphins (*Tursiops truncatus gephyreus*) in Patos Lagoon Estuary (PLE) and Laguna (LGN), Brazil. Both have been the focus of long-term ecological studies that provide a good source of information on the conservation status of the subspecies. Mark-recapture studies indicate year-round residency and permanent emigration is unlikely. Population sizes are small (85 dolphins in PLE and 60 in LGN) with low to moderate genetic diversity (mtDNA and nuclear DNA variation) in both areas. Pollutant analyses indicated moderate levels of persistent organic pollutants (POPs). Of additional concern is a chronic dermal infection which is apparent in 14% of the LGN population, which may be related to pollution but this is not clear. The greatest threat to both populations is bycatch in artisanal gillnet fisheries. Whilst there is no clear evidence of a negative trend in abundance, there is a high probability of population decline in the near future, given the small population, the high degree of residency and the continuing mortality as a consequence of IUU (illegal, unreported, unregulated) fishing and other human activities in these areas.

In Santa Catarina, Paraná, and São Paulo provinces, Brazil, north of LGN and PLE, a total of 119 bottlenose dolphins (sub species unknown) and 442 Guiana dolphins were recorded stranded over 2 years. There was strong evidence that entanglement was indicated as the cause of death for bottlenose dolphins. The Committee was informed that the Brazilian Government is looking into this issue and is seeking ways to improve legislative effectiveness in protecting dolphins and other threatened species in these locations.

Attention: SC, CG-R

The Committee draws the attention of the range states (Argentina, Brazil, Uruguay) to its conservation concerns over the entire sub-species of Lahille's bottlenose dolphins (T. t. gephyreus) given their relatively small population sizes and constricted ranges, the high levels of bycatch and the high incidence of individuals with chronic dermatitis. The Committee therefore recommends:

(1) immediate action to reduce the level of bycatch in the southern Brazil populations;
(2) continued monitoring and photo-identification work on the populations throughout the subspecies' range to refine survival estimates and to assess trends in abundance and the prevalence and etiology of the chronic skin infections; and
(3) that the conservation status of the subspecies be prioritised for assessment in the future.

17.4 Franciscana CMP

In 2016, the IWC created a Conservation Management Plan (CMP) for the franciscana – see Item 10.1.4. In 2019, a review will be presented to the Committee. The review will be jointly conducted by the SM and CMP sub-committees and will include input from other relevant sub-committees.

17.5 Report of the 2018 *Tursiops* Taxonomy Workshop

In 2014 (IWC, 2015b) it was agreed that the Committee would undertake a review of taxonomy and population structure in the genus *Tursiops*, over several meetings. Understanding whether there is any consistency in the derivation of various local forms across the range, and to which taxonomic or population unit(s) they belong, has been challenging, and the taxonomy of the various forms is still unresolved. An additional aim of this exercise was to develop a widely applicable taxonomy assessment framework for small cetaceans. The review process concluded with an intersessional workshop, held in La Jolla in January 2018.

The 3-year review and workshop brought together researchers and experts from around the world to discuss this topic, motivated focussed research, and promoted new collaborations. Results from studies presented at previous meetings (2015-2017) and at the workshop itself were compiled and formed the basis for evaluation of taxonomic and population distinction issues in each geographic region.

Attention: SC, G

Having reviewed the extensive information included in the 2015-2017 review and 2018 workshop for evaluation of Tursiops *species, subspecies and population distinctions, the Committee* ***draws attention to*** *the need for* Tursiops *research in the areas identified as data deficient (the African coast of the eastern Atlantic, southern and eastern Mediterranean Sea, eastern South Pacific, Pacific coast north of California and off the Mexican mainland, Central American coast of the eastern North Pacific, Central American Atlantic and Caribbean Sea and Atlantic coast of northern and north-eastern Brazil, eastern Australia and in the western Pacific the islands of Micronesia, Melanesia, Polynesia, the Philippines and Vietnam). The Committee therefore* ***encourages****;*

(1) collection of additional data, including morphometrics, and high-resolution genetic analyses (e.g. ddRAD which may also be useful in other areas where there are similar questions requiring high-resolution analysis), to better characterise divergence between coastal and offshore forms in the western South Atlantic Ocean, to help confirm whether subspecies or species classification is more appropriate for T. t. gephyreus;
(2) further investigation of T. aduncus *lineages in the Indian Ocean and western South Pacific to assess potential subspecies recognition, extending the geographic coverage to include eastern Africa, the region between Pakistan and Indonesia, and the region between Australia and China;*
*(3) continued study of the genetics and morphology of southern Australia bottlenose dolphins with the "*T. australis*" mtDNA lineage, in the context of both* T. truncatus *and* T. aduncus;
(4) examination of the level of male-mediated gene flow between the coastal and offshore forms in the western North Atlantic to determine whether the coastal form should be elevated to species or subspecies status;
(5) more comprehensive morphometric analyses comparing T. truncatus in the Mediterranean, Black Sea, and eastern Atlantic to integrate with genetic data and evaluate whether any regions in addition to the Black Sea (T. t. ponticus) harbour a taxonomic unit above the level of population;
(6) comprehensive morphometric analyses of coastal and offshore T. truncatus in the eastern North Atlantic and comparison to those from the western North Atlantic to better evaluate potential regional differences;
(7) morphometric analyses of Gulf of California coastal and offshore dolphins relative to those from California and the eastern tropical Pacific, with a particular focus on the level of divergence of coastal dolphins in the upper Gulf of California to other areas; and
(8) the collection of additional genetic and morphological data throughout the eastern South Pacific and further studies to investigate coastal versus offshore forms throughout the region, including coastal and offshore waters from Central America to Mexico, and if possible around the southern tip of South America to Argentina.

The Committee also ***agrees*** *to continue compilation of specimen, study, and researcher details, and concentrated effort to improve our understanding of* Tursiops *in data-deficient areas.*
Finally, after reviewing the 2018 Tursiops *Taxonomy Workshop's evaluation of the support provided for taxonomic (subspecies, species) and population-level distinctions proposed in the publications reviewed, the subcommittee* ***concludes*** *that:*

(1) the current taxonomy provided for Tursiops *by the Society for Marine Mammalogy's Committee on Taxonomy is well supported by morphological and molecular genetic data, as well as ecological and distributional data; and*
*(2) discordance in currently available results from morphometric analyses and across different genetic markers of the recently described '*T. australis*' from southern Australia calls into question its validity at this time.*

In addition to the information and recommendations on *Tursiops*, the Committee noted that the review provided an opportunity to formulate some generic conclusions on taxonomic issues related to small cetaceans.

Attention: SC, G

After reviewing the development and use of a strategy for objective evaluation of species, subspecies, and population-level distinctions by the 2018 Tursiops *Taxonomy Workshop, the Committee:*

(1) ***agrees*** *with the strategy implemented at the workshop for the evaluation of species, subspecies and population level distinctions;*
(2) ***encourages*** *use of the criteria and guidelines in Reeves et al. (2004) for the assessment of species-level taxonomy, in Taylor et al. (2017) for subspecies-level taxonomy, and in Martien et al. (2015) for Demographically Independent Populations; and*
(3) ***concludes*** *that future taxonomic questions should be examined within an appropriately wide and inclusive geographic context and that multiple lines of evidence are necessary when positing taxonomic changes.*

The Committee applauded Natoli, Rosel and Cipriano for their considerable work and organisational skills during this effort.

17.6 Poorly documented takes for food, bait or cash and changing pattern of use

17.6.1 Intersessional Workshop on the use of Small Cetaceans for Food and Non-Food Purposes in South America

The poorly documented take of small cetaceans for use as wildmeat has been assigned as a priority topic. An ICG (and see Annex Y) has been tasked with the development of a toolbox of techniques that could guide and co-ordinate research into this topic, and as such a series of workshops were proposed to fulfil this task. The second of these workshops focused on South America and incorporated a detailed review of the use of Amazon river dolphins as bait in the piracatinga fishery, which, in turn, fed into the priority topic of the 2018 meeting.

Information was summarised for all countries, except Guyana and Suriname, and it was recognised that products from small cetaceans have been used throughout the region for both food and non-food purposes. This type of use is referred to as 'aquatic wildmeat'. The usefulness of various tools and techniques was discussed, including data gathering techniques and forensic investigation. A database, comprising more than 3000 references, was used to map existing knowledge and understand data gaps. A framework was also established that had the purpose of standardised future data collection. The workshop participants populated a database from which regional patterns were mapped. Areas that were highlighted as a cause of conservation concern were; Bolivia, Brazil, Colombia, Costa Rica, Ecuador, Peru and Venezuela.

The take of Amazon river dolphins as bait in the piracatinga fishery was also reviewed. All range countries of *Inia* and *Sotalia* have laws in place to protect dolphins and prohibit intentional killing. Fishing for piracatinga is banned in Brazil and its trade is prohibited in Colombia, due to its impact on river dolphins and other wildlife. The practice of using dolphins as bait has recently expanded to Peru, Bolivia and Venezuela, following the imposition of restrictions in Brazil, however, no other range country has developed specific legislative or regulatory action, beyond the general protection of river dolphins, in response to the emergence of this practice.

The workshop concluded that some species and population required urgent attention both due to the extent of their use as wildmeat and from other threats.

17.6.1.1 SCIENTIFIC CONCLUSIONS AND RECOMMENDATIONS

Attention: SC, G, CG-A

The Committee ***endorses*** *the scientific conclusions and recommendations from the recent intersessional workshop on the use of Small Cetaceans for Food and Non-Food Purposes in South America aimed at improving regional knowledge and conservation research. In particular, the Committee:*

(1) ***agrees*** *that potential divisions within the genus* Inia *should be evaluated and genetic conservation units established;*
(2) ***agrees*** *that an evaluation of historical data on river dolphins should be undertaken to better understand other threats (e.g., from bycatch), to provide further insights into current trends;*
(3) ***encourages*** *the use of new technologies, such as drones and satellite telemetry, to establish trends, habitat use and dispersion patterns of Inia within Amazon River Basin and*
(4) ***encourages*** *new efforts to improve regional research capacity.*

The Committee ***draws attention*** *to the evidence showing that several small cetacean species and/or populations are being negatively impacted by their use as wildmeat in South America, and therefore* ***recommends*** *that abundance and distribution surveys, in tandem with investigation into the magnitude of aquatic wildmeat use, be conducted on these species. Appropriate survey designs should be implemented that consider the statistical power required to detect trends and the resultant data should then be used to estimate the impact of deliberate take for wildmeat on the following populations:*

(1) Boto in Purus and Japurá rivers, Brazil, and Içá/Putumayo river in both Brazil and Colombia, using previously established standardised methods (studies should also be expanded into other areas where take for bait may be a cause for concern);
(2) Chilean dolphin in Chile;
(3) Burmeister's porpoises in both Chile and Peru, noting that current evidence suggests that the Peruvian population is distinct;
(4) Dusky dolphins in Peru, noting that evidence shows that landings of this species has decreased and populations may have been heavily impacted;
(5) Guiana dolphins and other small cetaceans in Amapá, Pará, Maranhão, Piauí, Ceará, Espírito Santo, São Paulo and Paraná, in Brazil, where there is a documented use of bycatch for wildmeat purposes;
(6) Bottlenose dolphins and pantropical spotted dolphins) in Bahia Solano, Colombia, noting that deliberate takes for a long line fishery is ongoing;
(7) Tucuxi throughout its range, in Brazil, Colombia, Ecuador, as it shares most of the same threats as Inia geoffrensis, *and may also be used as bait in the piracatinga fishery; and*
(8) Guiana dolphin (Sotalia guianensis) in Lake Maracaibo in Venezuela, noting that deliberate take for food is ongoing.

The Committee also ***draws attention to*** *the Boto dolphins that have been isolated within the dam system of the Tocantins and Maderia Rivers in Brazil. Given the confined condition of the dolphins' habitat, the Committee* ***agrees*** *that the status of these dolphins be evaluated, to include abundance, genetic, habitat, prey availability assessments, with a view to developing a translocation protocol, including under what circumstances such a protocol should be enacted.*
Finally, given the concerns over the extensive habitat modification that will result from the Mega Project 'Arco Minero del Orinoco', a large scale mining operation proposed along the river and watershed of Venezuela, the Committee ***recommends*** *that population sizes and trends of both* Inia geoffrensis *and* Sotalia guianensis, *in the Orinoco River basin, be monitored before and during this project.*

17.6.1.2 CONSERVATION AND MANAGEMENT ISSUES

Attention: CG-R, S, CC

The Committee ***draws attention to*** *the management recommendations within the Report of the Workshop on the Use of Small Cetaceans for Food and Non-Food Purposes in South America, in particular, the need to have a regionally co-ordinated fisheries management plan for the Amazon River basin and a regional strategy for the conservation of river dolphins. Given continued concern over the use of dolphins as bait in the piracatinga fishery, the Committee:*

(1) ***commends*** *the Government of Brazil on its swift action in declaring a moratorium on the piracatinga fishery and respectfully requests that it maintains the moratorium to allow sufficient time to evaluate the effectiveness of protective measures and ensure the necessary protection of river dolphins;*
(2) ***reiterates*** *previous recommendation of the IWC Scientific Committee that range states (Bolivia, Brazil, Colombia, Peru and Venezuela) engage in a co-ordinated effort to strengthen legislative, enforcement, management and scientific efforts to ensure protection of the Amazon River dolphins;*
(3) ***encourages*** *range state authorities to work together and exchange information on the movement of piracatinga products across international borders; and*
(4) ***requests*** *that progress reports be submitted to the Scientific and Conservation Committees.*
(5) ***recommends*** *that the Commission asks the IWC Secretariat to send a letter to the Buenos Aires Group highlighting the issue of dolphins being used as bait in the piracatinga fishery and requesting joint efforts to enhance enforcement on wildlife and trade laws.*

17.6.2 Wildmeat Database

In 2016 (IWC, 2017) an intersessional group was established to work with the IWC Global Database Repositories Convenor, to develop an overarching aim for any future cetacean wildmeat database and identify the specific questions that such a database might address. The results of this work were presented, including a research agenda the formulation of key questions that could be addressed through the development and analysis of an aquatic wildmeat database. The Aquatic Wildmeat Database, developed independently of the IWC, was presented again and the Committee was updated on its improvements made following suggestions made last year. The future value of this data repository was highlighted and this and related issues will be considered intersessionally (see Annex Y).

The work of the Steering Group (see Annex Y) will continue and a third workshop, focusing on Africa, will be conducted intersessionally. The framework for an IWC Wildmeat database established at the workshop in South America will be further refined and will be used at the forthcoming workshop.

17.7 Small cetacean task team

The Scientific Committee continues to support the Task Team Initiative and the latest Task Team, for the South Asia River Dolphin, is in the process of being established with Dipani Sutaria and Nachiket Kelkar nominated as co-conveners. The task team currently comprises 14 members with representation from Bangladesh, India, Nepal and Cambodia and includes university associated researchers and NGOs (WWF and the Wildlife Institute of India).

Under its Task Team Initiative (e.g. IWC, 2016), the Committee ***strongly supports*** *the work of a Task Team for the South Asia River Dolphin and* ***agrees*** *that its first meeting which will occur before the 2019 meeting, if sufficient funding is available.*

17.8 Progress on previous recommendations

17.8.1 Vaquita

The Report of the Tenth Meeting of the International Recovery Team for Vaquita (CIRVA-10) was summarised and the results of the acoustic monitoring program for vaquitas were presented (SC/67b/SM01). This shows a continued decline in vaquita detections with no change in the trend since the last report in 2016. A brief review of the VaquitaCPR project was presented. This initiative, conducted in October and November 2017, aimed to capture vaquitas and bring them into human care. Ninety experts from nine countries were involved, including researchers experienced in the capture and handling of harbour porpoises, animal care professional, and veterinarians. Two vaquitas were successfully captured (an immature female [V01F] and an adult female [V02F]). In both cases, medical and behavioural evaluations were conducted to determine the suitability of the animals for transport to the floating pen or shore-based facility. Through the whole process the animals' health was continuously monitored by a team of experienced marine mammal veterinarians. The first vaquita caught (V01F) was in good condition initially, but did not acclimate to either the vaquita care centre pool or to the sea-pen facility, and the vaquita was released. V02F was also considered to be in good condition for transport to the sea-pen, however, after initially showing signs of adapting to the facility, the animal stopped swimming and an emergency release was initiated. The release was unsuccessful and the vaquita was quickly recaptured for administration of emergency care. Following three hours of emergency response, the animal went into cardiac arrest and did not respond to resuscitation attempts. Analyses of tissues and material obtained from VH02 is ongoing and a full report on VaquitaCPR will be reported at SC68A.

The survival of the vaquita depends on gillnet-free habitat and efforts to remove gillnets, both derelict and active, have increased dramatically in the last three years, particularly, during the ongoing 2017-18 totoaba season. The net removal programme demonstrates that illegal totoaba gillnets are still routinely set in great numbers in vaquita habitat. Despite enhanced enforcement efforts, there is a continued failure to prevent illegal fishing. CIRVA have stated that immediate action is needed to improve the situation through implementation of a series of recommendations. In particular, CIRVA recommended that the Government of Mexico establish an enhanced enforcement area, extending the boundaries of the existing vaquita refuge.

Attention: SC, CC, CG-R

The Committee has stressed for many years that the vaquita population is at a critically low level, and the most recent evidence demonstrates that the cause of the decline – use of illegal large-mesh gillnets – continues, making extinction in the wild increasingly likely; *the long-term decline in the vaquita reported previously has continued in 2017.* The Committee yet again **re-emphasises the serious concerns** it has raised on the status of the vaquita, and in particular its recommendations of the past two Committee meetings. Whilst again **commending** the Government of Mexico for its attention and response to the CIRVA findings and recommendations, the Committee:

(1) respectfully ***requests*** *that reports continue to be provided annually to the IWC Scientific Committee on actions and progress towards saving the vaquita;*
(2) ***strongly endorses*** *the recommendations of CIRVA10 that:*

(a) the CIRVA10 acoustic monitoring programme, critical for evaluating the effectiveness of conservation actions, be continued as in previous years to provide an annual empirical estimate of population trend;
(b) all Mexican enforcement agencies increase their efforts on land and in water immediately and continue this enhanced enforcement programme for the duration of the period of illegal totoaba fishing (at least until June 2018) to eliminate all setting of gillnets in the range of the vaquita;
(c) emergency regulations be promulgated immediately to strengthen the current gillnet ban and enhance enforcement and prosecution by:

- *(i) eliminating all fishing permits for transient fishermen and limiting fishing access to only those fishermen who can demonstrate residency in the fishing villages;*
- *(ii) confiscating any vessel that does not have the appropriate vessel identification, permits, and the required vessel monitoring system;*
- *(iii) requiring vessel inspection for each fishing trip at the point of departure and landing;*
- *(iv) prohibiting the sale or possession of gillnets on land and at sea within the area of the current gillnet ban and on adjacent lands within a specified distance of the coastline.*
- *(v) requiring that all gillnets be surrendered or confiscated and destroyed.*

(vi) eliminating the exemptions for all gillnet fisheries, including the curvina and sierra fisheries.

(d) efforts to remove gillnets from vaquita habitat be continued and enhanced and the numbers and locations of new nets recovered be published monthly;
(e) the number of inspections, interdictions, arrests, sentences, and other enforcement actions be published monthly, together with information on observed levels of illegal activities obtained from intelligence operations, for example from drones;
(f) successful prosecution and subsequent penalties be sufficient to deter illegal fishing; and
(g) development of gillnet-free fisheries be enhanced and linkages to incentivise the conversion of the fleet to gillnet-free operations be strengthened.

17.8.2 Yangtze finless porpoise

A rangewide survey of Yangtze finless porpoises (*Neophocaena asiaeorientalis asiaeorientalis*) was conducted in 2017, giving a preliminary abundance of around 1,000 individuals. This indicates that the rapid decline observed between 2006 and 2012 has now slowed, and that numbers may even be increasing in some areas. Nevertheless, the Critically Endangered status of this species remains unchanged. The survey results were encouraging and regarded as a possible indication that *in situ* conservation of Yangtze finless porpoises is feasible, given the marked increase of the number of individuals in Dongting and Poyang Lakes. For the population to make a sustained recovery in both numbers and range, current measures directed towards improving the habitat in the Yangtze River as well as the Dongting and Poyang Lakes must be continued and expanded. The Government of China was commended for the efforts undertaken to improve the YFP habitat. Nevertheless, concern remain over threats such as vessel strikes, bycatch, underwater noise and bridge construction. In addition, the planned construction of a dam across the channel connecting Poyang Lake to the river is an additional concern.

Attention: SC, CG-R

Given the extensive and pervasive nature of the threats facing the Yangtze finless porpoise population, the Committee:

*(1) **commends** the efforts of the Government of China to improve its habitat; and*
*(2) **reiterates** that the primary conservation actions should focus on (a) restoring and maintaining suitable habitat throughout the Yangtze River and associated lakes, including the maintenance of a network of* in situ *reserves and (b) ensuring that genetic diversity is preserved and that harmful human activities are limited.*

17.8.3 Maui Dolphin

The Government of New Zealand reported that its review of management measures is scheduled for later this year. An update was provided on observer coverage of the set net fishery in Taranaki and the trawl fisheries adjacent to existing closure areas (95.5%, and 88.3%, respectively). Outside of this target coverage area, an additional 114 trawl fishing days were observed. No captures of Māui dolphins were reported by observers or fishermen in commercial fisheries in the 12-month reporting period to 31 March 2018. A species-specific, spatially explicit, multi-threat risk assessment is being developed for Māui and Hector's dolphins, the results of which will inform an updated Threat Management Plan later in 2018.

Attention: SC, CG-R, CC

The Committee notes that no new management action regarding the Māui dolphin has been enacted since 2013. It therefore concludes, as it has repeatedly in the past, that existing management measures in relation to bycatch mitigation fall short of what has been recommended previously and expresses continued grave concern over the status of this small, severely depleted subspecies. The human-caused death of even one individual would increase the extinction risk. In addition, the Committee:

*(1) **re-emphasises** that the critically endangered status of this subspecies and the inherent and irresolvable uncertainty surrounding information on most small populations point to the need for precautionary management;*
*(2) **reiterates** its previous recommendation that highest priority should be assigned to immediate management actions to eliminate bycatch of Māui dolphins including closures of any fisheries within the range of Māui dolphins that are known to pose a risk of bycatch to dolphins (i.e. set net and trawl fisheries);*
*(3) **notes** that the confirmed current range extends from Maunganui Bluff in the north to Whanganui in the south, offshore to 20 n. miles, and it includes harbours - within this defined area, fishing methods other than set nets and trawling should be used;*
*(4) **welcomes** the update on Maui dolphins provided and looks forward to receiving the species-specific, spatially explicit, multi-threat risk assessment in 2019.*
*(5) **respectfully encourages** the New Zealand; Government to commit to specific population increase targets and timelines for Māui dolphin conservation,*
*(6) **respectfully requests** that reports be provided on progress towards the conservation and recovery goals as updates become available.*

17.8.4 Cruise report from North Western Africa
For the third year, survey results were reported from cruises conducted in north western Africa waters. Fourteen schools comprising some five species and totalling 433 individuals were sighted, including bottlenose dolphins, both pantropical and Atlantic spotted dolphins and, spinner dolphins. This area is poorly surveyed and the continuation of this work was encouraged. The Committee **suggests** that a more substantive analysis of the data from all surveys be conducted and reported back next year, particularly as SC68A priority topic will be on African small cetacean species.

17.8.5 Monodontids Workshop Report
NAMMCO hosted a workshop and produced a Global Review of Monodontids. Researchers and subsistence hunters from across the Arctic and subarctic participated. Several IWC scientists also participated, including Litovka, Reeves, and Suydam. The report[9], summarises what is known about the status of 12 stocks of narwhals and 22 stocks of white whales. There may be more stocks than this as information on stock structure is incomplete for some areas. The summary information and identification of threats and concerns within the report will be helpful in prioritising future research. Some stocks are doing well, but conservation actions are desperately needed for some others. The IUCN Red List status and documentation for both species was updated to Least Concern in December 2017 and that the information summarised in the NAMMCO review was very useful for those assessments.

Attention: C-A

*The Committee **welcomes** the report of the NAMMCO workshop reviewing the monodontids[9]. It **draws attention to** the recommendations contained in the report and **encourages** their implementation, particularly those pertaining to the stocks of greatest concern.*

17.9 Takes of small cetaceans
7.9.1 New information on takes
The Committee received the summary of takes of small cetaceans in 2016–17 extracted from the online National Progress Reports and prepared by the IWC Secretariat, in addition to information obtained online.

No direct takes of small cetaceans were reported in the 2017 National Progress Reports. The Committee **notes** that it would be helpful if the Secretariat encouraged all member countries and IGOs (e.g. NAMMCO) to submit information on direct takes as a routine procedure.

The content of the Japan Progress Report on Small Cetaceans, a public document available from the website of the Fishery Agency of the Government of Japan[10], was summarised. It was noted that catch statistics in the Japan Progress Report on small cetacean cover catches in the calendar year, that is, from 1 January to 31 December, following the guidelines for IWC National Progress Report, while the catch quota of small cetacean fisheries are set seasonally. Thus, in some cases, the calendar yearly catch may exceed the seasonal (yearly) catch in appearance, but in such cases, the actual seasonal catch is aligned with the allocated catch quota. The Committee noted that the catch of 1,057 Dall's porpoises in the hand harpoon hunt was significantly lower than previously recorded reported and below the quota. It was stated that this is a result of the destruction of the community that conducts this hunt, rather than a change in the cetacean population, following the earthquake and tsunami of 2011.

7.9.2. Live captures
The Pacific Scientific Research Institute of Fisheries and Oceanography (TINRO) will consider a quota of 13 killer whales for 2018 and a public hearing was held on 3 May 2018 to make comments on this plan. This proposed new quota considers killer whales in the Sea of Okhotsk as one population, which is estimated to have an abundance of over 3,000 individuals. This number is considered minimal as only 50% of the sea was surveyed. In addition, the information available to the Russian Government on colour and fin patterns, feeding behaviour and distribution do not allow clear identification of different ecotypes, and that all genetic samples analysed to date belong to a single population. It was noted that most published information on Okhotsk Sea killer whale abundance and stock structure is in Russian-language literature, or as part of internal documentation.

Attention: C-A, CG-A
With respect to live captures, and specifically the capture of killer whales from the Sea of Okhotsk, the Committee:

*(1) **reiterates** its long-standing recommendation that no small cetacean removals (live capture or directed harvest) should be authorised until a full assessment has been made of their sustainability;*
*(2) **notes** that this is especially important for killer whales because populations are generally small and have strong social bonds and removals have unknown effects on their demographic structure; and*
*(3) r**eiterates** its concern that removals of killer whales are occurring from the Okhotsk Sea population.*

[9] https://nammco.no/wp-content/uploads/2018/05/report-global-review-of-monodontids-nammco-2018_after-erratum-060518_with-appendices_2.pdf
[10] http://www.jfa.maff.go.jp/j/whale/w_document/attach/pdf/index-9.pdf

In light of the verbal report received at this meeting that Russian authorities intend to proceed to consider limits of allowable live-capture removals of killer whales in the Sea of Okhotsk on the basis that there is no stock structure and there are no ecotype differences between the populations in this region, the Committee:

*(1) **encourages** more extensive effort to examine these issues; and*
*(2) **requests** that relevant analyses be provided for the Scientific Committee's consideration at its next meeting.*

17.10 Status of the voluntary fund for small cetacean conservation research

In 2017, donations for the Voluntary Fund for Small Cetacean Conservation Research totalling £13,122 were received from the Government of Italy. At the end of the financial year 2017, this brought the total of the fund to £81,077.

The Committee **expresses its sincere gratitude** for Italy's contributions and notes that these funds support critical conservation research projects of direct relevance to the work of the Committee.

Five projects were offered funding in 2016 and were implemented in 2017. One of the projects has since been withdrawn and one project, the Indus river dolphin abundance survey, was completed and reported on in 2017. The remaining three projects, on the 'Chilean Dolphin' in Chile, the 'Use of small cetaceans as wildmeat in China' and the 'Development of a business model for sustainable fisheries in the Upper Gulf of California, Mexico', are all near completion and will be reported on fully next year. Updates are available on the IWC website.

17.11 Work plan and budget requests

17.11.1 Priority topics for 2019 to 2024

The sub-committee on Small Cetaceans discussed ongoing priorities and will continue the development of these intersessionally; however, given the location of the meeting it is likely that the focus will be on African species or areas during 2019-20. Other potential priorities identified in discussions were *Inia* (e.g. taxonomy), *Sotalia guianensis*, *Phocoena phocoena*, *Delphinus delphis*, southern hemisphere beaked whales, *Steno bredanensis*, Northwest Pacific *Orcinus orca* and 'the Caribbean'.

17.11.2 Work plan for 2019 – 2020

The workplan on issues related to small cetaceans is given in Table 23.

Table 23

Work plan on small cetaceans

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Franciscana CMP	ICG (Annex Y) to co-ordinate outcomes of CMP across sub-committees	Report	ICG (Annex Y) to synthesis actions from 2019 SC report and develop a work plan	Report
Wildmeat	ICG (Annex Y) to plan and conduct African Workshop.	Report	ICG (Annex Y) group to summarise workshop series and develop future work plan.	Report
Small Cetacean Task Team	Intersessional Workshop on South Asian river dolphins.	Report	Act on recommendations from 2018/19 River dolphin workshop.	Report
Sotalia	SG (Annex Y) to plan and conduct workshop #1 (at SOLOMAC)	Report	SG (Annex Y) to plan and conduct workshop #2	Report

18. WHALE WATCHING[11]

The report of the sub-committee on whale watching is given as Annex N.

18.1 Assess the impacts of whale watching and swim-with-whale operations on cetaceans

18.1.1 Review progress of Modelling and Assessment of Whale Watching Impacts (MAWI)

Modelling and Assessment of Whale Watching Impacts (MAWI) has been on the Committee's agenda for several years. In April 2018, an intersessional workshop was held to identify the key research questions for understanding the potential impacts of whale watching on cetaceans (SC/67b/Rep03). A number of issues were highlighted, including: (a) the need to better understand the impact of recreational whale watching vessels as compared to commercial vessels; (b) the importance of looking at the potential impact of whale watching at short-term (e.g., behaviour change), mid-term (e.g., shift in habitat use) and long-term (e.g., population dynamics) time scales; (c) the use of existing and new data to explore the mid- and long-term impacts, as opposed to replicating short-term studies; and (d) the importance of building scientific capacity in the locations where the research would take place. More information can be found in Annex N, item 2.1.

[11] In response to a request from the Chair of the Whale Watching Working Group of the Conservation Committee, we have changed our past practice of treating whalewatching as a single word to the use of two words.

Attention: SC, C-R

The Modelling and Assessment of Whale Watching Impacts (MAWI) initiative held a workshop in Italy in April 2018, in conjunction with the 32nd European Cetacean Society conference.

The Committee ***endorses*** *the following recommendations from this workshop:*

(1) the incorporation of both social and natural sciences to better understand whale watching impacts;
(2) the development of a Strategic Framework, supported by a Decision Tree, to aid in the prioritisation of policy and research choices;
(3) the development of toolkits and resources that can be accessed globally; and
(4) the standardisation of data collection.

The Committee also ***agrees*** *that a third MAWI workshop be held intersessionally, ideally just before or after the 2nd World Marine Mammal Science Conference in 2019, in Barcelona, with the following objectives:*

(1) to determine in detail which data should be collected to best answer the natural and social science research questions developed in SC/67b/Rep03;
(2) to identify the best locations for conducting research projects that address these questions; and
(3) to continue to develop modelling approaches for assessing the long-term impacts of whale watching on cetacean populations (using data on short- and mid-term impacts).

18.1.2 Review specific papers assessing impacts

The Committee received several papers regarding impacts to cetaceans from whale watching activities. Those papers included (1) efforts to assess stress hormones in baleen of southern right whale calves, (2) 'solitary sociable' cetaceans, (3) land-based observations in the Canary Islands to assess and mitigate potential impacts of whale watching vessels on cetaceans, (4) a Whale Welfare Assessment Tool (also presented and discussed in Plenary) and (5) the 15th year of a summary of papers published in the previous year related to a better understanding of impacts, mitigation and compliance to regulations. Additional details on these papers and projects can be found in Annex N, item 2.2.

Attention: SC, CG-A

The term 'solitary sociable dolphin' or cetacean is usually taken to apply to cetaceans that have little or no contact with conspecifics and who regularly closely approach humans, often including touch, social, sexual and play behaviours (Wilke et al.*, 2005). Given that solitary sociable cetaceans often end up in circumstances where they are harmed and killed and that they may come to present a threat to human swimmers, the Committee:*

(1) ***agrees*** *to continue intersessionally to monitor the phenomenon of solitary sociable cetaceans as part of its work;*
(2) ***advises*** *that, where these animals occur, research be conducted to determine whether the emergence of harmful behaviours either to the animal or to people can be reversed; and*
(3) ***advises*** *local authorities and other concerned parties to keep people away from them in order not to encourage behaviour that may prove harmful to the animal or swimmers.*

In addition, the Committee ***agrees*** *that the Whale Welfare Assessment Tool (currently being developed at the Royal Veterinary College, University of London, in the context of the IWC Whale Killing Methods and Welfare Issues Action Plan), for which a hypothetical whale watching case study was trialled (Annex N, item 2.2), be applied to real-world whale watching situations. The southern resident killer whales in Washington, USA and the bottlenose dolphins in Bocas del Toro, Panama were proposed. These two populations are subject to intense whale watching pressure and may be suffering welfare and health impacts related to this pressure. Both locations have data relevant to the assessment tool and therefore seem ideal as pilot projects for its application.*

18.1.3 Consider documented emerging areas of concern (e.g., habituation, new areas/species, new technologies, in-water interactions) and how to assess them

The Committee received several papers about emerging areas of concern regarding whale watching, including (1) human-induced behavioural changes, (2) impacts from recreational in-water interactions with cetaceans and (3) purposeful and inadvertent feeding by humans.

The Secretariat for the Convention of Migratory Species (CMS) submitted several documents to SC/67b including a global review of in-water interactions with aquatic mammals. That review had resulted in a CMS resolution that encouraged Parties to facilitate research allowing for an assessment of the long-term effects and biological significance of disturbances from 'swim-with-marine-mammal' programmes. The topic of swimming with cetaceans is also addressed under Item 18.6.

The Committee received reports about several studies to assess the impacts and compliance with regulations of commercial 'swim-with-whale' operations in Australia. The discussion of this issue can be found in Annex N, item 2.3.

Attention: SC, CC, S

The Committee ***agrees*** *that the habituation intersessional correspondence group, now named human-induced behavioural changes of concern, should continue (see Annex N, table 3).*

Given the substantial effort the Convention on Migratory Species (CMS) Secretariat has made in preparing several documents for the Committee to consider this year, the Committee:

(1) ***recommends*** *a continuation and an expansion of this exemplary collaboration between the IWC and CMS Secretariats and their various committees;*
(2) ***endorses*** *the intention of CMS to work with the IWC Scientific Committee on guidelines for in-water interactions with aquatic mammals and* ***offers*** *to provide the scientific underpinning for these guidelines;*
(3) ***agrees*** *that the Committee's intersessional correspondence group on swim-with-whales work intersessionally with the CMS Aquatic Mammals Working Group to develop draft guidelines; and*
(4) ***offers*** *to review draft guidelines when they are ready, with a view to* ***agreeing*** *a joint product of the IWC and CMS and hosted by both websites as a global resource.*

See also Item 18.6 for additional recommendations related to swimming with cetaceans.

18.2. Consider information from platforms of opportunity of potential value to the Scientific Committee
The Committee received examples of several platforms of opportunity where data have been collected concerning habitat use, behaviour, changes in distribution and potential risks from shipping for multiple different species in several different areas. Of particular interest was Peninsula Valdés, Argentina, where approximately 460,000 photographs have been taken from whale watching boats and provided to researchers from the Instituto de Conservación de Ballenas and Ocean Alliance (SC/67b/WW04). See Annex N, item 3.

The Committee offered numerous suggestions as to how to handle the large number of images and **encourages** the researchers to network with other researchers around the world, particularly humpback whale researchers dealing with similarly large numbers of photographs and multiple catalogues, to improve the processing time of the photographs.

18.3 Whale watching in east Africa and the wider Indian Ocean
A proposal for Concerted Action for Arabian Sea humpback whales was passed by CMS with strong support from range states. This was discussed in Annex N, item 4.

Attention: CC, S, CG-A

Noting the Committee's discussions over several years on the status of the Arabian Sea humpback whales (see Item 10.2.1), the Committee:

(1) ***welcomes*** *the CMS proposal for Concerted Action for Arabian Sea humpback whales;*
(2) ***notes*** *that humpback whales are the target of one emerging whale watching operation in the south of Oman and* ***highlights*** *the likelihood that the population could become the target of future whale watching activities;*
(3) ***emphasises*** *the need for regulators and scientists to work with the industry to ensure that whale watching does not add to the many other pressures on this small, isolated, non-migratory and endangered population.*

The Committee therefore:

*(1) r****ecommends*** *that building capacity to conduct needed research and to ensure consistent training of whale watching operators be a high priority for Omani authorities and other parties working on the recovery of the endangered Arabian Sea humpback whale population;*
(2) ***notes*** *that boat operators for cetacean watching operations appear to turn over at a high rate in this area, and* ***recommends*** *that training workshops should be regularly offered and conducted;*
(3) ***welcomes*** *the offer from the Pacific Whale Foundation to help organise and conduct another training workshop, but* ***recommends*** *a more comprehensive plan be implemented by the Omani authorities, working with the IWC and other interested parties, to build local capacity for such training; and*
(4) ***agrees*** *to retain a review of whale watching in east Africa and the wider Indian Ocean region in its work plan (see Annex N, table 4) and to conduct an intersessional review of whale watching in these areas, to be presented at SC/68a.*

18.4 Review Whale Watching Strategic Plan (2018-2024) and joint work with the Conservation Committee
18.4.1 Review and provide recommendations on the draft Strategic Plan
At SC/67a, the Conservation Committee's SWG on Whale Watching requested the Scientific Committee to review a draft of the next iteration of the IWC's Strategic Plan (2018-2024) on Whale Watching (see SC/67b/WW02). This was accomplished primarily during a SC/67b pre-meeting and then further discussed in Annex N (item 5 and appendix 2).

Attention: CC

The Committee ***draws the attention*** *of the Conservation Committee's Standing Working Group on Whale Watching (SWG) to Annex N, appendix 2, which provides a full set of comments on the draft Strategic Plan (2018-2024) on Whale Watching. The most important comments and recommendations from the appendix are highlighted below:*

(1) The addition of an Action 1.5: Develop a communications strategy to actively promote IWC whale watching resources (e.g., the Handbook, reports and training opportunities), with approaches tailored to target key audiences. These audiences include the public and whale watching managers, researchers, operators, and on-board naturalists. Communication actions could include preparing publicly accessible summaries of IWC whale watching reports, improving the whale watching pages on the IWC website (which is already underway with the new Whale Watching Handbook, see Item 18.5), and promoting resources on social media, at key meetings and via press releases to industry bodies and trade publications. The implementation of this action could be coordinated intersessionally via the Secretariat. A joint intersessional working group, which includes key Secretariat staff, could develop a communications strategy for consideration at IWC/67 (the Brazil Plenary meeting) and/or the joint session of the CC/SC at SC/68a.

(2) The replacement of the actions of Objective 2 in the draft Strategic Plan with the following:

a) Action 2.1 – Continue the Modelling and Assessment of Whale Watching Impacts (MAWI) initiative, to develop tools and methodologies to assist researchers and managers in their efforts to assess potential impacts of whale watching on cetaceans and to mitigate them. This initiative is ongoing and could focus on:

i) Investigating modelling methods to link short- (e.g., behavioural reactions) and medium-term (e.g., changes in population distribution) responses with potential impacts from whale watching to long-term (i.e., >10 to 20 years) consequences (e.g., vital rates).

ii) Establishing standard data collection methodologies, including from platforms of opportunity.

iii) Identifying key locations for whale watching research projects and programmes, taking into consideration logistics, capacity and management urgency;

b) Action 2.2 – Develop a long-term integrated research programme to better understand the potential impacts of whale watching on the demographic parameters of cetacean populations. Seek to:

i) Investigate whether there is a causal relationship between whale watching exposure and the survival and vital rates of exposed cetacean individuals and populations;

ii) Understand the mechanisms involved in causal effects, if they exist, in order to define a framework for improved management;

c) Action 2.3 – Develop processes and mechanisms for whale watching activities to collect and provide scientifically robust and useful data to researchers and research programmes; and

d) Action 2.4 – Develop an approach (e.g., hold an intersessional workshop; establish a joint intersessional working group) to integrate social and ecological scientific research within the IWC to inform whale watching management and promote potential benefits. This is a coordinated action between the SWG and the sub-committee.

In particular, Action 2.2 will require a dedicated person to guide and coordinate the development and implementation of a research programme or plan. The best option would be for the SWG to contract with someone, full- or part-time, to carry out this task, whilst recognising the budgetary concerns. Therefore, the Committee ***recommends*** *that the search for funding for this and all other actions in the Strategic Plan be focused, broad-ranging, and innovative. An alternative, if budgetary issues are prohibitive, is to have the research programme developed intersessionally by an intersessional correspondence group or the convenor and co-convenor of the Committee's sub-committee on whale watching.*

Lastly, the Committee ***reiterates*** *its previous recommendation to improve the coordination between the SWG and the Committee's sub-committee on whale watching in the development and implementation of a Strategic Plan on Whale Watching. This year's 21 April pre-meeting to review the draft Strategic Plan was intended to improve coordination and provided an opportunity to contribute to the draft Strategic Plan but it did not completely achieve the goal of coordination, as a limited number of SWG members were able to attend the pre-meeting.*

18.4.2 Develop procedures to provide scientific advice as requested in the plan (including the online handbook) and make the Committee more effective at providing information to the Commission

The revised Actions 2.1-2.4 in Item 18.4.1 outline how the sub-committee on whale watching will collect information needed to inform the Conservation Committee's SWG on Whale Watching. Procedures for providing this advice will be discussed and determined cooperatively with the Conservation Committee, during the joint meeting immediately after SC/67b and intersessionally through the intersessional correspondence group (see Annex N, table 3,).

18.5 Whale watching handbook

18.5.1 Review and provide comments on the IWC's Whale Watching Handbook

The Whale Watching Handbook (Handbook) was presented. Before being made available to the public it will also be translated into French and Spanish with support from CMS. Annex N (item 6) provides additional comments and suggestions for fine-tuning and improving the already-admirable Handbook.

Attention: CG-R, SC, S, CC, C-R

The Committee ***welcomes*** *the presentation of the online Whale Watching Handbook and* ***agrees*** *that it is comprehensive, scientifically substantive, user-friendly and well designed.*

To ensure the IWC Whale Watching Handbook comes to the attention of the international whale watching community, including managers, operators and the public, the Committee ***recommends*** *that all Contracting Governments provide a link to the Handbook on the relevant agency pages of their own government websites once the Handbook goes 'live'.*

The Committee also ***recommends*** *that the Conservation Committee and the Commission develop a plan for identifying and securing long-term funding for the further development (e.g., translations into additional languages, writing additional case studies or country profiles) and the ongoing maintenance (e.g., periodic reviews of content) of the IWC Whale Watching Handbook. The Handbook must be updated regularly to remain a vibrant, living document.*

18.6 Review reports from intersessional correspondence groups

The Committee received information from the intersessional correspondence groups (ICG) of swim-with-whale operations and communication with IORA. Annex N provides details of (1) the discussion related to the intersessional work of the ICG on swim-with-whale operations (item 7.1) and (2) the discussion related to the intersessional work of the ICG on IORA communication (item 7.2).

Attention: S, SC, CC, CG-A, CG-R

Regarding swim-with-cetacean operations, the Committee:
(1) ***agrees*** *that the intersessional correspondence group on swim-with-whale operations (Annex N, table 3) should continue;*
(2) ***draws attention*** *to guiding principles for whale watching, including in-water interactions, that are being or have been developed by various regional bodies, such as the Convention on Migratory Species and UNEP in the Wider Caribbean (see Annex N, item 2.3 and UNEP-CEP, 2012), that advise that swimming with cetaceans be discouraged where it is not already established; and*
(3) ***recommends*** *that, in jurisdictions where swim-with-cetacean activities have not been occurring or are just starting, this practice be prohibited until there is scientific evidence that supports allowing it, noting that the risks to both humans and cetaceans are substantial if operators are inexperienced and not following any relevant guidelines; and*

The Committee also ***welcomes*** *the increased communications between IORA and the IWC over the past year. The IORA Sustainable Whale and Dolphin Watching Tourism Network was established and Australia will convene the Network in its first year of operation and will produce a biannual newsletter. Consequently, the Committee:*

(1) ***agrees*** *that the intersessional correspondence group on communication with IORA (Annex Y) should continue; and*
(2) ***encourages*** *greater engagement between the IWC and IORA on whale watching, beyond the exchanges amongst the intersessional correspondence group (Annex N, table 3).*

18.7 Review progress on scientific recommendations

18.7.1 Global influence of recommendations

The Committee received information about the influence of previous recommendations in numerous countries. Details can be found in Annex N, item 8.1.

18.7.2 Tracking progress on previous recommendations

The sub-committee on whale watching reviewed 27 of its recommendations and agreed statements from the past two years. Of those, 15 were completed or partially completed, nine are on-going, and three have not yet been addressed. Annex N, item 8.2, provides details about those recommendations and agreed statements. There is also ongoing work to update and finalise the terms of reference for the sub-committee on whale watching.

18.7.3 Update on dolphin watching in Bocas del Toro, Panama

Concern continues about the number of dolphins from the small population in Bocas del Toro, Panama that are found dead. Nine deaths in 2016 and 2017 are known to have occurred, five of them confirmed boat strikes. These losses are unsustainable. Research to better understand impacts on the population includes measuring stress hormones in biopsy samples and acoustic monitoring. A regulatory update to strengthen management of whale and dolphin watching in Panama, including Bocas del Toro, was released in October 2017, with the support of the Ministry of Environment.

Attention: SC, C, CG Panama

The Committee ***reiterates*** *its grave concern regarding the intense and uncontrolled dolphin watching in Bocas del Toro, Panama. This concern has been expressed and reiterated for several years due to continuing mortalities, including from vessel strikes, in this small population (probably fewer than 100 animals). In this regard, the Committee:*
(1) ***welcomes*** *the ongoing research to monitor this dolphin population and the impacts it is facing from dolphin watching;*
(2) ***reiterates*** *its welcome of Panama's increased responsiveness to protect the local dolphin population by minimising negative impacts from dolphin watching (IWC, 2018a) and* ***welcomes*** *the regulatory update, supported by the Ministry of Environment, which is meant to lead to stronger management of whale and dolphin watching in Panama, including Bocas del Toro; and*

*(3) **expresses serious concern** at the number of deaths reported in 2016 and 2017 and **recommends** action from the Government of Panama as a matter of urgency, including the immediate and committed implementation of the updated regulations.*

18.8. Work plan and budget requests for 2019-2020

18.8.1 Work plan for 2019-2020

The work plan for matter related to whalewatching is shown in Table 24.

Table 24

Summary of the work plan for matters related to whale watching. Many of these items have intersessional correspondence groups (ICG) or intersessional advisory groups (IAG). Those groups will work intersessionally and provide updates at SC/68a (see Annex X)

19. SPECIAL PERMITS

19.1 General considerations on improving the evaluation process

This issue is considered as part of the process to revise 'Annex P' (see discussion in Item 28.3).

19.2 NEWREP-A

Summaries of NEWREP-A papers are given in Annex U1.

19.2.1 Report on ongoing research

In plenary, the Committee received and briefly discussed four papers on ongoing work – as indicated below, some of these were discussed more fully in sub-groups.

SC/67b/SP08 presented the results of the third biological field survey of NEWREP-A during the 2017/18 austral summer season. In discussion, it was noted that the high apparent pregnancy rate (95.3%; 122 of 128 mature females) of Antarctic minke whales was consistent with previous results (e.g. from JARPA and JARPA II).

SC/67b/ASI07 presented a summary of results of the NEWREP-A dedicated sighting survey during the 2017/18 austral summer season whilst SC/67b/ASI11 presented the research plan for the next systematic vessel-based sighting survey in the Antarctic under NEWREP-A 2018/19. The new NEWREP-A 2018/19 sighting survey plan has been endorsed by the Committee; Annex Q (item 4.2) provides more details on both these papers.

SC/67b/EM05 presented results of the krill and oceanographic surveys undertaken during the third NEWREP-A survey in Area V-E and VI-W (see Annex L, item 6.1 for details).

19.2.2 Update on previous recommendations

19.1.2.1 AGE DATA AND RMP/IST (RECOMMENDATION 1)

SC/67b/RMP03 provided updated draft specifications for an RMP/IST type simulation exercise to evaluate management procedures based on modified catch limit algorithms that use information on recruitment inferred from age data from Antarctic minke whales. Details and discussion are given in Annex D, section 2.3.2.

Attention: S

*The Committee **agrees** that methods currently used or proposed to be used in the Committee that use age data should (as necessary) be investigated to evaluate the relationship between their results and the accuracy and precision of the age data that they use where this is pertinent to the results of import from these methods. The Committee **agrees** to include this as an agenda item for next year's meeting.*

19.1.2.2 BIOPSY SAMPLING AND TELEMETRY FEASIBILITY STUDIES (RECOMMENDATIONS 4 AND 5)

SC/67b/SP04 summarised the results of a feasibility study on biopsy sampling and satellite tagging of Antarctic minke whales under NEWREP-A. The authors concluded that in the context of the NEWRREP-A objectives, (a) the efficiency of biopsy sampling is much lower than that of lethal sampling for Antarctic minke whales and (b) that the amount of tissue derived from biopsy samples is insufficient to conduct the suite of biomarkers targeted by NEWREP-A. They therefore concluded that biopsy sampling was not a feasible approach to fulfil the objectives of NEWREP-A.

This paper prompted considerable discussion in the Committee, both with respect to ‘efficiency’ of the method and the amount of material required.

One issue raised was that there was the need for better clarification of terminology used in the paper (e.g. ‘sampling’ versus ‘killing) in order, for example, to interpret properly the conclusion that biopsy sampling took approximately three times longer than lethal sampling. It was not clear, for example, whether the median times for biopsy and lethal sampling provided were truly comparable because of the lack of information on when the time for these methods started and ended. In particular, handling time for lethal sampling appeared to not be included in the total time calculations.

The authors responded that in SC/67b/SP04 ‘the efficiency’ of sampling techniques was defined as ‘Success Proportion’ rather than ‘Time of Experiment’ because ‘Success Proportion’ represents a better indicator of the efficiency. To fulfil the purposes of NEWREP-A, random sampling is required in which generally only one animal from a school is sampled. Notwithstanding this clarification, they provided definitions of ‘Time of Experiment’ (see details in Yasunaga *et al*. in Annex U2).

Another issue raised was that the NEWREP-A review workshop (ref) had suggested ‘involving people with expertise in successfully biopsy sampling common minke whales in the North Atlantic’, meaning collaborating in the field with experienced foreign experts. However, Table 2 of SC/67b/SP04 showed an ongoing decline in success proportion (number of biopsy samples / number of targeted whales which were chased for sampling by the SSVs) between 2015/2016 and 2017/2018 rather than the increase one would expect with increasing experience. The authors responded that they had consulted with foreign scientists although they were not on the vessels, that they used experienced marksmen and that the decline was an artefact of weather and sea state conditions under which samples were collected. However, the counter-comment was made that in authors’ analyses, the best model did not include “weather conditions” as a significant factor.

In response the authors provided results of a GLM analysis based on the binomial distribution assumption to examine the differences in success proportion in the biopsy sampling experiment using research seasons as explanatory variables. The coefficients for each year were not significant, suggesting that the differences of success proportions among the seasons are not statistically significant and consequently provide no evidence that shooters’ efficiency has decreased significantly over the three research seasons (see details in Yasunaga *et al*. in Annex U2).

Some Committee members (see Clapham et al. I, in Annex U2) disagreed with the authors’ conclusion that the study revealed that biopsy sampling was not feasible for the NEWREP-A programme. Rather, they believed that it showed that it was both feasible and appropriate. They also disagreed that the amount of tissue obtained was insufficient, citing the large number of research programmes that successfully use biopsy samples to fulfil research objectives including using a single sample for a variety of biomarkers (e.g. stable isotopes, fatty acids, hormones, genetics).

In response, the authors agreed that the amount of epidermal tissue collected by biopsy sampling is enough for the requirement of genetic, epigenetic and stable isotope analyses. However, they stressed that the amount of adipose tissue collected by biopsy sampling was not large enough to measure progesterone, lipid content and fatty acid in the context of the objectives of NEWREP-A (see details in Yasunaga *et al*. in Annex U2).

In their closing comments, the authors stated that in response to the recommendation of the Expert Panel, dedicated experiments for biopsy sampling of Antarctic minke whales had been carried out which had generated the results presented at this meeting and from which the authors had drawn their conclusions. No further dedicated time for biopsy experiments was planned at this stage, but this could be reconsidered at the mid-term review. Meanwhile, NEWREP-A will only collect additional biopsy samples opportunistically.

With respect to the best approach to assess the efficiency of biopsy versus lethal sampling, a standard approach for measuring the efficiency of biopsy sampling and to compare this to the process of lethal sampling was proposed (Clapham et al. II, in Annex U2).

Attention: S

The Committee had last year agreed on establishing an intersessional Advisory group tasked ‘to provide advice on developing an experimental protocol for ascertain whether it is possible to reliably biopsy minke whales and, if so, under what circumstances (experience, vessel type, equipment, environmental conditions, etc.). This group could use as starting point the advice provided by the Expert Panel’ (JCRM 19 suppl:431-490). Due to a clerical error the group did not convene. Attention was drawn to a protocol to evaluate non-lethal techniques presented to SC66b (Mogoe et al., 2016). This protocol included four questions to help identify the feasibility and practicability of non-lethal methods.

The Committee ***agrees*** *to re-establish the Advisory group (Annex Y), under Palka for consideration at SC68a. It also* ***agrees*** *that suggestions for refining questions in the method used by Mogoe and colleagues (2016) should be added to the tasks of this group.*

19.1.2.3 EPIGENETIC AGEING (RECOMMENDATION 8)

Recently, epigenetic (DNA-methylation) ageing has been successfully used to estimate age in humpback whales (Polanowski *et al.* 2014). As noted under Item 11.4.4, this year, the Committee invited Jarman, the leading specialist in this technique to give an overview presentation to the Committee as a special night session. This covered topics such as current and future prospects for this class of methods (see Annex I, item 5.5).

SC/67b/SDDNA04 presented a feasibility study on epigenetic ageing in Antarctic minke whales in response to Recommendation 8 from the Expert Panel (for details see Annex I, item 5.5).

Some suggestions were made on how to improve resolution (in particular, evaluate more loci and then restrict to those loci highly correlated with age); the current set of loci do not provide sufficient precision for use in the population dynamics modelling exercise recommended for NEWREP-A. Given that there is an upper limit to the degree of precision that can be achieved using this technique, the Committee noted that the utility of epigenetic age estimation (and other methods of age determination) will depend on the degree of precision needed for the specific application of interest (see recommendation under Item 11.4.1).

19.1.2.4 DETERMINING SEXUAL MATURITY IN BLUBBER (RECOMMENDATION 9)

SC/67b/SCSP05 presented results from the NEWREP-A research component focused on determining sexual maturity in female Antarctic minke whales, during the feeding season based, on concentrations of progesterone in blubber. The authors concluded that the progesterone concentration in blubber samples cannot be used as a diagnostic index to discriminate between mature and immature female Antarctic minke whales and that lethal sampling is required to obtain information on sexual maturity for use in population dynamic models.

Some members of the Committee disagreed with that conclusion, as they demonstrated that the amount of misclassification in immature versus mature females would be small (~1%, see Wade *et al.* in Annex U2) and thus that progesterone levels in biopsy samples would allow discrimination between mature and immature animals.

They noted that the stated purpose of the study was to discriminate between immature and mature females for fitting population dynamics models such as the catch-at-age analysis; the only misclassification that occurred was a total of 3 (out of 230) whales between the resting and the immature classes, and therefore the only misclassification rate that is important remains ~1% of the total sample.

Some other members noted, also in relation to recommendation 10, that misclassification for discriminating between resting and immature animals was higher and thus the method less reliable for that task.

In response to a request, the authors provided a histogram showing the numbers of immature, resting, ovulating and pregnant animals (Figure 1 of Yasunaga *et al*. in Annex U2). Based on the assumption of cut off values (1.0 ng/g) of progesterone set in Wade *et al.* (see in Annex U2), six of 56 immature whales and three of 11 resting whales were misclassified. Misclassification ratios were thus10.7% and 27.2%, respectively, and these were not considered negligible by the authors (see details in Yasunaga *et al*. in Annex U2).

19.1.2.5 SAMPLE SIZES REQUIRED TO DETECT CHANGE IN ASM (RECOMMENDATION 26)

SC/67b/SCSP01 focused on the need to complete NEWREP-A recommendation 26 on the calculation of sample size. The Committee discussed its previous conclusions in this regard. In 2016, the Committee assessed that three of six aspects of the Expert Panel's recommendations had been adequately addressed in relation to sample sizes. Some members of the Committee consider that until the proponents fully implement the Expert Panel recommendations for calculating sample sizes, the proponents have not demonstrated that they are able to meet their stated objectives in relation to the NEWREP-A programme. The proponents' position and that of some Committee members is that the work has been completed to a reasonable level and that any further work on sample sizes will be afforded a low priority.

The Proponents reiterated their position regarding the work on and status of recommendation 26 ('Provide a thorough power analysis of sample sizes required to detect change in ASM and follow the other recommendations in this item') from the NEWREP-A Review Workshop (IWC, 2016). In view of the proponents, the work on recommendation 26 has been completed to a reasonable level. Details can be found in GOJ (2015; 2016a) and GOJ (2016b). The IWC SC has already concluded that the approach being taken to address the recommendation is appropriate (IWC 2018). Consequently, the proponents have concluded that the reasonableness of the proposed sample size (333) has been adequately demonstrated. The proponents recognize that in 2016 the Scientific Committee suggested some further refinement work; however, they consider that such refinement work goes beyond the original scope of recommendation 26 from the NEWREP-A review workshop. Nevertheless, in deference to the Committee, it was the proponent's intention to address the refinement work for this year's Scientific Committee. However, because of unanticipated specialist personnel unavailability, this has had to be postponed. The proponent's intention is to continue contributing to this work subject to logistical constraints and the availability of specialist analysts.

19.1.2.6 COMMITTEE'S ADVICE

The table in Annex U4, provides a detailed update of the Committee's view of progress on previous recommendations. An overview is given in Table 25.

Table 25

NEWREP-A – Overview on progress with recommendations.

Recommendations in are not in priority order. Recommendations that relate to purposes A, B, C and D are higher priority for completion. Recommendations coded uniquely as "*E: Relevant to improve existing components of the proposed programme*" are excluded from this table as they were optional. Key for 'Purpose': *A: To evaluate the contribution of a particular objective or sub-objective of the programme to meet conservation and management needs*; *B: To evaluate the feasibility of particular techniques (whether lethal or non-lethal)*; *C: Relevant to a full evaluation of whether any new lethal sampling is required*; *D: Relevant to issues related to sample size (irrespective of method used to obtain data).*

Recommendation	Purpose	Deadline	Proponents self-evaluation on progress as of SC67b	Committee's comments
(1) Age data and RMP/IST	A, C, D	August 2016	Completed to a reasonable level	SC66b: A range of opinions as to the extent to which this recommendation has been addressed. SC67a: No new information. SC67b: Some information presented (See section 19.1.2.1).
(2) Stock definition	A, D	May 2016	In progress.	SC66b: No progress. SC67a: As in SC66b. SC67b: As in SC66b.
(3) Mixing rates (simulations on precision and bias)	A, D	May 2016	To be completed by the mid-term review.	SC66b: No progress. SC67a: As in SC66b. SC67b: As in SC66b.
(4) Biopsy feasibility study	B, C, D, E	Field season 2017-2018	Completed.	SC66b: Some progress (SC/66b/IA05). SC67a: Some progress (SC/67a/ASI07). SC67b: Partially completed, further refined analysis is needed (see 19.1.2.2). A WG was formed to review and improve methods.
(5) Telemetry feasibility study	B, E	Field season 2018-2019	Completed.	SC66b: Some progress (SC/66b/IA05). SC67a: Some progress (SC/67a/ASI07). SC67b: Completed.
(8) DNA methylation ageing technique	B, C, D	March 2017	Completed.	SC66b: No progress. SC67a: As in SC66b. SC67b: Partially completed, further refined analysis is encouraged. See section 19.1.2.3.
(9) Hormones in blubber and sexual maturity	B, C, D	March 2018	Completed.	SC66b: No progress. SC67a: As in SC66b. SC67b: Blubber hormones analysis completed. On accuracy see section 19.1.2.4.
(10) SCAA and misassignment 'resting' females/immature females.	A, C, D	August 2016	To be completed by the mid-term review*.	SC66b: No progress. SC67a: As in SC66b. SC67b: New information presented (SC/67b/SCSP05).
(11) SCAA, density- dependence, and stock mixing	A, C, D	May 2016	Completed*.	SC66b: Partially completed: updates on stock mixing and mixing rates still necessary. SC67a: As in SC66b. SC67b: As in SC66b.
(12) Time-varying natural mortality and SCAA	A, C, D	August 2016	To be completed by the mid-term review*.	SC66b: No progress. SC67a: As in SC66b. SC67b: As in SC66b.
(13) Time varying ASM data and SCAA	A, C, D	May 2016	To be completed by the mid-term review*.	SC66b: No progress. SC67a: As in SC66b. SC67b: As in SC66b.
(15) Krill acoustic sampling	B, E	March 2017	Completed.	SC66b: Completed.
(17) Power analysis for krill abundance	A, E	August 2016	To be addressed.	SC66b: Will be addressed in consultation with CCAMLR specialists SC67a: No progress. SC67b: As in SC66b.
(18) Stomach contents vs krill survey	A, B, C	May 2016	To be addressed.	SC66b: Will be addressed in consultation with CCAMLR specialists SC67a: No progress. SC67b: As in SC66b.
(22) Energy intake (requirements)	A, B, D	August 2016	To be addressed. Need clarification from the IWC SC	SC66b: No Progress. SC67a: As in SC66b. SC67b: As in SC66b.
(23) Stable isotopes in baleen plates	B	August 2016	Completed.	SC66b: Will be addressed in consultation with other research institutions. SC67a: Some progress presented. SC67b: Completed.
(26) Sample sizes required to detect change in ASM	D	May 2016	Completed to a reasonable level	SC66b: Overall, the approach being taken to address the recommendation is appropriate, but some further refinements are required. SC67a: No Progress. SC67b: As in SC67a.

*See note in Table #, Annex U4.

19.3 JARPN II

The new information provided on JARPN II is relevant only to the discussion of the NEWREP-NP 'non-lethal vs lethal' feasibility study (see Item 19.3).

19.4 NEWREP-NP

19.4.1 Report on ongoing research

Three papers were presented on progress made during the 2017 surveys of different aspects of the NEWREP-NP programme (SP03, 06, 07, see Annex U3 for summaries).

In particular, SC/67b/SP03 reported the results of the satellite tagging ofn North Pacific sei whales. A total of 44 tagging attempts were made using SPOT6 tags with the LKArts attachments system. A total of 15 tags were deployed on sei whales, and eight whales were tracked. Two sei whales were tracked for more than 35 days, and both showed longitudinal movement. The authors concluded that the tagging experiment showed that deploying such tags from sighting/sampling vessels was practical, but identified technical improvements to try to increase the tracking period.

In discussion, it was noted that the proportion of successful deployments was low (7 failures in 15 attempts); and suggestions on how to improve this included: (a) strategic placement of tags on the upper body of whales to ensure tag longevity and reduce potential physical impacts (e.g. lesions) and (b) replacement of the current screw-on anchor system with an integrated tag design to decrease the possibility of tag breakage. It was noted that guidelines for cetacean tagging should become available within the next year and published in the IWC Journal. It was noted by the authors that the cause of the failures in SP03 were difficult to evaluate since a tag in an optimal position on the whale had also failed. New tags with a modified anchor system and stopper will be used during the next season.

The Committee welcomes new information on the feasibility of satellite tagging sei whales and notes the valuable movement data collected from two of the longer-term (>35 days) deployments. The Committee **encourages** the collection of more telemetry data and notes that this may help improve abundance estimation (by providing information on correction factors) and provide inferences on stock structure.

SC/67b/ASI10 presented a summary of results of the NEWREP-NP dedicated sighting survey in the western North Pacific in 2017 whilst SC/67b/ASI06 presented the research plan for the next systematic vessel-based sighting survey in the western North pacific under NEWREP-NP in 2018 and 2019. As indicated under Item 24.3, the new NEWREP-NP sighting cruise plan has been endorsed by the Committee; Annex Q (item 4.2) provides more details on both these papers.

19.4.2 Update on previous recommendations

The table in Annex U4, provides a detailed update of the Committee's view of progress on previous recommendations. An overview is provided in Table 26 (see next page).

Table 26

Summary of status of recommendations relevant to NEWREP-NP

No. of recommendation	Priority by the Committee	Timeline	Proponents self-evaluation on progress as of SC67b	Scientific Committee Evaluation
(1) Lethal vs non-lethal quantitative review of data	Very high	Before start	SC67a: Completed.	SC67a: Different opinions as to whether the recommendation has been met. SC67b: No progress.
(3) Sexual maturity (blubber and serum)	High	Before start	SC67a: Completed.	SC67a: The Proponents demonstrated intention to include analysis of blubber for progesterone, but there are few details of how. SC67b: Partially addressed.
(4) Sightings surveys	High	Before start and annually	Addressed and ongoing.	SC67a: Completed: survey plan was presented. SC67b: Completed: survey plan was presented.
(5) Stomach contents	High	Before start	SC67a: Completed.	SC67a: Completed.
(7) Immune function assays	High	Before start	SC67a: Completed.	SC67a: Completed.
(8) Lipophilic compounds	High	Before start	SC67a: Completed.	SC67a: Completed.
(10) Coordination with IWC-POWER	High	Before start and annually	Addressed and ongoing	SC67a: Completed annually.
(11) Coastal component: sampling strategy	High	Before start	Disagree with Panel	SC67a: No progress as proponents disagree with Panel. SC67b: No progress.
(12) Offshore components: sampling strategy	Very high	Before start	SC67a: Completed.	SC67a: Completed.
(13) downweight historical age-composition data	Very high	Before start	Disagree with Panel.	No progress.
(15) efficiency of biopsy sampling (additional captures unnecessary)	Very high	High priority ASAP in 2017	Disagree with Panel.	No progress.
(17) Telemetry	High	Before start	Ongoing	SC67a: Partially addressed. SC67b: New information (SC/67b/SCSP03).
(21) Sample size (potential reduction of lethal sample size)	Very high	Before start	To be considered by the mid-term review.	SC67a: The possibility for further work has been considered. SC67b: No progress.
(22) Sample size (in general)	Very high	Before start	Not relevant.	SC67a: Small progress. SC67b: No progress.
(23) Impact of catches on common minke whales (subset of 2013 *Implementation*)	Very high	Before start	Disagree with Panel.	SC67a: Major concerns addressed. SC67b: Completed. Refined analyses were presented. It could be reconsidered in the next *Implementation Review*.
(24) Impact of catches on common minke whales (new abundance)	Very high	Before start	Disagree with Panel.	SC67a: Major concerns addressed. SC67b: Completed. Refined analyses were presented. It could be reconsidered in the next *Implementation Review*.
(25) Sei whale (abundance, $MSYR_{1+}$=1%, $MSYR_{mat}$=4%)	Very high	Before start	SC67a: Completed.	SC67a: Completed.
(27) Higher priority to analyses and modelling	High	Before start	Ongoing	SC67a: It is not clear that additional qualified personnel have been hired. SC67b: No progress.
(28) Sample and data archiving, relational database(s)	High	Before start	Ongoing	SC67a: Partially addressed for DNA data and associated biological information.
(29) Contingency plan	High	Before start	Ongoing	SC67a: Partially addressed.

20. WHALE SANCTUARIES

20.1 Review of the Southern Ocean Sanctuary Management Plan

The Schedule amendment establishing the Southern Ocean Sanctuary (SOS) requires the Sanctuary to be reviewed at succeeding ten-year intervals, unless otherwise revised by the Commission. The first review of the SOS took place in 2004 (IWC, 2005) and the second review was completed in 2016 (IWC, 2017). In 2014 (IWC, 2015c), the Commission adopted eight objectives for the SOS (summarised in Annex R, item 3). The Commission also provided terms of reference for the review to be undertaken by the Scientific and Conservation Committees. The Scientific Committee review made several recommendations (IWC, 2017c). These recommendations were taken into account in a draft Southern Ocean Sanctuary Management Plan (SC/67b/SAN01) developed by Australian scientists and discussed in Annex R (item 3). It was noted that, while the draft Plan does contain performance measures, it does not contain criteria for its own review.

The purpose of the draft Management Plan is twofold: (1) to inform the Commission and public about the sanctuary objectives and actions planned for the next ten years; and (2) to propose strategies toward the achievement of the SOS's goals using the best means available and provide clear performance measures for each proposed action.

The operative part of the Plan is a Research and Action Plan that involves assessing and addressing threats and research on the recovery of whale populations and their habitats. The Research and Action Plan is structured based on the Commission's agreed objectives for the SOS. Each objective is linked directly to a measurable objective, action or approach and performance measure.

The Committee also discussed the potential contributions that data and results from the Japanese whale research programme in the Southern Ocean (NEWREP-A) could make to the objectives and goals of the Plan and the Committee agrees to incorporate reference to NEWREP-A under Objectives 4-6.

The amended Plan, with Objectives 1 and 8 (relating to policy) and the chapeau of Objective 5 redacted to clarify that the Committee did not address these elements of the Plan, is given as Annex R (Appendix 2).

A statement from the Government of Japan regarding its position on the SOS and this draft Management Plan is attached as Annex R, Appendix 3.

Attention: C-A, CC, SC,

The Committee reviewed the components of a draft Management Plan for the Southern Ocean Sanctuary (SOS) that are related to science and therefore within its remit and:

*(a) **endorses** the measurable objectives, approach/actions and performance measures of Objectives 2 -7 of the amended draft Southern Ocean Sanctuary (SOS) Management Plan (Annex R, appendix 2); and*
*(b) **agrees** to include a new standing item on the agendas of all relevant sub-committees and working groups: 'new information relevant to the SOS Management Plan' in order to assist the Commission in monitoring and measuring progress on the scientific objectives of the Plan.*

21. SATELLITE TAGGING DEVELOPMENT AND BEST PRACTICES

21.1 Tag Workshop Meeting, Silver Spring, MD, USA 6-8 September 2017

A workshop on cetacean tag development, tag follow-up and tagging best practices was held at the National Marine Fisheries Service in Silver Spring, Maryland, USA from 6-8 September 2017. The workshop was co-sponsored by the Office of Naval Research (ONR), the International Whaling Commission (IWC), and the National Oceanic and Atmospheric Administration's National Marine Fisheries Service (NOAA/NMFS). The purpose of the workshop was to review and evaluate progress in tag design and attachment since the 2009 ONR Cetacean Tag workshop (ref - attached), with an emphasis on (a) recent tag attachment improvements, (b) follow-up studies that examined the effects of tagging, and (c) reviewing and providing input on draft cetacean tagging best practices guidelines.

Several presentations were made, with a focus on sharing information and discussion of the best available science of design and effects of tagging to facilitate future advancements in tag design and application, maximising attachment durations to the extent required to answer the questions being posed, whilst minimising potential impacts to the animals.

Discussion on the status of tag attachment development and follow-up studies occurred, along with extensive discussion regarding the cetacean tagging best practices guidelines. While much was accomplished towards the collective goals of the workshop, one item not covered in sufficient detail was discussion on the future directions in tag attachment technology. Therefore, a second smaller workshop will be convened in June of 2018 with a subset of the original attendees that focus specifically on tag attachments. The final report will merge the results of the September 2017 workshop and the June 2018 workshop.

22. IWC LIST OF RECOGNISED SPECIES

The Committee has agreed to follow the guidance of the Society for Marine Mammalogy's Committee on Taxonomy. This year (see Item 17.5), in completing its review of the taxonomy of *Tursiops*, the Committee noted that the current taxonomy provided by the SMM Committee for *Tursiops* was well supported by morphological and molecular genetic data, as well as ecological and distributional data.

23. IWC DATABASES & CATALOGUES

23.1 Guidelines for IWC catalogues and photo-ID databases

At last year's meeting, the Committee agreed IWC Guidelines for Photo-identification Catalogues (IWC, 2018f), noting that adding technical Appendices would be valuable in the future. Draft items for inclusion as Appendices were discussed by the *Ad hoc* Working Group on Photo-identification (Annex S, item 5.1) covering five issues: (1) cataloguing software; (2) image matching software; (3) seminal papers defining individual identification, by species; (4) photo quality guides; and (5) photo/data collection apps. Work will continue on developing these appendices intersessionally (Annex Y).

23.2 Progress with existing or proposed new catalogues

23.2.1 Integration of eastern South and Central Pacific blue, humpback, and fin whale photo-catalogues

There was no new information specific to this item this year.

23.2.2 Southern Hemisphere and Indian Ocean humpback whale catalogues

23.2.2.1 ANTARCTIC HUMPBACK WHALE CATALOGUE

The Antarctic Humpback Whale Catalogue (AHWC), maintained at College of the Atlantic, USA, was established in 1987 and during the past 30 years its data have been used in dozens of studies and publications (Stevick *et al.*, 2017). With a recent loss in funding, the catalogue database is now 'frozen' and is not being actively updated. The Working Group expressed strong disappointment at this news as well as the hope that the AHWC's funding situation will change and enable the catalogue to continue.

Attention: SC, G

The Scientific Committee has been informed that due to a loss of funding, the Antarctic Humpback Whale Catalogue curated by the College of the Atlantic, USA will no longer be updated. The Committee:

(1) ***draws attention*** *to the great value this catalogue (established in 1987) has provided to the Committee, including receiving photographs from the IWC IDCR and SOWER cruises and providing information for the Committee's Comprehensive Assessment of Southern Hemisphere humpback whales;*
(2) ***welcomes*** *news that the existing catalogue will remain a resource for scientists; and*
(3) ***encourages*** *potential funders to support future continuation of the catalogue.*

The Committee also received an update on the development and status of 'Happywhale', a web-based marine mammal photo-ID crowd-sourcing platform (SC/67b/PH05)[12]. This is discussed in Annex S (item 2.2). In recent months Happywhale provided images to catalogues relevant to the IWC and IWC-SORP of Southern right whales, Antarctic blue whales, and Antarctic killer whales. It will also contribute to the ongoing in-depth assessment of North Pacific humpback whales (see Annex F item 4.2.1).

23.2.2.2 ARABIAN SEA WHALE NETWORK'S FLUKEBOOK

In 2016 (IWC, 2017), the IWC approved funding for the development of a regional data platform for the Arabian Sea Whale Network (ASWN), to be implemented in collaboration with Wild Me, the developers of Flukebook. This year the Committee received information SC/67B/PH/03 that described Flukebook, a non-profit, open source cetacean data archiving and photo matching tool as discussed in Annex S (item 2.1; SC/67B/PH/03). The ASWN is joining Flukebook with two primary objectives: (1) to consolidate and more effectively manage humpback whale and other cetacean data collected in Oman over the past 20 years; and (2) to provide an online platform that will allow comparison and regional-level analysis of cetacean data collected by different research groups throughout the Arabian Sea (so far photographs are mainly from Oman, with a few from Pakistan and India). The Committee **looks forward** to updates on this work.

23.2.3 Southern Hemisphere Antarctic and pygmy blue whales: Catalogues and databases

23.2.3.1 SOUTHERN HEMISPHERE BLUE WHALE CATALOGUE (SHBWC)

The SHBWC has become the largest repository of Southern Hemisphere blue whale photo-identifications. It now includes a total of 1,519 individual blue whale photo-identifications from areas off Antarctica, Chile, Peru, Ecuador-Galapagos, Eastern Tropical Pacific (ETP), Australia, Timor Leste, New Zealand, southern Africa, Madagascar and Sri Lanka. The Committee received information on the progress made with the catalogue (SC/67B/PH/04), especially in light of the recommendations made last year to conduct catalogue comparisons in the Indo-Australian region (IWC, 2018b). This is discussed in more detail in Annex S (item 3.2). Comparison work (SC/67B/SH16) found (a) no matches between Australia, New Zealand and Sri Lanka, reinforcing the hypothesis of separate populations; and (b) exchange within Australia, suggested a single population; and (c) re-sights found in New Zealand suggest some site fidelity. Additional work is underway. The relevance of the catalogue to population assessments is discussed in Annex H Item 7.1.1.2.

23.2.3.2 ANTARCTIC BLUE WHALE CATALOGUE (ABWC)

In 2017, the Antarctic Blue Whale Catalogue compared photographs from the IWC IDCR/SOWER cruises in 1989/1990, 1993/1994, and 1997/1998 as well as opportunistic photographs collected by collegial scientists, naturalists, and tourists 2015-2018. The catalogue now contains almost 460 individuals. The results of the comparison of new Antarctic blue whale identification photographs to the ABWC is summarised in SC/67B/PH02 and discussed in Annex S (item 3.1); 17 new individual blue whales were identified. The collection of Antarctic blue whale identification photographs provide data for capture-recapture estimates of abundance (SC/67B/SH08) as well as information on the movement of individual blue whales within the Antarctic region. The relevance of the catalogue to population assessments is discussed Annex H, Item 7.1.1.1.

Attention: SC

(1) The Southern Hemisphere Blue Whale Catalogue provides data useful for estimating abundances and examining connectivity between feeding and breeding grounds. The Committee ***agrees*** *that the catalogue continue.*
(2) The Committee ***agrees*** *that the Antarctic Blue Whale Catalogue continue its work collecting adding photo-identification data to the catalogue in order to assist with developing estimates of population abundance for Antarctic blue whales.*
(3) The Committee ***agrees*** *that the development of a simple guide (physical and electronic versions) to help tourists and naturalists take photos that are suitable for photo-identification should be undertaken. This will support the photo-ID*

[12] https://happywhale.com

catalogues from the Antarctic region for use in population assessments by the IWC, particularly for blue whales, right whales, fin whales, and humpback whales.

23.2.4 Southern Hemisphere fin whale photo catalogues

The Committee received information on on a new photo-identification catalogue of Antarctic fin whales. Photographs from SOWER cruises 2004-2008 are included as well as those collected opportunistically near the South Orkney Islands during a Commission for the Conservation of Antarctic Marine Living Resources (CCAMLR) fisheries research voyage (SC/67B/PH01). This is discussed in Annex S (item 4.1). The catalogue serves as a foundation for future photo-ID studies, especially those proposed for the western Antarctic Peninsula. The relevance of the photo-identification of fin whales to population assessments is discussed Annex H, Item 7.1.2.

Attention: S, SC

1) The Committee ***encourages*** *continuation of the Antarctic Fin Whale Catalogue which can potentially provide data toward estimating abundance or identifying movement patterns.*
2)The Committee ***agrees*** *that an exhaustive search be conducted to locate SOWER photos that are missing from the IWC archives, including those of fin whales.*

23.2.5 Western Pacific gray whale photo catalogues

The Committee received information on two photo-identification catalogues relating to the Sakhalin Island feeding aggregation: one (SC/67B/ASI04), based on work undertaken as part of an industry-sponsored Exxon Neftegas Limited-Sakhalin Energy Investment Company joint monitoring program discussed in Annex S, item 4.2); and the other conducted by the Russia gray whale project (SC/76b/CMP/7) discussed in Annex O (item 2.1.3). The Committee welcomed news that the two catalogues would be unified under the auspices of the IWC.

23.3 Work plan

The work plan on work related to catalogues is provided in Table 27.

Table 27

Work plan on issues related to catalogues.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Appendices for IWC Guidelines for Photo-identification	Continue compilation	Appendices ready for review	Continue compilation	Appendices ready for review
Upload all available New Zealand blue whale identification photographs to SHBWC (also pertains to Annex H item 7.1.1)	Cross-reference between separate area catalogue holdings before uploading to SHBWC avoid duplication; intersessional correspondence group (Annex Y)	Included in SHBWC report	-	-
Development of how-to photo-ID materials for naturalists and citizen scientists (also pertains to Annex H item 7.1.1.2)	Prepare hard copy and PPT photo-ID guides	Guide completed and available (pending funding)		
4) Search for missing SOWER photographs, especially fin whale photos from 2006/2007	Search Secretariat archives and contact SOWER researchers for personal copies of photos	Report		

23.4 Potential future IWC databases

23.4.1 Global database for disentanglement activities

As discussed under Item 13.2, development of a dedicated entanglement database will be considered further at the June 2018 meeting of the Global Whale Entanglement Response Network (see Annex J, item 2.3).

23.4.2 Global bycatch database

No new information was presented on the development of a global bycatch database was presented this year. Consideration of such a database could take place as part of the Bycatch Mitigation Initiative and should it be taken further, follow the guidelines for the proposal of new databases developed last year (IWC, 2018, pp. 403-404).

23.4.3 Development of simple technical guidelines for new proposals

No changes were suggested to the guidelines developed at last year's meeting (IWC, 2018, pp. 403-404).

24. IWC MULTINATIONAL RESEARCH PROGRAMMES AND NATIONAL RESEARCH CRUISES THAT REQUIRE IWC ENDORSEMENT

24.1 IWC-POWER

The Committee received the results of the 8th annual IWC-POWER cruise conducted between 3 July and 25 September 2017 in the eastern Bering Sea. Researchers from Japan, USA and IWC participated on the surveys (SC/67b/ASI12). The Committee also received the report of the planning meeting for the 2018 IWC-POWER cruise, which will be conducted in the central Bering Sea, and cruise plans for the 2019 and 2020 cruises (SC/67b/Rep02). Details and preliminary results of the 2017 IWC-POWER survey and future plans for 2018, 2019 and 2020 are provided in Annex Q, item 4.1.

Attention: SC, C-A, CG-R

*The Committee **reiterates** to the Commission the great value of the data contributed by the IWC-POWER cruises which cover many regions of the North Pacific Ocean not surveyed in recent years and so address an important information gap for several large whales. The Committee:*

*(1) **thanks** Japan who generously supplies the vessel and crew, for their continued support of this IWC programme;*

*(2) **thanks** the USA who provided an acoustician and acoustic equipment for the 2017 cruise and will do so for the 2018 cruise;*

*(2) **agrees** that the 2017 cruise was duly conducted following the requirements and guideline of the Committee (IWC, 2012) and looks forward to receiving abundance estimates based on these data;*

*(3) **endorses** the plans for the 2018, 2019 and 2020 POWER cruise and **recommends** a meeting of the Technical Advisory Group along with the planning meetings for 2019 and 2020 cruises;*

*(4) **strongly recommends** that Russia facilitates the proposed research by providing permits for the IWC-POWER cruise to survey the Russian Exclusive Economic Zone in 2019;*

*(5) **looks forward** to receiving a report from the 2018 survey at the next SC meeting.*

24.2 Southern Ocean Research Partnership (IWC-SORP)

The Southern Ocean Research Partnership (IWC-SORP) was established in March 2009 as a multi-lateral, non-lethal scientific research programme with the aim of improving the coordinated and cooperative delivery of science to the IWC. The Partnership currently has 13 member countries: Argentina, Australia, Belgium, Brazil, Chile, France, Germany, Italy, New Zealand, Norway, South Africa, the United States of America, and Luxembourg was welcomed at this meeting. New members are warmly welcomed.

There are five ongoing IWC-SORP themes:

(1) ‘The Antarctic Blue Whale Project’;

(2) ‘Distribution, relative abundance, migration patterns and foraging ecology of three ecotypes of killer whales in the Southern Ocean’;

(3) ‘Foraging ecology and predator-prey interactions between baleen whales and krill’;

(4) ‘Distribution and extent of mixing of Southern Hemisphere humpback whale populations around Antarctica?’ focused initially on east Australia and Oceania; and

(5) ‘Acoustic trends in abundance, distribution, and seasonal presence of Antarctic blue whales and fin whales in the Southern Ocean’.

Bell presented the IWC-SORP Annual Report 2017/18 on the continued progress of research undertaken researchers involved in the five themes since last year (SC/67b/SH21). This progress includes the production of 33 peer-reviewed publications during 2017/18, bringing the total number of peer-reviewed publications related to IWC-SORP since the start of the initiative to 126. In addition, 125 IWC-SORP related papers have been submitted to the Scientific Committee, 22 of them this year.

Fieldtrips were undertaken to a variety of places during the past year, including the western Antarctic Peninsula, Marion Island, the Ross Sea, the Chesterfield-Bellona Reef complex west of mainland New Caledonia, and the Great Barrier Reef, Australia. Thousands of images for photo-identification have been collected; a variety of satellite tag-types deployed on Antarctic minke whales, humpback whales and killer whales as well as biopsy samples collected from these same species; video suction cup tags have been deployed on Antarctic minke whales and humpback whales; and hundreds of hours of acoustic recordings have been made and analysed. The support of tour companies in providing opportunistic research platforms to facilitate these activities and external data contributors were acknowledged by the Committee.

Attention: SC, G

The Committee reiterates the great value of the IWC-SORP (Southern Ocean Research Partnership) programme to its work. The Committee:

(1) ***encourages*** *the continuation of the Southern Ocean Research Partnership programme;*

(2) ***commends*** *the researchers involved who are key to the overall success of the Partnership in IWC-SORP for:*

(a) the impressive quantity of work carried out across diverse member nations;

(b) their contributions to the work of the Committee; and

(3) ***encourages****:*

(a) the continued development, testing and implementation of leading edge technology; and

(b) the continued development of collaborations between ships of opportunity and external bodies that can provide platforms for research and/or contribute data, inter alia, photo-identification data, to IWC-SORP and the wider Committee

24.2.1 Workplan

The work plan for issues related to IWC-SORP is given in Table 28.

Table 28

Workplan for the Southern Ocean Research Partnership.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Analyses	Continued analysis of data/samples from previous IWC-SORP voyages/fieldwork	Report	Continued analysis of data/samples from previous IWC-SORP voyages/fieldwork	Report
Voyages	Argentine coastguard '*Tango*' voyage along Western Antarctic Pensinsula (early 2019)	Cruise report		
	Almirante Maximiano voyage along Western Antarctic Pensinsula (early 2019)	Cruise report		
	Australian-led *RV Investigator* voyage to Ross Sea (early 2019)	Cruise report		
	New Zealand-led *RV Tangaroa* voyage to Ross Sea (early 2019)	Cruise report		
	German-led *RV Polarstern* voyage to Scotia Sea (early 2019)	Cruise report		
	Baleen whale and krill research voyages along Western Antarctic Peninsula	Reports	Baleen whale and krill research voyages along Western Antarctic Peninsula	Reports
Ships of opportunity	Continued use of ships of opportunity to conduct cetacean research	Reports	Continued use of ships of opportunity to conduct cetacean research	Reports
Acoustics	Retrieval and redeployment of passive acoustic recorders	Report	Retrieval and redeployment of passive acoustic recorders	Report
	Completion of annotated library of acoustic detections	Report		

24.3 National cruises that require IWC oversight

The Committee welcomed plans for national research cruises to be conducted in the intersessional period of 2018-2019. Details on the cruise plans and cruise reports are presented in Annex Q, item 4.2.

Attention: SC, C-A

The Committee ***recognises*** *the great value to its work provided by data from national cruises. The Committee:*

(1) ***endorses*** *the proposed sighting survey plans for cruises to be conducted with IWC oversight in the southwestern Okhotsk Sea by Russia, and in the North Pacific and the Antarctic by Japan; and*
(2) ***encourages*** *submission of abundance estimates from these studies the future.*

24.4 Review of cruise reports from national programs with IWC oversight

The Committee considered a process to optimise the review of cruise reports from national research programs with IWC oversight. Details are given in Annex Q, item 2.7

Attention: SC, CG-R

The Committee ***recognises*** *the value of information provided by national cruises with IWC oversight. The Committee noted that a process to optimise the review of national cruise reports is needed and*

(1) ***recommends*** *contracting governments to submit reports of multi-year cruises with IWC oversight biennially, in years between Commission meetings (e.g., SC "A" years);*
(2) ***agrees*** *that cruise reports will be summarised in a table;*
(3) ***notes*** *that that in certain circumstances, cruise reports may require additional evaluation; and*
(4) ***agrees*** *that the 'Requirements and Guidelines for Conducting Surveys and Analysing Data within the Revised Management Scheme' should be modified at next year's meeting to accommodate procedural changes with respect to the submission and review of national cruise reports.*

24.5 Work Plan
The Committee's work plan for continuing the IWC-POWER programme in 2019 and 2020 is provided below in Table 29.

Table 29

Workplan for issues related to IWC-POWER.

Item	Intersessional 2018-19	SC68a	Intersessional 2019-20	SC68b
IWC-POWER Cruise	Conduct 2018 survey and planning meeting for the 2019 Cruise (Bering Sea)	Review cruise report, report from the planning meeting and new abundance estimates from IWC-POWER cruises.	Conduct 2019 survey and planning meeting for the 2020 Cruise	Review cruise report, report from the planning meeting and new abundance estimates from IWC-POWER cruises.

25. SCIENTIFIC COMMITTEE BUDGET FOR THE CURRENT BIENNUM

25.1 Status of previously funded research, workshop proposals, data processing and computing needs
25.1.1 Funded proposals for the current biennium 2017-2018
Table 30summarises the status of the work funded by the Committee last year. The majority have been completed, but several remain ongoing. The projects all contributed considerably to the work of the Committee and the Committee thanked all of those involved.

25.1.2 Funded proposals in previous years still ongoing
A number of projects from previous years are still ongoing (see Table 30). These are all still of great value to the Committee and should be completed before the next meeting. Details of all ongoing projects can be found in SC/67B/01 Rev1.

25.1.3 Report on funds reallocations and contingencies for the Research Fund, Voluntary Fund for Small Cetaceans and SORP Voluntary Fund
SC/67b/01Rev1 provides information on the actual position against budget for the Research fund for 2017 as well as the position to 31st March for the 2018 financial year. The paper gives summary level and detailed information for the Research fund as well as the expected level of contingency available, which remains static at around 10% of the Research budget, or £32k. The document also provides details of the reallocations of budget amongst budget headings for 2017 and the 2018 year-to-date. Annex 1 gives a detailed position along with a status report for each budget line. Section 3 also provides details of voluntary funds which relate to Scientific Committee business – the Gray Whale Tagging Fund, the Small Cetaceans Fund and the SORP fund. For each there is an update of 2017 expenditure and 2018 to-date information along with details of commitments to future work in these funds.

Table 30

Summary of progress on proposals funded at SC67a

SC/67a RP no.	Title	Status
SC01	Invited Participants - SC/67b	Completed
IA01(67a)	Workshop for an in-depth assessment of North Pacific humpback whales	Ongoing (Annex F)
EM01	Two joint SC-CAMLR and IWC-SC Workshops	Ongoing (Annex L)
AWMP01	AWMP first intersessional Workshop and genetic work	Completed (SC/67b/Rep06)
AWMP02	AWMP second intersessional Workshop	Completed (SC/67b/Rep06)
CMP01(67a)	5th Workshop on the rangewide review of population structure and status of North Pacific gray whales	Completed (SC/67b/Rep07rev1)
BRG04	Satellite tagging best practices Workshop	Ongoing, Item 21
WW01	Intersessional Workshop: data gaps and modelling requirements for assessing the impacts of whale watching	Completed (SC/67b/Rep03rev1)
RMP01	Intersessional Workshop: *Implementation Review* of North Pacific Bryde's whales	Completed (SC/67b/Rep02)
RMP01(67a)	Intersessional Workshop: *Implementation Review* for Western North Pacific minke whales	Completed (SC/67b/Rep05)
WW01(67a)	Review CC Strategic plan on whalewatching pre-meeting on intersessional workshop	Completed (Annex N)
E05/E01(67a)	Cumulative impacts - pre-meeting or intersessional meeting	Completed (Annex K)
SM01	Intersessional Workshop: resolving *Tursiops* taxonomy	Completed (SC/67b/SM18rev1)
SM01(67a)	Intersessional Workshop: boto mortality	Completed (SC/67b/Rep01)
SH07	Defining blue whale population boundaries and estimating associated historical catches, using catch data in the Southern Hemisphere and northern Indian Ocean	Completed (SC/67b/SH23)
AWMP02	AWMP developers fund	Completed (Annex D)
IA02	Assessment modelling for an in-depth assessment of North Pacific sei whales	Ongoing (SC/67b/IA01)
RMP02	Essential computing support to the Secretariat for RMP	Completed (Annex D)
Research		
BRG01	Aerial photographic survey of southern right whales on the South Africa Cape nursery ground	Completed (SC/67b/SH01)
BRG03	Passive acoustic monitoring of the eastern South Pacific southern right whales, improving CMP outputs	Completed (SC/67b/CMP18)
SH03a	Northern Indian Ocean humpback subspecies determination-genetics	Ongoing (Annex H)
IA03	IWC-POWER cruise	Completed (SC/67b/Rep04)
SH01(67a)	Coding for Australian blue whale photo catalogue	Ongoing (Annex PH)
E02(67a)	Mercury in cetaceans (requested by the Commission)	Ongoing (SC/67a/E08)
SH02	Southern Hemisphere Blue Whale Catalogue	Completed (SC/67a/PH04)
SH08	Development of a permanent blue whale song reference library	Completed (SC/67a/SH11Rev1)
HIM01	Ship Strike Database Coordinator	Completed (SC/67a/HIM11)
E01	Cetacean Diseases of Concern	Ongoing (Annex K)
E03(67a)	IWC strandings initiative	Ongoing (Annex K)
E04	SOCER (State of the Cetacean Environment Report)	Completed (SC/67a/E01)

The Committee received a brief report on the IWC-SORP Research Fund. Following an open, competitive Call for Proposals (26 July to 17 August 2016) a total of £144,058 GBP was allocated from the IWC-SORP Research Fund to 10 research projects, ahead of the 2016-2017 austral summer survey season. Progress on these projects is detailed in SC/67b/SH18.

The Committee also noted that since SC67a, substantial vessel time has also been secured by IWC-SORP researchers for the 2019 and 2020 austral field seasons.

Attention: C, F&A, S

A full report on the new Call for Proposals, opened in September 2017 and closed in January 2018, was also received. A total of 19 proposals were received and evaluated by the Assessment Panel under the coordination of the Chair of the Scientific Committee. The Committee thanks Fortuna for convening the Assessment Panel and expressed its gratitude to the Panel members who all provided valuable and thoughtful input into the assessment process. The Committee welcomes the outcome of the Assessment Group and agrees with the allocation of a total of £493,544 GBP from the IWC-SORP Fund to 15 projects (Table 31).

The Committee agrees on these recommended allocations and requests the Secretariat to submit them to the Finance and Administration Committee, as soon as feasible, for it consideration. Should the Commission endorse these financial recommendations, the Committee requests the Secretariat to inform successful and unsuccessful proponent immediately after the next Commission's meeting.

Table 31
List of the funding allocations by project recommended by the IWC-SORP Assessment Panel

ID	Chief Investigator	Title	Requested amount (£)	Recommended amount (£)	Level of funding (Partial/Full)
1	Baker & Steel	Is migratory connectivity of humpback whales in the Central and Eastern South Pacific changing? A decadal comparison by DNA profiling	27,598	26,375 (deducted in house instrument expenses)	P
2	Charrassin	Application of satellite telemetry data to better understand the breeding strategies of humpback whales in the Southern Hemisphere	21,200	21,200	F
3	Branch	Modelling somatic growth and sex ratios to predict population-level impacts of whaling on Antarctic blue whales	32,594	32,594	F
4	Friedlaender & Constantine	Pregnancy rates in Southern Ocean humpback whales: implications for population recovery and health across multiple populations	29,334	19,984 (equipment deducted and some analytical costs)	P
5	Herr	Recovery status and ecology of Southern Hemisphere fin whales (*Balaenoptera physalus*)	82,300	81,900 (equipment deducted)	P
6	Friedlaender & Constantine	A circumpolar analysis of foraging behaviour of baleen whales in Antarctica: Using state-space models to quantify the influence of oceanographic regimes on behaviour and movement patterns	34,711	34,711	F
7	Buchan & Miller	A standardized analytical framework for robustly detecting trends in passive acoustic data: A long-term, circumpolar comparison of call-densities of Antarctic blue and fin whales	43,369	41,369 (publication costs)	P
8	Lang & Archer	Inferring the demographic history of blue and fin whales in the Antarctic using mitogenomic sequences generated from historical baleen	22,710	22,710	F
9	Zerbini & Clapham	Assessing blubber thickness to inform satellite tag development and deployment on Southern Ocean whales	22,646	22,426 (supply costs deducted)	P
10	Širović & Stafford	Acoustic ecology of foraging Antarctic blue whales in the vicinity of Antarctic krill studied during AAD interdisciplinary voyage aboard the *RV Investigator*	34,183	30,107 (airfares deducted)	P
12	Kelly &Maire	Development of statistical and technical methods to support the use of long-range UAVs to assess and monitor cetacean populations in the Southern Ocean	30,576	30,576	F
13	Reisinger & de Bruyn	An integrative assessment of the ecology and connectivity of killer whale populations in the southern Atlantic and Indian Oceans	33,650	33,650	F
14	Bengston Nash	Implementation of humpback whales for Antarctic sea-ice ecosystem monitoring; Inter-program methodology transfer for effective circumpolar surveillance	91,202	51,555 (equipment costs deducted)	P
17	Carroll, Torres, Graham	Circumpolar foraging ecology of southern right whales: past and present	21,290	21,290	F
18	Iñíguez Bessega	Habitat use, seasonality and population structure of baleen and toothed whales in the Scotia sea and the western Antarctic Peninsula using visual and passive acoustic methods and genetics	26,579	23,097 (equipment costs reduced, communication & network costs deducted)	P
		TOTAL	693,195	493,544	

Finally, the Committee was informed that the next Call should open prior to SC/68b (i.e. late 2019/early 2020) in readiness for IWC68 (2020). This timing would allow strategic prioritisation of the research toward which the Call is directed in order to meet IWC-SORP and IWC/SC priorities; allow knowledge gaps to be identified; and allow the IWC-SORP SSC to seek additional funding to augment the funds available in the IWC-SORP Research Fund.

26. COMMITTEE PRIORITIES AND INITIAL AGENDA FOR THE BIENNUM 2019-2020

The Committee's priorities and work plan by broad subject matter are provided in Tables under the relevant agenda items.

The Committee ***agrees*** *that the Chair, Vice-Chair and Head of Science, in co-operation with the Convenors, should examine the individual work plans by topic and develop an overall Committee biennial workplan and priorities taking into account the overall work load, meeting venues and efficiency. This should be submitted to the Commission meeting as an Annex to their two-year overview.*

27. SCIENTIFIC COMMITTEE BUDGET FOR THE BIENNUM 2019-2020

27.2 Budget for the next biennium

As in 2016, the Committee has developed a two-year budget, based on the proposed work plans. The process given in Annex S IWC, 2016) was applied, with extensive discussion carried out in each of the sub-committees and Working Groups to establish priorities among the presented proposals. Funding was not approved for one project (*Gulf of Penas, Southern right whales*) as further information is needed before funding can be agreed. The savings from 2018, some self-reductions and adjustments between years allowed inclusion of all funding proposals for 2019 and 2020 in the new budget of £315,800 per year.

Table 32

Workshop proposals agreed during this meeting (TBD: to be decided).

Title	Relevance	Date	Venue
Western gray whale update of CMP and conservation issues within modelling framework	CMP		
Marine debris	E	December 2019	Barcelona, Spain
Noise pre-meeting	E	Pre-meeting 2020	TBD
Cetaceans & ecosystem functioning: a gap analysis*	EM	TBD	TBD
Joint IWC-IUCN workshop to evaluate how the data and process used to identify Important Marine Mammal Areas (IMMAs) can assist the IWC to identify areas of high risk for ship strike	HIM	April 2019	Greece
Comprehensive Assessment of North Pacific humpback whales	NH		
Comparative biology, health, status & future of NA right whales	NH	Late 2019	Boston, USA
Implementation Review: North Pacific minke whales	RMP		
Catch series: Southern right whales	SH	Pre-meeting 2020	TBD
Intersessional workshop of the task team on South Asian River dolphins	SM	Feb 2019	TBD
Guiana dolphin pre-assessment	SM	October 2019	Curitiba, Brazil
Modelling whale watching impacts (MAWI)	WW	December 2019	
POWER planning meeting	ASI	Oct 2018	Tokyo, Japan
Wildmeat workshop	SM	Late 2019/early 2020	Africa
Tagging best practices	ASI	Jun 2018	Seattle, USA

* Japan referred to its statement on the adoption of the Agenda (Annex Z) and considered that several of the items for the proposed workshop (Item 16.4.4) are outside the competence of IWC. Therefore, it cannot support the proposed workshop or associated funding from the Committee's budget.

Table 33 shows the Committee budget requests for the biennium for each of the proposed priority activities.

27.2.1 Invited Participants

INVITED PARTICIPANTS

Invited participants (IPs) are a vital component of the working of the IWC's Scientific Committee. IPs contribute in many ways including as sub-committees and Working Groups Convenors, co-Convenors and rapporteurs, subject area experts and Convenors of intersessional groups. All sub-committees and Working Groups benefit from this budget item. This year under this budget item, 62 scientists from Australia, Argentina, Belgium. Brazil, Canada, Chile, China, Colombia, France, Germany, Italy, Japan, Mexico, Netherlands, Norway, Oman, Peru, Slovenia, South Africa, Spain, UK, USA were supported.

27.2.2 Workshops

RP16 WESTERN GRAY WHALE UPDATE OF CMP AND CONSERVATION ISSUES WITHIN MODELLING FRAMEWORK

The CMP is over 10 years old and requires updating. Initial work has been undertaken but the results of the rangewide workshop need to be incorporated and conservation-related questions need to be developed that can be addressed within the new population modelling framework developed as a result of the Committee's work. This is primarily related to the CMP and AWMP groups, however, it is also of importance to the work of IA and ASI in terms of precedents for future assessments and the work of HIM in terms of examining scenarios that take into account bycatch and the uncertainty associated with estimating it.

RP06 MARINE DEBRIS WORKSHOP

There remains an urgent need to better understand and address the threats posed by marine debris to cetaceans. The most effective way to do this, building on earlier work by the IWC and taking into account the greatly expanded interest in this topic by many other international bodies, is to hold a workshop. It is proposed that the workshop is held in Barcelona in December 2019 just before the World Conference on Marine Mammalogy (the joint meeting of the SMM and ECS).

RP05 NOISE PRE-MEETING

The sub-committee on Environmental Concerns will address Anthropogenic Noise as a focus topic during the Scientific Committee meeting in 2020. A pre-meeting workshop is proposed for SC68b, to address emerging issues related to the management of underwater noise and its impacts on marine species.

RP08 CETACEANS & ECOSYSTEM FUNCTIONING: A GAP ANALYSIS

Experts on the role and impact of cetaceans on ecosystem functioning will participate in a workshop/pre-meeting to discuss the current state of knowledge on the ecosystem functioning provided by cetaceans as requested by the Commission in Resolution 2016-3. This Resolution directed 'the Scientific Committee to further incorporate the contribution made by live cetaceans to ecosystem functioning into [its] work' and asked 'the Scientific Committee to screen the existing research studies on the contribution of cetaceans to ecosystem functioning, to develop a gap analysis regarding research and to develop a plan for remaining research needs'.

RP17 JOINT IWC-IUCN WORKSHOP TO EVALUATE HOW THE DATA AND PROCESS USED TO IDENTIFY IMPORTANT MARINE MAMMAL AREAS (IMMAS) CAN ASSIST THE IWC TO IDENTIFY AREAS OF HIGH RISK FOR SHIP STRIKE

The identification of 'high risk areas' for ship strikes of cetaceans is a key step toward establishing mitigation actions, through scheduling, re-routing or speed reduction. IUCN's proposed initiative to identify Important Marine Mammal Areas (IMMAs), would likely assist this effort. The SC has encouraged cooperation with the IUCN Task Force on this. The IUCN TF has completed three regional IMMA workshops, including the Mediterranean Sea. This proposed joint workshop will focus on identifying overlap between shipping and the IMMAs identified in the Mediterranean Sea.

Table 33
Summary of budget requests for the 2019-20 period. For explanation and details of each project see text.

RP no.	Title	Sub-committee/ working group	2019 (£)	2020 (£)
Invited Participants				
	Invited Participants - SC/68a and SC/68b	SC	85,000	65,000
Meeting/Workshop				
RP16	Western gray whale update of CMP and conservation issues within modelling framework	CMP	10,500	0

RP02	Amendment of RMP Guidelines to incorporate spatial modelling approaches to estimate abundance	RMP	3,000	0
General items				
	Implementation: resolutions and instructions from Commission & follow up from previous years' recommendations	SC	10,313	28,470
Total request			£315,800	£315,800

Notes: [1]Budget was reduced from £22,200, [2]£20,300 was the expected financial need for 2019 but savings from 2018 allowed for the reduced budget of £0; [3]£11,400 was the expected financial need for 2019 but savings from 2018 allowed for the reduced budget of £1,000; [4]£15,000 was the expected financial need for 2019 but savings from 2018 allowed for the reduced budget of £13,000. [5]Budget was reduced from £8,958, [6]£20,000 was the expected financial need for 2020 but financial savings for 2018 allowed for the reduced budget of £17,000, [7]£32,500 was the expected need for 2019 but financial savings from 2017 allowed for the reduced budget of £22,500, [8]£32,500 was the expected need for 2020 but financial savings from 2018 allowed for the reduced budget of £22,500, [9]The requested budget was £15,000 but further information is required before funding can be considered. The project will be re-evaluated at the 2019 SC meeting, [10]£6,185 was the expected financial need for 2019 but financial savings from 2018 allowed for the reduced budget of £0, [11]budget was reduced from £10,000, [12]budget was reduced from £10,000, [13]funding of approximately £7,280 may be requested for 2020 next year depending on progress, [14]£4,000 was the expected financial need for 2019 but savings from 2018 allowed for the reduced budget of £0, [15]budget was reduced from £4,000, [16]budget was reduced from £4,000.

27.2.1 Invited Participants

INVITED PARTICIPANTS

Invited participants (IPs) are a vital component of the working of the IWC's Scientific Committee. IPs contribute in many ways including as sub-committees and Working Groups Convenors, co-Convenors and rapporteurs, subject area experts and Convenors of intersessional groups. All sub-committees and Working Groups benefit from this budget item. This year under this budget item, 62 scientists from Australia, Argentina, Belgium. Brazil, Canada, Chile, China, Colombia, France, Germany, Italy, Japan, Mexico, Netherlands, Norway, Oman, Peru, Slovenia, South Africa, Spain, UK, USA were supported.

RP19 COMPREHENSIVE ASSESSMENT OF NORTH PACIFIC HUMPBACK WHALES

At SC67a, following discussion of the results of an assessment workshop held in April 2017, a Steering Group was established to facilitate a second North Pacific humpback whale assessment workshop, and to coordinate work required for this meeting. This meeting was not held prior to SC67b and the workshop is now planned for prior to the 2019 meeting of the Scientific Committee, with a view to completing or significantly advancing the assessment.

RP37 BALAENID WORKSHOP: BIOLOGY, HEALTH, STATUS

The North Atlantic right whale's population rate of increase is much lower than that of all other well-studied balaenid populations. This workshop will compare reproductive biology, health and status of North Atlantic right whales with those of other balaenid populations with the goal of determining their potential for growth and assessing the role of anthropogenic mortality as a driver of current population decline. Possible causes of the NARW's lower reproductive rate need reassessment include: sub-lethal effects of entanglements; environmental contaminants or marine biotoxins; inadequate prey base; stress from noise; genetic factors; and infectious diseases. This review will also help understanding of population changes for other balaenid populations.

RP21 *IMPLEMENTATION REVIEW*: NORTH PACIFIC MINKE WHALES

These workshops are essential in order for the Committee to conduct a full *Implementation Review* for Western North Pacific common minke whales following the Committee's Requirements and Guidelines. Conducting *Implementation Reviews* are a required activity under the RMP.

RP29 CATCH SERIES: SOUTHERN RIGHT WHALES

A new review of available catch data for measuring regional takes of southern right whales is overdue and the availability of new sources suggests that it is timely to do this. The expected outcome of this workshop is updated regional estimates of southern right whale catches, which can be used to conduct regional assessments of southern right whale past exploitation and develop population trajectories to measure past abundance and current recovery levels.

RP25 INTERSESSIONAL MEETING OF THE TASK TEAM ON SOUTH ASIAN RIVER DOLPHINS

The South Asian river dolphin, *Platanista gangetica*, is listed as an endangered cetacean species by the IUCN Red List assessment. Across its range, in the countries of India, Pakistan, Nepal, and Bangladesh, the species remains highly threatened by a range of anthropogenic activities at multiple scales. These range from localised threats caused by hunting, fisheries bycatch, or local disturbances as well as from large-scale alterations of the rivers by dams, barrages, waterways and river-linking schemes. In particular, large-scale and rapidly accelerating water development in the Indo-Ganges-Brahmaputra floodplains make the outlook for the South Asian river dolphin conservation grim. In recognition of this situation, the Scientific Committee has established a Task Team for the species and the team of experts will meet in person and discuss how to go forward.

RP26 GUIANA DOLPHIN PRE-ASSESSMENT (*SOTALIA GUIANENSIS*)

An intersessional workshop will assess the geographic extent of Guiana dolphin threats and conservation measures needed in both national and international contexts. The outcomes of the workshop shall include: (1) a Comprehensive Assessment of the status of Guiana dolphins; (2) recommendations to potentially improve management actions and the monitoring efforts associated with the current conservation plans of actions; and (3) a consolidated report to be presented to the SC at next year's meeting for review.

RP27 MODELLING WHALE WATCHING IMPACTS (MAWI)

There is little research on the potential mid- and long-term impacts of whale watching on cetacean populations. This is due to the complexity of the required modelling approaches, lack of clarity regarding the data needed to inform them, and the need to identify locations suitable for data collection. Without addressing these issues understanding the potential mid- and long-term impacts of whale watching is not possible. The workshop will bring together modellers and field researchers to achieve the following outcomes: (1) identify existing modelling approaches that could be used to understand the potential mid- and long-term impacts of whale watching, and determine whether new approaches are required; (2) determine which data currently being collected are suitable for answering questions regarding the mid- and long-term impacts of whale watching, and what new data are required; and (3) determine the feasibility of data collection, and identify locations where this has already been done or could be achieved.

27.2.3 Modelling/computing

RP20 ASSESSMENT MODELING FOR AN IN-DEPTH ASSESSMENT-NORTH PACIFIC SEI WHALES

The IA sub-committee is currently conducting a Comprehensive Assessment for North Pacific sei whales. This involves evaluating the status of a population using a population dynamics model that is specific to the biological parameters and movement behaviour of that particular population and is fitted to monitoring data. During the intersessional periods after the 2018 SC meeting and possibly also after 2019 SC meeting, it is expected that population dynamics models will be finalised and run using the existing data. This will result in an assessment of the status of the population.

RP22 DEVELOP AN AGE-STRUCTURED EMULATOR FOR THE INDIVIDUAL-BASED ENERGETICS MODEL (IBEM)

An IBEM provides an alternative population dynamics model to the usual cohort models, particularly because density dependence in births, growth and age-specific mortality are emergent properties of a species in a given environment (which can be stochastic). The IBEM is computationally infeasible for conducting *IST*s; the proposal is to develop a computationally efficient cohort model (emulator) which uses demographic parameters and their covariances generated using the IBEM.

RP23 ESSENTIAL COMPUTING SUPPORT TO THE SECRETARIAT

Regular *Implementation Reviews* are required under the RMP and AWMP. Computing support is alos required for Comprehensive and in-depth assessments. The Committee is currently about to undertake an *Implementation Review* for the North Pacific common minke whales, and more will follow. The Committee has developed a complex trials structure for *Implementation Reviews*. A key task in this process is to develop and validate the code for the simulation trials that are the core component of this process. Experience has shown that the Secretariat staff alone cannot handle this complete process themselves, so computing support is needed.

RP36 SIMULATING LINE TRANSECT DATA TO INVESTIGATE ROBUSTNESS OF NOVEL ANALYSIS METHODS

The IWC SC has already invested time and money in developing simulated line transect data to evaluate the robustness of the Norwegian minke whale and Antarctic minke whale survey data. This project will update the old code for the simulator to make it more user-friendly so that it can be made available to all SC members and to produce some standard data sets in accordance to the specifications of the ASI sub-committee.

27.2.4 Databases/catalogues

RP01 IWC-POWER CRUISE

The Committee has strongly advocated the development of an international medium- to long-term research programme involving sighting surveys to provide information for assessment, conservation and management of cetaceans in the North Pacific, including areas that have not been surveyed for decades. This is one of the most important international collaborations undertaken by the IWC and the cost to the IWC is minimal given the generous contribution of a vessel by Japan and acoustic equipment by the USA . Committee objectives have been developed for the overall plan and requested funding will allow for the continuing work of the initial phase and progress on developing the medium-term phase. The IWC contribution is for: (1) IWC researchers and equipment; (2) to allow the Committee's Technical Advisory Group to meet to review the multi-year results thus far and develop the plans for the next phase of POWER based on the results obtained from Phase I; and (3) to enable analyses to be completed prior to the 2020 Annual Meeting.

RP11 ABUNDANCE ESTIMATES OF THE FRANCISCANA DOLPHIN IN BUENOS AIRES PROVINCE, ARGENTINA

Abundance estimates of franciscanas will be based on a series of aerial surveys along the coast of Buenos Aires Province, with the same survey design of surveys carried out in 2003 and 2004 (Crespo *et al*., 2010). The new estimate will allow comparing density values with those obtained in the previous surveys. This item represents only one third of the funds required for the project, with the remainder being provided by the Government of Argentina.

RP09 GULF OF PENAS, SOUTHERN RIGHT WHALES

Eastern South Pacific (ESP) Southern right whales (SRW) are classified as critically endangered as there are no more than 50 SRW in this population and there is no information on the ESP SRW breeding and feeding grounds. Gulf of Penas is one of the most remote and exposed areas in Chile, with limited access and wild weather that have prevented its exploration. The largest baleen whale mass mortality of almost 400 sei whales occurred in this area and almost remained unnoticed. Recently, a local living nearby the Gulf of Penas recorded the presence of SRWs, including several calves. The Gulf might be the unknown breeding ground of the ESP SRW. This area will be explored during the austral winter breeding season with a group of researchers and government officers to confirm this finding and if so, start immediately working towards the protection and management of the species and the area.

RP10 POPULATION DYNAMICS OF SOUTHERN RIGHT WHALES AT PENÍNSULA VALDÉS, ARGENTINA: THE INFLUENCE OF KELP GULL LESIONS ON THE HEALTH, CHANGES IN INCREASE AND MORTALITY RATES IN THE CONTEXT OF A DENSITY-DEPENDENT PROCESS

The recent mortality of southern right whales at Península Valdés, Argentina is the highest ever recorded for the species. Understanding the causes is critical to propose management and mitigation actions. Preliminary results from glucocorticoids in baleen from stranded calves show that stress from injuries due to Kelp Gull attacks negatively affects their physiological homeostasis, potentially leading to death. Also, aerial counts show an important reduction in population rate of increase as a whole (from 7% in the past to 0.5% at present), and changes in distribution (mainly of adults) and density along the Argentinian coast.

RP12 PASSIVE ACOUSTIC MONITORING OF THE EASTERN SOUTH PACIFIC SOUTHERN RIGHT WHALE

The Eastern South Pacific southern right whale population is Critically Endangered and in 2012 the IWC adopted a Conservation Management Plan (CMP). Over the years, few opportunistic sightings have been recorded and no breeding area has yet been identified. Until a breeding ground is found many CMP priority actions cannot be implemented. Thus, in 2016 the IWC Scientific Committee decided to support this passive acoustic monitoring (PAM) project to facilitate the identification of potential breeding areas along the coast of Chile and Peru. This project seeks to obtain temporal coverage over a complete annual cycle and spatial coverage depending on the number of sites. The PAM project is likely the most cost-effective way to investigate the seasonal and temporal distribution of southern right whales along the coast of Chile and Peru. The information will be crucial to identify aggregation areas and facilitate the implementation of CMP for this population.

RP13 SAMPLE THE HOLOTYPE SPECIMEN OF *MEGAPTERA INDICA* (GERVAIS, 1883) AT THE MUSÉUM NATIONAL D'HISTOIRE NATURELLE (PARIS)

Several lines of evidence suggest that humpback whales in the Arabian Sea/Northern Indian Ocean comprise a discrete, isolated and non-migratory population that merits a taxonomic revision. Genetic analyses of available samples are now underway in order to determine whether sub-species/species designation is merited. The resultant nomenclature will necessarily draw on a description of the type specimen of *Megaptera indica*, which is held at the Muséum National d'Histoire Naturelle in Paris. This work will develop an approach for examining and sampling this specimen so that the taxonomy of Arabian Sea humpback whales can be accurately defined, better informing regional conservation efforts, highly relevant to the IWC's stated interest in the establishment of a Conservation Management Plan for Arabian Sea humpback whales.

RP14 ASSESSING ISOLATION OF THE ARABIAN SEA HUMPBACK WHALE POPULATION AND CONTINUITY ACROSS THE ARABIAN SEA THROUGH GEOGRAPHIC VARIATION IN SONG

A study of geographic variation in humpback whale song indicates that the Arabian Sea song from Oman is distinct from the Southwest Indian Ocean (SWIO) song, and evidence from a small Indian sample suggesting continuity in song between the western and eastern Arabian Sea. This work will be followed up on with a detailed comparison of song across the Arabian Sea and continued assessment of song differences with the SWIO: The project will (1) assess the connectivity of Arabian Sea humpback whales from Oman to India by comparing existing samples of song between the two regions from several different years; and (2) assess and re-examine the differences in song exhibited between Oman and the SWIO with more recent data, particularly in light of evidence that SWIO singers were found off Oman during the Boreal summer of 2012.

RP15 A QUANTITATIVE ASSESSMENT OF THREATS TO ARABIAN SEA HUMPBACK WHALES USING EXISTING PHOTOGRAPHIC AND UAV DATA

The research will assess the prevalence of anthropogenic and natural threats to Arabian Sea humpback whales through a robust and quantitative assessment of available photographic data. These data include the entire Oman photo-ID catalogue, imagery recently acquired using UAVs (drones) and images provided by third parties. The latter include several images from elsewhere in the populations range. The project will provide an assessment of the relative prevalence of a suite of indices typically associated with major threats (fisheries entanglements, ship-strikes, other scars) as well as scars associated with natural sources (barnacles, cyamids, Penella sp., killer whales). Project outcomes will include assessment of the risks posed by each threat, as well as the development of a set of metrics with which further changes can be monitored. Project results will be reported to the IWC SC in 2019 and will contribute to the development of a draft Conservation Management Plan for this population.

RP24 COLLABORATIVE ANALYSIS OF WNP MINKE WHALE STOCK STRUCTURE USING JAPANESE MICROSATELLITE DNA DATABASE AND SPATIALLY EXPLICIT POPULATION STRUCTURE ANALYSES.

This item will help address the recommended 'analysis 2' from the report of the workshop on Western North Pacific common minke whale stock structure (SC/67b/Rep05) in support of the next intersessional meeting on WNP common minke whale stock structure. This specific aspect of the work will apply spatially explicit population structure analyses that provide greater power than the program STRUCTURE together with geographic context. The data will be analysed as a total dataset (not based on any assignment in STRUCTURE), but also include temporal subdivision to assess possible seasonal changes in patterns of connectivity. The latter aspect may be critical to understanding the true pattern of structure, but it will also be the most time-consuming, requiring extensive replication of the analyses. The results of these analyses will provide an assessment of structure in the context of biogeography using methods that have considerably more power than the program STRUCTURE and using an approach that will consider temporal patterns of movement.

RP28 UPDATED CATCH SERIES AND ASSESSMENTS OF FOUR PYGMY BLUE WHALE POPULATIONS

The SH sub-committee is conducting in-depth assessments of populations of Southern Hemisphere blue whales. Assessments have previously been conducted for two of the six populations (Antarctic blue whales, and Chilean blue whales), but not for the four pygmy blue whale populations addressed by this research. This project will provide crucial catch separation data and associated uncertainty needed to conduct stock assessments and provide the first stock assessments for each of the four populations. Such data are critical inputs for the assessments planned by the SC.

RP30 MULTI-OCEAN ANALYSIS OF SOUTHERN RIGHT WHALE DEMOGRAPHIC PARAMETERS AND ENVIRONMENTAL CORRELATES

This study aims to compare population demographics of southern right whales in Southern Hemisphere wintering grounds and investigate correlations between reproductive success and abundance trends, and environmental variables. This study is a component of the proposed SORP project - The right sentinel for climate change: linking foraging ground variability to population recovery in the southern right whale.

RP 31 ANALYSIS OF FIN WHALE SONG VARIABILITY ACROSS SOUTHERN HEMISPHERE

Fin whale songs consist of short pulses repeated at regular interpulse intervals (IPIs). These songs have been suggested as a tool to distinguish populations. Features that have be used for fin whale song separation include: spectral structure of individual pulses; their patterning; the IPIs; and presence of a higher frequency component of the pulses. Based on this higher frequency component, there appear to be two fin whale song types in the Southern Ocean. We propose to use a combination of song feature measurements to identify whether fin whale songs in the Southern Hemisphere could be indicative of population structure. Data to be used include recorders deployed in the Western Antarctic Peninsula, Weddell Sea, and Eastern Antarctica (Kerguelen and Casey) from 2014-16. Additional SH lower-latitude recordings are available in southeastern Pacific and South Indian Ocean. Overall, the analysis will enable a comprehensive review of fin whale song variability across the SH.

RP34 PHOTO-IDENTIFICATION INFORMATION PLACARDS FOR NATURALISTS AND CITIZEN SCIENTISTS

Pre-cruise training and reference placards describing examples of photo-identification subjects (large whales) will be developed for distribution to the tourist vessel industry in the South Georgia and Antarctic Peninsula region. Information will include primary ID features used for seven species likely to be encountered; right, blue, sei, fin, humpback, sperm and killer whales (key species). A Powerpoint presentation will be developed for distribution to naturalists working on tourist vessels, to orient them and their clients to the basics of whale identification photography. Minimal training is required for a considerable improvement to the quality of identification photographs that are collected by naturalists and citizen scientists and ultimately provided to the established photo-ID catalogues from the region. A formal collaboration with the global photo-ID platform, HappyWhale will be established.

RP07 IWC STRANDINGS INITIATIVE – EMERGENCY RESPONSE AND INVESTIGATIONS

Over the next two years, the Emergency Response and Investigations fund will support response, collection of data to determine the cause(s) or contributing factors for the event and/or to fill critical data gaps identified by the SC or Commission. The Initiative will be evaluated annually and policies and procedures adapted according to feedback from responses and through Steering Group/Expert Panel advice.

27.2.5 Databases and catalogues

RP18 SHIP STRIKE DATABASE COORDINATOR

The ongoing development of the IWC ship strike database requires data gathering, communication with potential data providers and data/database management. This project will provide support for expanding and maintaining the database.

RP33 ANTARCTIC BLUE WHALE CATALOGUE: COMPARISON OF NEW PHOTOGRAPHS FROM 2014-2020

In year one (2019) this project will compare the identification photographs of an estimated 45 individual Antarctic blue whales collected during ICR cruises 2014-17, to the Antarctic Blue Whale Catalogue. These identifications would increase the size of the catalogue (458 individuals) by almost 10%. In year two (2020) additional photos representing approximately 12 IDs are expected from collaborating scientists and citizen scientists that will be compared to the catalogue. The expected outcome is an expanded dataset that may improve estimates of population abundance and reveal new information on movement patterns.

RP32 SOUTHERN HEMISPHERE BLUE WHALE PHOTO CATALOGUE

The Southern Hemisphere Blue Whale Catalogue (SHBWC) is an international collaborative effort to facilitate cross-regional comparison of blue whale photo-identifications catalogues. To date more than 1,500 individual blue whales have been contributed to the SHBWC from researchers groups working on areas off Antarctica, Chile, Peru, Ecuador-Galapagos, Eastern Tropical Pacific, Australia, Timor Leste, New Zealand, Madagascar and Sri Lanka. Therefore, the SHBWC has become the largest repository of Southern Hemisphere blue whale photo-identifications. Results of comparisons among different regions will improve the understanding of basic questions relating to blue whale populations in the Southern Hemisphere such as defining population boundaries, migratory routes, visual health assessments, and to model abundance estimates. The results will contribute primarily to the IWC Southern Hemisphere blue whale assessments.

RP38 DATABASE MANAGEMENT

The IWC Secretariat hosts several databases for the SC. These have annual service costs associated with them including, web/database servers, storage, backups, software licences and other associated infrastructure or costs.

27.5.6 Reports

RP03 MERCURY IN CETACEANS: BIOGEOCHEMICAL CYCLING, TOXICOLOGICAL IMPACTS

In response to the Commission resolution on mercury, the objective of the work is to comple the global review of mercury in cetaceans, resulting in the documentation and mapping of decadal trends. The Scientific Committee will also invite experts in mercury in the environment and its cycling and in mercury and selenium cetacean toxicology to participate to provide further detail and interpretation of the current status and potential impact of mercury on cetacean populations at an ocean basin scale.

RP04 PRODUCTION OF ANNUAL STATE OF THE CETACEAN ENVIRONMENT REPORT (SOCER) FOR THE SCIENTIFIC COMMITTEE AND COMMISSION (2019 AND 2020)

SOCER is a long-standing effort to provide information to Commissioners and Committee members on key current global developments that are affecting the cetacean environment. Focus will be on the Atlantic Ocean (2019) and the Pacific Ocean (2020). It will, in both years, also present key current global developments that are affecting the cetacean environment. It will also contain a glossary of technical terms used and species names. A 5-year compendium spanning all regions is also being produced.

RP02 AMENDMENT OF THE RMP GUIDELINES TO INCORPORATE SPATIAL MODELLING APPROACHES TO ESTIMATE ABUNDANCE

The 'Requirements and Guidelines for Conducting Surveys and Analysing Data within the Revised Management Scheme', referred to as the 'RMP Guidelines' (IWC, 2012) constitutes a document prepared by the Scientific Committee to state the requirements and to guide the collection and analysis of survey data to compute abundance estimates for use in the Revised Management Procedure (RMP). Currently this document provides detailed guidance for developing estimates using design-based line transect shipboard and aerial surveys. Amendments are required to consider other methods, for example, model-based analysis of survey data and mark-recapture models. This project will update the RMP Guidelines as required by the Scientific Committee. This update will be completed in consultation with the project's steering committee and presented for consideration of the SC by SC68b. The expected outcome is a new, revised document of with the 'RMP Guidelines'.

27.5.7 General items

***IMPLEMENTATION*: RESOLUTIONS AND INSTRUCTIONS FROM COMMISSION & FOLLOW UP FROM PREVIOUS YEARS' RECOMMENDATIONS**

This line is required to accommodate additional work requested by the Commission at IWC67 and work generated by meetings, workshops and projects funded and concluded in the first year (2019). This line can also accommodate new project proposals generated during the 2019 Scientific Committee meeting.

28. WORKING METHODS OF THE COMMITTEE

28.1 Rules of Procedure of the Scientific Committee

Attention: C, S

As per usual practice in the last biennium the Committee has been reviewing its working methods to improve transparency and align its processes with the biennial pace of the Commission. These changes and a number of changes that were made in previous years and approved by the Commission (i.e. SORP Voluntary Fund, new process to allocate and manage the Research Fund and the Small Cetacean Voluntary Fund Rules of Procedure) require a number of adjustments and additions to the Commission Rules of Procedure, Financial Regulations and Scientific Committee Rules of Procedure. The Committee ***agrees*** *to submit all proposed amendments to the Commission for its consideration (Annex W).*

The updated Rules also refer to the online 'Scientific Committee Handbook' that has been updated at this meeting. The Committee ***requests*** *the Secretariat to post the updated version online as soon as feasible. The Committee also* ***agrees*** *to that a pdf version of the Handbook be made available as a document for the Commission meeting.*

28.2 Biennial reporting and related matters

At its 2015 meeting, the Joint Conservation Committee and Scientific Committee Working Group (Joint CC/SC WG) agreed to undertake a collation and analysis of conservation-relevant recommendations from the Scientific Committee and organise these recommendations into key issues/areas highlighting those that feature regularly, including the creation of a pilot database. Double, Convenor of the Global Databases and Repositories Steering Group (GDR), presented an update on the development of this database. The Scientific Committee is fully engaged in this process and, this year, a standing agenda item was added to all sub-committee agendas to ensure a regular, more formal review of progress in delivering recommendations than was the case in the past.

Attention: SC, CC

The Committee ***welcomes*** *the development of the IWC Database of Recommendations, noting that this tool will give recommendations more prominence and improve the ability to measure progress. The Committee* ***agrees*** *to:*

(1) continue to improve its standardised way to present recommendations to include core information[13] to facilitate input into the database; and
(2) to work closely with the Secretariat to assist with the overall process of data entry.

28.3 Additional proposals for revisions to 'Annex P'

The Committee continued this year the work begun last year to update Annex P in response to Commission Resolution 2016-2 and recommendations by previous Expert Panels.

Attention: C-R, SC,

The Committee ***recommends*** *the revisions to the previous Annex P reported in Annex P in response to Resolution 2016-2 and recommendations made by Expert.*

[13] IWC/MAY18/CCSC/01

28.4 Succession plan for key Scientific Committee experts

Last year, the Committee had identified the need to consider 'succession planning' for key participants, particularly in relation to the *Implementation Reviews* and assessment processes. Informal discussions continued informally during the intersessional period and invitations were issued to three modellers to evaluate their interest in becoming active members of the IWC Scientific Committee, but only one could attend. Concern regarding succession planning of these other key positions on the Committee still remains and an intersessional group has been re-established to look at this and report back to the Committee next year (Annex Y).

The Committee also refers to its discussion related to a Deputy Head of Science in its review if the governance report (see Item 28.6.2).

28.5 Update on Data Availability requests

Suydam provided a summary of requests received under the Data Availability Agreement shown in Table 34.

Table 34

Summary of requests under the Data Availability Agreement.

Date	Requested by	Objective/Subject	Outcome
June 2015	de la Mare Australia) – Procedure B	(a) Consistent with recent advice of the Scientific Committee with particular respect to minke whale nutritive condition analyses, to develop a set of models that best capture the Committee's previous recommendations, taking into account the structure of the underlying processes giving rise to the data; and (b)To provide analyses relevant to the determination of sample sizes for detecting specified trends in the age at sexual maturity (ASM).	SC/66B/EM/02, SC/67A/EM/01, SC/67A/EM/02, SC/67A/EM/03, SC/67A/EM/04, SC/67A/EM/07, SC/67A/EM/08, SC/67B/EM/01 Rev1, SC/67B/EM/02, SC/67B/EM/03, SC/67B/EM/08, See EM Annexes, 2016 to 2018. Differing results between research groups about changes in body condition of Antarctic minke whales
January 2018	Baker (USA	The intent of the request is to examine plausible stock hypotheses. Analyses will rely primarily on tests of Hardy-Weinberg expectations, exact tests of differentiation, randomized Chi-squared tests (contingency tables), Analyses of Molecular Variance (AMOVA), as well as mixed-stock analyses, clustering methods and kinship (parent offspring pairs), to investigate dispersal and differences in haplotype frequencies, genotypes and sex for various geographic and temporal strata.	On-going

28.6 Any other matters

28.6.1 Welfare Assessment Tool

Since our last discussion in 2015 on animal welfare related matters relevant to the Committee (IWC, 2016, p.86), Dr. Nicol (Professor of the Royal Veterinary College, London) developed a 'Welfare Assessment Tool' following the recommendations of the Workshop to 'Develop Practical Guidance for the Handling of Cetacean Stranding Events' (South Africa, 2016) on this matter. This year, the Committee received a report from Nicol on the latest phase of the development of such a tool, that is being developed to help assess non-hunting related threats in the context of the IWC's Welfare Action Plan and in a joint project between the RVC and Humane Society International, supported by the UK Department for Environment, Food and Rural Affairs (Defra). The approach is based on application of the 'five domains model' (Beausoleil and Mellor, 2015; Mellor *et al*., 2015) and two hypothetical case studies have been explored, one related to marine debris and the other to whale-watching.

Trial assessments were presented and the Scientific Committee was asked for assistance and advice in the development of real examples for consideration. The Committee welcomed the information provided and further discussions were held informally. The Tool was also considered by the Whale Watching Subcommittee (see Annex N) and will be presented for consideration by the Commission at the next meeting of the Working Group on Whale Killing Methods and Associated Welfare Issues.

28.6.2 Review of the IWC review report

The final report from the Governance Review was released on the 16th April 2018 (downloadable here: https://archive.iwc.int/?r=6890). The Independent Review Panel report represents the view of the three panellists, based on a survey, in-person interviews and analysis of documents. It represents only the first step of the Governance Review process. The Chair of the Operational Effectiveness Working Group of the Finance and Administration Committee asked the Scientific Committee to provide a voluntary feedback to the Commission on recommendations related to the Committee.

The Scientific Committee formed an *ad hoc* Working Group to develop an initial response, which was then discussed in Plenary. The initial WG membership was restricted to the Scientific Committee Chair and Vice Chair, all Heads of Delegations present at the meeting, sub-groups Convenors that are also delegates, and former Scientific Committee Chair present at the meeting. This subset represented the view of Committee members that, given their roles, had a strong knowledge on the current and past structure and procedures of the Committee. More delegates and invited participants joined the discussion in Plenary. The final version of this preliminary feedback, which has the support of all 32 delegations attending the meeting and additional members of the Scientific Committee is provided in Annex X.

The Scientific Committee organised its discussion and feedback on Review Panel's recommendations and comments around five mutually exclusive subject areas (pre-eminence of the Scientific Committee, IWC strategic planning, communication, Scientific Committee function in relation to Commission and other subsidiary bodies, Secretariat function in relation to the Scientific Committee). Within each subject area, those recommendations of perceived importance to the WG were identified. Where feasible, a timeline for developing a response was proposed.

Attention: C, SC

Given the fact that both the Chair of the Commission (Morishita) and the Chair of the F&A Working Group on Operational Effectiveness (Phelps) reminded the Committee that the Commission has not yet decided the fate of the 'IWC review report', nor has yet requested a full engagement by the Committee, the Committee ***agrees*** *to submit the preliminary feedback on the report (Annex X) for the Commission's consideration.*

In addition, given the productive exchange of opinions and ideas on several aspects of the Committee working methods that occurred in during its discussions, the Committee ***agrees*** *to establish an Intersessional Correspondence Group on 'Improving on-going working practices of the IWC Scientific Committee' under DeMaster (see Annex Y). The ICG will provide a written summary of its proposals to the Scientific Committee 60 days prior to the start of the annual meeting of the Scientific Committee in 2019. This ICG will also be in charge dealing with the preparation of a draft document for the follow-up on Governance Review, should the Commission instruct the Committee to do so at its next biennial meeting.*

28.6.3 Additional discussion on other issue related to the Committee working procedures

A number of suggestion for improving the ability to follow a topic during the Scientific Committee meeting were discussed by the Committee and the Convenors group. In order to facilitate the full participation of members of the Committee to various sub-groups and, especially, to the discussion of cross-cutting issues relevant to different groups, the Committee **agrees** that next years the Convenors should: (a) organise joint-sessions early in the meeting and release draft reports of those discussion, as soon as feasible; (b) adopt a simple coding system for 'hot topics' (e.g. North Pacific common minke whales: NPMW, Antarctic minke whales: AMW; biopsy sampling; etc.), which will be included in the daily timetable together or instead of the Agenda item. The Convenors group will carefully consider these issues intersessionally.

29. PUBLICATIONS

The Secretariat reported on the excellent progress made with the *Journal* this year, and in particular that the previously noted backlog has now been dealt with. This has been particularly assisted by the excellent work of the new Associate Editors including Fortuna, Leaper, New, Jackson, Punt, Tiedemann, Zerbini. The Committee **thanked** the Publications Team for its dedication and hard work and **reiterated** the importance of the *Journal* and *Supplements* to its work.

30. ELECTION OF OFFICERS

This was the final year of office for the Chair (Fortuna) and the Vice-Chair (Suydam). In accordance with its Rules of Procedure, the Vice-Chair becomes the new Chair for the next three years. The Committee elects Zerbini (Brazil) to be the new Vice-Chair by consensus. The outgoing Chair will provide the formal report to IWC67 in Florianopolis, Brazil of the SC Reports from the 67a and 67b SC meetings.

The Committee rose in appreciation to thank the outgoing Chair. It wished to formally record its immense gratitude for her excellent leadership over the past three years. Dr. Fortuna's scientific and organizational skills provided a lasting legacy to the Committee. She adeptly faced the many complex and challenging issues during her term and tremendous progress has been made for the benefit of the entire Commission in meeting its science and stewardship objectives. The Chair, Head of Science, and Executive Secretary of the Commission added their thanks and congratulations to the many participants expressing their appreciation to Dr. Fortuna.

The Committee also welcomed with enthusiasm the new team of Suydam and Zerbini and looked forward to working with them over the next three years.

31. ADOPTION OF REPORT

The Committee adopted the report at 17:45 hrs on 6 May 2018, apart from the final items discussed during the last session. As is customary, these items were agreed by the Chair, rapporteurs and convenors. The Chair thanked the participants for their scientific contributions as well as their constructive dialogue. Given the sensitivity of several agenda items, this positive approach helped ensure that all views could be presented and rigorously discussed for a productive outcome. The Chair especially thanked the convenors, rapporteurs, Head of Science, and Vice-Chair for their excellent assistance. Finally, she reiterated her thanks to the government of Slovenia and the hotel staff for the facilities and great service, which contributed greatly to the success of the meeting.

Fortuna concluded that it had been an honour to serve as the IWC Scientific Committee Chair over the past three years. She expressed her gratitude for all the support provided by so many as she led this effort. She voiced her thanks for the Secretariat, and in particular her deep appreciation for the guidance provided by the Head of Science (Donovan) without whom she could not have accomplished her work.

Suydam congratulated Fortuna for having expertly led the Scientific Committee as their Chair over the past three years. He noted that the praise and applause from the participants in the room were well very much deserved given her outstanding leadership. Suydam noted that it will be a particular challenge to follow the incredible example set by Fortuna and thanked her for her mentorship. The Executive Secretary (Lent) added to these words of gratitude and commendation on behalf of the Secretariat and wished her all the best. She also offered the full support of the Secretariat to the incoming SC Chair Suydam.

Echoing the sentiments raised under Item 30, participants thanked the Chair for her adept, fair and efficient handling of the meeting, her unflagging dedication and her great contribution to the effective working of the Committee.

Annex P[1]

Amendments to the Schedule Adopted at the 67th Meeting

At the 67th meeting of the International Whaling Commission held in Florianopolis, Brazil from 10-14 September 2018, no modifications were made to the provision for zero catch limits for commercial whaling with effect from the 1986 coastal and 1985/86 pelagic seasons.

The following updates to the Schedule of the International Convention for the Regulation of Whaling therefore become necessary (changes in ***bold italic*** type):

For paragraphs 11 and 12, and Tables 1, 2 and 3:

> . Substitute the dates 2016/2017 pelagic season and 2017 coastal season for ***2018/2019*** pelagic season and ***2017*** season as appropriate.

Modifications were made to the provisions for aboriginal subsistence whaling at the 67th meeting of the International Whaling Commission and the following updates to the Schedule of the International Convention for the Regulation of Whaling with regards to aboriginal subsistence whaling therefore become necessary (text to be deleted is shown in ~~strikethrough~~ and text to be added is shown in **underline** **and bold**).

Other Operations

5. Each contracting Government shall declare for all whale catchers under its jurisdiction not operating in conjunction with a factory ship or land station one continuous open season~~s~~ not to exceed six months out of any period of twelve months during which the taking or killing of minke whales by such whale catchers may be permitted. Notwithstanding this paragraph one continuous open season not to exceed nine months may be implemented so far as Greenland is concerned. **This paragraph shall not apply to aboriginal subsistence whaling under paragraphs 13(b)(3)(ii) and 13(b)(3)(iii).**

Baleen Whale Catch Limits

13(a) . . .

(6) Commencing in 2026, and provided the appropriate Strike Limit Algorithm has been developed by then, strike/catch limits (including any carry forward provisions) for each stock identified in sub-paragraph 13(b) shall be extended every six years, provided: (a) the Scientific Committee advises in 2024, and every six years thereafter, that such limits will not harm that stock; (b) the Commission does not receive a request from an ASW country relying on the stock ('relevant ASW country'), for a change in the relevant catch limits based on need; and (c) the Commission determines that the relevant ASW country has complied with the approved timeline and that the information provided represents a status quo continuation of the hunt.

(7) The provisions for each stock identified in sub-paragraph 13(b), especially the provisions for carryover, shall be reviewed by the Commission in light of the advice of the Scientific Committee.

13(b) Catch limits for aboriginal subsistence whaling are as follows:

---

[1] **The 90 day objection period will expire on 29 December 2018. In the absence of objections by that date the updates will become effective. Contracting Governments will be notified accordingly.**

(1) The taking of bowhead whales from the Bering-Chukchi-Beaufort Seas stock by aborigines is permitted, but only when the meat and products of such whales are to be used exclusively for local consumption by the aborigines and further provided that:

(i) For the years ~~2013, 2014, 2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, the number of bowhead whales landed shall not exceed ~~336~~ **392**. For each of these years the number of bowhead whales struck shall not exceed 67, except that any unused portion of a strike quota from ~~any year (including 15 unused strikes from the 2008–2012 quota)~~ **the three prior quota blocks** shall be carried forward and added to the strike quotas of ~~any~~ subsequent years, provided that no more than ~~15 strikes~~ **50 percent of the annual strike limit** shall be added to the strike quota for any one year.

(ii) ~~This provision shall be reviewed annually by the Commission in light of the advice of the Scientific Committee.~~

(2) The taking of gray whales from the Eastern stock in the North Pacific is permitted, but only by aborigines or a contracting Government on behalf of aborigines, and then only when the meat and products of such whales are to be used exclusively for local consumption by the aborigines.

(i) For the years ~~2013, 2014, 2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, the number of gray whales **landed** ~~taken in accordance with this sub-paragraph~~ shall not exceed ~~744~~ **980**, provided that the number of gray whales **struck** ~~taken~~ in any one of the years ~~2013, 2014, 2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025** shall not exceed 140**, except that any unused portion of a strike quota from the prior quota block shall be carried forward and added to the strike quotas of subsequent years, provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year**.

(ii) ~~This provision shall be reviewed annually by the Commission in light of the advice of the Scientific Committee.~~

(3) The taking by aborigines of minke whales from the West Greenland and Central stocks **from the East Greenland hunt** and fin whales from the West Greenland stock and bowhead whales from the West Greenland feeding aggregation and humpback whales from the West Greenland feeding aggregation is permitted and then only when the meat and products are to be used exclusively for local consumption.

(i) The number of fin whales struck from the West Greenland stock ~~in accordance with this subparagraph~~ shall not exceed 19 in each of the years ~~2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025, except that any unused portion of a strike quota from the prior quota block under a Strike Limit Algorithm management advice shall be carried forward and added to the strike quotas of subsequent years, provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year**.

(ii) The number of minke whales struck from the Central stock ~~in accordance with this sub-paragraph~~ shall not exceed ~~12~~ **20** in each of the years ~~2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, except that any unused portion of ~~the~~ **a** strike quota ~~for each year~~ shall be carried forward ~~from that year~~ and added to the **strike** quota**s** of ~~any~~ subsequent years, provided that no more than 3 **strikes** shall be added to the **strike** quota for any one year. **Commencing in 2020, and provided a Strike Limit Algorithm for this stock has been developed by then, any unused portion of a strike quota from the prior quota block under a Strike Limit Algorithm management advice shall be carried forward and added to the strike quotas of subsequent years, provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year.**

(iii) The number of minke whales struck from the West Greenland stock shall not exceed 164 in each of the years ~~2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, except that any unused portion of ~~the~~ **a strike** quota ~~for each year~~ **from the prior quota block under a**

Strike Limit Algorithm management advice shall be carried forward ~~from that year~~ and added to the strike quota**s** of ~~any of the~~ subsequent years, provided that no more than ~~15 strikes~~ **50 percent of the annual strike limit** shall be added to the strike quota for any one year. ~~This provision will be reviewed if new scientific data become available within the 4 year period and if necessary amended on basis of the advice of the Scientific Committee.~~

(iv) The number of bowhead whales struck off West Greenland ~~in accordance with this sub-paragraph~~ shall not exceed 2 in each of the years ~~2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, except that any unused portion of ~~the~~ **a strike** quota ~~for each year~~ **from the prior quota block under a Strike Limit Algorithm management advice** shall be carried forward ~~from that year~~ and added to the **strike** quota**s** of ~~any~~ subsequent years, provided that no more than ~~2 strikes~~ **50 percent of the annual strike limit** shall be added to the **strike** quota for any one year. ~~This provision will be reviewed if new scientific data become available within the 4 year period and if necessary amended on basis of the advice of the Scientific Committee.~~

(v) The number of humpback whales struck off West Greenland ~~in accordance with this sub-paragraph~~ shall not exceed 10 in each of the years ~~2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, except that any unused portion of ~~the~~ **a strike** quota ~~for each year~~ **from the three prior quota blocks under a Strike Limit Algorithm management advice** shall be carried forward ~~from that year~~ and added to the strike quota**s** of ~~any of the~~ subsequent years, provided that no more than ~~2 strikes~~ **50 percent of the annual strike limit** shall be added to the strike quota for any one year. ~~This provision will be reviewed if new scientific data become available within the remaining quota period and if necessary amended on basis of the advice of the Scientific Committee.~~

(4) For the seasons ~~2013-2018~~ **2019-2025** the number of humpback whales to be taken by the Bequians of St. Vincent and The Grenadines shall not exceed ~~24~~ **28**. The meat and products of such whales are to be used exclusively for local consumption in St. Vincent and The Grenadines.

Baleen Whale Size Limits

15(b) It is forbidden to take or kill any fin whales below 57 feet (17.4 metres) in length in the Southern Hemisphere, and it is forbidden to take or kill fin whales below 55 feet (16.8 metres) in the Northern Hemisphere; except that fin whales of not less than 55 feet (16.8 metres) may be taken in the Southern Hemisphere for delivery to land stations and fin whales of not less than 50 feet (15.2 metres) may be taken in the Northern Hemisphere for delivery to land stations, provided that, in each case the meat of such whales is to be used for local consumption as human or animal food. **This paragraph shall not apply to aboriginal subsistence whaling under paragraph 13(b)(3)(i).**

PROPOSAL FOR A SCHEDULE AMENDMENT ON ABORIGINAL SUBSISTENCE WHALING

(SUBMITTED BY THE KINGDOM OF DENMARK, RUSSIAN FEDERATION, ST. VINCENT AND THE GRENADINES AND THE UNITED STATES OF AMERICA)

The governments of the Kingdom of Denmark, the Russian Federation, Saint Vincent and the Grenadines and the United States of America jointly submit this amendment to the Schedule to enable our respective indigenous peoples to continue meeting their aboriginal subsistence needs. As further detailed in the accompanying **EXPLANATORY NOTE**, the proposal includes the following elements:

- Updated carryover provisions related to the Aboriginal Whaling Scheme
- One-time 7-year extension through 2025
- Limited automatic renewal with safeguards to protect whale stocks
- Minor technical adjustments to Schedule paragraphs 5 and 15(b), which were originally intended to apply to commercial hunts
- Increased annual strike limit for common minke whales off East Greenland in order to satisfy ASW need
- Increased annual strike limit for Eastern North Pacific gray whales in order to address the "stinky" whale problem and to satisfy ASW need
- Technical adjustment to Schedule paragraph 13(a) to include an overarching provision for Commission review of catch/strike limits in light of the advice of the Scientific Committee

This amendment is being circulated in accord with: (1) advice from the 2018 Scientific Committee meeting; (2) Rules of Procedure J.1 and J.4; and (3) the pilot timeline for submission of Aboriginal Subsistence Whaling Schedule amendments to IWC67. The co-sponsors welcome comments from Contracting Governments.

Text proposed to be deleted is shown in ~~strikethrough~~ and text proposed to be added is shown in **underline and bold**.

PROPOSED SCHEDULE AMENDMENT

Other Operations

5. Each contracting Government shall declare for all whale catchers under its jurisdiction not operating in conjunction with a factory ship or land station one continuous open season~~s~~ not to exceed six months out of any period of twelve months during which the taking or killing of minke whales by such whale catchers may be permitted. Notwithstanding this paragraph one continuous open season not to exceed nine months may be implemented so far as Greenland is concerned. **This paragraph shall not apply to aboriginal subsistence whaling under paragraphs 13(b)(3)(ii) and 13(b)(3)(iii).**

Baleen Whale Catch Limits

13(a) . . .

(6) Commencing in 2026, and provided the appropriate Strike Limit Algorithm has been developed by then, strike/catch limits (including any carry forward provisions) for each stock identified in sub-paragraph 13(b) shall be extended every six years, provided: (a) the Scientific Committee advises in 2024, and every six years thereafter, that such limits will not harm that stock; (b) the Commission does not receive a request from an ASW country relying on the stock ('relevant ASW country'), for a change in the relevant catch limits based on need; and (c) the Commission determines that the relevant ASW country has complied with the approved timeline and that the information provided represents a status quo continuation of the hunt.

(7) The provisions for each stock identified in sub-paragraph 13(b), especially the provisions for carryover, shall be reviewed by the Commission in light of the advice of the Scientific Committee.

13(b) Catch limits for aboriginal subsistence whaling are as follows:

(1) The taking of bowhead whales from the Bering-Chukchi-Beaufort Seas stock by aborigines is permitted, but only when the meat and products of such whales are to be used exclusively for local consumption by the aborigines and further provided that:

(i) For the years ~~2013, 2014, 2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, the number of bowhead whales landed shall not exceed ~~336~~ **392**. For each of these years the number of bowhead whales struck shall not exceed 67, except that any unused portion of a strike quota from ~~any year (including 15 unused strikes from the 2008- 2012 quota)~~ **the three prior quota blocks** shall be carried forward and added to the strike quotas of ~~any~~ subsequent years, provided that no more than ~~15 strikes~~ **50 percent of the annual strike limit** shall be added to the strike quota for any one year.

(ii) ~~This provision shall be reviewed annually by the Commission in light of the advice of the Scientific Committee.~~

(2) The taking of gray whales from the Eastern stock in the North Pacific is permitted, but only by aborigines or a contracting Government on behalf of aborigines, and then only when the meat and products of such whales are to be used exclusively for local consumption by the aborigines.

(i) For the years ~~2013, 2014, 2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, the number of gray whales **landed** ~~taken~~ ~~in accordance with this sub-paragraph~~ shall not exceed ~~744~~ **980**, provided that the number of gray whales **struck** ~~taken~~ in any one of the years ~~2013, 2014, 2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025** shall not exceed 140**, except that any unused portion of a strike quota from the prior quota block shall be carried forward and added to the strike quotas of subsequent years, provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year**.

(ii) ~~This provision shall be reviewed annually by the Commission in light of the advice of the Scientific Committee.~~

(3) The taking by aborigines of minke whales from the West Greenland and Central stocks **from the East Greenland hunt** and fin whales from the West Greenland stock and bowhead whales from the West Greenland feeding aggregation and humpback whales from the West Greenland feeding aggregation is permitted and then only when the meat and products are to be used exclusively for local consumption.

(i) The number of fin whales struck from the West Greenland stock ~~in accordance with this subparagraph~~ shall not exceed 19 in each of the years ~~2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022,**

2023, 2024 and 2025, except that any unused portion of a strike quota from the prior quota block under a Strike Limit Algorithm management advice shall be carried forward and added to the strike quotas of subsequent years, provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year.

(ii) The number of minke whales struck from the Central stock ~~in accordance with this sub-paragraph~~ shall not exceed ~~12~~ **20** in each of the years ~~2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, except that any unused portion of ~~the~~ **a** strike quota ~~for each year~~ shall be carried forward ~~from that year~~ and added to the **strike** quota**s** of ~~any~~ subsequent years, provided that no more than 3 **strikes** shall be added to the **strike** quota for any one year. **Commencing in 2020, and provided a Strike Limit Algorithm for this stock has been developed by then, any unused portion of a strike quota from the prior quota block under a Strike Limit Algorithm management advice shall be carried forward and added to the strike quotas of subsequent years, provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year.**

(iii) The number of minke whales struck from the West Greenland stock shall not exceed 164 in each of the years ~~2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, except that any unused portion of ~~the~~ **a strike** quota ~~for each year~~ **from the prior quota block under a Strike Limit Algorithm management advice** shall be carried forward ~~from that year~~ and added to the strike quota**s** of ~~any of the~~ subsequent years, provided that no more than ~~15 strikes~~ **50 percent of the annual strike limit** shall be added to the strike quota for any one year. ~~This provision will be reviewed if new scientific data become available within the 4 year period and if necessary amended on basis of the advice of the Scientific Committee.~~

(iv) The number of bowhead whales struck off West Greenland ~~in accordance with this sub-paragraph~~ shall not exceed 2 in each of the years ~~2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, except that any unused portion of ~~the~~ **a strike** quota ~~for each year~~ **from the prior quota block under a Strike Limit Algorithm management advice** shall be carried forward ~~from that year~~ and added to the **strike** quota**s** of ~~any~~ subsequent years, provided that no more than ~~2 strikes~~ **50 percent of the annual strike limit** shall be added to the **strike** quota for any one year. ~~This provision will be reviewed if new scientific data become available within the 4 year period and if necessary amended on basis of the advice of the Scientific Committee.~~

(v) The number of humpback whales struck off West Greenland ~~in accordance with this sub-paragraph~~ shall not exceed 10 in each of the years ~~2015, 2016, 2017 and 2018~~ **2019, 2020, 2021, 2022, 2023, 2024 and 2025**, except that any unused portion of ~~the~~ **a strike** quota ~~for each year~~ **from the three prior quota blocks under a Strike Limit Algorithm management advice** shall be carried forward ~~from that year~~ and added to the strike quota**s** of ~~any of the~~ subsequent years, provided that no more than ~~2 strikes~~ **50 percent of the annual strike limit** shall be added to the strike quota for any one year. ~~This provision will be reviewed if new scientific data become available within the remaining quota period and if necessary amended on basis of the advice of the Scientific Committee.~~

(4) For the seasons ~~2013-2018~~ **2019-2025** the number of humpback whales to be taken by the Bequians of St. Vincent and The Grenadines shall not exceed ~~24~~ **28**. The meat and products of such whales are to be used exclusively for local consumption in St. Vincent and The Grenadines.

Baleen Whale Size Limits

15(b) It is forbidden to take or kill any fin whales below 57 feet (17.4 metres) in length in the Southern Hemisphere, and it is forbidden to take or kill fin whales below 55 feet (16.8 metres) in the Northern Hemisphere; except that fin whales of not less than 55 feet (16.8 metres) may be taken in the Southern Hemisphere for delivery to land stations and fin whales of not less than 50 feet (15.2 metres) may be taken in the Northern Hemisphere for delivery to land stations, provided that, in each case the meat of such whales is to be used for local consumption as human or animal food. **This paragraph shall not apply to aboriginal subsistence whaling under paragraph 13(b)(3)(i).**

EXPLANATORY NOTE

This explanatory note provides an overview of the proposed Schedule amendment, which is intended to:

- Update carryover provisions related to the Aboriginal Whaling Scheme (AWS) and allow for variability in environmental conditions affecting the hunts;

- Alleviate the chronic political challenges surrounding the renewal of Aboriginal Subsistence Whaling (ASW) catch limits through a one-time 7-year extension and a limited automatic renewal with safeguards to protect whale stocks;

- Adjust Schedule paragraphs 5 and 15(b), which were originally intended to apply to commercial hunts, so that they do not apply to affected ASW hunts;

- Increase the annual strike limit for common minke whales off East Greenland from 12 to 20 in order to satisfy ASW need in that area;

- Increase the annual strike limit for Eastern North Pacific gray whales in order to address the “stinky” whale problem and to satisfy ASW need; and

- Technical adjustment to Schedule paragraph 13(a) to include an overarching provision for Commission review of catch/strike limits in light of the advice of the Scientific Committee.

<u>Updated Carryover Provisions Related to the Aboriginal Whaling Scheme</u>. After nearly 20 years developing the Aboriginal Whaling Management Procedure (AWMP), completion of all the Strike Limit Algorithms (SLAs) and the Aboriginal Whaling Scheme (AWS) has remained an impediment to final acceptance of the AWMP. The AWS incorporates several components:

(a) Operational rules (generic to the extent possible) including carryover provisions, block quotas and interim relief allocations;

(b) Guidelines for *Implementation Reviews*; and

(c) Guidelines for data and analysis (e.g., guidelines for surveys, other data needs)

Carryover is the use of a limited number of previously allocated, but unused strikes in subsequent years, in order to adjust for variation in hunting conditions. In 2018, the Scientific Committee explained:

> “Carryover is a provision to enable (some) strikes not used in one year to be used in a subsequent year or years, in order to allow for the inevitable fluctuations in the success of hunts (e.g., due to environmental conditions and/or whale availability). Whilst providing flexibility, carryover does not allow hunts to take more than the total number of strikes agreed by the Commission. . . . The concept is not new, and ad hoc provisions incorporating carryover have been included in the Schedule for many [more than 30] years.”

Carryover provisions contained in Schedule paragraphs 13(b)(1) and (3) address unused strikes and how they can be used in subsequent years. At SC67b, the Scientific Committee indicated that a carryover approach should include: (a) a start date/expiration period for unused strikes so that unused strikes cannot be carried over indefinitely; and (b) limits on use of strikes in any one year.

With regard to limits on the use of strikes in any one year, the Scientific Committee reiterated its previous advice, applicable for all SLAs, that inter-annual variation of 50 percent within a block, with the same allowance from the last year of one block to the first year of the next, is acceptable. The rationale for this limitation has not changed from a scientific perspective. SLAs are robust with respect to this carryover provision, particularly since all allocated strikes are considered as taken in the testing process.

Proposed updates to the carryover provisions would address the need for management flexibility to deal with increasing variability in environmental conditions currently affecting the success of the hunts from one year to the next, within limits that conserve the whale stocks.

Given that the Scientific Committee has advised that the 50 percent carryover provision is acceptable for all SLAs, the Russian Federation and the United States propose the addition of a 50 percent carryover provision to Schedule paragraph 13(b)(2), regarding Eastern North Pacific gray whales. Likewise, the Kingdom of Denmark proposes the addition of a 50 percent carryover provision to Schedule paragraph 13(b)(3)(i), regarding fin whales from the West Greenland stock.

Also at SC67b, the Scientific Committee advised that, for the Bowhead SLA (applicable to the Bering-Chukchi-Beaufort Seas stock) and the Humpback SLA (applicable to the West Greenland feeding aggregation), provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50 percent of the annual strike limit, has no conservation implications.

After the Scientific Committee evaluates the other Greenland SLAs in 2019, the carry forward allowance from one previous quota block would be changed, commencing in 2020, provided the Scientific Committee advises that provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50 percent of the annual strike limit, has no conservation implications.

Unused strikes would initially be counted from the year a Strike Limit Algorithm was first used to provide management advice for a particular stock. The start date/expiration period would then follow a rolling timeline consisting of a defined number of prior quota blocks ranging from one to three depending on the evaluation of the Scientific Committee.

Hunters would still be subject to applicable block limits. Further, hunters would also continue to be subject to annual reporting requirements about hunting efficiency and infractions. The efficiency of the hunt (i.e., the number of whales landed compared to the number of whales struck) is very important to the hunters. For the Alaska Natives, hunting efficiency has increased from about 50 percent between 1973 and 1978 to an average of 75.2 percent in the last ten years (i.e., 2007-2016). In 2017, hunting efficiency was 88 percent, near the highest level recorded. Improvements reported in both the struck and lost rate and the time to death of the five different stocks hunted in Greenland is shown in the "Description of the hunt, information on recent catches."

Comparison of Current and Proposed BCB Bowhead Whale Carryover Provisions

Schedule Component	**Current**	**Proposed**
Start/Expiration dates	". . . any unused portion of a strike quota from any year (including 15 unused strikes from the 2008-2012 quota) shall be carried forward and added to the strike quotas of any subsequent years . . . "	". . . any unused portion of a strike quota from the three prior quota blocks shall be carried forward and added to the strike quotas of subsequent years . . . "

Carryover limit	"... provided that no more than 15 strikes shall be added to the strike quota for any one year."	"... provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year."

Note that the carryover limit would increase from 15 strikes to 50 percent, i.e., 33 strikes. The initial starting year for accumulation of unused strikes would be 2003. The Scientific Committee has advised that this increase in the carryover limit would have no conservation implications. Note also that the hunters would continue to be subject to the total block cap of landed whales, which for a six-year block is 336 landed whales and would be 392 landed whales for a seven-year block.

Comparison of Current and Proposed ENP Gray Whale Carryover Provisions

Schedule Component	Current	Proposed
Start/Expiration dates	There is no carryover provision.	"... any unused portion of a strike quota from the prior quota block shall be carried forward and added to the strike quotas of subsequent years."
Carryover limit	There is no carryover provision.	"... provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year."

Note that the carryover limit would 50 percent, i.e., 70 strikes. The Scientific Committee has advised that a 50 percent carryover limit would have no conservation implications. Note also that the hunters would continue to be subject to the total block cap of landed whales, which for a six-year block is 744 landed whales and would be 980 landed whales for a seven-year block.

Comparison of Current and Proposed West Greenland Fin Whale Carryover Provisions

Schedule Component	Current	Proposed

Start/Expiration dates	There is no carryover provision.	". . . any unused portion of a strike quota from the prior quota block under a Strike Limit Algorithm management advice shall be carried forward and added to the strike quotas of subsequent years …"
Carryover limit	There is no carryover provision.	". . . provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year."

Note that the carryover limit would be 50 percent, i.e., 9 strikes. The initial starting year for accumulation of unused strikes would be 2018. The Scientific Committee has advised that this increase in the carryover limit would have no conservation implications. Note that in the event unused strikes are available for carryover from the previous block, the block cap could be increased by up to 50 percent.

<u>Comparison of Current and Proposed East Greenland Minke Whale Carryover Provisions</u>

Schedule Component	**Current**	**Proposed**
Start/Expiration dates	". . . any unused portion of the quota for each year shall be carried forward from that year and added to the quota of any of the subsequent years . . ."	". . . any unused portion of a strike quota shall be carried forward and added to the strike quotas of subsequent years…" "…Commencing in 2020, and provided a Strike Limit Algorithm for this stock has been developed by then, any unused portion of a strike quota from the prior quota block under a Strike Limit Algorithm management advice shall be carried forward and added to the strike quotas of subsequent years…"

Carryover limit	". . . provided that no more than 3 shall be added to the quota for any one year."	". . . provided that no more than 3 strikes shall be added to the strike quota for any one year. ". . .provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year."

Note that the carryover limit would remain 3 strikes in 2019 and 2020. When the Strike Limit Algorithm has been established, the carryover limit would increase from 3 strikes to 50 percent, i.e., 10 strikes based on the evaluation of the Scientific Committee that this increase in the carryover limit will have no conservation implications. The initial starting year for accumulation of unused strikes would be 2020. Note that in the event unused strikes are available for carryover from the previous block, the block cap could be increased by up to 50 percent.

Comparison of Current and Proposed West Greenland Minke Whale Carryover Provisions

Schedule Component	**Current**	**Proposed**
Start/Expiration dates	". . . any unused portion of the quota for each year shall be carried forward from that year and added to the strike quota of any of the subsequent years . . ."	". . . any unused portion of a strike quota from the prior quota block under a Strike Limit Algorithm management advice shall be carried forward and added to the strike quotas of subsequent years."
Carryover limit	". . . provided that no more than 15 strikes shall be added to the strike quota for any one year."	". . . provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year."

Note that the carryover limit would increase from 15 strikes to 50 percent, i.e., 82 strikes. The Scientific Committee has advised that this increase in the carryover limit would have no conservation implications. The initial starting year for accumulation of unused strikes would be 2018. Note that in the event unused strikes are available for carryover from the previous block, the block cap could be increased by up to 50 percent.

Comparison of Current and Proposed West Greenland Bowhead Whale Carryover Provisions

Schedule Component	**Current**	**Proposed**

Start/Expiration dates	". . . any unused portion of the quota for each year shall be carried forward from that year and added to the quota of any subsequent years. . ."	". . . any unused portion of a strike quota from the prior quota block under a Strike Limit Algorithm management advice shall be carried forward and added to the strike quotas of subsequent years . ."
Carryover limit	". . . provided that no more than 2 shall be added to the quota for any one year."	". . . provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year."

Note that the carryover limit would decrease from 2 strikes to 50 percent, i.e., 1 strike. The Scientific Committee has advised that this decrease in the carryover limit would have no conservation implications. The initial starting year for accumulation of unused strikes would be 2015. Note that in the event unused strikes are available for carryover from the previous block, the block cap could be increased by up to 50 percent.

Comparison of Current and Proposed West Greenland Humpback Whale Carryover Provisions

Schedule Component	**Current**	**Proposed**
Start/Expiration dates	". . . any unused portion of the quota for each year shall be carried forward from that year and added to the strike quota of any of the subsequent years . . ."	". . . any unused portion of a strike quota from the three prior quota blocks under a Strike Limit Algorithm management advice shall be carried forward
		and added to the strike quotas of subsequent years . . ."
Carryover limit	". . . provided that no more than 2 strikes shall be added to the strike quota for any one year."	". . . provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year."

Note that the carryover limit would increase from 2 strikes to 50 percent, i.e., 5 strikes. The Scientific Committee has advised that this increase in the carryover limit would have no conservation implications. The initial starting year for accumulation of unused strikes would be 2014.[1] Note that in the event unused strikes are available for carryover from the previous block, the block cap could be increased by up to 50 percent.

[1] Unused strikes would initially be counted from 2014, the year a Strike Limit Algorithm was first used to provide management advice for this stock. The start date/expiration period would then follow a rolling timeline consisting of the three prior quota blocks.

One-Time 7-Year Extension through 2025. Another proposed revision for each ASW stock would be to create a "buffer" year by updating the number of years for each block to seven years rather than six. This "buffer" year would accommodate issues arising from the "objections" procedure, and provide an additional year for the Commission to agree upon catch/strike limits, if necessary. The Scientific Committee agrees that there is no conservation issue associated with a one-time seven-year extension of the catch limits. In practice, the one-time seven-year extension would work as follows: Even though the seven-year block would not expire until 2025, at the 70th Commission meeting in 2024, the catch limits would be reviewed and, in accord with Scientific Committee advice, extended for an additional six years from 2026 through 2031.

Note that the block limits would be increased to account for the 7th year. For all the stocks except for Eastern North Pacific gray whales and Central Stock minke whales, as discussed below, block limits would be increased by ⅙ to account for the 7th year.

Limited Automatic Renewal with Safeguards for Whale Stocks. A third proposed revision, for Schedule paragraph 13(a), would address the challenges the Commission faces regarding ASW catch limit renewals. This proposal is intended to eliminate the fear of voting down a catch limit proposal while continuing to safeguard the stocks. Allowing limited automatic renewal for status quo catch limits would not only build trust and transparency, but also increase the time and resources that the Commission could spend on other issues.

There would be restrictions on the application of the automatic renewal in order to safeguard the stocks. Subject to Scientific Committee advice on the sustainability of the hunt, the catch limits from the previous block would be extended for an additional six years, provided the following conditions were met:

(a) The catch limits do not change;

(b) The Scientific Committee continues to advise that the status quo catch limits will not harm the stock; and

(c) The Commission determines that the relevant ASW country has complied with the approved timeline and that the information provided represents a status quo continuation of the hunt.

In addition:

(d) Annual Scientific Committee review and regular (5-6 years) *Implementation Reviews* will continue; and

(e) ASW countries would still follow any approved timeline and provide all the relevant information they do now.

If all of these conditions are met and events occur, then the proposed renewal provision would automatically extend the catch limits for an additional six years.

Accordingly, the automatic renewal would ***not*** occur if: (1) there is a requested change in the catch limit based on need; (2) the Scientific Committee is unable to advise that the status quo catch limits will not harm the stock; or (3) the ASW countries do not follow an approved timeline for review of catch limits or do not report relevant information on the hunts such that the Commission and its Scientific Committee were unable to evaluate the status quo continuation of the hunt. At that point, the Commission would have to decide whether to extend the catch limits.

The continued requirement for Scientific Committee advice that the status quo catch limits will not harm the hunt is an important safeguard. If, for example, there were a catastrophic decline in abundance, or any other basis for concern by the Scientific Committee such that it was unable to advise on the sustainability of the hunt, then the renewal would not automatically occur. Alternatively, if there were a request in the catch limits based on a change in need, then the automatic renewal would also not occur.

Example Timeline: Proposed Change in Commission Practice Every Six Years

Year	Commission Activities	Scientific Committee Activities
2019	**Year 1**: ASW catch limits for a one-time seven-year block begin. No Commission meeting.	Annual SC review of ASW catch limits. Appropriate *Implementation Reviews* completed.
2020	IWC 68 - **Year 2** of seven-year block. Commission evaluation of SC advice on ASW catch limits.	Annual SC review of ASW catch limits. Appropriate *Implementation Reviews* completed.
2021	**Year 3** of seven-year block. No Commission meeting.	Annual SC review of ASW catch limits. Appropriate *Implementation Reviews* completed.
2022	IWC 69 - **Year 4** of seven-year block. Commission evaluation of SC advice on ASW catch limits.	Annual SC review of ASW catch limits. Appropriate *Implementation Reviews* completed.
2023	**Year 5** of seven-year block. No Commission meeting.	Annual SC review of ASW catch limits. Appropriate *Implementation Reviews* completed.
2024	IWC 70 - **Year 6** of seven-year block. Commission evaluation of SC advice. ASW countries provide updated information and Commission reviews ASW catch limits. **Status quo and no change in science**: *Proposed change in Commission practice.* If the SC advises that status quo ASW catch limits *will not* harm the relevant stock(s), and the Commission makes the appropriate determination, then the relevant ASW catch limits are automatically extended for an additional six years from 2026 through 2031. **Status quo and change in science**: Current Commission practice. If the SC is *unable to* advise that the status quo ASW catch limits will not harm the relevant stock(s), and the Commission is unable to make the appropriate determination, then the relevant ASW catch limits *will not* automatically be extended, and a Commission decision will be required. **Change in need**: Current Commission practice. A request for a change in ASW catch limits would also require a Commission decision.	Annual SC review of ASW catch limits. Appropriate *Implementation Reviews* completed. **Status Quo**: SC review of existing ASW catch limits. **Change in science**: SC review of existing and/or proposed ASW catch limits. **Change in need**: SC review of proposed ASW catch limits.

2025	**Year 7** of seven-year block, i.e., "buffer" year. Seven-year block of ASW catch limits expires. No Commission meeting.	Annual SC review of ASW catch limits. Appropriate *Implementation Reviews* completed.
2026	IWC 71 - **Year 1** of new six-year block begins if: (1) status quo ASW catch limits were automatically extended at IWC 70; or (2) Commission approved new ASW catch limits at IWC 70. Commission evaluation of SC advice.	Annual SC review of ASW catch limits. Appropriate *Implementation Reviews* completed.

Adjustments to Schedule Paragraphs 5 and 15(b). A fourth proposed revision would make adjustments to Schedule paragraphs 5 and 15(b) so that these provisions would not apply to the affected ASW hunts. These paragraphs were intended to apply to commercial hunts, not ASW, and the changes would facilitate the Commission's objectives for management of ASW. For Schedule paragraph 5, the allowable minke whale hunting season would increase from nine months to 12 months, as it is for the other ASW hunts. For Schedule paragraph 15(b), the length limit for fin whales would be removed for ASW hunts given that there are already ASW prohibitions relating to the taking of calves. In each case, the existing provisions in Schedule paragraphs 5 and 15(b) unnecessarily limit the affected ASW hunts. In each case, the Scientific Committee has advised that the changes would have no conservation implications.

Increased Annual Strike Limit for Common Minke Whales off East Greenland in Order to Satisfy ASW Need. A fifth proposed revision would increase the annual strike limit for the Central stock of minke whales from 12 to 20. The Scientific Committee has advised that an annual strike limit of 20 whales will not harm the stock and meets the Commission's conservation objectives. As indicated in Resolution 2014-1 and the 2015 IWC Maniitsoq Expert Workshop Report, and consistent with the concept of respect for the rights of indigenous peoples, it is up to the Contracting Government to determine ASW needs. The Kingdom of Denmark has determined that East Greenlanders' need for Central stock minke whales has increased because of the reduced availability of other food sources. The Commission's 1979 Expert Workshop on ASW describes those other sources.

Increased Annual Strike Limit for Eastern North Pacific Gray Whales in Order to Address the "Stinky" Whale Problem and to Satisfy ASW Need. A sixth proposed revision would increase the annual strike limit for Eastern North Pacific gray whales from a six-year block of 744 whales to a seven-year block of 980 whales. In order to accommodate increased subsistence need *as well as* a 7th year in the Eastern North Pacific gray whale quota block, the Russian Federation, taking into account interests of the United States, requested Scientific Committee advice on the following:

> *'For the seven years 2019, 2020, 2021, 2022, 2023, 2024 and 2025, the number of gray whales taken in accordance with this sub-paragraph shall not exceed 980 (i.e. 140 per annum on average) provided that the number of gray whales taken in any one of the years 2019, 2020, 2021, 2022, 2023, 2024 and 2025 shall not exceed 140, except that any unused portion of the strike quota for each year shall be carried forward, provided that no more than 50 percent of the annual strike limit shall be added to the strike quota for any one year.'*

The Scientific Committee advised that an average annual strike limit of 140 whales for the Russian Federation and United States will not harm the stock and meets the Commission's conservation objectives. The estimated annual strike limit of 140 gray whales would remain unchanged, and so, the six-year block limit of 744 would increase to a seven-year block limit of 980. The Russian Federation's basis for this proposed change is twofold: (1) the use of the term "strike"[2] instead of the term "take," where "strike" includes all whales landed, as well as stinky whales

[2] The block limit would be for whales landed instead of whales struck.

and struck and lost whales (not just landed edible whales); and (2) increased need of the Native population of Chukotka. (See SC/67B/AWMP/17 and SC/67B/AWMP/20.)

Safeguards, Commitments and Process for Limited Automatic Renewal

The following statement is for incorporation into the report of the 2018 meeting in order to assure countries of safeguards associated with a limited automatic renewal process.

The four ASW countries reaffirm their commitment to continued management by the Commission of ASW at the same level of scrutiny as now. We look forward to continued review of the ASW hunts by the Commission, informed by the advice and recommendations of the Scientific Committee, the Infractions Subcommittee, the ASW Subcommittee, and the Whale Killing Methods and Welfare Issue Working Group. This ongoing oversight will ensure that the Commission's objectives for management of ASW will continue to be met.

There would be restrictions on the application of the automatic renewal in order to safeguard the stocks. Subject to Scientific Committee advice on the sustainability of the hunt, the catch limits from the previous block would be extended for an additional six years, provided the following conditions were met:

(a) The catch limits do not change;

(b) The Scientific Committee continues to advise that the status quo catch limits will not harm the stock; and

(c) The Commission determines that the relevant ASW country has complied with the approved timeline and that the information provided represents a status quo continuation of the hunt.

In addition:

(d) Annual Scientific Committee review and regular (5-6 years) *Implementation Reviews* will continue; and

(e) ASW countries will still follow the approved timeline and provide all the relevant information in the descriptions of the hunt.

If all of these conditions are met and events occur, then the proposed renewal provision would automatically extend the catch limits for an additional six years.

Accordingly, the automatic renewal would ***not*** occur if: (1) there is a requested change in the catch limit based on need; (2) the Scientific Committee is unable to advise that the status quo catch limits will not harm the stock; or (3) the Commission cannot determine that the relevant ASW country has complied with the approved timeline and that the information provided represents a status quo continuation of the hunt. At that point, the Commission would have to decide whether to extend the catch limits.

The continued requirement for Scientific Committee advice that the status quo catch limits will not harm the stock is an important safeguard. If, for example, there were a catastrophic decline in abundance, or any other basis for concern by the Scientific Committee such that it was unable to advise on the sustainability of the hunt, then the renewal would not automatically occur. Alternatively, if there were a request in the catch limits based on a change in need, then the automatic renewal would also not occur.

The Commission has endorsed at this meeting the Scientific Committee's recommendations on the scientific components of an Aboriginal Whaling Scheme, including operational rules on carryover, block quotas, Interim Relief allocations and the guidelines for Implementation Reviews, for surveys and other data.

The four ASW countries reaffirm the continued importance of reporting relevant hunting data to the WKM&WI-WG, including time to death information, instantaneous death rates where possible, and struck and loss, and recognize the importance of ensuring transparency and improving the welfare of ASW hunts. To that end, the four ASW countries further reaffirm their commitment to Resolution 1994-4 on Review of Aboriginal Subsistence Whaling Management Procedures, Resolution 1997-1 on Improving the Humaneness of ASW Hunts, Resolution 1999-1 arising from the working on whale killing methods, and in particular, the provision of relevant information, and Resolution 2014-1 on Aboriginal Subsistence Whaling.

Commitments from the Russian Federation

Implement more humane killing methods/weapons/training: Pursuant to available funds, including in the Aboriginal Subsistence Whaling Voluntary Fund, the Russian Federation will:

I. Participate in an expert (IWC and relevant organizations) workshop, including ballistics experts, veterinarians, native whalers from the United States, federal and regional government officials, and other invited experts to identify more humane methods and weapons for use in the gray whale hunt and recommend a programme to implement improvements;

II. Implement the improvement program recommended by the expert workshop; and

III. Report the outcomes of this implementation of the workshop, including any time to death data, to the WKM&WI-WG in order to facilitate the measurement of progress achieved by 2024.

IV. Report time to death information (including instantaneous death rates where possible), and struck and loss data, to all meetings of the WKM&WI-WG in order to facilitate measurement of progress.

Determining the cause and extent of stinky whales: Pursuant to available funds, including in the Aboriginal Subsistence Whaling Voluntary Fund, the Russian Federation will participate in collaborative efforts with scientists, other contracting governments, laboratories, relevant wildlife trade enforcement and permitting authorities, and academics with a view to determine the cause and extent of stinky whales by 2025.

TRENDS AND STATUS OF HARBOR SEALS IN WASHINGTON STATE: 1978–1999

STEVEN JEFFRIES,[1] Marine Mammal Investigations, Washington Department of Fish and Wildlife, 7801 Phillips Road S.W., Tacoma, WA 98498, USA
HARRIET HUBER, National Marine Mammal Laboratory, Alaska Fisheries Science Center, National Marine Fisheries Service, 7600 Sand Point Way NE, Seattle, WA 98115, USA
JOHN CALAMBOKIDIS, Cascadia Research Collective, Waterstreet Building, 2181/2 West 4th Avenue, Olympia, WA 98501, USA
JEFFREY LAAKE, National Marine Mammal Laboratory, Alaska Fisheries Science Center, National Marine Fisheries Service, 7600 Sand Point Way NE, Seattle, WA 98115, USA

Abstract: In the first half of the twentieth century, harbor seal (*Phoca vitulina richardsi*) numbers were severely reduced in Washington state by a state-financed population control program. Seal numbers began to recover after the cessation of bounties in 1960 and passage of the Marine Mammal Protection Act (MMPA) in 1972. From 1978 to 1999, aerial surveys were flown at midday low tides during pupping season to determine the distribution and abundance of harbor seals in Washington. We used exponential and generalized logistic models to examine population trends and size relative to maximum net productivity level (MNPL) and carrying capacity (K). Observed harbor seal abundance has increased 3- fold since 1978, and estimated abundance has increased 7 to 10-fold since 1970. Under National Marine Fisheries Service (NMFS) management, Washington harbor seals are divided into 2 stocks: coastal and inland waters. The observed population size for 1999 is very close to the predicted *K* for both stocks. The current management philosophy for marine mammals that assumes a density-dependent response in population growth with MNPL > K/2 is supported by growth of harbor seal stocks in Washington waters.

JOURNAL OF WILDLIFE MANAGEMENT 67(1):208–219

Key words: generalized logistic, harbor seal, Marine Mammal Protection Act, maximum net productivity level, optimum sustainable population, *Phoca vitulina*, pinniped, population growth, trend, Washington.

The MMPA of 1972 established criteria for management of marine mammals by the NMFS and U.S. Fish and Wildlife Service (USFWS). These criteria stated that marine mammal populations "should not be permitted to diminish beyond the point at which they cease to be a significant functioning element in the ecosystem of which they are a part, and, consistent with this major objective, they should not be permitted to diminish below their optimum sustainable population" (16 U.S.C. 1361 Sec. 2). The intent of the MMPA was clear, but the language was too vague to provide an operational definition for management.

Eberhardt (1977) suggested that optimum sustainable population (OSP) should be interpreted as the range of population sizes from the maximum (*K*) down to the size that gives maximum productivity or maximum sustainable yield (MSY). The NMFS adopted the definition for OSP as a population level between *K* and the population size that provides the maximum net productivity level (MNPL; Federal Register, 21 December 1976, 41FR55536). Maximum net productivity level was chosen because, unlike MSY, MNPL is independent of harvest structure (Gerodette and DeMaster 1990).

Defining OSP was a first step, but implementing the definition was difficult due to a lack of biological knowledge about population parameters and sufficiently precise data (Gerodette and DeMaster 1990, Ragen 1995). Difficulties in implementing an OSP management scheme led to the 1994 amendments to the MMPA that provided an alternative approach based on managing incidental take. In this approach, potential biological removals (PBR) must remain below a percentage of a minimum population size (Wade 1998, Read and Wade 2000). However, determinations of OSP and population status are still required by the MMPA to transfer management authority to a state government. Also, an assessment of population growth rates and status relative to MNPL can be incorporated into the calculation of PBRs in the existing management scheme.

Ragen (1995) questioned the utility of MNPL because he was unable to measure it precisely in a well-studied northern fur seal (*Callorhinus ursinus*) population. He stated that "under ideal conditions, MNPL would be determined by accurate and precise monitoring of a discrete population unit during natural growth from some level well below MNPL ... to a level above MNPL." Those ideal conditions are rare indeed, but they did exist for harbor seals in Washington state. Harbor

The inland stock includes Strait of Juan de Fuca (3), San Juan Islands (4), Eastern Bays (5), Puget Sound (6), and Hood Canal (7).

seal numbers were severely reduced in the early 1900s by bounty hunters under a state-financed program that considered harbor seals to be predators in direct competition with commercial and sport fishermen. After the bounty program ceased in 1960 and MMPA was passed in 1972, Washington harbor seals began to recover. Newby (1973) estimated that 2,003,000 harbor seals resided in Washington state in the early 1970s. Beginning in 1978, systematic surveys of Washington's harbor seal population were initiated by Washington Department of Fish and Wildlife (WDFW) and continued through 1999.

This 22-year time series of systematic surveys provided a unique opportunity to describe an unharvested marine mammal's population growth. Because a large number of harbor seals haul out onto land in discrete aggregations at specific times, we were able to count a large proportion of the population to provide an index of population trends. We described population growth using exponential and generalized logistic models.

METHODS

Study Area

As managed by NMFS, harbor seals in Washington and Oregon have been separated into coastal and inland stocks because of differences in cranial morphology, pupping phenology, and genetics (Temte 1986, Lamont et al. 1996). The Washington inland stock includes all harbor seals in U.S. waters east of a line extending north-south between Cape Flattery on the Olympic Peninsula and Bonilla

Point on Vancouver Island (Fig. 1). Harbor seals on the outer coast of Washington are part of a stock that includes seals in Oregon, from the Columbia River southward to the Oregon/California border.

Interchange between inland and coastal stocks is unlikely, since no radiomarked seals from the inland stock (n = 140) were observed in coastal areas or vice versa (n = 188). Harbor seal haulout sites in Washington state were combined into 7 survey regions: Coastal Estuaries, Olympic Coast, Strait of Juan de Fuca, San Juan Islands, Eastern Bays, Puget Sound and Hood Canal (Fig. 1). In the Strait of Juan de Fuca, seals were counted annually in the eastern portion of the strait (east of Port Angeles). The western portion—where few suitable haulout sites exist and few pups are born—was surveyed only twice and was excluded from our analysis. Survey regions were determined by pupping phenology and a geographic area that could be surveyed within a 34 hr tidal window.

Survey Methods

Harbor seal aerial surveys were flown at low tide during the pupping season when maximum numbers were onshore. All known haulout sites were surveyed and potential new sites were examined on each survey. Seals in the water were not counted. Because of differences in pupping phenology among regions, surveys were flown in late May to mid-June for the coastal stock and August through September for the inland stock. Surveys were scheduled as closely as possible (tides permitting) to the time when peak number of pups were expected to be present. All regional surveys occurred within a week of peak pupping for each region (Huber et al. 2001). Surveys were flown between 2 hr before low tide to 2 hr after low tide in a single engine plane at 700–800 ft altitude at 80 knots. To provide consistency in data collection, about 80% of pupping season surveys were flown by 1 observer, while the others were flown by a second observer. Data collected during surveys included date, time, location, a visual estimate of seal numbers, and photographs of all sites with ≥25 seals. We took photographs with a 35mm SLR camera with 70210 mm lens, using 200 or 400 ASA Ektachrome film, and shutter speeds of 1/500 to 1/1,000 s. We counted the seals (including pups) at each site from slides. Evidence of recent disturbances (haulout marks on the beach or seals milling in the water off the haulout site) also was noted.

We scheduled at least 2–3 surveys for each region during annual survey windows, although some surveys were canceled because of inclement weather. A complete survey of each region was attempted in 1 day; if this was impossible, we combined surveys from 2 to 3 days. We excluded surveys with low counts (due to disturbance on a haulout or bad weather, and surveys outside the survey window were discarded. In some years, no count was available for ≥1survey regions.

Population Growth Models

Two simple non-age-structured deterministic models of population growth were considered to represent the growth in the harbor seal stocks: exponential and generalized logistic (Pella and Tomlinson 1969, Gilpin et al. 1976). These models are discrete in nature with an annual time step to represent the annual pupping pulse. Exponential growth assumes that the population grows without limit at a constant annual rate (R_{max}):

$$N_t = N_{t-1} + N_{t-1}R_{max} \tag{1}$$

Clearly, the exponential model cannot be true forever, but populations can experience exponential growth prior to approaching K. Therefore, the exponential model can be used as a null model to test for density dependence. In the generalized logistic growth model, the rate of increase is a function of the population size relative to the maximum population size K:

$$N_t = N_{t-1} + N_{t-1}R_{max}\left[1-\left(\frac{N_{t-1}}{K}\right)^z\right] \tag{2}$$

Annual net production is the difference in consecutive population sizes and the MNPL is the value of N_{t-1} when annual net production is maximized. The shape of the growth curve and the per capita production curve is governed by the exponent z, which determines the timing of the density dependent effect and the position of MNPL relative to K:

$$\frac{N_t - N_{t-1}}{N_{t-1}} = R_{max}\left[1-\left(\frac{N_{t-1}}{K}\right)^z\right] \tag{3}$$

The standard logistic curve is obtained when z = 1: per capita production is a linear function of N and MNPL/K= 0.5. If z >1, per capita production is a concave nonlinear function of N and MNPL/K> 0.5 and if z < 1, per capita production is a convex nonlinear function of N and MNPL/K < 0.5.

An approximate relationship between MNPL/K and z (Polachek 1982) is given by:

$$\text{MNPL}/K \approx (z+1)^{-1/z} \quad (4)$$

Incorporating z into the growth model is important for harbor seal populations because long-lived marine mammals are expected to demonstrate the strongest density-dependent effect as N approaches K ($z > 1$; Eberhardt and Siniff 1977, Fowler 1981). However, in most cases, survey data were not sufficiently precise to estimate z adequately (Goodman 1988, Hilborn and Walters, 1992, Ragen 1995). The parameters R_{max} and z have a strong negative correlation in the model and diametrically opposed parameter values can yield nearly identical population trajectories for portions of the overall trajectory (Fig. 2). Without precise population estimates, z will almost surely be poorly estimated. The correlation between R_{max} and z is lessened by observing the population over a wide range of growth.

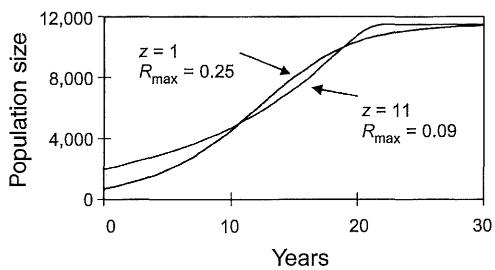

Fig. 2. Two similar generalized logistic growth curves of harbor seals in Washington, USA, achieved by choosing different values for z, R_{max}, and initial population size. Discriminating between these 2 growth curves would be nearly impossible if the population were observed from year 10 and beyond. However, if the population is observed from year 0, the parameters would be estimated more precisely as the 2 models imply different starting population sizes.

Growth Model Fitting

Our survey count data represented some variable proportion of the population (Jeffries 1985, Huber et al. 2001). Fitting growth models to the harbor seal count data involved finding parameter values that provided the best fit to the data. The best fit depended on the assumed statistical model for the observed data. We used deterministic population growth models (i.e., given the parameter values, the population size in year N_t determined exactly the size in year N_{t+1}) but the observed count C_t of harbor seals represented some unknown and variable proportion of the population abundance N_t:

$$C_t = N_t p_t \quad (5)$$

If p_t has a normal distribution with expectation p and variance s^2, the statistical model for the counts can be expressed as:

$$C_t = N_t(p+\delta_t) = N_t p + N_t\delta_t = N_t p + \varepsilon_t \quad (6)$$

where the distribution for δ_t is $N(0, s^2)$, and the distribution for $\varepsilon_t = N_t\,\delta_t$ is $N(0, s^2 N_t^{\,2})$. Thus, the coefficient of variation (c) of the errors ε_t is constant:

$$\text{c} = \text{CV}(\varepsilon_t) = \frac{sN_t}{pN_t} = \frac{s}{p} \quad (7)$$

An estimate of p requires additional data (e.g., radiomarking; Huber et al. 2001). If p had been estimated for each region and year, the growth model could have been based on estimates of population size. However, estimates of p were only available for 2 regions in different years. Thus, we fitted growth models to the count data and our inference to population growth depends on the assumption no temporal trend in p_t exists.

Based on these assumptions, we used the following statistical model:

$$C_t = N_t + \varepsilon_t \quad (8)$$

where N_t is now the size of the population onshore at time t as specified by the generalized logistic or exponential growth model, and ε_t are independent normal errors with zero expectation and constant coefficient of variation. The growth model parameters are R_{max}, K, z, and an intercept N_0, which is an initial size of the population onshore for some arbitrarily chosen time designated as $t = 0$. We only used counts to fit the growth models, but to express N_0 and K in terms of the population we multiplied N_0 and K by the correction factor (CF) of 1.53 (Huber et al. 2001), which is the reciprocal of the average proportion ashore (p) for an assumed age–sex structure. The parameters R_{max} and z remain unchanged by the constant scaling but would be affected by any trends in p_t.

To obtain parameter estimates for the growth curve, we used maximum likelihood. For k counts conducted at years $t_1, t_2, ..., t_k$, the log-likelihood is:

$$\ln L = -\frac{k}{2}\ln\left(\sum_{i=1}^{k}\left[\frac{C_{t_i}-N_{t_i}}{N_{t_i}}\right]^2\right) \quad (9)$$

The log-likelihood is a function of the growth curve parameters which define the values for N_t from equations (1) or (2). Maximizing (9) is equivalent to minimizing the sum of squared proportional residuals:

$$\sum_{i=1}^{k}\left[\frac{C_{t_i}-N_{t_i}}{N_{t_i}}\right]^2 \quad (10)$$

Use of the normal distribution probably is reasonable as long as p is not close to 0 or 1 and c^2 is sufficiently small such that there is little area in the tails of the distribution >1 or <0. A more complex alternative model could be constructed by assuming p_t follows a Beta distribution, which is bounded between 0 and 1, and C_t follows a binomial distribution with parameters N_t and p_t (or normal approximation).

Parameter estimates were obtained by using an optimization search algorithm in a FORTRAN program to find the values which maximize (9) or likewise minimize (10). We estimated variances and confidence intervals based on parametric bootstrapping (Efron and Tibshirani 1993). We implemented a parametric bootstrap by using the estimated parameters to construct a single "true" population trajectory. For each bootstrap, we constructed a data set by adding a random set of residuals drawn from the fitted error distribution to the true population trajectory. The model was then fitted to the new bootstrap data. We repeated the bootstrapping process 1,000 times to develop a distribution of parameter estimates.

One of the complications in the harbor seal data was missing counts. A count for each year was unnecessary. Ideally, however, for any year, the entire range should have been counted completely. In certain instances, some regions were not surveyed due to bad weather, disturbance, logistical problems, or lack of funding. In other instances, surveys began in 1 region and then expanded into other regions over time. For example, in Washington, the Coastal Estuaries were surveyed as early as 1975 but surveys of the Olympic coast region were not begun until 1980 (Table 1). Although counts for inland waters for 1978 were available (Calambokidis et al. 1979), consistent counts for all regions in the inland waters stock did not begin until 1983. A simple solution was to limit counts to years in which seals were counted in all regions. However, this would have wasted valuable data and severely restricted the survey time frames.

Instead, we fitted separate growth curves for each of the 7 regions (Fig. 1) using counts that were available for each region. Fitting separate growth models to the regions used only observed data but required more parameters that applied to the regions and not the entire population. Any random movement between regions would create additional variation in counts and any directed movement (i.e., permanent emigration/immigration) would be reflected in the parameters of regional growth models.

Separate growth models for each of the 7 regions were fitted by maximizing the sum of the regional log-likelihoods (9) assuming separate and independent regional error models:

$$\ln L = -\frac{1}{2}\sum_{j=1}^{r} k_j \ln\left(\sum_{i=1}^{k_j}\left[\frac{C_{t_{ij}}-N_{t_{ij}}}{N_{t_{ij}}}\right]^2\right) \quad (11)$$

where k_j is the number of surveys in the j^{th} region and r is the number of regions. Because the predicted abundance for survey i in region j (N_t) may be determined by unique regional parameters, the number of estimated parameters expands substantially. However, some of the parameters could be held constant for some or all of the regions. In general, z is difficult to estimate (Hilborn and Walters 1992), and our data would not likely support a different z for each region. Also, R_{max} was likely to be constant among regions unless there was a strong movement component. However, K and N_0 were unlikely to be constant across regions because of differences in region size and habitat quality.

We fitted a series of models for each of the 5 regions in the inland Washington stock and separately for the 2 regions in the coastal stock. For each model, we assumed that N_0 and K (for the logistic model only) were different for each region. We fitted exponential models that assumed R_{max} was constant or varied by region. Likewise, we fitted logistic models that assumed R_{max} and z were either constant or varied by region. After selecting the best logistic model for each stock, we also explored whether R_{max} and z varied by stock.

We used the small sample Akaike Information Criterion ($AIC_c = -2 \ln L + 2m + 2m[m+1]/[n-m-1]$, where m is the number of parameters and n is the number of surveys) to choose the most

Table 1. Average annual harbor seal haulout counts for 2 regions in the coastal stock and 5 regions in the inland stock of Washington, USA, 1975–1999.

	Coastal stock		Inland stock

1998			1,734	4,441	1,810	1,026	577
1999	7,117	3,313	1,752	3,588	1,873	1,025	711

parsimonious model (Burnham and Anderson 1998). We evaluated the model goodness of fit with the Kolmogorov-Smirnov test to examine whether the standardized residuals were normally distributed. For graphical display of the growth curve for each stock and the entire state, we summed the predicted values across regions. For observed values, we summed the average of regional counts for years in which 1 counts were available for each region. To supplement the observed values for the entire state, we added predicted counts for a few years with missing counts in 1 or 2 areas.

Status Determination

A harbor seal stock was considered to be at OSP if the current predicted population size was above MNPL. We determined whether OSP > MNPL by comparing population sizes as a proportion of K, because (4) provides a simple computation of MNPL/K. For each parametric bootstrap, we compared $\hat{N}_{1999}/K$ to MNPL/K. If <5% of the replicates were below MNPL/K, we concluded that the stock was at OSP. We also constructed bootstrap confidence intervals for $\hat{N}_{1999}/K$, MNPL/K, and $\hat{N}_{1999}$/MNPL. A similar approach was taken by Wade (1999) to investigate whether a spotted dolphin population was above or below MNPL.

Proportion Ashore

Our growth model based on seal counts would only reflect population growth if no trend in the proportion of seals ashore existed. A trend in p could occur if, over the 2 decades of surveys, the seals spent more or less time ashore as the population increased. A plausible scenario would be a decrease in the time ashore because more time could be required for foraging as the population increased and food resources decreased.

We examined whether the proportion ashore changed in Grays Harbor or Boundary Bay during the 1990s. Huber et al. (2001) applied VHF radio-transmitters to harbor seals in 1991 at Grays Harbor (GH; coastal stock) and in 1992 at Boundary Bay (BB; inland stock) to estimate p. We applied the same techniques as Huber et al. (2001) at GH in 1999 and BB in 2000. In each survey, all seals

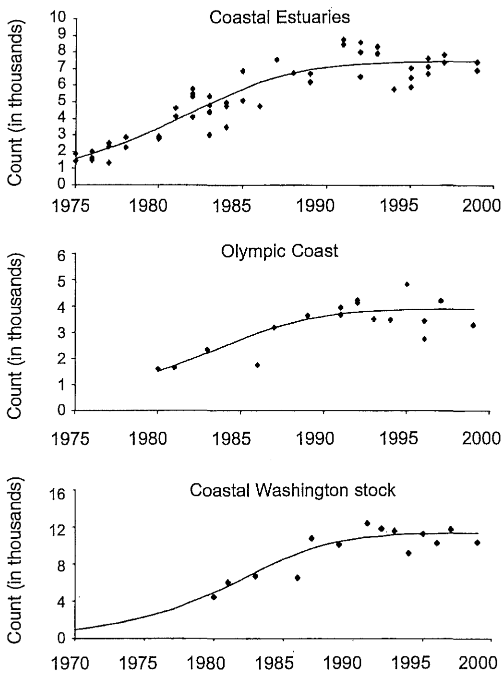

Fig. 3. Generalized logistic growth curves of harbor seals in Washington, USA, portion of the coastal stock for coastal estuaries and outer Olympic Peninsula coast regions and their sum.

with active tags were determined to be either ashore or not. Using each seal as a sample, we modeled the number of surveys the seal was ashore using a generalized linear model based on a binomial distribution and logit link function.

We fitted models that included 4 age–sex categories (adult female, adult male, pup subadult), year (1991–1992 vs. 1999–2000), and region (GH or BB) and the interaction of these parameters. Using the most general model with all interactions, we estimated an overdispersion scale (residual deviance/df; McCullagh and Nelder 1991) to adjust model selection using minimum $QAIC_c$ (Burnham and Anderson 1998). We also examined whether any observed annual differences in the proportion ashore would influence our conclusion regarding population growth.

RESULTS

Aerial Surveys

Between 1978 and 1999, counts of harbor seals in Washington state increased nearly 3-fold, from 6,786 to 19,379. The earliest surveys began in 1975 in the Coastal Estuaries (Table 1). By 1978, surveys had begun in all areas (Calambokidis et al. 1979) except the outer coast of the Olympic Peninsula where surveys began in 1980 (Table 1). Consistent surveys of inland waters did not begin until 1983 (Figs. 3, 4). The regions were not always surveyed annually nor were they surveyed an equal number of times/year. Growth between 1978 and 1999 was not evenly distributed throughout all regions. Most growth occurred in the San Juan Islands and the Strait of Juan de Fuca, and the least growth occurred in Hood Canal (Table 1).

Growth Model

The generalized logistic model with constant R_{max} and z was clearly the best model (Table 2) to describe inland and coastal seal stock population growth. The large discrepancy in AIC_c between exponential and logistic models provides strong evidence for a density dependent response in population growth (Table 2). When we examined models that shared R_{max} and z parameters between stocks the choice was less clear.

We selected the model with separate parameters for each stock because these stocks are genetically different and unlikely to be demographically linked. As expected, we estimated N_0 and K of the onshore population with reasonable precision, whereas less precision was achieved for R_{max} and z (Tables 3, 4). The initial size estimates, using 1970 as the base year, were quite consistent with counts for 1970–1972 by Newby (1973), with the exception of San Juan Islands region (Tables 3, 4). The growth curves demonstrate the growth rate slowing as numbers approached K (Figs. 3–5) and demonstrate a reasonable fit. Pooled standardized residuals did not differ from the assumed normal distribution (KS = 0.05, P = 0.21).

Status Relative to Optimal Sustainable Population

Although the evidence is not strong, the growth models of both stocks agree with the speculation that MNPL is indeed $>K/2$ (Table 5; Eberhardt and Siniff 1977, Fowler 1981). The predicted population size for 1999 is very close to K for both stocks (Table 5), and none of the bootstrap replicates predicted a 1999 population size that was below MNPL. The coastal stock recovered earlier than the inland stock, as evidenced by the status of the stocks in 1990 (Table 5).

Proportion Ashore

We radiomarked 29 seals and conducted 5 surveys at GH in 1999. We radiomarked 43 seals and

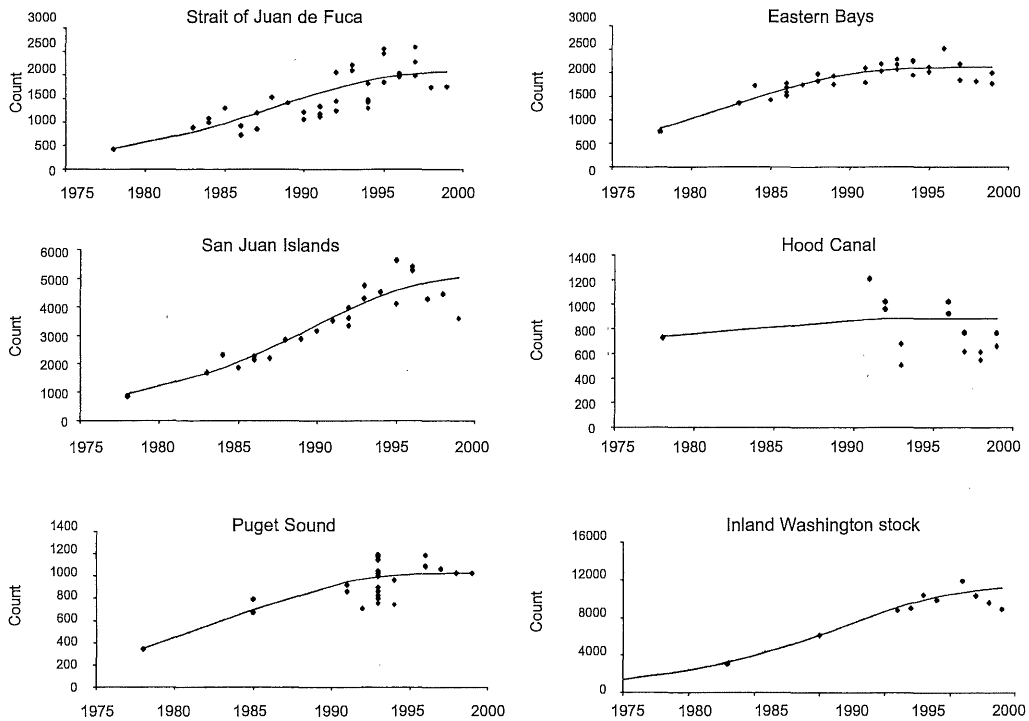

Fig. 4. Generalized logistic growth curves of harbor seals in the Washington, USA, inland stock for Strait of Juan de Fuca, Eastern Bays, San Juan Islands, Hood Canal, and Puget Sound regions and their sums.

conducted 7 surveys at BB in 2000 (Table 6). As expected during the pupping season, adult males and subadults spent considerably less time ashore than adult females and pups (Fig. 6). The full model with 16 parameters for age–sex, year, region, and parameter interactions explained 59% of the deviance. The residual deviance/df (124.82/113 = 1.11) suggested a minor amount of overdisper-

Table 2. Model selection results for exponential and generalized logistic growth models of inland and coastal harbor seal stocks in Washington, USA, 1975–1999. In addition to R_{max} and z, the number of parameters m includes initial size and carrying capacity (for logistic models) for each region.

	Puget Sound	0.135			

sion. The model with minimum $QAIC_c$ included all of the main effects and 2-way interactions ($QAIC_c = 145.6$), although a much simpler model with only age–sex, year and their interaction had a similar value ($QAIC_c = 145.8$). Based on $QAIC_c$, these 2 models are indistinguishable. The model with age-sex only ($QAIC_c = 150.3$) accounted for 63% of the explained deviance of the full model.

The year influence was not consistent across the age–sex classes (Fig. 6). Females and pups spent less time ashore in 1999–2000 than in 1991–1992, whereas adult males and subadults spent more time ashore 1999–2000 than in 1991–1992. Most of the annual difference and the interaction resulted from shifts at GH. We computed an annual average proportion ashore for all seals (Table 6) by weighting age–sex specific values against the expected age–sex proportions of seals in the population (Huber et al. 2001), which adjusted for differences in sample sizes between the age–sex classes across years. The largest decrease in the average proportion ashore occurred at GH, with very little change at BB.

DISCUSSION

Aerial Surveys

Haulout behavior of harbor seals varies with season. In general, the number of seals ashore is highest during annual pupping and molt and

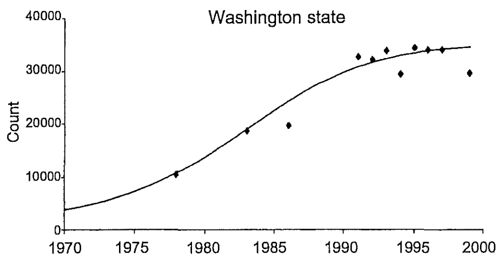

Fig. 5. Generalized logistic growth curve for harbor seals in Washington, USA, expressed population size. The observed values for 1978, 1983, 1986, 1994, and 1995 were supplemented with model predictions for regions with missing counts that accounted for 17, 12, 13, 5, and 8% of the total abundance.

lowest during winter. Many variables, such as height of tide, time of day, weather, and disturbance affect seal haulout patterns. The proportion of seals ashore during a pupping survey will depend on tide state, timing relative to peak pupping, age, sex, and reproductive condition of seals using the haulout. Several approaches exist to obtain maximum counts and reduce variability in counts within a chosen season. Some researchers have surveyed during a broad range of time and tide conditions and adjusted counts for date and tide height after the fact (Frost et al. 1999, Olesiuk et al. 1990). In contrast, we reduced variability in our counts by restricting our surveys to a narrow time frame at the peak of the pupping season in each survey region and surveying only at low tides between 2.0 and +2.0 feet, when maximum numbers of seals were hauled out.

Corrections for Proportion Ashore

Harbor seal haulout behavior varies by age, sex, and reproductive condition of seals. During pupping season, adult females and nursing pups spend 90–100% of their time on shore during the 4–6 week nursing period (Huber et al. 2001). After weaning, pups spent an increased amount of time in the water and hauled out only infrequently, whereas males and subadults were on shore during 40–60% of surveys. These differences in haulout behavior have strong implications for timing of surveys and the use and interpretation of correction factors associated with seasonal surveys.

We did find changes in the proportion of seals ashore during our surveys in 1991–1992 and 1999–2000. However, these changes do not invalidate our conclusions regarding growth and status of harbor seal stocks in Washington. The largest decrease in the proportion ashore occurred at GH, declining from 0.71 to 0.62. However, the seal counts reflected this change decreasing from 8,681 in 1991 to 7,118 in 1999. If we apply the individual annual correction factors (Table 6), we get estimates of 12,285 and 11,548, respectively. Thus, the population estimates are even closer than the counts, which is consistent with our conclusion that the population stabilized during the 1990s.

At BB little difference was noted in the average proportions ashore but the counts were not as consistent, decreasing from 797 in 1992 to 564 in 2000. However, these values are consistent with a lack of growth during the 1990s. We believe that the leveling trend in seal abundance is real and not related to a change in proportion of seals hauled out during surveys.

Trends and Status

Because the analysis was based on counts of seals ashore during a survey, estimated K and N_0 represent only a proportion of the entire population. To get estimates of the true population size,

Table 5. Parameter estimates for status determination of inland and coastal stocks of harbor seals in Washington, USA, with bootstrap standard errors and 95% confidence intervals.

Parameter	Stock	Estimate	Standard error	95% confidence interval
MNPL/K	Inland	0.60	0.064	0.51 to 0.77
	Coastal	0.56	0.066	0.49 to 0.74
$\hat{N}_{1999}/K$	Inland	0.98	0.025	0.90 to 1.00
	Coastal	1.00	0.004	0.99 to 1.00

	Coastal	0.94	0.034	0.88 to 1.00
$\hat{N}_{1999}$/MNPL	Inland	1.63	0.14	1.29 to 1.85
	Coastal	1.78	0.18	1.35 to 2.10

Table 6. Comparison of proportion of radiomarked harbor seals ashore during surveys at 2 sites 1991–1992 and 1999–2000 in Washington, USA. 1991–1992 data from Huber et al. (2001). The average proportion ashore was computed as a weighted average of the age-sex specific proportions using an assumed structure of 31% adult females, 26% adult males, 23% pups and 19% subadults.

	Grays Harbor		Boundary Bay	
	1991	1999	1992	2000
Active radio tags	33	29	24	43
Adult female	9	9	7	14
Adult male	7	7	5	16
Pup	8	8	7	8
Subadult	9	5	5	5
Number of surveys	4	5	5	7
Average proportion ashore (p)	0.71	0.62	0.69	0.72
Correction factor ($1/p$)	1.42	1.62	1.44	1.38

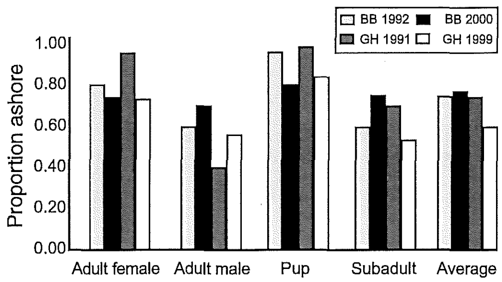

Fig. 6. Average proportion ashore for radiotagged harbor seals in each of 4 age–sex categories and a weighted average for Boundary Bay (BB) in 1992 and 2000 and Grays Harbor (GH) in 1991 and 1999, Washington, USA.

K and N_0 must be scaled by a correction factor (the inverse of the proportion ashore). Using the correction factor of 1.53 (Huber et al. 2001), we estimated that during 1999, Washington coastal stock contained 15,958 harbor seals (95% CI: 13,645 to 18,662) and the inland stock contained 13,692 seals (95% CI: 11,707 to 16,012). Because there are no records of the pre-exploitation population size in Washington, whether the present population is more or less than before is unknown. Changes that may have lowered K include decreases in harbor seal prey such as hake (*Merluccius productus*; Gustafason et al. 2000) and herring (*Clupea pallasi*; Stout et al. 2001), reduced habitat, and increased disturbance. However, we have shown that both stocks of Washington harbor seals are above MNPL and are near the current carrying capacity of the environment. These stocks can decline or be reduced by 20% and they will still be above MNPL with a high degree of certainty (Table 5).

MANAGEMENT IMPLICATIONS

Management implications for harbor seal stocks in Washington are quite clear. If formally determined to be at OSP, NMFS could return management authority for harbor seals to Washington state, if requested. Local selective removals of seals could be considered at river mouths where endangered or threatened salmonids occur, if harbor seals are consuming and threatening fish populations of concern (National Marine Fisheries Service 1997). From our analysis, selective removal of harbor seals around river mouths is unlikely to have detrimental effects on harbor seal populations in Washington state. Harbor seal stocks in Washington could decline by 20% and still be above MNPL.

The current management philosophy for marine mammals that assumes a density-dependent response in population growth with MNPL $>K/2$ is supported by growth of harbor seal stocks in Washington waters. We expect that further monitoring of other pinniped and cetacean stocks (Wade 2002) will also support this concept. Our analysis demonstrated that it was not possible to determine whether harbor seals in Washington had reached MNPL until several years after the fact. Our study highlights the importance of long-term, precise monitoring to help understand population dynamics and support management decisions.

Gray whale southbound migration surveys 1967–2006: an integrated re-analysis

Jeffrey L. Laake[1], Andre E. Punt[2], Roderick Hobbs[1], Megan Ferguson[1], David Rugh[1] and Jeffrey Breiwick[1]

Contact e-mail: Jeff.Laake@noaa.gov

ABSTRACT

Between 1967 and 2007, 23 seasons of shore-based counts of the Eastern North Pacific (ENP) stock of gray whales (*Eschrichtius robustus*) were conducted throughout all or most of the southbound migration near Carmel, California. Population estimates have been derived from these surveys using a variety of techniques that were adapted as the data collection protocol evolved. The subsequent time series of estimates was used to evaluate trend and population status, resulting in the conclusion that the population was no longer endangered and had achieved its optimum sustainable population (OSP) level. We re-evaluated the data from all of the surveys using a common estimation procedure and an improved method for treatment of error in pod size and detection probability estimation. The newly derived abundance estimates between 1967 and 1987 were generally larger (–2.5% to 21%) than previous abundance estimates. However, the opposite was the case for survey years 1992 to 2006, with estimates declining from –4.9% to –29%. This pattern is largely explained by the differences in the correction for pod size bias, which occurred because the pod sizes in the calibration data over-represented pods of two or more whales and underrepresented single whales relative to the estimated true pod size distribution.

KEYWORDS: ABUNDANCE ESTIMATE; GRAY WHALES; WHALING – ABORIGINAL

INTRODUCTION

The National Marine Fisheries Service (NMFS) has conducted shore-based counts of the Eastern North Pacific (ENP) stock of gray whales (*Eschrichtius robustus*) in central California during December–February for 23 years with the first survey in 1967–1968 and the most recent in 2006–2007. Since 1974–1975 these surveys have been conducted from a cliff overlooking the ocean at Granite Canyon (36° 26’ 41” N), 13km south of Carmel. Prior surveys (1967–1974) were conducted at Yankee Point (36° 29’ 30” N), 6km north of Granite Canyon. The surveys have been conducted in this region because most gray whales migrate within 6km of land along this section of the coastline (Shelden and Laake, 2002), apparently due to the deep marine canyons north of Granite Canyon.

These survey data have been used to estimate abundance of the gray whale stock using various techniques (Buckland *et al.*, 1993; Hobbs *et al.*, 2004; Laake *et al.*, 1994; Reilly, 1981; Rugh *et al.*, 2008b; Rugh *et al.*, 2005). The resulting sequence of abundance estimates has been used to estimate the population’s growth rate (Buckland and Breiwick, 2002; Buckland *et al.*, 1993), which resulted in removal of ENP gray whales from the US List of Endangered and Threatened Wildlife on 16 June 1994 (Federal Rule 59 FR 31095), and the more recent conclusion reported by Angliss and Outlaw (2008) and Angliss and Allen (2009) that the ENP gray whale stock was within its optimum sustainable population (OSP) range as defined by the US Marine Mammal Protection Act (MMPA).

Recently, Rugh *et al*. (2008c) evaluated the accuracy of various components of the shore-based survey method, with the focus on pod size estimation. They used a pair of observers working together to track one pod of whales at a time to evaluate error in pod size estimates made by the independent observers conducting the standard survey. They compared their correction factors to similar values constructed from aerial surveys in 1978–1979 (Reilly, 1981), 1992–1993 and 1993–1994 (Laake *et al.*, 1994), and from paired thermal sensors in 1995–1996 (DeAngelis *et al.*, 1997). The additive correction factors that had been used to compensate for bias in pod size estimates differed among the various data sets; in particular, the correction factors estimated by Laake *et al.* (1994) were substantially larger than those estimated by Reilly (1981). This was of concern because the 1987–88 abundance estimate (Buckland *et al.*, 1993) used the correction factors from Reilly (1981) and all subsequent estimates (1992–1993 to 2006–2007) used the correction factors from Laake *et al.* (1994). Also, the estimates for the surveys prior to 1987 in the trend analysis were scaled based on the abundance estimate from 1987–88. This meant that the first 16 abundance estimates used one set of correction factors, and the more recent seven abundance estimates used different (and larger) correction factors which would influence the estimated trend and population trajectory.

Additionally, there have been other subtle differences in analysis methods used for the sequence of abundance estimates. For example, the number of hours on watch has been reduced from 10 to 9 per day. Also, a pod was the sample unit used for fitting the migration curve for estimates prior to 1995, whereas whales were used (after correcting for bias in pod size estimates) subsequently. Thus, a re-evaluation of the analysis techniques and a re-analysis of the abundance estimates were warranted to apply a more uniform approach throughout the years. We have explored the additive correction factor for pod size bias developed by

[1] *National Marine Mammal Laboratory, Alaska Fisheries Science Center, National Marine Fisheries Service, NOAA, 7600 Sand Point Way NE, Seattle, WA 98115.*
[2] *School of Aquatic and Fisheries Sciences, University of Washington, Seattle, WA 98195-5020.*

Reilly (1981) and show that it requires some strong assumptions that are unlikely to be met in practice. We devised a better approach with weaker assumptions and incorporated it into an analysis that was used to estimate abundance for all 23 surveys.

METHODS

Field survey methods

The survey data collection protocol has remained largely unchanged over the 40-year time span, but some refinements to the protocol have been made to reduce observer fatigue, collect more data, and provide more accurate data measurements (Table 1). During the survey, an observer scans the ocean (typically without binoculars) and locates passing whales that are visible when they blow, surface or dive showing their flukes. For all surveys, the sighting times, pod size estimates, and some measure of offshore distance were recorded. Also, start and end of watch effort and environmental conditions (e.g. Beaufort sea state (wind force) and visibility) were also recorded. In earlier years, observers may have searched a wide area, but since the late 1980s, there has been increasing emphasis on searching only the area directly west and north of the site. This has reduced confusion with sightings at great distances. In more recent years, when a whale was first seen, the time, horizontal angle, and reticle were recorded for the initial sighting and, if seen again, when the whale surfaced again near an imaginary line perpendicular to the coast (at a magnetic angle of 241°). This allowed calculation of travel speed and trajectory relative to the coast.

The primary shift in survey protocol occurred in 1987–1988 when several important changes were made (Table 1):

(1) Prior to 1987–1988, changes in environmental conditions (i.e. Beaufort sea state and visibility classification) were recorded only at the beginning of a watch and when a sighting occurred, or up to two more times during the watch if no sightings occurred during the watch. This approach precluded measuring the exact amount of time spent surveying at specific environmental conditions, which is important because these factors affect the observers' ability to detect whales. That was corrected starting in 1987–1988 when the survey protocol was changed to record the time and conditions whenever they changed, regardless of whether any sightings occurred.

(2) Offshore distance (perpendicular to the coast at the observer's location) prior to 1987–1988 was estimated visually without calibration, and the accuracy of these estimates is unknown. All subsequent measurements of distance were made with reticle readings etched in 7 × 50 binoculars. These marks provided quantification of the angle from the horizon to a sighting. Using an observer's eye height above the surface of the ocean (between 21 and 23m depending on which part of the research station bluff was used), the reticle measurements were converted to a radial distance from the observer to the whale (Lerczak and Hobbs, 1998). The distance offshore is computed from the radial distance and the horizontal angle measured with the

Table 1

Gray whale shore-based count locations, dates, and field methods. The index y for year refers to the year at the beginning of the survey (e.g. y = 1995 for the 1995–1996 survey). YP refers to Yankee Point and GC to Granite Canyon survey locations.

Year(y)	Location	Start date	End date	Watch periods per day[1]	Paired obs.	Distance data[2]	Visibility[3]	Pod size bias
1967	YP	18/12/1967	03/02/1968	2–5h each	–	Intervals	Sky/dist	–
1968	YP	10/12/1968	06/02/1969	2–5h each	–	Intervals	Sky/dist	–
1969	YP	08/12/1969	08/02/1970	2–5h each	–	Intervals	Sky/dist	–
1970	YP	09/12/1970	12/02/1971	2–5h each	–	Intervals	Sky/dist	–
1971	YP	18/12/1971	07/02/1972	2–5h each	–	Intervals	Sky/dist	–

[1]1967–68 to 1984–85: two watch periods per day of 5 hours each, from 07:00–17:00; 1985–86 to 1992–93: three watch periods per day (07:00–10:30 hours, 10:30–13:30 hours, 13:30–17:00 hours); 1993–94 to 2006–07: three 3 hour watch periods (07:30–10:30 hours, 10:30–13:30 hours, 13:30–16:30 hours).
[2]Intervals were 0–¼ nautical miles (nmi), ¼–½ nmi, ¾–1 nmi, 1–1.5 nmi, 1.5–2 nmi, etc. Distances have been based on binocular reticles since 1987–88.
[3]No visibility codes were recorded prior to 1978–79. Instead observers recorded sky conditions and sometimes miles as an indication of visibility. Those values were translated to visibility codes 1–5 used through 1987–88. In 1992–93 observers began recording visibility in six subjective categories (1 = excellent; 6 = useless), a system used since.
[4]Small-scale trial double-observer study conducted for 6 days but not used in the analysis.
[5]Thermal data for pod size bias were not used in this analysis because pod and observer were not recorded.

binocular compass. During the 1987–1988 and 1992–1993 surveys, a reticle measurement was recorded only for the whale sighting closest to the 241° line. For all subsequent surveys, reticle readings were recorded for both the north and south sightings of a pod, if it was seen twice. This provided calculations of whale travel speed.

(3) Until 1987–1988, all surveys were conducted with a single observer on watch at a time, with the exception of a small test conducted in 1986 (Rugh *et al.*, 1990). To enable estimation of pods missed by an observer during the watch, a second concurrent independent observer was used throughout the 1987–1988 survey and for portions of the survey in all subsequent surveys. By matching the measurements of offshore distance, timing of the whale passage across the 241° line, and pod size, it was possible to assess which pods were seen in common and which were missed by one of the observers. This double-count approach follows standard capture-recapture methodology (Buckland *et al.*, 1993; Otis *et al.*, 1978).

Analysis methods

Past abundance estimates have been derived as the product of the count of pods and a series of multiplicative correction factors. Buckland *et al.* (1993) and Laake *et al.* (1994) used the following abundance estimator:

$$\hat{N} = m\bar{s}f_t f_n f_m f_s \ , \quad (1)$$

where the observed number of pods (under acceptable visibility conditions), *m,* was multiplied by the mean pod size ($\bar{s}$) (i.e. $m\bar{s}$ is the total whale count) and correction factors for: (1) pods passing outside watch periods, f_t; (2) night travel rate, f_n ; (3) pods missed during watch periods, f_m ; and (4) bias in pod size estimation, f_s. Not included in these corrections are whales passing beyond the viewing range of the observers (only 1.28% of the population, according to Shelden and Laake (2002)) and whales passing the station well before or after the census, which is assumed to be a very small number. Estimates from 1995–1996 to 2006–2007 used the abundance estimator of Hobbs *et al*. (2004):

$$\hat{N} = \hat{W}f_t f_n \ , \quad (2)$$

where $\hat{W}$ is an estimate of the number of whales that passed during the watch periods and includes corrections for both pod size bias (f_s) and pods missed by the observers during the watch (f_m).

The analysis method developed here is even more integrated than the method used by Hobbs *et al*. (2004), and the resulting abundance estimator can be expressed simply as:

$$\hat{N} = \hat{W}f_n \ , \quad (3)$$

where $\hat{W}$ is an estimate of the number of whales that passed during the entire migration with corrections for pod size bias and missed pods but without differences in night vs. day passage rates. Although explicit multiplicative correction factors are not used, equivalent values for comparison to previous analysis were calculated.

Ideally, there would be data in each year to construct a year-specific value for each correction factor. However, there is no single year in which all of the data were collected to estimate each correction factor (Table 1). Despite this shortcoming, it is possible to estimate $f_{t,y}$ for each year, so a naïve estimate of abundance ($\tilde{W}_y$) can be constructed for each year (y):

$$\tilde{W}_y = m_y \bar{s}_y f_{t,y} \ , \quad (4)$$

where $\tilde{W}_y$ is an estimate of whales passing during the migration with a correction only for whales that passed outside of the watch periods, $f_{t,y}$.

Calibration data for pod size bias were collected during only five surveys (Table 1), so year-specific data were not available but the correction factor ($f_{s,y}$)was partially year-specific due to annual differences in the distribution of pod sizes. A year-specific value for missed pods ($f_{m,y}$) was computed for each of the last eight surveys (Table 1) because independent double-observer data were collected for all or portions of the survey such that each observer's detection probability could be estimated. Thus, for the last eight surveys a more 'complete' estimate of abundance with year-specific correction factors $f_{t,y}$, $f_{m,y}$, and $f_{s,y}$ but a constant night time correction factor was constructed. To construct comparable estimates for the first 15 surveys when these data were not available, a conventional ratio estimator (Cochran, 1977) was used with $\hat{W}_y$ and $\tilde{W}_y$ values for the last eight surveys and that estimated ratio was used to scale the naïve abundance estimates from each of the first 15 surveys.

Detail of each of the methods for handling pod size error, pods missed by the observer while on watch and estimation of abundance for each year are outlined below. All of the methods described here were implemented in the R (*R* Development Core Team, 2009) statistical computing environment. Both the data and the R code have been archived into an R package named ERAnalysis[3] that can be used with R to reconstruct the analysis and results presented here.

Pod size calibration

Estimates of the size of migrating gray whale pods are subject to error, with a tendency to undercount the number of whales in a pod because of the observer's oblique view from shore and the asynchrony of diving among whales in a pod. That is, multiple whales surfacing separately within a pod are often confused with a single whale surfacing multiple times. The magnitude and sign of the errors obviously depends on the true size of the pod. For example, it is possible that close, multiple dives of a single whale could be misconstrued as more than one whale in a pod, but by definition, underestimation cannot occur for a single whale. In contrast, a large pod of whales could be potentially counted as a single whale if the whales were close together and no more than one whale was observed at the surface simultaneously. The most reliable count of a pod occurs when all of the whales are observed at the start of a deep dive, when there is some synchrony to the group and each shows its fluke.

To address this source of error, two calibration methods were used (Table 2). In the first method, an aircraft was used to observe whale pods and count the number of whales in a pod while observers from shore recorded their independent

[3] *http://www.afsc.noaa.gov/nmml/software/eranalysis.php*

Table 2

Summary of gray whale pod size calibration data. Some observers provided estimates in more than one year and each pod was not observed by each observer. Only one or two estimates per pod were obtained via land tracking because they calibrated the single or double observers during the standard watch.

Year	Type	No. of pods	No. of observers	No. of observations
1978–79	Aerial	25	12	295
1992–93	Aerial	21	5	79
1993–94	Aerial	39	7	157
1997–98	Land tracking	111	10	192
Total		196	28	723

estimates of pod size. With the aerial view and relatively clear water, an accurate count of whales in a pod could be obtained, considered here to be the true pod size. Aerial surveys were conducted during the 1978–1979 southbound survey (Reilly, 1981) and during the 1992–1993 and 1993–1994 surveys (Laake *et al.*, 1994). To avoid the expense of an aircraft survey, another test of pod size estimation was conducted wherein pairs of observers tracked whales continuously through the viewing area with a theodolite or binoculars while observers on the standard watch maintained an independent effort (Rugh *et al.*, 2008c). The pod size measurements determined during the tracking were considered to be the true pod size and were later compared to the estimates of the observers conducting the standard watch. The aerial survey has the obvious advantage of providing a more reliable true pod size but was not as realistic because the shore-based observers were not conducting a standard watch and were focused solely on estimation of a single pod size. The tracking experiments more closely emulated pod size measurement for an observer conducting a standard watch, but the 'true' pod size measurement from the trackers may have not always been accurate because their view was similar to the shore observer. Pod size calibration data were also generated with paired thermal sensors in 1995–1996 (DeAngelis *et al.*, 1997). However, these data were not recorded such that each pod and observer could be identified (W. Perryman, Southwest Fisheries Science Center, National Marine Fisheries Service, pers. comm.), so these data were not considered in this analysis because it was not possible to evaluate those random effects.

It is important to examine the methodology of Reilly (1981) to understand the differences between the correction factors from these various data sources as reported by Rugh *et al*. (2008c). Initially we develop the notation and outline an alternative method with a much weaker assumption to be used in the re-analysis. Let S represent true pod size and s represent recorded pod size. With the survey data, we can measure $h(s)$, the distribution of observed (recorded) pod sizes, but we want to measure $f(S)$, the distribution of true pod sizes. If we knew the probability that an observer would record a pod of true size S as size s, $g(s|S)$, we could solve for $f(S)$ from the following convolution:

$$h(s) = \sum_S f(S) g(s|S) \ . \qquad (5)$$

For the calibration data, we know S. We measure the proportion of times observers record s for a pod of true size S, which provides a direct measurement of $g(s|S)$. Determination of $f(S)$ from equation (5) is a standard approach with discrete data for deriving the distribution of the true values (S) from the recorded values (s) and estimated calibration function, $g(s|S)$. (e.g. Heifitz et al. 1998). This approach does assume that $g(s|S)$ remains constant but $f(S)$ can vary annually, so the 'correction factor' expressed as the ratio of average true pod size to average recorded pod size ($\sum_S Sf(S)/ \sum_s sh(s)$) will likely vary.

In contrast, Reilly (1981) constructed a set of adjustments, $c(s)$, from the pod size calibration data that were added to each recorded pod size s in the survey data. The c(s) were constructed by tabulating the values of S for each pod the observers recorded as size s and computing $c(s) = \bar{S} - s$. In the Appendix we provide the details to demonstrate that these additive adjustments are valid only if the distribution of true pod sizes selected for calibration $f^*(S)$ equals the distribution of true pod sizes during the survey $f(S)$. However, a simple thought experiment can demonstrate why the method could be substantially biased and hence is not appropriate in general. Consider, a survey in which $f(S) = 0.25$ for $S = 1, \ldots, 4$, but for the calibration experiment only pods of true size $S = 4$ were selected. That would lead to $c(s) = 4 - s$ because the average true size in the calibration data ($\bar{S}$) would always be 4 regardless of the value of s. Use of those data would lead to an estimate of 4 for the average pod size when the true value was 2 for the scenario we proposed. While such a pod selection strategy would never be chosen, it does demonstrate the potential bias that could occur if the distribution of selected pods for calibration did not match the true pod size distribution. While it may be possible to select pods randomly with regard to true size, the Reilly (1981) approach would require the pod size calibration data to be collected each year unless true pod size distribution never changed, which seems unlikely.

Differences in adjustment values, $c(s)$, for different calibration data sets as reported in Rugh *et al.* (2008c) can result from differences in either $f^*(S)$ or $g(s|S)$. If the differences reported by Rugh *et al.* (2008c) are due to differences in $g(s|S)$, that may reflect inherent variability in observer ability or variability due to inherent difference in the calibration pods (e.g. frequency and timing of surfacing, proximity of whales within a pod, and distance from observer). However, substantial bias could result if the differences are due to the selection of pods $f^*(S)$ during the different calibration experiments and $f(S)$ varies annually.

Four pod size calibration data sets (Table 2) were used to estimate $g(s|S)$, an Sxs calibration matrix with a row for each true value S and a column for each observed value s up to some reasonable maximum true pod size S^{max}. We used $S^{max} = 20$. If there were sufficient calibration data for all true pod sizes, a saturated multinomial model could be used with each cell estimated as the proportion of observations that were recorded to be size s that were in fact a true pod size S. However, the available calibration data were fairly sparse for true pod sizes >3 because most pods contain only 1–3 whales. Instead, a more parsimonious approach of fitting parametric distributions for $g(s|S)$ was chosen. We considered a truncated Poisson (for s–1)

$$g(s|S) = \frac{\alpha_S^{s-1} e^{-\alpha_S}}{(s-1)!\mu_S} \ , \qquad (6)$$

and a truncated discretised gamma distribution defined as:

$$g(s|S) = \int_{s-1}^{s} \frac{b_S^{a_S} x^{a_S-1} e^{-xb_S}}{\Gamma(a_S)\mu_S} dx \ . \quad (7)$$

Each of the distributions was truncated such that $s \le S^{max}$ (i.e. $\mu_S = \sum_{s=1}^{s_{\max}} g(s|S)$). The calibration function depends on S through the parameters. Models with separate parameters for S = 1,2,3 were considered because they represented the majority of the data, and we collapsed pods of true size >3 (4+). For $S > 3$, the log of the rate parameter (b_S in the gamma and α_S in the Poisson) of the distribution was expressed as a linear function of S. For the gamma shape parameter (a_S), four parameters, one for each S in the set S = 1,2,3,4+ were specified. The likelihood without any random effects is:

$$\mathcal{L}(\psi \mid s_{ij}) \propto \prod_i \prod_j g(s_{ij} \mid S_i) \ , \quad (8)$$

where ψ is the vector of parameters for the distributions, i indexes the pod, j indexes the observer and $g(s|S)$ is replaced with either of the parametric distributions. The dependence of $g(s|S)$ on ψ is implicit. As an example, the likelihood for a Poisson distribution is:

$$\mathcal{L}(\alpha_1,\alpha_2,\alpha_3,a,b \mid s_{ij}) \propto \prod_{S=1}^{3} \left(\frac{\alpha_S^{s-1} e^{-\alpha_S} / (s-1)!}{\mu_S} \right)^{n_{s,S}} \prod_{S>3} \left(\frac{e^{(s-1)(a+bS)} e^{-e^{(a+bS)}} / (s-1)!}{\mu_S} \right)^{n_{s,S}} \ , \quad (9)$$

where the parameter vector for this example is ψ = ($\alpha_1,\alpha_2,\alpha_3,a,b$), $n_{s,S}$ is the number of observers that recorded size s when the true size was S and μ_S is the S-specific normalising sum over s = 1,…20 to ensure that the largest pod size s was less than or equal to S^{max} ($s \le S^{max}$).

The four calibration data sets (Table 2) were pooled and models fitted with a single set of S-dependent parameters. Models were also fitted with different S-dependent parameters for each of the four calibration data sets. In addition models with random effects for pod, observer and year (data set) were considered. The random effect was implemented by assuming a normal distribution $N(0,\sigma_\varepsilon^2)$ for the random effect (ε) on the log of the rate. Using the gamma distribution, a general likelihood for any single random effect was:

$$\mathcal{L}\left(\boldsymbol{a_S},\boldsymbol{b_S},\sigma|s_{ij},S_i\right) \propto \sum_k log \int_{-\infty}^{\infty} \left[\prod_{i\in I_k} \prod_{j\in J_k} \int_{s_{ij}-1}^{s_{ij}} \frac{e^{a_{S_i}(\log(b_{S_i})+\varepsilon)} x^{a_{S_i}-1} e^{-xe^{(\log(b_{S_i})+\varepsilon)}}}{\Gamma(a_{S_i})\mu_{S_i}} dx \right] \frac{e^{-\varepsilon_k^2/2\sigma_\varepsilon^2}}{\sqrt{2\pi}\sigma_\varepsilon} d\varepsilon_k, \quad (10)$$

where the summation is over the k sets defined by the random effect (e.g. k = 1,....,n), i,j indexes the pods and observers within the respective sets I_k, J_k defined by the k^{th} random effect value, and $\boldsymbol{a_S}$ = (a_1,a_2,a_3,a_{4+}) and $\boldsymbol{b_S}$ = (b_1,b_2,b_3,b_{4+} = $e^{\beta_0+\beta_1 S}$). As an example, for a pod random effect k = 1,....,n = 196, $I_k = k$ and J_k is the set of observers that made estimates for the k^{th} pod. For the gamma random effect model $g(s \mid S)$ is:

$$g(s|S) = \int_{-\infty}^{\infty} \int_{s-1}^{s} \frac{e^{a_S(\log(b_S)+\varepsilon)} x^{a_S-1} e^{-xe^{(\log(b_S)+\varepsilon)}}}{\Gamma(a_S)\mu_S} dx \frac{e^{-\varepsilon^2/2\sigma_\varepsilon^2}}{\sqrt{2\pi}\sigma_\varepsilon} d\varepsilon \ . \quad (11)$$

Random effects models for the Poisson were constructed similarly. Each parametric distribution was fitted by solving for the maximum likelihood estimates using *optim* in R 2.9.1 (*R* Development Core Team, 2009); the most parsimonious model was selected using AIC.

Using the estimated $g(s|S)$ from the calibration data, allows derivation of an estimate of $f(S)$from the survey data for any year using a multinomial likelihood with either a saturated model (i.e. separate parameter for each value of S) or a parametric model for $f(S)$. The latter was chosen because it was more parsimonious and used a discretised gamma distribution:

$$f(S \mid \theta) = \int_{S-1}^{S} \frac{b^a x^{a-1} e^{-bx}}{\Gamma(a)} dx \ , \quad (12)$$

where $\boldsymbol{\theta}$ = (a,b). Other parametric models could be formulated for $f(S)$ but the gamma is sufficiently flexible to fit a variety of distribution shapes. To derive an estimate of $f(S)$ directly from the observed distribution of pod sizes $h(s)$, involves an assumption that the size of the pod did not influence the probability that the pod was seen. However, previous analyses (Buckland *et al.*, 1993; Hobbs *et al.*, 2004; Laake *et al.*, 1994; Rugh *et al.*, 2008b) show that larger pods are more likely to be seen. Consequently, an unbiased estimator for $f(S)$ from the observed data cannot be derived without accounting for detection probability.

Correcting for missed pods

From 1967 to 1985, a single observer searched and recorded migrating gray whale pods during the surveys. Beginning in 1987, two observers surveyed independently for all or some portion of the survey timeframe. These independent counts provided the mark-recapture framework (Buckland *et al.*, 1993) to estimate the proportion of pods that were missed by an observer by matching recorded pods based on offshore distance, timing, and pod size (Rugh *et al.*, 1993). The Appendix contains the details of the algorithm that was used to assess which pods were seen by both observers and which were missed by one of the observers. As part of that matching process pods seen in close proximity (time and offshore distance) by the same observer were linked (combined) for both observers prior to matching. Pods were linked to cope with situations in which one observer combined two close pods and the other observer recorded them as two separate pods. Estimated detection probability from the mark-recapture analysis and the abundance estimates were based on these linked pods. The notation n^* is used for the number of pods recorded by an observer and n ($\le n^*$) is used to denote the number of linked pods used in the analysis.

In each of the prior analyses of the gray whale survey data (Buckland *et al.*, 1993; Hobbs *et al.*, 2004; Laake *et al.*, 1994; Rugh *et al.*, 2008b), pod size was an important predictor for pod detection. A pod with more whales will involve more surfacings and will provide more obvious visual cues resulting in a greater number of opportunities for detection. In each of those prior analyses, the recorded pod size (s) was used as the covariate but this approach has a couple of disadvantages. When a pod was seen by both observers, disagreement between the recorded sizes was ignored in the analysis. In addition, recorded pod size s is not the best predictor for detection probability. For example, an observer might record a pod of three whales as a single whale if only one whale was at the surface at a time. Yet, one would expect far more surfacing events from asynchronous surfacing of a pod of three whales than a single whale, and would expect that it would be more likely to be detected than the single whale even though $s = 1$ in both cases. Detection probability was represented in terms of the true unknown size S and summed over the distribution of true pod sizes $f(S)$ which was simultaneously estimated from the data by including the pod size calibration matrix (eqn 11). Independent errors in pod size measurement were used when both observers detect a pod.

The additional notation ignores the year index to simplify the notation. Let,

x_{ij} = an indicator variable = 1 if the i^{th} of n pods is seen by the observer at the j^{th} station (j = 1,2) and 0 otherwise;

s_{ij} = recorded size of the i^{th} pod by the observer at the j^{th} station (j = 1, 2) if it was seen by the observer at the j^{th} station; and

$\gamma_j(\boldsymbol{C}_i,S)$ = probability that the observer at the j_{th} station (j = 1,2) sees the i^{th} pod which has a vector of associated covariates $\boldsymbol{C}_i$ and a true pod size S.

S is unknown, and the recorded pod size (s) is known only for observed pods. Either one or two estimates of pod size result if observers at one or both stations detect the pod. We sum over all possible values of S (1 to S^{max}) weighting by the estimated probability distribution $f(S)$ and the estimated pod size calibration matrix $g(s|S)$. For each observed pod, we compose the vector of indicator variables (x_{i1}, x_{i2}) which has the possible observable values (1,0), (0,1) and (1,1). The vector (0,0) represents a pod that was missed by the observers at both stations.

Given that at least one observer detected the pod, the probability of observing the vector (x_{i1}, x_{i2}, s_{i1}, s_{i2}) for the i^{th} pod is:

$$p(x_{i1},x_{i2},s_{i1},s_{i2}) = \sum_S f(S)\prod_{j=1}^{2} g(s_{ij}|S)^{x_{ij}} \frac{\gamma_j(\boldsymbol{C}_i,S)^{x_{ij}}\left[1-\gamma_j(\boldsymbol{C}_i,S)\right]^{1-x_{ij}}}{1-\prod_{j=1}^{2}\left[1-\gamma_j(\boldsymbol{C}_i,S)\right]}, \quad (13)$$

Let $\boldsymbol{\theta}$ be the parameter vector for $f(S)$ and let $\boldsymbol{\varphi}$ be the parameter vector for the detection function γ. Then, the likelihood for the double-observer data, conditional on $g(s|S)$ is:

$$\mathcal{L}(\theta,\varphi|\psi,\boldsymbol{x}_1,\boldsymbol{x}_2,\boldsymbol{s}_1,\boldsymbol{s}_2) = \prod_{i=1}^{n} p(x_{i1},x_{i2},s_{i1},s_{i2}), \quad (14)$$

where $n = n_1+n_2-n_3$ is the total number of pods seen by either observer, and n_1 were seen by the primary observer, n_2 were seen by the secondary observer, and n_3 were seen by both observers. When there was only a single observer on watch, no information about γ can be derived, but the single observers' sightings for estimation of $f(S)$ can be used and γ will influence those measurements through the effect of S on detection. The conditional distribution for true pod size S for detected pods with covariates $\boldsymbol{C}$ is:

$$f(S|detected) = \frac{f(S)\gamma(\boldsymbol{C},S)}{\sum_S f(S)\gamma(\boldsymbol{C},S)} \quad (15)$$

The likelihood for the n_1 observations by the single observer also conditional on $g(s|S)$ is:

$$\mathcal{L}(\theta,\varphi|\psi,s_1,\ldots,s_{n_1}) = \prod_{i=1}^{n_1} \frac{\sum_S f(S)\gamma(\boldsymbol{C}_i,S)g(s_i|S)}{\sum_S f(S)\gamma(\boldsymbol{C}_i,S)} \quad (16)$$

The two component likelihoods for the single- and double-observer data can be multiplied (or log-likelihoods summed) to derive the maximum likelihood estimates for the parameter vector ($\boldsymbol{\theta},\boldsymbol{\varphi}$). Pod size calibration data alone provide information about the $g(s|S)$ parameter vector $\boldsymbol{\psi}$ because there is no known true pod size contained in the double-observer data to assess bias.

A logistic distribution was used for the detection function $\gamma(\boldsymbol{C},S)$ and models considered with covariates $\boldsymbol{C}$ containing offshore (perpendicular) distance (km) with intervals (0–1, 1–2, 2–3, 3–4, 4+), and observer (each person). Additional models with Beaufort sea state or visibility as numeric covariates or visibility classified as Excellent–Good and Fair–Poor were then considered. The data from each of the eight years were analysed separately. The model that minimised Akaike Information Criterion (AIC) in each year was used but any models containing Beaufort sea state or visibility that showed an increase in detection probability with worsening environmental conditions were excluded.

Abundance estimation

With the correction for pod size bias and missed pods, we expanded the recorded number of whales during a watch to an estimate of the number of whales that actually passed during the watch. That prediction could be based on data from observers at both stations when two observers were on watch and a single observer when only one station was occupied. However, we chose to avoid this complication and used only the data from the observer at the designated primary station because in most years the additional data would not have improved precision very much. The predicted number of whales was based on a Horvitz-Thompson estimator ($1/p$), which provides an estimate of the number of pods (whales) that passed from those that were seen using the estimated detection probabilities. The reasoning for this estimator can be illustrated with a simple example. If one observes a pod and estimates its detection probability to be 0.5, then it is expected that one pod was missed for every pod that was seen, so the Horvitz-Thompson estimator results in a doubling of the observed number of pods ($1/0.5 = 2$).

The observed pod size was used with the correction for pod size bias and the estimate of $f_y(S)$ to make inference about the probable true pod size S from the recorded size s using the conditional distribution:

$$f_y(S|s) = \frac{f_y(S)g(s|S)}{\sum_S f_y(S)g(s|S)} \quad , \tag{17}$$

where we now use index y for survey year to be explicit about which portions vary by year. Using this conditional distribution, the estimator for the number of pods passing during the j^{th} period of year y when the primary observer was searching (on watch) in year y from the n_{1jy} linked pods is:

$$\hat{P}_{jy} = \sum_{i=1}^{n_{1jy}} \sum_S f_y(S|s_{ijy}) \frac{1}{\gamma_y(\boldsymbol{C}_{ijy}, S)} \quad , \tag{18}$$

and the estimator for the number of whales is:

$$\hat{W}_{jy} = \sum_{i=1}^{n_{1jy}} \sum_S f_y(S|s_{ijy}) \frac{S}{\gamma_y(\boldsymbol{C}_{ijy}, S)} \quad . \tag{19}$$

Surveys were conducted for 9 to 10 hours a day, and it is known that whales migrate throughout the day and night (Perryman *et al.*, 1999). In addition, the environmental conditions can compromise sighting probability or become so poor that migrating whales are not visible to the observer and survey effort is suspended. Thus, it is also necessary to expand the estimate from the time observed to the total migration timeframe to account for whales that passed when no observers were surveying.

This second prediction component of the abundance estimate uses a migration curve fitted to the predicted number of whales passing when the observer was searching (on watch) to predict the total number passing including periods when the observer was not on watch (i.e. night time or poor visibility). The fitted migration curve is needed because the migration rate changes during the course of the survey (typically exhibiting a peak in mid-January) and because the amount of survey effort throughout the migration timeframe varies unpredictably due to varying visibility conditions. The timing and duration of those off-effort periods can severely impact the observed count of whales due to the variation in the migration rate (e.g. missing a day in mid-January has a greater impact than missing a day in early December).

For each survey year y, consider a sample of $j = 1, \ldots, m_y$ effort periods of length $l_{1y}, l_{2y}, \ldots, l_{m_y y}$ for time intervals that are not always consecutive such that $l_{jy} = t_{1jy} - t_{0jy}$, where the 0 and 1 indices represent the beginning and ending times of the interval. A curve can be fitted to the sequence of migration passage rates (whales/hour) $\hat{W}_{jy}/l_{jy}$, at the time mid-points ($t_{jy} = (t_{0jy} + t_{1jy}) / 2$). Following Buckland *et al.* (1993), we added an assumed value of 0 whales passing for day 0 and T to anchor the fitted curve when it was assumed whales did not pass. For each year a generalised additive model (GAM) was fitted with an assumed quasi-Poisson family for the $\hat{W}_{jy}$ $j = 1,\ldots,m_y$ with an offset of $\log(l_{jy})$ to account for varying length of observation period and to allow for over-dispersion. The function *mgcv* (version 1.5–5) (Wood, 2006) in R 2.9.1 (*R* Development Core Team, 2009) was used to fit the GAMs. The Poisson mean $\lambda_y(t) = e^{\xi_y(t)}$ used a log-link with a default smoother over time $\xi_y(t)$. This approach provides a much more flexible modelling technique than the normal-Hermite adjustment modelling of Buckland *et al.* (1993).

With a fitted migration curve, abundance was estimated by summing the expected value of the number of whales passing each day from time 0 to T_y:

$$\hat{W}_y = \sum_{t=0.5}^{T_y - 0.5} \hat{\lambda}_y(t) \quad . \tag{20}$$

For most years, $T_y = 90$ where the days are counted with the origin ($t = 0$) at 12:00 am 1 December. The only exceptions were 2000 and 2001 when the migration extended to $T_y = 100$ days. Buckland *et al.* (1993) constructed a multiplier as the integral of the migration model over the migration period (0, T_y) divided by the integral over the sampled periods:

$$f_{ty} = \frac{\int_0^{T_y} \lambda_y(u)du}{\sum_{j=1}^{m_y} \int_{t_{0jy}}^{t_{1jy}} \lambda_y(u)du} \quad , \tag{21}$$

and the multiplier was used to inflate the estimate of the whales passing during the sampled periods to the entire migration as follows:

$$\hat{W}_y = f_{ty} \sum_{j=1}^{m_y} \hat{W}_{jy} \quad . \tag{22}$$

The formulation for abundance (eqn 20) provided an easier way to formulate a variance and it provided nearly identical results as eqn 22.

For each of the eight survey years from 1987–1988 to 2006–2007, an estimate of abundance $\hat{W}_y$ (y indexes the year) was derived using the above methods. However, there were no double-count data prior to 1987, and there was almost no overlap in personnel during these two periods. Offshore distance was also not reliably measured prior to 1987. From prior analyses, it is known that detection of whales depends on the observer and offshore distance (Buckland *et al.*, 1993; Hobbs *et al.*, 2004; Laake *et al.*, 1994; Rugh *et al.*, 2008b; Rugh *et al.*, 2005). Thus, we could not use a common detection model from recent years and apply it to the earlier years because both distance and observer could not be used as covariates for years prior to 1987. As an alternative, we chose to construct a common total correction factor for a naïve estimate of abundance ($\tilde{W}_y$) was developed by fitting a GAM with a smooth over time $\tilde{\lambda}_y(t)$ for the observed count of whales $\tilde{W}_{jy} = \sum_{i=1}^{n^*_{1jy}} s_{ijy}$ in each of the m_y effort periods of length l_{jy} and predicting total abundance based on the sum of the predicted daily numbers of whales passing $\tilde{W}_y = \sum_{t=0.5}^{T_y - 0.5} \tilde{\lambda}_y(t)$. This was essentially the same process defined above but without any correction factors for missed pods, pod size bias, etc. A conventional ratio estimator (Cochran, 1977) was then constructed using the $\hat{W}_y$ and $\tilde{W}_y$ values for the eight surveys from 1987 to 2006:

$$\hat{R} = \frac{\sum_{y=1987}^{2006} \hat{W}_y}{\sum_{y=1987}^{2006} \tilde{W}_y} \quad , \tag{23}$$

The ratio was used as a multiplicative correction factor for the naïve estimates prior to 1987 ($y = 1967, \ldots, 1985$):

$$\hat{W}_y = \hat{R}\tilde{W}_y \tag{24}$$

Applying the ratio estimator to naïve abundance estimates for previous years, involves the assumption that the factors that affect detection of whales and bias in pod size measurement were similar on average across years. Survey data that were collected only when the conditions were such that the Beaufort sea state was 4 or less and visibility was fair or better (codes 1 to 4) were used to minimise variation due to environmental conditions. Data were filtered based on entire watch periods, because environmental conditions were not recorded continuously prior to 1987. If recorded environmental conditions exceeded the criterion for any sighting or effort period within the watch, all of the data for the watch were excluded. This filter was applied to all surveys, even though that was not necessary for the last eight surveys, because we thought that it was important to maintain a consistent treatment of the data to apply the ratio and to obtain a valid assessment of trend and population status.

Estimation of the variance-covariance matrix for the sequence of abundance estimates is complicated because there are three sources of estimation error: (1) Σ_1 includes variation from parameter estimation error for pod size ($\boldsymbol{\theta}$) and detection probability ($\boldsymbol{\varphi}$), (2) Σ_2 includes variation from parameter estimation error for the pod size calibration parameters ($\boldsymbol{\psi}$), and (3) Σ_3 includes variation from estimation error in fitting the GAM passage rate parameters and residual temporal variation in the number of migrating whales. The element-wise total of the three component matrices, each 23 × 23 (23 surveys), provides the variance-covariance matrix of the abundance estimates. We will use i = 1,...,23 and j = 1,...,23 to index the rows and columns of the elements of the covariance matrix. The estimates of abundance co-vary because the first 15 estimates depend on $\hat{R}$ which was computed from the last eight estimates, and the last eight estimates co-vary because they all used the same estimated set of pod size calibration parameters $\boldsymbol{\psi}$ for $g(s|S)$.

The delta method was used to estimate each of the variance-covariance matrices for abundance. The estimator can be represented in general as $\mathbf{D}'\mathbf{\Sigma}_\zeta\mathbf{D}$ where $\boldsymbol{\zeta}$ is a vector of k parameters, $\mathbf{\Sigma}_\zeta$ is the kxk variance-covariance matrix for $\boldsymbol{\zeta}$ and $\boldsymbol{D}$ is a kxm matrix of first derivatives of the quantities derived from $\boldsymbol{\zeta}$. For this specific case, m = 23 for the 23 estimates of abundance and k varied depending on the set of parameters in the variance component. For some of the parameters, the complex interaction of the parameters and the abundance estimators was such that it was only reasonable to estimate the derivative matrix $\boldsymbol{D}$ numerically, which meant computing each of the abundance estimates for each value of $\zeta_k \pm \delta\zeta_k$ (where δ = 0.001 and ζ_k is the maximum likelihood estimator of the k^{th} parameter) and estimating the rate of change (first derivative) for each abundance estimator.

For Σ_1, the variance-covariance matrix of the pod size ($\boldsymbol{\theta}$) and detection probability ($\boldsymbol{\varphi}$) parameters was obtained from the inverse of the Hessian matrix derived from the optimization of the log-likelihood, which was derived with the function *optim* in R 2.9.1 (*R* Development Core Team, 2009). The first derivative matrix was estimated by varying each parameter, which in turn would change the predicted number of whales passing in each watch, so each GAM model was refitted to predict the change in total abundance. The detection and pod size parameters for each of the 8 recent survey years were fitted separately so the covariances are all 0 (σ_{ij} = 0 for i = 16, …, 23 and j = 16, …, 23 and $i \neq j$). All other σ_{ij} were non-zero due to the use of R to scale the first 15 survey estimates.

For Σ_2, the variance-covariance matrix of the pod size calibration parameters ($\boldsymbol{\psi}$) were also obtained from the inverse of the Hessian matrix using the selected parametric distribution for S = 1, 2, 3, and 4+. The same general technique used for Σ_1 was used for this variance-covariance matrix except that the pod size calibration parameters affect both estimated detection probability ($\boldsymbol{\varphi}$) and pod size ($\boldsymbol{\theta}$) parameters and the fitted GAM model. For each of the pod size calibration parameters in $\boldsymbol{\psi}$, evaluating the first derivative numerically required optimising the likelihood for the detection and pod size model and then subsequently re-fitting the GAM and predicting each abundance.

For Σ_3, the variance components required the computation of the variance for the predicted total abundance from the fitted GAM. The smooth function derived using *mgcv* is represented as a matrix of linear predictors (**L**) and parameters ($\boldsymbol{\beta}$). For year y, let $\mathbf{\Sigma}_{\mathbf{L}y}$ be the variance-covariance matrix of the k parameters for the linear predictor and let $\mathbf{L}_\mathbf{y}$ be the T_yxk linear predictors for the GAM. Then the variance estimator for total abundance in year y (for $y \geq 1987$) is:

$$v\hat{a}r(\hat{W}_y) = \left(\lambda_y \boldsymbol{L}_y\right)' \Sigma_{L_y} \left(\lambda_y \boldsymbol{L}_y\right) + c_y \hat{W}_y \ , \qquad (25)$$

where $\boldsymbol{\lambda}_y = e^{\boldsymbol{L}_y\boldsymbol{\beta}_y}$ is a vector of T_y predicted daily abundances of migrating whales, $\boldsymbol{\beta}_y$ is the vector of k parameters and c_y is the over-dispersion scale parameter of the fitted quasi-Poisson. A similar variance can be constructed for naïve abundance estimator $\tilde{W}_y$ for all surveys derived from fitting the GAM to the observed whale counts:

$$v\hat{a}r(\tilde{W}_y) = \left(\tilde{\lambda}_y \tilde{\boldsymbol{L}}_y\right)' \tilde{\Sigma}_{L_y} \left(\tilde{\lambda}_y \tilde{\boldsymbol{L}}_y\right) + \tilde{c}_y \tilde{W}_y \ , \qquad (26)$$

For σ_{ii}, i = 1,…,15, the diagonal elements $v\hat{a}r(\tilde{W}_y)$ for y < 1987 are estimated using the delta method:

$$v\hat{a}r(\hat{W}_y) = \tilde{W}_y^2 \sigma_R^2 \left(k+1\right) + \hat{R}^2 v\hat{a}r\left(\tilde{W}_y\right) \ , \qquad (27)$$

where σ_R^2 is the variance of the ratio estimator $\hat{R}$ (Cochran, 1977) for the k = 8 surveys. The first term is the prediction variance for $\hat{R}$ and the second term includes variance for the naïve abundance estimator. For the off-diagonal elements i = 1,...,15 and j = 1, …,15 and $i \neq j$, $\sigma_{ij} = \tilde{W}_{yi}\hat{W}_{yj}\sigma_R^2$. For i = 1, ...,15 and j = 16,...,23,

$$\sigma_{ij} = \sigma_{ji} = \tilde{W}_{y_i} \left(\frac{v\hat{a}r(\hat{W}_{y_j})}{\tilde{W}_{y_j}} - \frac{\hat{W}_{y_j}^2}{\tilde{W}_{y_j}^3} v\hat{a}r(\tilde{W}_{y_j}) \right) . \qquad (28)$$

Night time differential

For surveys conducted during 1994–1996, Perryman *et al.* (1999) demonstrated that the night time passage rate was 28% higher during the latter half of the migration (> 15 Jan.). Using this as the median migration date (f = 0.5; 50% migrated before and 50% after), based on a 9-hour day and 15-hour night, Rugh *et al.* (2005) estimated a multiplicative correction factor of 1.0875 with a standard error of $f \times 15$ / 24 × 0.116 after correcting the typographical errors in Perryman *et al.* (1999). Here, a 14-hour night is assumed to avoid the minor but complicating adjustment that would be needed to account for the 10-hour survey from 1967 to 1987 and 9-hour survey since 1992. A constant night time correction factor of f_n = 1.0817 (SE = 0.0338) was applied to each of the 23 estimates to create the final abundance estimates

$$\hat{N}_y = f_n \hat{W}_y \quad (29)$$

The adjusted variances and covariances in the matrix $\boldsymbol{V}$ are:

$$\hat{var}\left(\hat{N}_y\right) = \hat{var}\left(f_n \hat{W}_y\right) = (f_n \hat{W}_y)^2 \left(\left(\frac{0.0338}{1.0817}\right)^2 + \frac{\hat{var}(\hat{W}_y)}{(\hat{W}_y)^2} \right) \quad (30)$$

and

$$\hat{cov}(\hat{N}_{y_i}, \hat{N}_{y_j}) = f_n^2 \hat{cov}(\hat{W}_{y_i}, \hat{W}_{y_j}) \quad (31)$$

Where $\hat{var}(\tilde{W}_y)$ are the diagonal elements of $\Sigma_1+\Sigma_2+\Sigma_3$ and are the off-diagonal elements.

RESULTS

Naïve abundance estimates

GAMs were fitted to the observed passage rates (whales/hour) over time for each survey year (Fig. 1), using the recorded data from the primary observer during survey periods in which Beaufort sea state never exceeded 4 and visibility was fair or better (1 to 4). With the fitted GAMs, naïve estimates of abundance were computed (Table 3), that ranged from 7,000 to nearly 16,000. Without corrections for error in pod size, missed pods, or a night time differential, the naïve estimates would expectedly be lower than the true abundance.

Pod size calibration

Pod size calibration data were collected on 196 pods in four years (Table 2). The distribution of pods included 69, 56, 28, and 26 of true sizes S = 1 to 4, and an additional 8,6,2,1 pods of true sizes of 5, 6, 8, and 10, respectively. For each pod, as few as 1 and as many as 12 observers estimated a size for the pod (Table 2).

The more flexible gamma model provided a better fit than the Poisson (Table 4). A gamma mixed-effects model with a random effect for pod (eqn 10) was the most parsimonious (Table 5). A random pod effect captured the apparent variation amongst whale pods in the whale's behaviour, spatial separation of whales and synchronicity in surfacing of whales in a pod. As expected, pod size was typically underestimated with some small (usually <0.1) probability of overestimation (Fig. 2).

Correcting for missed pods

There were two independent observers throughout the 1987–1988 survey, so the number of matched observations was considerably greater than for the other survey years that had only partial double counts (Table 6). The average detection rate for the primary observer, ignoring any covariates, ranged from 0.70 to 0.81 across years (Table 6); thus, it can crudely be estimated that 20 to 30% of the pods that passed through the viewing area during watch periods with adequate visibility were missed by the observer at the primary station.

The fitted detection probability models (Table 7) demonstrated that the observers were most likely to miss pods of single whales and whales at offshore distances greater than 4km. There was also considerable variation among observers. For example, observers #6 and #10 in 2001 had respective detection probabilities of 0.91 and 0.71 for pods with two whales at the intermediate distances of 1 to 2km. With the exception of the 1995–1996 survey, observers were most likely to detect pods between 1 to 2km which was the corridor where most whales passed (Shelden and Laake, 2002). Pods within 1km were less likely to be detected because of the observer's focus farther offshore and because whales were in view for less time when travelling closer to shore. Visibility was an important predictor only in 1987 and 1993 and Beaufort sea state only in 2006 (Table 7).

Expected pod size $E(S)$ from the fitted survey-specific gamma pod size distributions, ranged from 1.72 to 2.63 whales per pod and was on average 11% (range: 3.9 – 18.8%) greater than the year-specific observed mean size of linked pods ($\bar{s}$) (Table 7). The computed $E(S)$ adjusts for two sources of bias $\bar{s}$ in with opposite directions. Inclusion of pod size calibration data $g(s|S)$ increased $E(S)$ relative to and accounting for size-biased detection of pods (i.e. larger pods are easier to see) decreased $E(S)$.

Abundance estimation

Whale passage rates (whales/hour) were estimated within each watch interval using the year-specific fitted models for pod size and missed pods (eqn 19), based on the observations from the primary observer after linking pods to correspond with the linking process for matched pods (Table 8). A year-specific GAM (Fig. 3) was fitted to the estimated whale passage rates to estimate total abundance ($\hat{W}_y$) (eqn 20) based on the daytime passage rate (Table 8). The ratio estimate $\hat{R}$ (eqn 23) was used to correct the naïve abundance estimates (eqn 24) for the 15 surveys from 1967 to 1985. Then all of the year-specific estimates were multiplied by the nighttime correction factor to obtain the final abundance estimate $\hat{N}_y$ (eqn 29) for each year (Table 9).

The newly derived abundance estimates (Fig. 4) between 1967 and 1987 were generally larger (–2.5% to 21%) than those reported by Rugh *et al.* (2008a). However, the opposite was the case for survey years 1992 to 2006 with estimates declining from –4.9% to –29%. This pattern is largely explained by the differences in the correction for pod size bias (Table 9) which occurred because the distribution of pod sizes from the calibration data over-represented pods of two or more whales and underrepresented single whales relative to the estimated true pod size distribution (Fig. 5).

DISCUSSION

When the southbound gray whale surveys were initiated in 1967 and a single observer searched and counted passing whales, those researchers had not anticipated that such a complicated process was needed to estimate abundance of the gray whale population. However, the data collection and estimation processes had to be adapted to account for the apparent deficiencies and biases resulting from variable environmental conditions, the limits of human visibility and cognition, and vagaries in whale behaviour as the survey process was evaluated (Perryman *et al.*, 1999; Reilly, 1981;

Rugh *et al.*, 1993; Rugh *et al.*, 2008c; Shelden and Laake, 2002; Swartz *et al.*, 1987). Ideally, we would have all of the data needed to construct independent year-specific estimates that accounted for all of the potential biases affecting the counts. However, there is no way to obtain those data for the early surveys. Even when the data needs were apparent, budgets were not always sufficient to collect the data in each year. Thus, compromises have been necessary to construct a complete time series of abundance estimates.

One of those compromises was incorporation of a 'correction' for error and bias in observers' estimation of the size of pods. Corrections are based on calibration data from aircraft and intense effort by dedicated shore-based teams. However, these data were not collected for each survey. In hindsight, both the method proposed by Reilly (1981) and

Table 4

Model selection results for pod size calibration data. The rate model ~size + True:plus represents the structure with separate rates for S = 1, 2, 3 and a linear model (intercept + slope × S) for S>3 (k = 5 parameters). Each of the Gamma models also contained four shape parameters for sizes S = 1, 2, 3, >3. The most parsimonious model (smallest AIC_c – small sample version of AIC) is shown in bold.

S > 3; log(β_1)	–0.1998	0.0085
S = 1; log(a_1)	0.4934	0.3361
S = 2; log(a_2)	1.7361	0.0089
S = 3; log(a_3)	1.8518	0.1920
S > 3; log(a_{4+})	1.1586	0.1644

Table 6

Number of pods seen by observers at primary and secondary station and by both observers upon completion of linking and matching for watch periods with double observers during acceptable environmental conditions (as determined by assessment of observer at primary station). Linking of pods in close proximity reduced number of pods by 1.1% to 4.6%. Linking and matching used the scoring algorithm with the defined weights as described in the Appendix.

Year	Seen by primary (n_1)	Seen by secondary (n_2)	Seen by both (n_3)	Primary detection rate (n_3/ n_2)
1987	2,258	2,296	1,710	0.745
1992	323	301	228	0.757
1993	719	697	532	0.763
1995	401	378	305	0.807
1997	748	788	588	0.746
2000	657	677	513	0.758
2001	603	691	483	0.699
2006	395	405	303	0.748

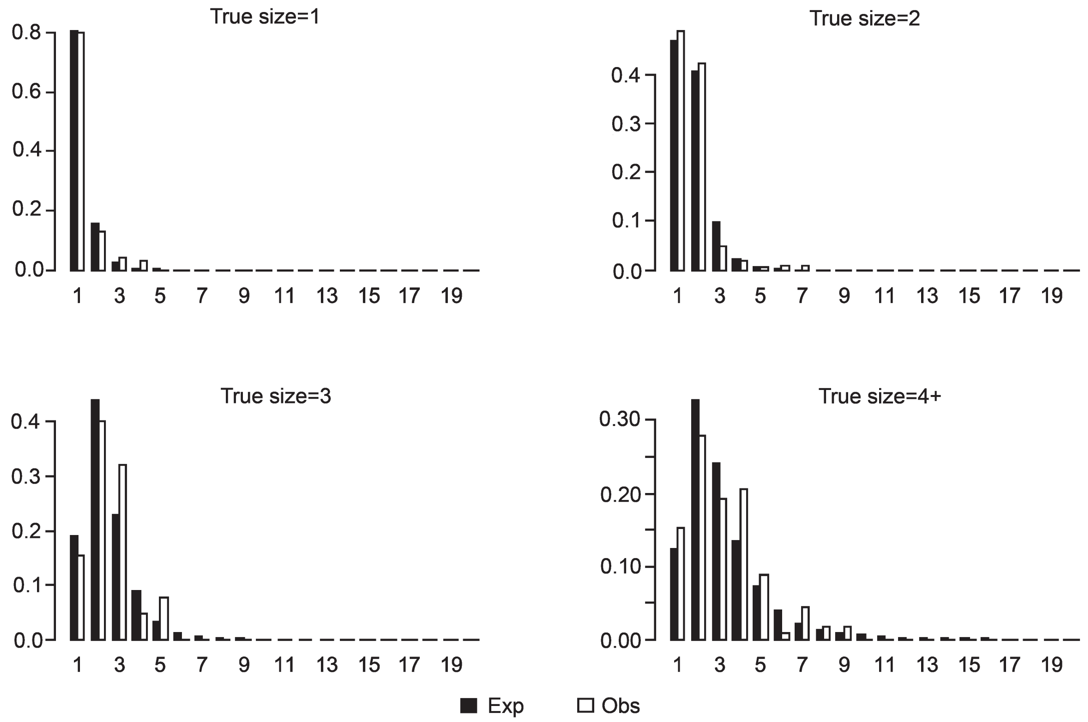

Fig. 2. For true pod sizes S = 1,2,3,4+, probability distributions for recorded (observed) pod sizes (s) and expected values from the gamma model with random pod effects for calibration data (Table 3).

the change in data selection for pod size bias (Buckland *et al.*, 1993; Hobbs *et al.*, 2004; Laake *et al.*, 1994; Rugh *et al.*, 2008b; Rugh *et al.*, 2005) were not optimal choices. At the very least all of the pod size calibration data should have been pooled to estimate a common correction factor for the entire time series. Here we have devised a more robust estimation approach for handling pod size bias, and we used all of the calibration data, with the exception of the thermal imaging data of DeAngelis *et al.* (1997).

Re-evaluation of the correction for pod size bias and the other changes made to the estimation procedure yielded a substantially different trajectory for population growth.

Table 7

Parameter estimates (standard errors in parentheses) for the gamma distribution of pod size (S), the expected pod size ($E(S)$) and detection probability parameters from the selected model for each year for the eight most recent southbound gray whale surveys. Parameters for the gamma distribution are on the log-scale (e.g., for 1987 shape = exp(0.422) and rate = 1/scale = exp(–0.326). Parameters for detection probability are on logit scale. Intercept represents observer #1 for pod of size 0 at distance < 1km and for either Vis <4 or Beaufort = 0 depending on model. For example, detection probability for observer #3 with pod size = 2 at distances between 2–3km in 1987 with visibility <4 was: 1/(1+exp(0.310+0.087+0.172–0.553×2). Observers are arbitrarily numbered and different for each year. Average pod size $\bar{s}$ here is for linked primary pods (Table 8).

Table 8

For recent eight gray whale surveys from 1987 to 2006, number of pods and linked pods seen by the primary observer, average linked pod size, naïve abundance, estimated abundance (without night-time correction) and ratio estimate for correction factor for estimates from surveys prior to 1987.

Year	Number of pods	Number of linked pods	Average linked pod size	Naïve abundance	Abundance	Ratio
Y	n^*_{1y}	n_{1y}	$\bar{s} = \sum_{i=1}^{n_{1y}} s_{iy} / n_{1y}$	$\widetilde{W}_y$	$\widehat{W}_y$	$\widehat{W}_y / \widetilde{W}_y$
1987	2,370	2,262	2.21	15,934	24,883	1.562
1992	1,002	991	1.79	10,438	14,571	1.396
1993	1,925	1,848	1.91	13,195	18,585	1.408
1995	1,439	1,388	1.93	13,741	19,362	1.409
1997	1,564	1,522	1.66	14,507	19,539	1.347
2000	1,089	1,043	1.79	10,571	15,133	1.432
2001	1,194	1,150	1.77	9,808	14,822	1.511
2006	1,254	1,213	2.12	11,484	17,682	1.540
Ratio						1.450
SE						0.030

Previously, the peak abundance estimate was in 1998 followed by a large drop in numbers (Rugh *et al.*, 2008c). Now the peak estimate is a decade earlier (Table 9; Fig. 4), and the predicted population trajectory has remained flat and relatively constant since 1980 (Fig. 4).

The correction for night time differential migration rate should be revisited and more data should be collected to evaluate within-year and annual variation in day and night migration rates described by Perryman *et al.* (1999). The assessment of population growth will be improved by collection of data in each survey that provides survey-specific correction factors. Incorporation of thermal imaging and land tracking in each survey would provide survey-specific estimates for pod size calibration and night time differential. In addition, independent double-observer data should continue to be collected as part of the survey protocol to provide survey-specific measures of detection probability for pods.

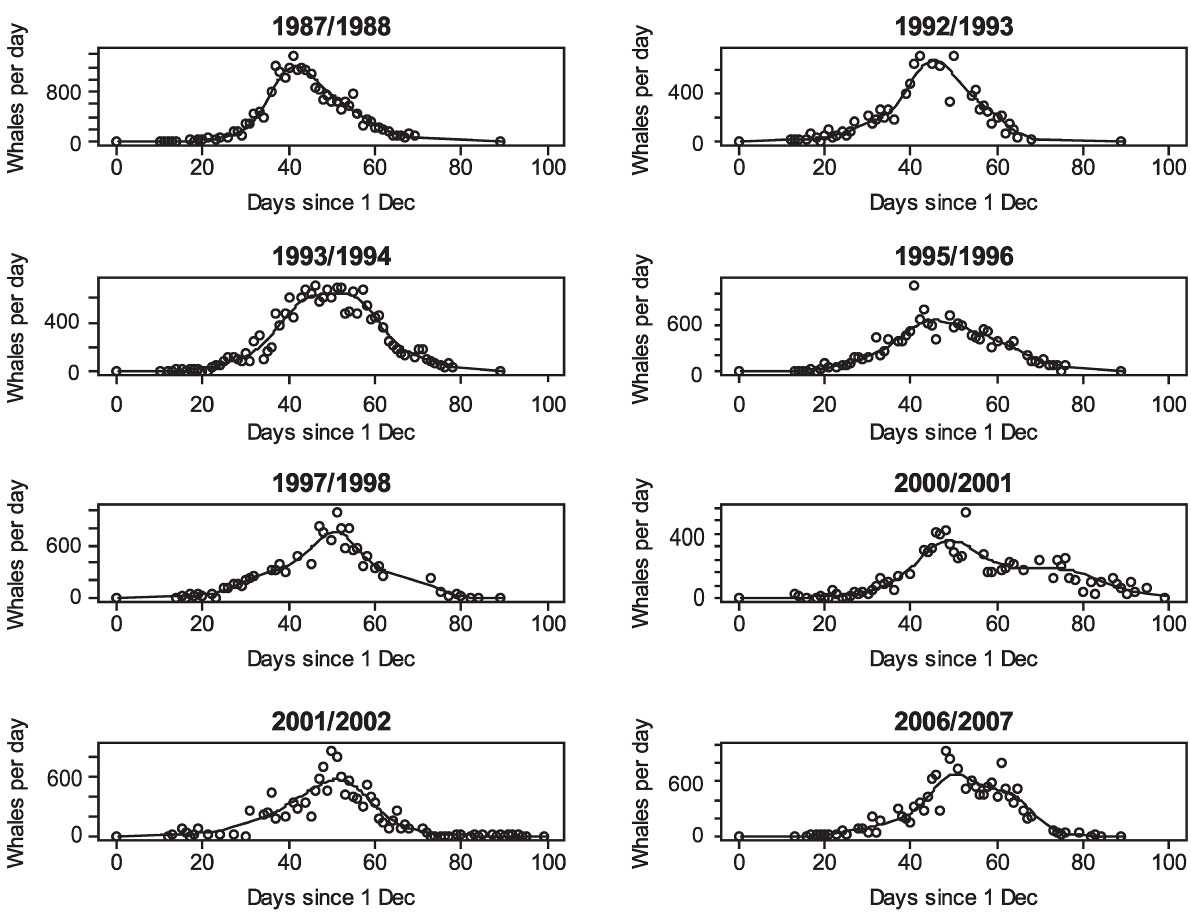

Fig. 3. Estimated number of whales passing per day during watch periods (circles) from year specific models for detection probability and pod size, and fitted GAM model (line) for the eight southbound gray whale surveys during 1987 to 2006.

Table 9

Current and previous gray whale abundance estimates and coefficient of variation (CV = standard error/estimate) constructed from southbound migration surveys conducted from 1967–68 to 2006–07. Ratio of current to previous estimates shows proportional change which is largely explained by f_s ratio which is $E(S)/\bar{s}$ from Table 7 divided by f_s, the pod size correction from previous surveys.

	Current		Previous				
Year	$\hat{N}_y$	$cv(\hat{N}_y)$	$\hat{N}_y$	$cv(\hat{N}_y)$	Ratio	f_s	f_s ratio

[1]Buckland *et al.*, 1993, [2]Laake *et al.*, 1994, [3]Hobbs *et al.*, 2004, [4]Rugh *et al.*, 2005, [5]Rugh *et al.*, 2008a.

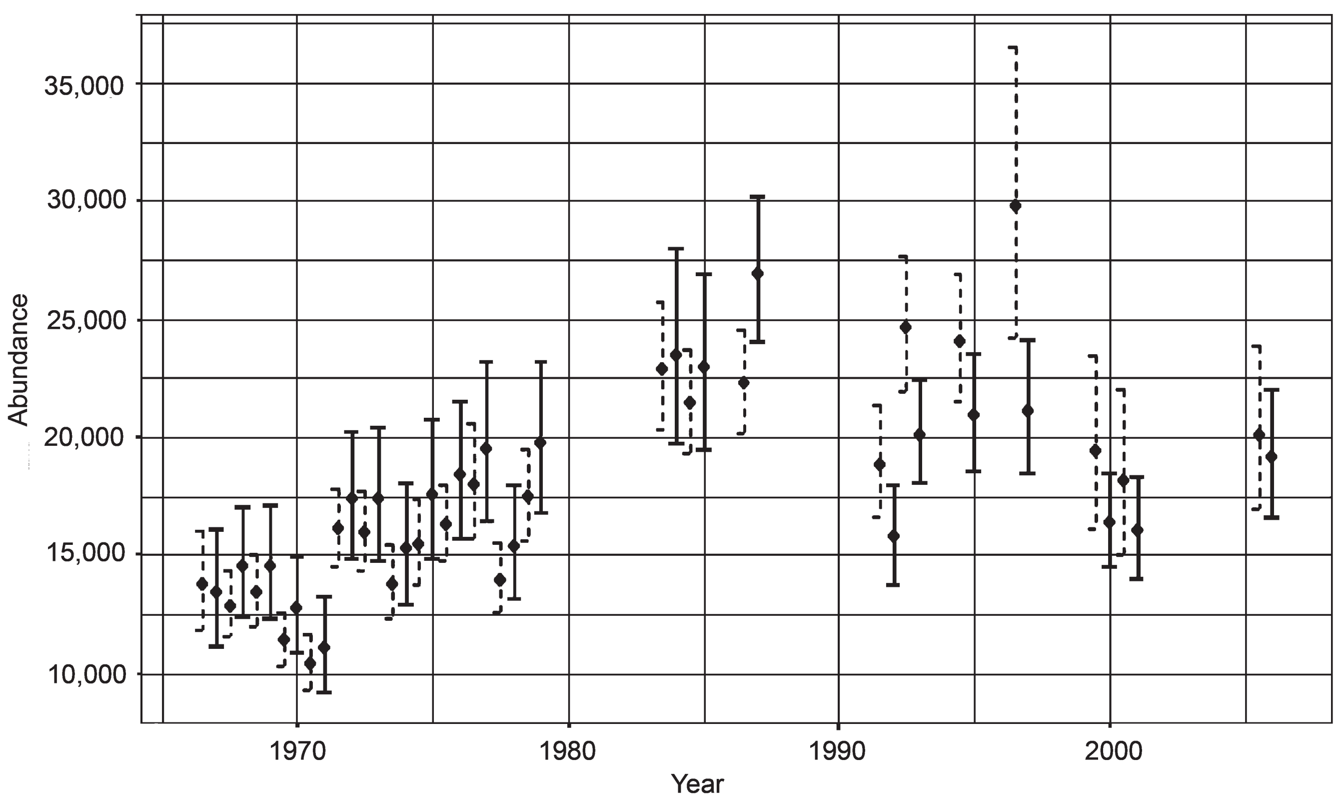

Fig. 4. Abundance estimates with 95% log-normal confidence intervals for previous estimates (dashed line) taken from Rugh *et al.* (2008a) and current estimates (solid line).

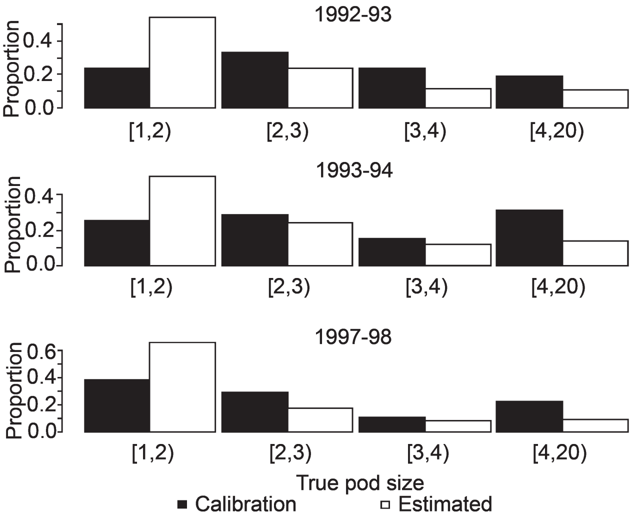

Fig. 5. Pod size distributions for calibration data (light) and estimated true pod size distribution using estimated parameters for gamma distribution (see Table 7). Calibration data from 1978–1979 are not shown because it was not possible to derive estimates of the true pod size distribution with the survey data in that year.

ACKNOWLEDGMENTS

We thank the numerous observers who spent countless hours searching and recording data on southbound gray whales for the last 40 years and Marcia Muto who helped pour through data records locating and correcting errors in the data. We thank John Durban, Steve Buckland and Steve Reilly for reviews of drafts of this paper. A previous version of this manuscript was NOAA Technical Memorandum NMFS-AFSC-203 (available at: *http://www.afsc.noaa.gov/Publications/AFSC-TM-AFSC-203.pdf*).

APPENDIX

Additive pod size correction factor

We will use the following notation to describe the methodology of Reilly (1981):

S = true pod size

s = recorded pod size

$f(S)$ = probability distribution of true pod sizes

$h(s)$ = probability distribution of recorded pod sizes

$g(s|S)$ = probability that an observer will record a group of true size S as size s.

$f^*(S)$ = probability distribution of true sizes in the calibration data

From the calibration data, the probability that a group is of true size of S given that it was recorded as size s is:

$$f^*(S|s) = \frac{f^*(S)g(s|S)}{\sum_S f^*(S)g(s|S)} .$$

With the method of Reilly (1981), the calibration data are used to construct a set of adjustments, $c(s)$, which are added to the recorded pod size s

$$c(s) = \sum_S (S-s) f^*(S|s) = \left[\sum_S S f^*(S|s)\right] - s ,$$

to get the estimate of the average group size

$$\hat{\bar{S}} = \sum_s [s + c(s)] h(s) ,$$

which can also be written as:

$$\hat{\bar{S}} = \sum_s \left[s + \sum_S (S-s) f^*(S|s) \right] h(s) =$$
$$\sum_s h(s) \sum_S S f^*(S|s) = \sum_s h(s) E_{f^*}[S|s] .$$

Differences in adjustment values, $c(s)$, for different calibration data sets as reported in Rugh *et al.* (2008c) can result from differences in either $f^*(S)$ or $g(s|S)$. If the differences reported by Rugh *et al.* (2008c) are due to differences in $g(s|S)$ that may reflect inherent variability in observer ability or variability due to inherent differences in the calibration pods (e.g. frequency and timing of surfacing, proximity of whales in pod, distance from observer). However, if the differences are due to the selection of pods $f^*(S)$ during the different calibration experiments and $f(S)$ varies annually, substantial bias could result with the correction method of Reilly (1981).

The method of Reilly (1981) will be unbiased as long as $f^*(S) = f(S)$ (i.e. calibration distribution was selected to match the true distribution). That assumption could hold if passing pods could be selected randomly for calibration. However, use of the calibration data beyond the year in which they were collected would not be warranted unless $f(S)$ was the same in each year. While that may be possible, it is a strong assumption that is not necessary with the analysis method we describe here.

Instead of trying to ensure equality ($f^*(S) = f(S)$), the calibration data should be viewed like a regression problem in that pods should be selected to provide a best estimate of $g(s|S)$. In general, one would want the selection of pods to balance both $f(S)$ and the variance of $g(s|S)$ to minimise the uncertainty. For example, if $g(1|1)$ was nearly 1.0, then one would not need many calibration pods of size 1 and instead may select more pods of size 2 or more even if most pods were of size 1 (e.g. mode of $f(S)$ was at $S = 1$).

Matching and linking criterion

Two observers searched for gray whales at the same time and recorded their data independently to provide a measure of how many pods were missed during the watch. From the separate independent data records, we needed to decide which pods were seen by both observers and which were missed by one or the other. We have used the term 'matching' for this process of comparing observer records. The observers had a working definition for a gray whale pod as a group of whales that were within a body length of each other. However, errors were quite possible with whales in a pod surfacing at different times, and what one observer treated as a single pod could have been recorded as more than one pod by the other observer. Thus, the matching process also had to consider this possibility, so prior to matching we used a 'linking' process whereby the proximity of all sightings from a given observer were compared to each other, and any pods that were sufficiently close were merged. The records of these 'linked' (merged) pods were then 'matched' by comparing their proximity and pod size. For instance, if one observer recorded a pod of two whales and a second observer saw the same whales but recorded them as two pods of single whales each, then the linking process would merge the two whales, providing a good match between the two observers' records. An underlying assumption in this system is that there are no false positives, that is, no one records a sighting unless there truly is a whale there, and the sighting data (time and location) are accurate enough to make a match.

We used a linking/matching criterion that was a modified version of the criterion described by Rugh *et al.* (1993). The criterion constructs a score based on a comparison of crossing times (t241), distance offshore (d241), and pod sizes (s) (Fig. A1). The time and distance computations assume that whales travelled parallel to the coast at a constant speed of 6km/hour. The t241 is the time the pod would cross an imaginary line perpendicular to the location of the observer on shore (241° magnetic). It is computed from the last (most southerly) time and location of the pod by projecting, either forward or backward, the time needed to travel the distance from the last location to the 241° line. The d241 is the perpendicular distance from shore to the projected point on the 241° line where the whale pod crossed; this is estimated via a simple trigonometric calculation from the distance and angle to the most southerly location. The score function can be represented as:

$$score_{ij} = f\left[W_t |t241_i - t241_j|, \frac{W_d |d241_i - d241_j|}{\max(d241_i, d241_j)} \right]$$
$$+ W_s |s_i - s_j| ,$$

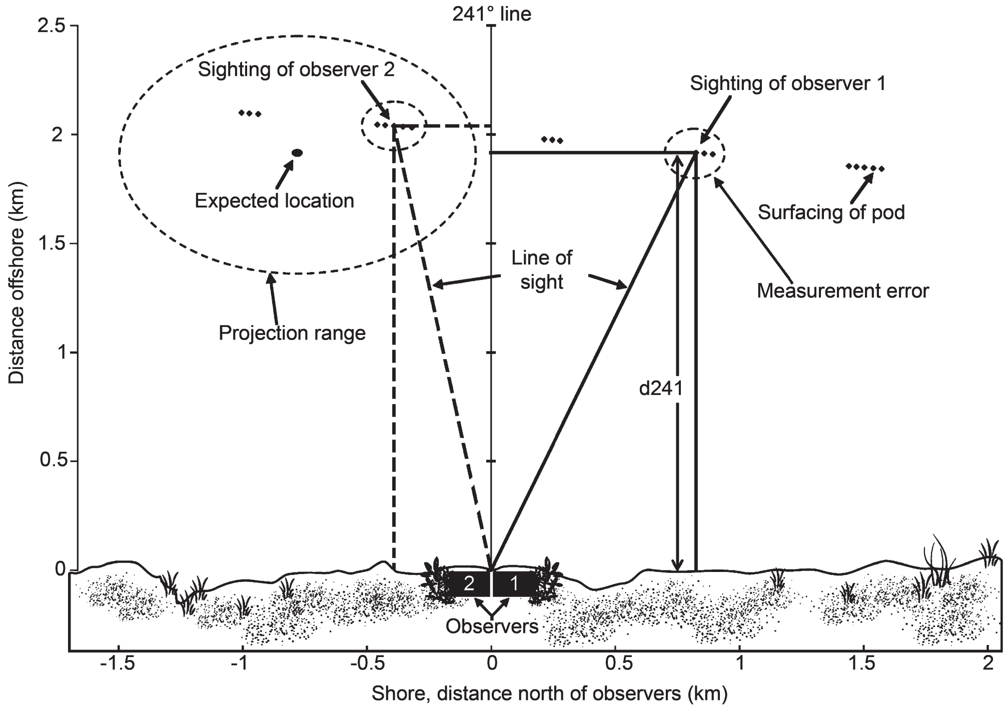

Fig. A1. Observers search from adjacent sheds (#2 and #1). As a pod passes offshore, each observer independently records time, magnetic angle, and vertical reticle. From these data, the sighting distance is calculated. The distance from shore and travel distance are calculated using trigonometry. The expected location at the time of the second sighting is estimated from the time difference and the assumption of parallel travel at 6Km/hr and the difference in t241 times is the parallel distance between these points divided by 6 km/hour. The projection range ellipse is a 95% probability area calculated from the fitted distributions for speed and deviation from parallel travel using the time difference.

where

(1) *i* and *j* are the indexes of the i^{th} and j^{th} pods of a single observer record for linking or the i^{th} and j^{th} pods recorded by independent observers for matching,

(2) the function *f* was a sum in Rugh *et al*. (1993) but here we have used a square root of the sum of the squared arguments, and

(3) W_t, W_d and W_s are defined weights for the time difference, distance difference, and pod size (*s*) difference.

All pods were scored against all other pods within an effort period. If the score was less than a maximum allowable score value, then the sightings met the criterion for linking/matching.

For linking, the pod size weight was set to zero. Pods were linked iteratively to allow for the potential that a pod was split into more than two separate pods. The pair of pods with the lowest score was merged into a single pod with the average t241 and d241 and the pod sizes summed to create a single pod replacing each subset. This was then repeated until no pair of pods met the criterion. For matching, the candidate matches were ranked by score with the lowest being the best match. The best match was recorded and the two pods in the match were removed from further matching. This process continued until there were no more candidate matches that met the criterion. The weights were scaled so that the matching maximum score was set to 1.0. The linking criterion was set to a lower value to limit the risk that a legitimate match could be lost due to the averaging of distance and time in merging pods.

The weights account for two types of errors involved in estimation of t241 and d241, measurement errors and projection errors. Measurement errors result from errors in measuring the horizontal angle, the angle below the horizon (via reticles), and the event time. These errors were estimated from comparisons between tracking teams and standard watch observers (Rugh *et al.*, 2008c). The frequencies reported in table 2 of Rugh *et al.* (2008c) were fitted by integrating the normal distribution between +0.5 and –0.5 of the horizontal degree difference and minimising the squared difference between the reported and the predicted frequency. The standard deviation for the error was estimated at 2.23°, which is consistent with the statement in Rugh *et al.* (2008c) that 95% of measurements differed by 3° or less. Reported frequencies of discrepancies in reticle measurements (Table 3 of Rugh *et al.*, 2008c) were fitted by integrating the normal distribution between +0.05 and –0.05 of the reticle difference and minimising the squared difference between the reported frequency and the predicted frequency. The standard deviation for the error was estimated at 0.14 reticles, which is consistent with the statement in Rugh *et al.* (2008c) that 95% of measurements differed by 0.4 reticles or less. Rugh *et al.* (2008c) found time precision to be limited to 45 seconds for the same surfacing of a pod which may include sequential surfacings of the pod members. Rugh *et al*. (2008c) reported time differences of less than 10 seconds for matches between tracked whales and standard watch data where the locations matched exactly (same angle and reticle), suggesting that it was the same whale surfacing. Transforming these measurement errors, the standard deviation for the error in t241 was 0.55 minutes at 1km offshore and 1.35 minutes at 3km of shore, and the standard deviations for the error in d241 were 0.032km and 0.319km respectively. When the d241 was compared between pods, this resulted in a 3.2% difference at 1km and 10.6% difference at 3km.

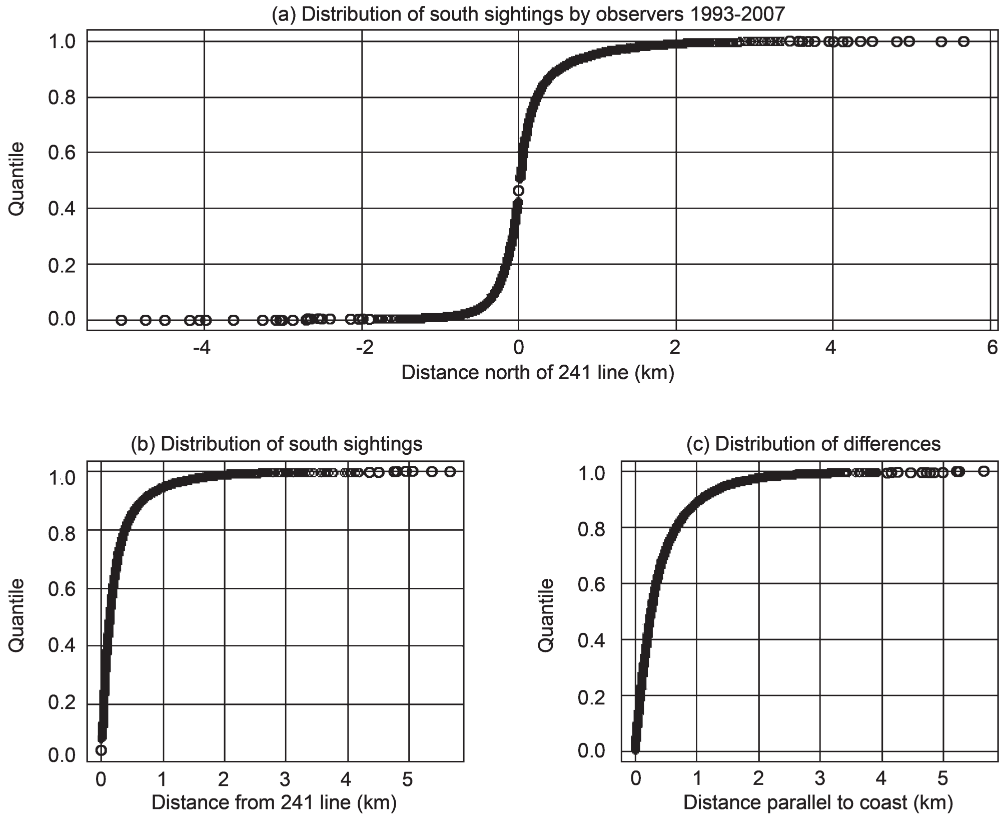

Fig. A2. (a) Distance north from the 241° line to the location of south sightings for all observers 1993–2007. (b) Absolute distance from 241° line. Note that 95% of south sightings fall between within 1 km and 99% within 2 km. (c) Distribution of differences between random pairs of sightings when sightings were drawn at random from the distribution of south sightings. Note that 90% of expected comparison distances between sightings were 1 km or less.

Projection errors resulted from differences between the actual speed and direction of a pod and the assumptions of 6km/hour and parallel travel (Fig. A1). The most southerly sightings were clustered around the 241° line with the median = 0.00km, mean = 0.079km (north) and standard deviation = 0.488 (Fig. A2a). Projection distance regardless of direction was zero (on the 241° line) for 8% of south sightings and 95% within 1km and 99% within 2km (Fig. A2b).

Travel speed was estimated directly from the sighting data using the travel time between north and south sightings. The sighting data incorporates the measurement error into the projection error. A subset of sightings was selected that have both north and south data, with a south sighting between –1.0km and +0.5km and a travel distance from north to south of 1.0 to 2.5km with a minimum time difference of 6 minutes and no other pods with t241 within 5 minutes. The south distance was chosen to insure that the travel occurred near the 241° line, the travel distance and minimum time were chosen to limit the effect of measurement errors. Only pods with no other recorded pods near were chosen to limit the effect of improperly linked sightings. Significant relations between speed and survey date and speed and pod size were found, but neither contributed significantly to reducing the variance. The average speed was 6.19km/hour (sd = 1.55, var = 2.41). The distribution of bearings relative to the 241° line was estimated from a similar data set except that all sightings with a minimum time difference of 3 minutes and travel distance between 0.02 and 2.5km were used. These were binned into 0.2km travel distance bins centered on the even tenths of a km and the mean deviation and variance about the track perpendicular to the 241° line were calculated. A linear fit of the mean deviation with the distance travelled yielded a significant but small trend shoreward of less than 30 meters/km travelled (Table A1). Two models for the change in variance were considered: (1) a ‘random walk’ in which the whales continually made small changes in heading as they proceeded south so that variance would increase linearly with distance, and (2) a fixed heading in which the square root of the variance would increase linearly with distance travelled. Of the two, the fixed heading model provided a better fit (Table A1).

The probability that a sighting by one observer was correctly matched to a sighting of the same pod by a second observer was estimated from the distribution of bearing and speed and applying the matching to the distribution of possible distances between sightings of the same group. Assuming that the distance between the sighting locations was the result of chance and observer behaviour rather than whale behaviour (e.g. sightings of faster pods are more likely to be farther apart), then the cumulative distribution of possible distances between sightings was determined by random draws of pairs from the distribution of south sightings (Fig. A2c). The projection errors were much greater than the measurement errors; consequently, it was not necessary to include the measurement errors explicitly in the choice of the weights.

While there are three measurements involved with each sighting, the determination of a match is reduced to a two dimensional comparison by relating the difference in time and distance parallel to the coast (and perpendicular to the 241° line) assuming a fixed speed of 6km/h and accepting a range of difference in the t241 times to allow for variation

Table A1

Parameter estimates for deviation from travel parallel to the coastline (perpendicular to the 241° line) in kilometres difference in d241 per kilometre of travel parallel to the coast.

Model	Mean(deviation km) = a + b(travel dist km)		Variance(deviation km) = a + b(travel dist km)		SD(deviation km) = a + b(travel dist km)	
Parameter	a	b	a	B	a	b

95%	95%	90%	0.27	5.06	45	2.86	27%
89%	89%	80%	0.46	6.66	27	3.56	15%

in speed. The range of time differences and consequently speeds that meet the criteria can be related to the distribution of distances between sightings (ignoring pod size and assuming travel parallel to the coast) by rewriting the difference in the t241 times in terms of the difference in time and difference in distance to the 241° line. Likewise the extremes of the deviations from parallel travel can be estimated assuming that speed was 6 km/hour.

$$S_{slow} = \frac{\Delta x}{\frac{\Delta x}{s} + \frac{K}{W_t}}$$

$$S_{fast} = \begin{cases} \dfrac{\Delta x}{\frac{\Delta x}{s} - \frac{K}{W_t}} & if\, \Delta x > \dfrac{Ks}{W_t} \\ \infty & otherwise \end{cases}$$

$$\text{Standard: } \Delta y_{near} = \frac{K}{W_d} y_1; y_1 \geq y_2,$$

$$\Delta y_{off} = \frac{\frac{K}{W_d} y_1}{1 - \frac{K}{W_d}}; y_1 < y_2, \text{ Alternative: } \Delta y = \pm \frac{K}{W_d},$$

where, S_{slow} and S_{fast} are the extremes of the distribution speed perpendicular to the 241° line; Δx is the difference in the distance perpendicular to the 241° line between the two sightings, note that S_{fast} is undefined until Δx is sufficient to make the denominator positive; K is the maximum allowable score for a match or link; and S is the speed used for the projection, in this case 6km/hour. Δy is the maximum allowable difference in the deviation distance parallel to the 241° line between the two sightings, with y_1 being the distance offshore of the northern of the two sightings and y_2 the southern. The standard version was described in Rugh *et al.* (1993) and was intended to account for the greater measurement error with distance offshore resulting from reticle measurements by allowing a larger deviation in the offshore direction and wider range with distance offshore. The alternative ignores the measurement error and uses a constant width.

The probability that two sightings of the same pod, at a given distance apart, are matched is estimated as the product of the probabilities that the speed and deviation fall into each of these ranges. Integrating over the distribution of distances gives the approximate probability that a match will be made. Note that this analysis ignores the discrete nature of the measurement errors and as a consequence will favour the alternative to some extent. However, it is satisfactory to optimise the parameters for the standard method and to estimate the potential for improvement of matching efficiency by using the alternative.

The probability of overmatching or mismatching is approximated by the likelihood that at least one other sighting falls within that range. The linking algorithm is modified to count the number of groups that could be matched. To fully estimate the probability of mismatching we would need to include a model of the probability of a second sighting of the pod being matched having a higher score as well, and the probability of overmatching would include the probability that the pod was missed by the second observer.

While there clearly is a trade off between the certainty of correctly matching the same pod and the risk of overmatching, the risk of under matching has the potential to result in an overestimate of abundance and a conservative analysis would limit this risk. We used the weights at the 95% probability of a match (0.18 and 3.95) as the best compromise while acknowledging that the rate of missed pods may be underestimated by 50%. This analysis suggests that the alternate model would reduce the risk of overmatching by about one-third; however simulations with a discrete measurement error structure are required to determine the actual matching rate.

ABSTRACT The California sea lion (*Zalophus californianus*) population in the United States has increased steadily since the early 1970s. The Marine Mammal Protection Act of 1972 (MMPA) established criteria for management of marine mammals based on the concept of managing populations within the optimal sustainable population (OSP), defined as a range of abundance from the maximum net productivity level (MNPL) to carrying capacity (*K*). Recent declines in California sea lion pup production and survival suggest that the population may have stopped growing, but the status of the population relative to OSP and MNPL is unknown. We used a time series of pup counts from 1975 to 2014 and a time series of mark-release-resight-recovery data from 1987 to 2015 for survival estimates to numerically reconstruct the population and evaluate the current population status relative to OSP using a generalized logistic model. We demonstrated that the population size in 2014 was above MNPL and within its OSP range. However, we also showed that population growth can be dramatically decreased by increasing sea surface temperature associated with El Niño events or similar regional ocean temperature anomalies. In this analysis we developed a critical tool for management of California sea lions that provides a better understanding of the population dynamics and a scientific foundation upon which to base management decisions related to complex resource issues involving this species. Published 2018. This article is a U.S. Government work and is in the public domain in the USA.

KEY WORDS birth rates, California sea lion, El Niño, generalized logistic, population growth, population status, survival, *Zalophus californianus*.

After centuries of exploitation of marine mammals, the Marine Mammal Protection Act of 1972 (MMPA) provided protection of all marine mammals in United States waters. The MMPA established criteria for management of marine mammals by the National Marine Fisheries Service (NMFS) and United States Fish and Wildlife Service (USFWS). The MMPA states that marine mammal populations “should not be permitted to diminish beyond the point at which they cease to be a significant functioning element in the ecosystem of which they are a part, and, consistent with this major objective, they should not be permitted to diminish below their optimum sustainable population” (16 U. S. C. 1361 Sec 2:5). The intent of the MMPA was to recover marine mammal populations to levels that ensured healthy and robust populations; however, translating the language into management actions presented numerous challenges.

The first challenge was defining optimum sustainable population (OSP). Eberhardt (1977) suggested that the OSP should be interpreted as the range of population sizes from the maximum size (*K*) to the size which gives maximum productivity or maximum sustainable yield (MSY). The NMFS adopted the definition for OSP as a population level between *K* and the population size that provided the maximum net productivity level (MNPL; i.e., greatest net change in the population; Federal Register, 21 Dec 1976, 41FR55536). A population can be designated as depleted under the MMPA if it is below the MNPL. Depleted populations are afforded more protection under the MMPA; consequently, determining OSP and MNPL is an important objective of agencies responsible for the management of marine mammals.

In practice, it is difficult to estimate MNPL for marine mammals because it requires substantial population data that

Received: 23 March 2017; Accepted: 23 October 2017

[1]*E-mail: sharon.melin@noaa.gov*

are not available for most species (Gerrodette and DeMaster 1990, Ragen 1995), but it is thought to be between 50% and 80% of *K* (Read and Wade 2000). There are some examples in which MNPL and OSP has been estimated for marine mammals. Jeffries et al. (2003) and Brown et al. (2005) fitted generalized logistic models to the counts of harbor seal (*Phoca vitulina*) pups and non-pups on land during the pupping seasons. The OSP (MNPL/*K*) was 0.56 and 0.60 for Washington populations (Jeffries et al. 2003) and 0.61 for the Oregon population (Brown et al. 2005). For northern fur seals (*Callorhinus ursinus*), Ragen (1995) estimated that the mode of MNPL/K was 0.65 with a range of 0.5–0.8. In an assessment of gray whales (*Eschrichtius robustus*), Punt and Wade (2010) integrated across the range of 0.4–0.8 for MNPL, with a resulting MNPL point estimate in their baseline analysis of 0.656. Similarly, in an assessment of spinner (*Stenella longirostris*) and spotted dolphins (*Stenella frontalis*), Wade et al. (2007) integrated across a prior distribution of 0.5–0.8 for MNPL in a generalized logistic model, although in that case there was not enough information in the data to update or change the prior distribution.

Following historical reductions in the population from harvesting and bounties, the California sea lion (*Zalophus californianus*) population in the United States has been steadily increasing since the early 1970s when it was protected under the MMPA (Carretta et al. 2016*b*). Although the growth of the population is a conservation success, the status of the population relative to the MMPA criteria has not been determined. As the population has increased and expanded its range, California sea lions have increasingly been involved in resource conflicts with humans and endangered fish along the west coast of the United States that have resulted in some controversial management actions (e.g., lethal removal of adult male sea lions that feed on endangered salmonids at the Bonneville Dam on the Columbia River, Oregon; Weise and Harvey 2005, Wright et al. 2010). Determination of the status of the population relative to the MMPA criteria will provide support for management decisions that address these complex resource conflicts.

For the United States population of California sea lions (Carretta et al. 2016*b*), pup production (Lowry et al. 2017), and survival (DeLong et al. 2017) have recently declined, suggesting that the population may have stopped growing. For California sea lions, only counts of pups are available for a sufficient period (1975–2014) to evaluate population growth, MNPL, and OSP (Lowry et al. 2017). Berkson and DeMaster (1985) determined that pup counts alone could be used to assess a population status relative to OSP, but they did not consider situations in which the production of pups varied widely from density-independent factors like El Niño events, which can result in low numbers of births and high mortality of pups (DeLong et al. 1991). When pup counts fluctuate widely because of increased pre-census pup mortality or reduced birth rates, the number of pups does not immediately reflect the same magnitude change in the population size. Thus, an analysis based solely on pup counts could be misleading with large reductions in pup numbers at the end of the time series. However, in lieu of a better method, the status of California sea lions is currently determined by a correction factor applied to annual pup counts (Carretta et al. 2016*b*).

As an alternative to assessing the status of the population from pup counts, we developed a model that numerically reconstructs the California sea lion population by integrating multiple data sources and that accounts for variability in birth rates. Our primary objectives were to assess the population growth of California sea lions since the mid-1970s, evaluate the current population status relative to MNPL, and describe environmental and density-dependent impacts on survival, population growth rate, and realized at-census birth rates.

STUDY AREA

Five genetically distinct populations of California sea lions have been identified and include the United States population (U.S. or Pacific Temperate), which breeds on offshore islands in California; the western Baja California population, which breeds offshore along the west coast of Baja California, Mexico; and 3 populations (southern, central, and northern) that breed in the Gulf of California, Mexico (Carretta et al. 2016*b*). Our study applies only to the U.S. population that inhabits coastal waters from the United States-Mexico border, along the west coasts of the United States, British Columbia, Canada, and southeast Alaska, USA (Fig. 1). During the breeding season from May through August each year, most of this population returns to offshore rookery islands along the California coast (Fig. 1). Most of the breeding (99.7%) occurs on 4 islands in the California Channel Islands: San Miguel, San Nicolas, Santa Barbara, and San Clemente. The data used in this study included summer pup censuses of the California Channel Islands and other offshore breeding areas, and survival estimates derived from a single colony at San Miguel Island, which represents about 45% of the United States population.

Pupping occurs over 6 weeks from late May to early July on uninhabited sandy beaches, rocky coves, or rocky points. Sea lion females give birth to a single pup and remain in constant attendance of the pup for 5–8 days postpartum. After the perinatal period, females begin an attendance cycle in which they alternate 2- to 4-day foraging trips at sea with 1- to 2-day nursing visits ashore until the pup is weaned at about 11 months of age (Antonelis et al. 1990, Melin et al. 2000). Breeding occurs about 4 weeks postpartum, beginning in late June and ending in early August. Adult females are nonmigratory and visit the rookery regularly throughout the year, particularly if they have dependent pups (Melin et al. 2000). Adult males arrive at the rookery islands in May, but peak numbers occur in July during the peak of breeding. A small proportion of adult males establish and maintain reproductive territories for 1–60 days. Nonreproductive males haul out in areas outside of the breeding territories. After the reproductive season, adult males migrate from the rookery islands to foraging areas and hauling sites along the California, Oregon, and Washington coasts, the islands of British Columbia, Canada, and southeast Alaska (Maniscalco et al.

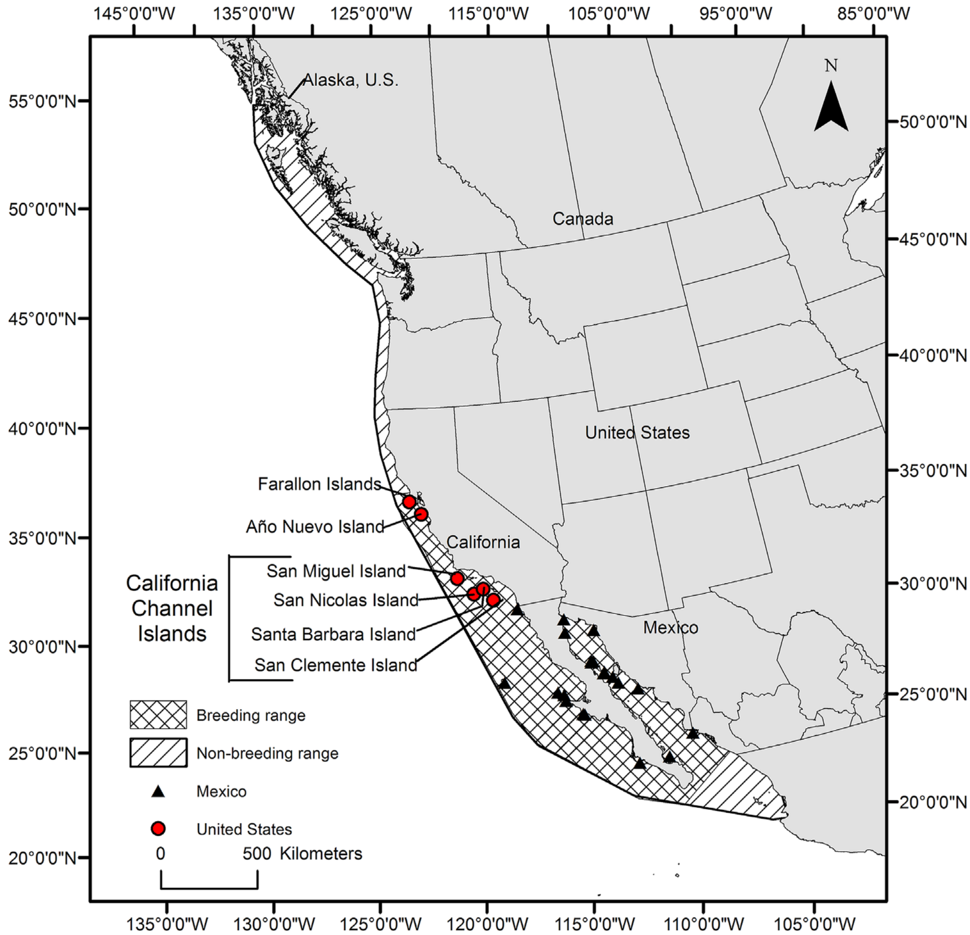

Figure 1. Range of male and female California sea lions and locations of breeding areas in the United States (circles) and Mexico (triangles). We used California sea lions branded at San Miguel Island, California between 1987 and 2014 to estimate survival rates.

2004). Juvenile (1–3 years old) females and males are present at the California Channel Islands throughout the year but also frequent hauling areas and feed along the central California coast during winter (Orr 2011).

California sea lion breeding colonies along the Pacific coast are regularly affected by the El Niño Southern Oscillation (ENSO), a global ocean-atmospheric pattern that consists of a warm El Niño phase followed by a cold La Niña phase. El Niño or La Niña conditions begin at the equator in the central Pacific ocean and then propagate northward along the west coasts of South America and North America dramatically affecting the productivity patterns of the California eastern boundary current (California Current) that the U.S. population of California sea lions relies on for food. El Niño conditions produce strong depressions of the thermocline, higher sea surface height anomalies, and warmer sea surface temperature anomalies in the California Current (King et al. 2011). These oceanographic changes result in reduced biomass of phytoplankton and zooplankton, which leads to changes in the abundance or distribution of fishes and invertebrates throughout the California Current (Bograd and Lynn, 2003). Sea lions feed on fishes and cephalopods, and during the El Niño phase of ENSO, these prey are redistributed northward or deeper in the water column in response to the warmer sea surface temperatures and the deepened thermocline. Consequently, prey become less available to sea lions, particularly nursing sea lions that are biologically tied to the colonies during the 11-month lactation period and have a limited foraging range (DeLong et al. 1991, Lowry et al. 1991, Melin et al. 2008). Pregnant and nursing sea lions travel farther and dive deeper during El Niño conditions, presumably in response to the changes in prey availability (Melin et al. 2008), resulting in significant declines in pup births and survival (Boness et al. 1991, DeLong et al. 1991, Francis and Heath 1991, DeLong and Melin 2000, Melin et al. 2012*a*).

METHODS

As an alternative to assessing the status of the population from pup counts, we numerically reconstructed the California sea lion population by integrating multiple data sources including 1) total pup counts for the U.S. population over a period from 1975 to 2014 (Lowry et al. 2017); 2) age- and sex-specific survival estimates derived from branding, resighting, and recovery data collected from 1987 to 2015 from a colony at San Miguel Island, California (DeLong et al. 2017); and 3) estimates of human-caused mortality (Carretta and Enriquez 2012; Carretta et al. 2016*a*, 2017).

We fitted a generalized logistic population growth curve to the annual reconstructed population sizes from which we could estimate MNPL and the status of the current population size relative to MNPL and OSP.

Our analysis involved 6 partially intertwined steps.

1. We imputed any missing values from available pup count data to construct an entire time series of annual pup counts for the United States population for 1975–2014.
2. We derived sex- and age-specific estimates of annual survival for 1975–2013.
3. With an initial population structure based on a stable age-distribution and the annual pup counts, we projected the abundances using survival estimates to reconstruct the age- and sex-specific population structure and total annual population size for 1975–2014.
4. We estimated annual sea lion bycatch from the halibut (*Paralichthys californicus*) set net fishery data as a minimal estimate of human-caused mortality for 1975–2014.
5. Using the bycatch estimates, we fit a generalized logistic growth curve to the time series of population size each year to estimate MNPL, K, and the status of the population in 2014 (N_{2014}/MNPL).
6. We conducted an analysis of realized birth rates derived from the sex- and age-specific population reconstruction.

These steps were partially recursive because we estimated missing survival rates using a density-dependence term derived from the population reconstruction that was, in part, based upon the survival estimates. This required a few iterations for convergence. Likewise, the analysis of birth rates contained a density-dependence term that was also derived from the generalized logistic fit. As described later, we propagated errors in the survival estimation and imputation of missing pup counts through each step using a bootstrap analysis.

Pup Counts

Pup counts for the entire United States population were available for 1975–1977, 1981–2008, and 2011–2014 using counts from Lowry et al. (2017) and for San Nicolas Island during 1985–1989 from previous reports (Bonnell et al. 1980, Stewart et al. 1993, Lowry and Maravilla-Chavez 2005). To accomplish the population reconstruction, we needed complete pup counts for each year (P_y). For missing years, we imputed values for 1978–1980 from predictions of a temporal trend using linear regression of the log of counts for 1975–2001. Lowry et al. (2017) describes how we imputed values for 2009–2010 from a complete ground count at San Miguel Island and a partial ground count at San Nicolas Island during those years. We assumed pup counts were known without error, but we propagated error from the missing imputed counts.

Age- and Sex-Specific Survival

Age- and sex-specific survival estimates from a mark-release-resight recovery model of branded California sea lions on San Miguel Island were available from 1987 to 2014 (DeLong et al. 2017). We used the annual survival estimates from the best model in DeLong et al. (2017). Pups were branded in fall at 3–4 months of age, but pup survival rates accounted for survival from the time of the pup counts in late July to branding by assuming a constant survival rate for that period as measured from 1 October to the following 1 July. Very early pup mortality can be higher, but it occurs before the pup count. Only pups were marked and released each year, so age-specific estimates were missing in year y for ages $a > y - 1987$ (e.g., only pup survival was available for 1987, only pup and yearling survival for 1988). Also, estimates of survival were not available for sea lions of any ages for 1975–1986. To provide estimates for these missing values, we fitted a linear mixed effects model to the logits (μ_{say}) of the set of survival estimates (S_{say}) for each sex ($s = m$ or f), age ($a = 0$–24), and year ($y = 1987$–2013), $\mu_{say} = log\left(S_{say}/\left(1 - S_{say}\right)\right)$. Predictive variables for fixed effects included sex, age, and annual covariates including average sea surface temperature (SST) anomaly, average pup weight, and N_y/K as a measure of density dependence in survival. For pup survival, we used the average SST anomaly from 1 October to 30 June and for juveniles and adults, we used the average SST anomaly from 1 July to 30 June to correspond to the survival periods in our models. In addition, for pup survival we also evaluated an average SST anomaly from 1 April to 30 September, which could affect pup weights at branding by affecting pregnant and lactating females. We used the local SST anomaly as a measure of environmental conditions during the study period and to identify years affected by El Niño conditions. Warmer SSTs are usually associated with lower productivity and prey availability, whereas cooler SSTs are associated with high productivity and good foraging conditions for sea lions. We used the average SST anomaly measured at 4 National Oceanic and Atmospheric Administration (NOAA) data buoys (stations: 46054, 46218, 46011, pslc1; NOAA National Data Buoy Center, http://www.ndbc.noaa.gov) located 26 km to 128 km north of San Miguel Island, California in the area where females from the colony primarily forage (Melin and DeLong 2000, Melin et al. 2008).

Annual estimates of pup and yearling survival were quite variable, so we included an annual random effect for those ages. From the fitted model, we predicted missing estimates of survival (e.g., for years <1987) with the fixed effect estimates, and where survival estimates were available from capture-recapture analysis (1987–2013), the estimated predictions included the fixed and random effect estimates.

The density-dependence term N_y/K in the mixed effects model for survival was only available after reconstructing the population and fitting the generalized logistic. Thus, we needed to iterate the model fitting for survival estimates, population reconstruction, and fitting of the logistic model. Carrying capacity in the mixed-effects model for survival primarily acts as a scalar for abundance N_y in N_y/K. With some reasonable starting values for N_y and K, we fitted the mixed-effects model, constructed the population size, predicted K, and repeated the process until the estimated parameters converged.

Human-Caused Mortality

To account partially for human-caused mortality in the population, we used data collected from the halibut set gillnet fishery, which is a primary cause of fishery entanglement and mortality for California sea lions (Carretta and Enriquez 2012). Total fishing effort data for the set gillnet fishery was available for 1981–2014 and the sea lion bycatch was observed in a sample of trips in 1990–1994, 1999–2000, 2006–2007, and 2010–2012 to estimate the average bycatch per unit effort. A gillnet closure area implemented in 1994 resulted in the halibut fishery being excluded from within 5.6 km of the southern California mainland. Consequently, we estimated 2 average bycatch rates: for years before and including 1994 and for years after 1994. We estimated the sea lion bycatch in a year (H_y) by multiplying the total annual fishing effort by the average bycatch rate for that year. The fishery was active from 1975 to 1980, but the amount of effort was not available, so we used a generalized additive model to predict the amount of fishing effort in those years using the log of fishing effort with a smoother across year.

Population Reconstruction

Population reconstruction for a set of years indexed by y is simply a series of estimates of the number of animals alive for each age a for females ($N_{f,a,y}$) and for males ($N_{m,a,y}$). The size of the total population in year y (N_y) is simply the sum of all the animals in each age for both sexes alive in that year, $N_y = \sum_{a=0}^{A} N_{f,a,y} + \sum_{a=0}^{A} N_{m,a,y}$, where A is the maximum age. From the number of pups in a year (P_y) and annual age- and sex-specific survival estimates ($S_{s,a,y}$) we can project forward to predict the number of animals in the population at each age over time for each sex. The population reconstruction assumes the population is geographically closed and only births add to the population. Assuming a 50:50 sex ratio of pups, $N_{f,0,y} = N_{m,0,y} = P_y/2$. For example, the expected number of yearling females in year $y+1$ is $N_{f,1,y+1} = N_{f,0,y}S_{f,0,y}$, where $S_{f,0,y}$ is female pup survival in year y and likewise for males using the male pup survival rate. In general, for any age and sex the equations are $N_{s,a+1,y+1} = N_{s,a,y}S_{s,a,y}$, where s is either f or m for females or males, respectively.

However, to initiate the reconstruction in the initial year (i.e., 1975), we also needed estimates of $N_{f,a,y}$ and $N_{m,a,y}$ for yearlings and older animals ($1 \leq a \leq A$) to estimate the population size for years 1975 to 1975+A-1. To develop estimates of the sex- and age-specific population sizes in 1975, we used the stable age-distribution equations of Cole (1954) as described by Eberhardt (1985). Let c_a be the proportion at age a. Assuming an instantaneous constant growth rate r, the proportion at age a is $c_a = e^{-ra} l_a / B_a$, where $l_a = \prod_{a=0}^{a-1} S_a$ and $B_a = \sum_{a=0}^{A} e^{-ra} l_a$. We used a value of r derived from the slope of a linear regression from the log of the pup count from the first 7 years (1975–1981) and computed separate age-distributions (c_a) for each sex using the estimated survival rates for 1975. Using the pup count in 1975, we estimated the number of females and males in the population as $N_{f,1975} = P_{1975}/2/c_{f,0}$ and $N_{m,1975} = P_{1975}/2/c_{m,0}$, respectively. Then we estimated the number at each age from the age-distribution formula (e.g., $N_{f,a,1975} = c_{f,a} N_{f,1975}$).

Birth Rates

California sea lion birth rate estimates were only available for a few cohorts over a short time frame within the population reconstruction period (Melin et al. 2012*a*), so we could not include them in the model fitting, but we computed implied birth rates (B_y) at the census time from the population reconstruction values for females >4 years old (Melin et al. 2012*a*), $B_y = P_y / F_y$, where $F_y = \sum_{a=4}^{A} N_{f,a,y}$. These values will be lower and likely more variable than true birth rates because of early pup mortality prior to the pup count.

Previous studies reported that birth rates in the 1970s and possibly later were lower because of premature births associated with high levels of total dichlorodiphenyltrichloroethane (DDT) and polychlorinated biphenyl (PCB) concentrations in the blubber of reproductive females (DeLong et al. 1973, Gilmartin et al. 1976). Also, the birth rate is often lower during El Niño conditions (DeLong et al. 1991, Melin et al. 2012*a*, Lowry et al. 2017) and as the population increased density-dependent reductions in birth rates may have occurred. To examine these potential effects, we fitted models for B_y using covariates allowing for density-dependent effects in birth rate (N_y/K), El Niño conditions as reflected by the local SST anomaly from 1 July to 30 June (DeLong et al. 2017), and impacts of DDT concentrations (lipid weight ppm) that declined from the early 1970s to the present.

Values of DDT concentration from adult female blubber tissue samples were available for only a few years including 1970 and 1972 (DeLong et al. 1973, Gilmartin et al. 1976), 1991 (R. L. DeLong, NMFS, unpublished data), and 2001–2003 (Randhawa et al. 2015). Values in 1970, 1972, and 1991 were taken from fixed sample sizes of premature parturient and full-term parturient females but not in proportion to their occurrence in the population. Thus, we computed a weighted average of the 2 means based on the proportion of premature parturient and full-term females in the population (R. L. DeLong, unpublished data). An average of DDT concentration for a sample of females was available for 2001–2003 (Randhawa et al. 2015), so we used the single average with a year of 2002. We derived yearly values of the DDT concentration covariate with predictions from a linear regression of the log of observed DDT concentration values (273, 268, 10.5, and 10.8) over time (1970, 1972, 1991, and 2002). For the model fitting of birth rates (B_y), we assumed that B_y was approximately normal with mean μ_y and variance $\tilde{B}_y \times (1 - \tilde{B}_y) \times (e^{\gamma} + 1)$, where $\tilde{B}_y$ is the predicted birth rate and the parameter γ inflates the binomial variance ($\tilde{B}_y \times (1 - \tilde{B}_y)$) for over-dispersion. We used linear combinations of the DDT, SST, and density-dependent (N_y/K) covariates to model μ_y with a logit link function. We estimated the parameters via maximum likelihood and selected from among models with various combinations of covariates based on Akaike's Information Criterion with small sample size correction (AIC_c).

Generalized Logistic Growth Model

In a discrete logistic model of population growth, $N_{y+1} = N_y[1 + R(1 - N_y/K)]$, where N_y is the population size in year y, R is the maximum growth rate, K is the carrying capacity of the population, and the derived value of MNPL is $K/2$. A generalized logistic model, $N_{y+1} = N_y[1 + R(1 - (N_y/K)^z))]$ has an additional exponent z with values >1, which allows MNPL/K to be >0.5 because MNPL/K is $(1+z)^{-(1/z)}$. To estimate K and MNPL of the California sea lion population, we used a generalized discrete logistic population growth curve fitted to the annual reconstructed population sizes (N_y). The basic equation for the growth curve is $N_{y+1} = N_y + N_y \times R \times (1 - (N_y/K)^z)) - H_y$, where R is the maximum rate of increase, K is carrying capacity, and H_y are the human-caused mortalities (bycatch) in year y. We expanded this equation to allow for variation in the population growth rate due to El Niño conditions as reflected by changes in the annual SST anomaly. Adding the SST anomaly in year y, the growth curve equation is $N_{y+1} = N_y + N_y \times (R + b \times SST_y)(1 - (N_y/K)^z) - H_y$, where b is an estimated slope for the effect of SST on the population growth rate and R is now the maximum rate of increase in years of average SST (anomaly = 0). We estimated the parameters (K, R, z, and b) using non-linear least squares with the function nls in R (R Core Team 2016). We used the reconstructed population size in 2014 divided by the estimate of MNPL as the measure of population status relative to OSP. If N_{2014}/MNPL >1, the population is within the OSP range.

To provide confidence intervals for parameter estimates and an evaluation of certainty about the population status relative to OSP, we used a parametric bootstrap approach with 1,000 bootstraps from which we computed 95% intervals, which were the 25th smallest and 975th largest value of the parameter estimates or derived statistics. We included all known sources of uncertainty including survival estimates derived from DeLong et al. (2017), imputed values of pup counts for missing values, estimates of human caused mortality, and DDT concentration values used in analysis of birth rates. For the latter 3 sources, we allowed the predictions to vary using the assumed error model in the regression or ratio estimation. For each bootstrap replicate, we completed 4 steps.

1. From the survival analysis, we assumed the logit of the sex- and age-specific survival estimates were distributed as a multi-variate normal with the mean vector computed from the estimated values and the variance-covariance matrix from the estimated model. The annual survival estimate for males >2 years old in 1996 was at a boundary of 1 with no valid variance estimate, which precluded evaluation of the multi-variate normal distribution, so we replaced it with the estimate from 1995 to allow the use of the parametric bootstrap. From the multi-variate distribution for the parameters, we drew a new sample of parameter estimates for the survival mode.
2. We generated a new set of imputed pup counts using the regression models described above and in Lowry et al. (2017).
3. We fitted the mixed-effects model to predict the complete set of age- and sex-specific survival estimates and reconstructed the population sizes from 1975 to 2014. In reconstructing the population size for the bootstraps, we used a binomial distribution to allow for stochastic variation in the proportion that survive from age a at time t to age $a+1$ at time $t+1$ rather than the deterministic equation.
4. After reconstructing the population over time, we fitted the logistic growth curve with one bootstrap set of human-caused mortality estimates and the fit of the model for birth rates using a bootstrap set of DDT concentration values.

This process provided 1,000 estimates of each parameter in the logistic growth curve, a ratio of predicted population size for 2014 divided by the MNPL estimate, and confidence intervals for the birth rate parameters. In the bootstrap process, we conducted model selection for the mixed-effects model of survival and the birth rate for each bootstrap to incorporate model selection uncertainty.

The research described in this paper was reviewed and approved by the National Atmospheric and Oceanic Administration, National Marine Fisheries Service, Alaska Fisheries Science Center/Northwest Fisheries Science Center Institutional Animal Care and Use Committee (IACUC) under approved protocol numbers A/NW 2010-7, A/NW 2013-5, and National Marine Fisheries Service MMPA Permit Numbers 717, 736, 782, 782-1812, 783-977, 1613, 16087, 16087-2 issued to the NMFS Alaska Fisheries Science Center, Marine Mammal Laboratory. The methods for marking and observing California sea lions for estimating survival are described in DeLong et al. (2017) and were approved under the permits and IACUC-approved protocols. Protocols for data collected prior to 2010 were not reviewed by the NMFS IACUC because the IACUC did not exist; however, protocols for pup censusing and the sea lion marking program have not changed since they began in the 1970s and 1980s. Research conducted by the NMFS Southwest Fisheries Science Center was authorized under MMPA Permit Numbers 347, 404, 684, 704, 774-1437, 774-1714, and 14097 and National Marine Sanctuary Permits GFNMS/MBNMS/CINMS-04-98, MULTI-2002-003, MULTI-2003-003, and MULTI-2008-003.

RESULTS

The California sea lion pup count in the United States population has increased steadily since 1975 except for

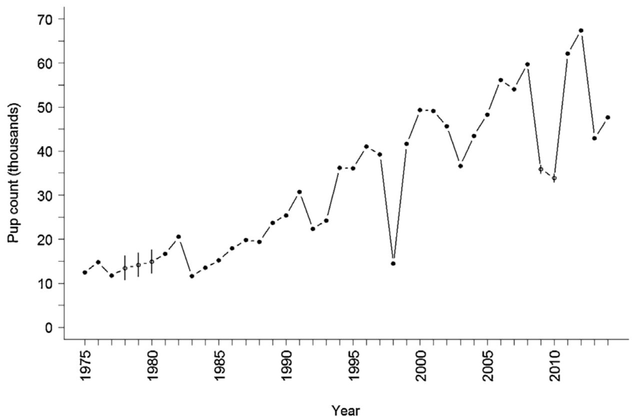

Figure 2. California sea lion population pup counts in the United States, 1975–2014. Open circles are imputed estimated values with vertical lines representing 95% bootstrap confidence intervals.

abrupt significant declines associated with El Niño events and recent declines in 2009, 2010, 2013, and 2014 (Fig. 2). These shifts in annual pup production are reflected throughout the age structure, which is dynamic over time (Fig. 3).

In addition to changes in the number of births, there has been significant annual variation in survival of pups and yearlings (DeLong et al. 2017). A recent decline in yearling and pup survival has resulted in low recruitment of females reaching age 2 and age 4 (Fig. 3). Even though the pup count in 2012 was the highest recorded (Fig. 2), the number of males and females reaching age 2 from this cohort was the lowest since the 1998 cohort (Fig. 3) when pup production was severely curtailed because of the strong 1997–1998 El Niño event.

The declines in pup births and juvenile survival from 2011 to 2014 have led to a leveling of the number of females ≥4 years old that comprise the reproductive age class (Fig. 4). This may have consequences for future population growth by depressing recruitment of reproductive females. Similar leveling occurred during other periods in the time series and followed the occurrence of El Niño events in 1982–1983 and 1997–1998 (Fig. 4). In each of these occasions, the high mortality of birth cohorts and poor survival of juveniles led to the leveling period, but each was followed by a period of strong population growth.

The reconstructed total population sizes (Fig. 5) are more variable over time than the reconstructed population sizes of females ≥4 years old (Fig. 4) because of the high degree of annual variability in pup and yearling numbers (Fig. 3). The sex- and age-partitioned population sizes (Table 1, Fig. 3) demonstrate the shifts in age structure with the number of sea lions <8 years old in recent years being lower than their peak abundance earlier in the time series and sea lions ≥8 years old being at their peak abundance. The sex- and age- partitioned population sizes also show the change in sex structure across age due to the sex-differential in survival at older ages (Tables S1 and S2, available online in Supporting Information). The abundance of males and females are similar up to age 8 but then diverge at older ages with females predominating because of lower survival of males of the same ages. From the population reconstruction values, we computed the multiplier that would be needed to derive the correct population size from the pup count in each year. The multiplier values ranged from 3.88 in 2000 to 10.06 in 1998 (Table 1). When the birth rate was >0.8 the average correction factor was 4.26, but the birth rate estimates were >0.8 in only 15% of the 39 years. For the remaining years, except 1999, the correction factor was >4.26.

The model-averaged estimates of parameters fitted to the annual birth rates computed from the reconstructed population sizes demonstrated a decline in birth rate from higher DDT concentrations in adult female blubber and

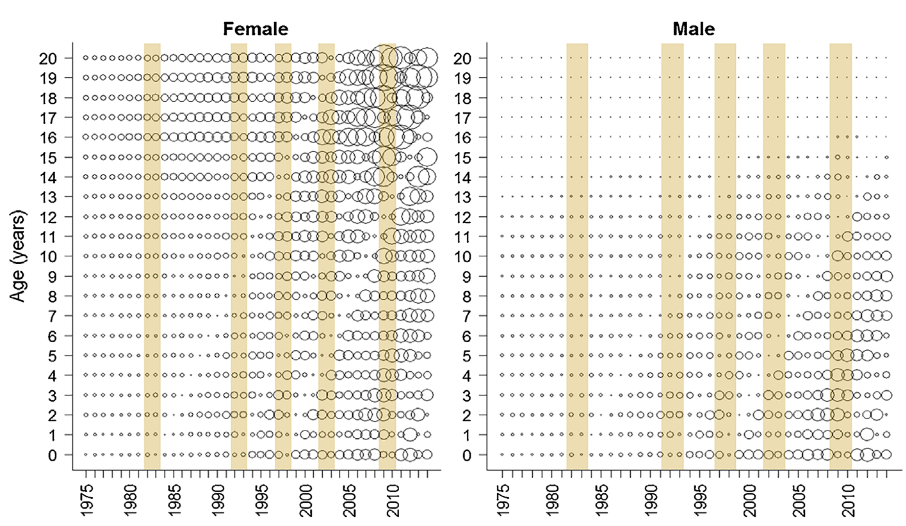

Figure 3. Relative abundance for female and male California sea lions in the United States, 1975–2014, for ages 0 to 20 years. Bubble size represents the proportion for age (a) in year (y) of females or males relative to the maximum number of animals (females+males) of age a among all years. Age axis is restricted to age 20 to improve visual for younger ages; most of the population (99.8%) was younger than age 21. Gold bars identify years affected by El Niño conditions.

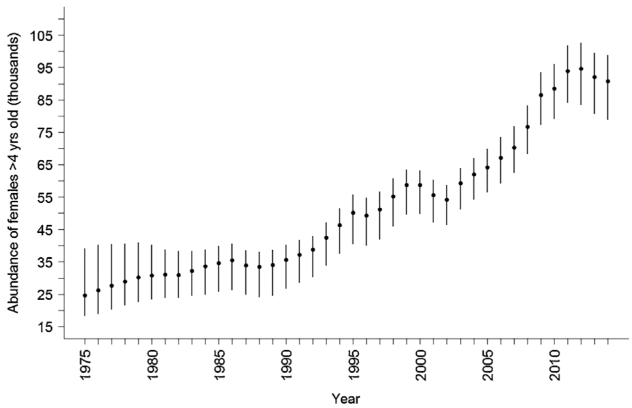

Figure 4. Predicted abundance of female California sea lions ages 4 and older in the United States population, 1975–2014, and 95% confidence intervals from parametric bootstrap.

higher SST anomalies associated with El Niño events and a possible density-dependent response in recent years (Table 2, Fig. 6). The birth rate odds $(B_y/(1-B_y))$ decline by 0.129 (95% CI = 0.004–0.563) for every 10 ppm DDT concentration increase, by 0.570 (95% CI = 0.491–0.702) for every 1°C of SST above normal, and by 0.155 (95% CI = 0.003–0.314) for each 0.1 N/K increase in abundance. The estimate of the SST effect was much more precise than either the DDT concentration or density-dependent responses.

For most of the period from 1974 to 2014, the estimated percentage of the California sea lion population killed as bycatch in the halibut set gillnet fishery was <2%, but during the period of highest fishing effort in the 1980s, it reached about 8.5%. In the past decade, it declined to <0.2%. Most of the bycaught California sea lions in the fishery were juveniles. If the bycatch is assumed to consist only of sea lions of age 0–3, those ages would represent a greater proportion of the total, but the pattern across time would be similar.

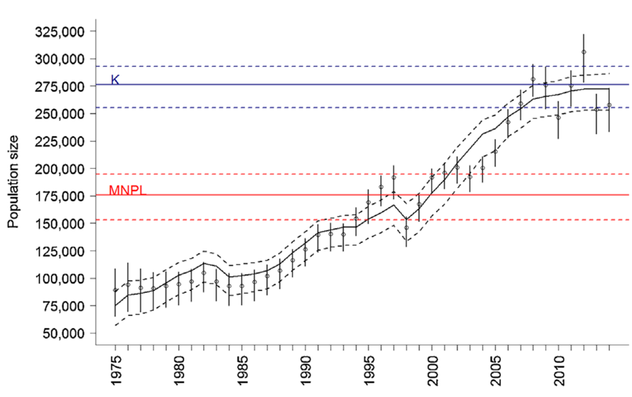

Figure 5. Fitted logistic growth curve (solid line) and 95% bootstrap intervals (dashed line) for reconstructed California sea lion annual population sizes in the United States, 1975–2014. Vertical lines are 95% bootstrap confidence intervals for reconstructed annual population sizes. We also present estimated carrying capacity (K; solid blue line) with 95% confidence intervals (dashed blue line) and maximum net productivity level (MNPL; red solid line) with 95% confidence intervals (dashed red line).

Table 1. Annual California sea lion pup counts from breeding areas in the United States and population sizes of female (F) and male (M) California sea lions from 1975 to 2014 estimated from a population reconstruction model. The multiplier is the correction factor for pup counts to derive the total population size.

		Population estimate

[a] Pup count estimated from imputed values from partial censuses or regression (Lowry et al. 2017).

From the fitted logistic growth model of the total reconstructed population size (Table 3, Fig. 5), the estimated maximum growth rate (R) for the California sea lion population was 0.07 under a normal SST regime. The California sea lion population size in 2014 (257,631) was estimated to be about 40% greater than MNPL (183,481) and the 95% confidence limit for N/MNPL (95% CI = 1.22–1.58) shows that the population is currently well within OSP (Table 3). Carrying capacity was estimated to be at 275,298 animals. Even with a substantial reduction in N, the population is expected to remain at OSP for the foreseeable future. However, an increase of 1° C SST was estimated to reduce the population growth rate by 0.07, thereby halting growth (Table 3). During strong El Niño events the SST anomaly can be ≥2° C resulting in a negative growth rate

Table 2. Model-averaged estimates of the logit of parameters for the California sea lion birth rate function computed from population reconstruction values for sea lions in the United States, 1975–2014. The 95% confidence intervals are from bootstrap replicates.

		95% CI	
Parameter[a]	Estimate	Lower limit	Upper limit
γ	8.02	7.88	8.61
Intercept	2.13	0.601	4.69
SST	−0.843	−1.21	−0.675
DDT	−0.0138	−0.0827	−0.000348
N/K	−1.68	−3.78	−0.0302

[a] γ is inflation value for binomial variance for over-dispersion, SST is sea surface temperature anomaly, DDT is concentration of dichlorodiphenyltrichloroethane in blubber of reproductive females, and *N*/K represents density dependence where *N* is abundance and *K* is carrying capacity.

[a] N_y is population size in year *y*, *K* is the population carrying capacity, *R* is the maximum growth rate, *z* is the generalized logistic exponent, MNPL is maximum net productivity level, and *b* is the slope of the sea surface temperature covariate for growth rate.

from decreases in pup births and pup and juvenile survival. Thus, rapid declines in abundance could occur with persistent ocean warming.

DISCUSSION

We have proposed a conceptually simple population reconstruction approach to estimate the total population size and population growth of California sea lions in the United States, resulting in the first age- and sex- specific population growth model for the species. The method has a side benefit of providing complete sex- and age-structure of the population over time and provides derived estimates of birth rates. However, this approach does require a long-term data set with counts of pups and age- and sex-specific survival estimates. We used 39 years of pup counts and 28 years of survival estimates, which allowed us to identify factors contributing to the dynamic nature of the population.

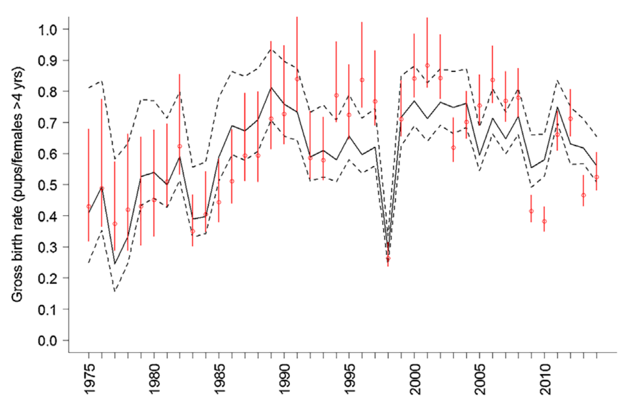

Figure 6. Model-averaged predicted birth rate function (solid line) for female California sea lions in the United States, 1975–2014, and 95% bootstrap confidence interval (dashed line). Model covariates included sea surface temperature anomaly in female foraging area, predicted dichlorodiphenyltrichloroethane (DDT) concentration in female blubber, and a density-dependence covariate (*N/K*) (abundance/carrying capacity). Points are the implicit gross birth rates computed from population reconstructions by dividing number of pups by number of females ≥4 years old. Error bars around points are 95% confidence intervals for birth rate computation from population reconstruction.

For this method, the population must be geographically closed with no immigration or emigration. Permanent emigration may be subsumed into the survival estimates so it was not a large concern. Immigration of California sea lions from Mexico's Pacific coast populations cannot be completely ruled out. If there is immigration, particularly of juvenile animals, then our estimates of population size derived from pup births will be too low in years when immigration occurred. Immigration that resulted in increased abundance of mature females not accounted for in our model could also affect our assessment of birth rates by making them higher than our model estimates.

Birth rates were very low during the first decade of the study in part because adult females suffered reproductive failure associated with high levels of DDT concentrations in their blubber (DeLong et al. 1973, Gilmartin et al. 1976). The effect of DDT concentrations on birth rates appeared to become less important after 1986, probably because of reduced levels of the contaminants in the southern California marine environment. Significant decreases in birth rates were clearly associated with warmer SSTs that occur during El Niño conditions, but elevated SSTs do occur outside El Niño events. Warmer SSTs negatively affect sea lion births because they are usually associated with other physical and biological oceanographic changes that occur in the California Current Ecosystem that lead to decreased prey availability to California sea lions (Chavez et al. 2002). The decreased prey availability leads to low pup growth rates, decreased birth rates, and higher mortality among sea lions (DeLong et al. 1991; Melin et al. 2010, 2012*a*,*b*). In some cases, the population response to warmer SSTs may span multiple years or may lag the event by months or years as indicated by the substantial variability in the abundance of pups and yearling age classes in our model. The relationships of SST, birth rates, and animal condition are sensitive to small- and large-scale changes in the marine environment and are likely not always a simple linear relationship nor the only environmental factor affecting changes in birth rates, animal condition, or survival. However, the strong relationship between warmer SSTs and changes in birth rates provides insight into the potential impacts of warming oceans on sea lion population trends due to climate change.

The very large estimate of the parameter γ to allow for over-dispersion from binomial variance, suggests the birth rate model is incomplete and other factors not included in our model are causing additional variation in either the reconstructed population sizes or the true birth rates. One such factor is early pup mortality that occurs prior to the pup census in mid- to late July. The 2009 birth rate was far below the long-term average and the predicted value from the birth rate model because of high pup mortality prior to the pup census (Melin et al. 2010). Many reproductive females left the rookery early during the 2009 breeding season because foraging conditions were poor owing to an oceanographic upwelling relaxation along the central California coast during summer (Bjorkstedt et al. 2010). Consequently, reproductive females were either not impregnated, did not implant, or prematurely aborted leading to a similarly low birth rate value in 2010.

Even with the large data sets we used, they were still incomplete. In our application, we had only a partial set of age- and sex-specific survival rates limited to San Miguel Island from 1987 to 2014, but we devised a scheme to derive the missing estimates. Our approach assumes the survival estimates apply to the entire population of California sea lions breeding in the United States and the model for the derived survival estimates is unbiased. We also had to assume that the population had a stable age distribution in 1975 and we could accurately reconstruct it. By starting in 1975, any errors in the estimated age distribution would be largely diminished by 1990. Therefore, we do not believe that any possible problems are sufficient to invalidate our conclusion that the population has expanded past its MNPL and it is within the range of OSP. The location of MNPL relative to K (0.67) seems very sensible considering the assumed range of 0.5–0.8 that was used by Wade et al. (2007) and MNPL estimates for harbor seals (Jeffries et al. 2003, Brown et al. 2005). The California sea lion population growth model and the OSP conclusion were largely influenced by the data from the last 24 years when we had adequate survival estimates and accurate pup counts.

We cannot rule out the possibility that the population will increase again at some point in the future. If the California Current returns to a highly productive marine environment with ample prey for sea lions, the population will likely respond with higher survival and birth rates. However, what the population has experienced since 2009 is very different than what occurred in the late 1990s and early 2000s when the California Current was a productive ecosystem. The 1997–1998 El Niño event affected the birth cohorts of 1996–1998, resulting in a temporary leveling of population size, but it was short-lived because of the small number of cohorts affected. This was followed by a rapid growth period between 1999 and 2009. Decreases in the survival and birth rates since 2009 have been influenced by environmental anomalies in central and southern California (e.g., an oceanographic upwelling relaxation event in 2009 (Bjorkstedt et al. 2010), an El Niño in 2010 (Bjorkstedt et al. 2011), and an oceanic heat wave [i.e., The Blob] in 2013–2015 (Leising et al. 2015, McClatchie et al. 2016)) that have affected prey availability for juveniles and pregnant and lactating females that remain in the coastal California waters year round and influence population dynamics (Melin et al. 2010, 2012*b*). If the population had been much smaller during these events, like it was in the 1990s, *per capita* resources would have been greater, and the environmental effect may not have been as dramatic. Future monitoring of the population and its vital rates will allow a more robust assessment of whether density dependence is regulating growth of the population at current levels of population abundance.

All sources of mortality, including human-caused mortality, are reflected in the survival rates used in the model. We attempted to estimate human-caused mortality because the Potential Biological Removal (PBR) level is one of the criteria in the MMPA for determining a population's status. It is the maximum number of animals that can be removed from the population because of human-caused mortality while allowing the population to reach or maintain its OSP (Wade 1998). The default maximum rate of increase (R_{max}) for pinnipeds in the PBR scheme (Wade 1998) is 0.12; our R_{max} estimate was only 0.07 (95% CI = 0.06–0.09). Our estimate should not be treated as the potential maximum rate of increase for California sea lions because we have been able to include only a fraction of the human-caused mortality and because at the time that sea lions should have been increasing at their maximum (in the 1970s and 1980s), their reproductive rate was being hampered by the effects of DDT and PCB pollution (DeLong et al. 1973, Gilmartin et al. 1976). With respect to human-caused mortality of California sea lions, the largest estimates of mortality have historically been attributed to the halibut set gillnet fishery (Julian and Beeson 1998). However, this fishery represents only one source of human-caused mortality, and other sources include the swordfish (*Xiphias gladius*) and common thresher shark (*Alopias vulpinus*) large-mesh drift gillnet fishery (Carretta et al. 2017), fishery-related shootings (Greig et al. 2005), the ingestion of fishing hooks from recreational fisheries, and entrainment in power plant intake systems (Carretta et al. 2016*a*). Estimated bycatch in the California common thresher shark and swordfish drift gillnet fishery totaled approximately 1,400 animals between 1990 and 2015 (Carretta et al. 2017), a value that is less than some individual year bycatch estimates reported in the halibut set gillnet fishery by Julian and Beeson (1998). Hook-and-line fishery and shooting removals are based on opportunistic stranding reports, which represent minimum counts, because not all carcasses are documented and there is currently no way to correct for this bias. Greig et al. (2005) reported on the causes for 3,692 stranded sea lions over 10 years and concluded that 12% of the strandings were caused by human-induced trauma and 71% of those trauma cases resulted from gunshot wounds. If undocumented human-caused mortality is significant, then our estimates of maximum rates of increase for the population may be too low.

The dynamic age structure of the California sea lion population has implications for estimation of sea lion abundance. In lieu of species-specific life-history parameters, a correction factor (multiplier) constructed from northern fur seal life-history parameters has been used to scale up the pup count to a total population estimate. For example, a value of 4.32 was used for the multiplier on the 2008 count of pups (Carretta et al. 2016*b*). However, our analysis shows that the multiplier could range from 3.88 to a maximum of 10.06 because of changes in pup production. Thus, constructing an estimate of abundance from the pup count with a constant multiplier is not a viable approach for California sea lions.

The challenges of maintaining a high-quality data set over multiple decades needed to reconstruct a population history are many and varied. Such studies for marine mammals are uncommon, largely because of the challenges associated with this long-lived group that spends very little time in view, ranges over vast expanses of ocean, and is costly to monitor (Bowen et al. 2010). However, the method we used here will be a useful tool for estimating the abundance of other MMPA pinniped species for which there are sufficient time series for abundance and vital rates. For example, the status of California and Eastern Pacific stocks of northern fur seals are currently computed using pup counts and a single life-history multiplier (Carretta et al. 2016*b*, Muto et al. 2017). A time series of pup counts and data on survival are available for both populations, so the approach we used here could be used to estimate abundance of the populations with some modification to allow for less complete time series.

MANAGEMENT IMPLICATIONS

The determination that the United States California sea lion population is at OSP has several important management implications. First, it indicates that the management objectives of the MMPA are being met for this species. Second, the determination that a population is at OSP provides the opportunity for individual states to request a transfer of the authority for management and conservation under the MMPA from NMFS to the state. In the case of California sea lions, the states of California, Oregon, and Washington could request this authority, but they must meet various criteria stipulated in the MMPA, including a state management program that is consistent with the purposes, policies, and goals of the MMPA and international treaty obligations.

The influence of changes in SST on the population growth of California sea lions needs to be considered in management of the species. If SST in the California Current increases 1°C in response to climate changes, our model predicts the annual growth rate would fall to zero and if the SST increased 2°C, the annual population growth rate would decline 7%. If this occurred, the population could rapidly fall below the range of OSP, potentially changing the population's status under the MMPA. This could lead to changes in management strategies and options.

Finally, in developing this analysis we have provided a critical tool for current and future management of California sea lions. Along the west coast of the United States, there are various resource conflicts involving this robust population of sea lions: fisheries interactions that lead to sea lion mortality and economic losses for the fisheries (Weise and Harvey 2005), interactions with people on public beaches and at marinas creating human safety concerns and inflicting property damage, and interactions with endangered fish possibly impeding the recovery of the fish populations (NMFS 1997, 2008). Perhaps the most high-profile management issue is at the Bonneville Dam on the Columbia River, where a controversial lethal removal program authorized under the MMPA, and managed by the states of Oregon and Washington, has been conducted in an attempt to alleviate sea lion predation pressure that may be impeding recovery of endangered salmonids (NMFS 2008). The model we presented here highlights the value of long-term research in support of management needs to meet MMPA mandates and the need to continue the research as the California sea lion population responds to environmental and anthropogenic changes that may alter its status. It is only through a long-term approach that managers will have a sufficient understanding of the dynamics of the California sea lion population on which to base future management decisions related to complex resource conflicts involving this species.

ACKNOWLEDGMENTS

The findings and conclusions in the paper are those of the authors and do not necessarily represent the views of the National Marine Fisheries Service, National Oceanic and Atmospheric Administration. We thank all the staff and volunteers that assisted with pup counts and observations in the field or in the lab. The University of California Santa Cruz and P. A. Morris provided access to Año Nuevo Island, California for resightings that were included in estimates of juvenile survival. Channel Islands National Park provided access to San Miguel Island and the United States Navy provided access to San Miguel, San Nicolas, and San Clemente Islands for pup counts and observations. We are thankful for the reviews and input of D. S. Johnson, P. R. Wade, A. E. Punt, C. E. Yates, J. D. Baker, and an anonymous reviewer on this manuscript. We also thank the Alaska Fisheries Science Center Publication Unit for editorial review. Funding was provided by the National Oceanic and Atmospheric Administration, National Marine Fisheries Service, Alaska and Southwest Fisheries Science Centers; the National Marine Fisheries Service West Coast Region; and the National Marine Fisheries Service Marine Mammal Health and Stranding Program. Aerial photographic surveys of pinnipeds at the Channel Islands and funding support for processing images from the surveys were supported by the United States Navy San Nicolas Island NAVAIR Ranges Sustainability Office and NAVFAC Naval Base Ventura County.

Update on the use of a simulation-based approach to evaluate plausible levels of recruitment into the Pacific Coast Feeding Group of gray whales

Lang, A.R., and Martien, K. K.
Protected Resources Division, Southwest Fisheries Science Center, La Jolla, CA 92037

ABSTRACT

Previous genetic comparisons of the Pacific Coast Feeding Group (PCFG) of gray whales with whales feeding north of the Aleutians have shown significant levels of mitochondrial differentiation. The magnitude of the differentiation, along with the relatively high levels of genetic diversity identified within the PCFG, have raised questions about how much immigration into the group could occur before the signal of mtDNA differentiation is erased. Here we use a simulation-based approach to evaluate the range of plausible levels of immigration into the PCFG that could be occurring. The simulations incorporate annual immigration ranging from between 0 and 16 animals per year (once the larger ENP population reaches K), and simulations both with and without a pulse of +20 immigrants over two years are included. Results suggest that under the scenarios tested, current immigration into the PCFG of one migrant per year or less would produce levels of genetic diversity and differentiation that are inconsistent with the empirical data. The simulations were less informative with regard to placing an upper limit on the number of animals per year which could be immigrating into the PCFG, although comparison of F_{ST} and χ^2 (per degree of freedom) values between the simulated and empirical data suggests that immigration higher than 8 animals per year is unlikely. Comparisons between the observed and simulated values for the number of haplotypes, F_{ST}, and χ^2 (per df), which were the most informative measures, suggest that immigration of approximately 4 animals per year is most plausible.

INTRODUCTION

Genetic comparisons of samples collected from gray whales considered to be part of the Pacific Coast Feeding Group (PCFG) with those from animals that feed north of the Aleutians have revealed small but significant levels of mtDNA differentiation but no nuclear differentiation (Lang *et al.* 2011). In addition, a relatively large number of mtDNA haplotypes were identified within the PCFG (n=23 haplotypes, Lang *et al.* 2011), which is estimated to contain ~200 animals (IWC 2011). Analysis of photo-identification data indicates that on average, 10 animals per year were recruited[1] into the PCFG between 2004 and 2008, with larger numbers of recruits identified between 2000 and 2002 (IWC 2011). These recruits could be internal (i.e., calves born to PCFG mothers) or external (animals that previously fed north of the Aleutians and subsequently immigrated into the PCFG). An average of three calves per year were identified in the PCFG between 1998 and 2008 (Calambokidis *et al.* 2010), and it is presumed that at least half of the calves born each year may not have been identified as such (IWC 2011). Based on those assumptions, an estimated four animals per year may have recruited into the PCFG from northern feeding area(s) between 2004 and 2008, and a pulse of higher immigration may have occurred between 1999 and 2002, potentially in response to the increase in gray whale mortality that occurred in 1999 and 2000.

The results of these genetic and photo-id studies of the PCFG have raised questions about how much external recruitment into the PCFG could occur while still maintaining the observed level of mtDNA differentiation between the PCFG and animals feeding north of the Aleutians. The use of a simulation-based approach has the potential to provide information relevant to this question. As part of a previous IWC exercise (the Testing of Spatial Structure Methods, or TOSSM, project), simulated genetic datasets representing different population structure archetypes were created for performance testing of different analytical methods (Martien *et al.* 2009). The demographic parameters underlying the dataset generation model were based on the vital rates of

[1] Here a 'recruit' is defined as an individual first photographed in the PCFG seasonal range (within the area spanning 41-52°N and between June 1 and November 30) in a given year and resighted within the seasonal PCFG range in at least one subsequent year.

eastern gray whales (Martien *et al*. 2004, Martien 2006). In discussions with the IWC Stock Definition subcommittee, it was agreed that the TOSSM dataset generation model could be useful in creating simulated datasets that would allow the plausibility of different hypotheses (e.g., different immigration rates into the PCFG) to be evaluated.

METHODS

Rmetasim

Simulated datasets were produced using the *rmetasim* package (version 1.1.05, Strand 2002) as run in the R statistical environment (R 2.14.1). *Rmetasim* performs individual-based population genetic simulations utilizing stage-based matrix population models. The transition probabilities in the matrices are used to randomly assign births, stage transitions, and deaths of individuals over time. Density dependent growth is implemented by the linear interpolation between matrices representing survival and reproduction rates at carrying capacity (K) and at zero population density (ZPD). A pre-birth pulse model is used, such that at the end of each simulation year, the youngest animals in the population are one year old.

Stage-based matrices

As previously mentioned, vital rate estimates for eastern Pacific gray whales (as described in Martien *et al.* 2004, Martien 2006) were used to parameterize stage-based matrices for the TOSSM exercise. Since the construction of these matrices, additional information has become available on the life history of gray whales. This new information was utilized to update the stage-based matrices from TOSSM, and when possible the vital rates used in constructing the new matrices were chosen to be the same as those utilized in the IWC's Implementation Review of gray whales. The following changes were made:

1) Adult survival rate was increased to the median estimate from Punt & Wade 2010 (S_A=0.982)
2) A separate term for calf survival rate (set to S_c=0.732, the median estimate in Punt & Wade 2010) was utilized. In the previous matrices, calf survival was the same as juvenile survival.
3) The median estimate from Punt & Wade 2010 was utilized for the rate of increase at ZPD (λ =1.063)
4) The age of first reproduction (AFR) was increased to 7 years at ZPD based on the Bradford *et al.* 2010 review.
5) A third juvenile stage was added to provide better control of AFR.

In addition, three identical adult stages for each sex were included in the new matrices. In contrast, the matrices used in the TOSSM project included a single adult male stage and separate fertile and lactating stages for adult females. This change was implemented for two reasons. First, it allowed for better control of generation time and greatly reduced the proportion of individuals in the simulations that lived to unrealistic ages under the increased adult survival rate. Secondly, it reduced the number of multiple births by the same female in a given year. In *rmetasim*, the fertility term represents the mean number of calves produced per female based on a Poisson distribution (Strand 2002). This results in some females producing more than one calf per year. Eliminating the separate fertile and lactating stages allowed us to reduce the fertility term (since it was applied to all adult females, not just a subset in the lactating stage), thereby reducing the number of multiple births (Table 1). However, this change also eliminated the minimum two-year calving interval that had been enforced in the TOSSM matrices. As such, under the new matrices some females in the simulation will give birth in consecutive years (Table 2).

Given the number of changes implemented in the new matrices, we ran the simulations using both the updated nine-stage matrices as well as the original five-stage matrices (as described in Martien 2006) utilized in the TOSSM exercise. The vital rates used to construct the original matrices and those utilized in the updated 9-stage matrices are detailed in Table 3. The parameter for juvenile survival rate was not derived from the literature but was calculated from the matrices to produce the desired value of lambda. The

Maximum Sustainable Yield Rate (MSYR) calculated from the 9-stage matrices is ~3.3%, while MSYR for the 5-stage TOSSM matrices is ~3.6%.

These vital rates were used to construct stage-based matrices representing the demography of the population near carrying capacity (K) and near zero population density (ZPD). Transition probabilities were calculated according to Caswell (2001) and the resulting matrices are shown in Table 4.

Population Trajectories

Dataset generation followed the steps outlined in Martien 2006, with the exception that coalescent datasets were generated using FastSimcoal (Excoffier and Foll, 2011) rather than SimCoal 2.1.2 (Laval and Excoffier 2004) to establish the effective size (Ne). In all scenarios, a single population was simulated in *rmetasim* for 4000 years to provide datasets representing the equilibrium population. This time period was shown to be sufficient for reaching equilibrium in a similar exercise for bowhead whales (Archer *et al.* 2010), that have a markedly longer generation time.

The mutation parameter incorporated in the simulations was adjusted to produce genetic diversity levels (as measured by the number of haplotypes and the haplotypic diversity) that are similar to the values observed for the "North" strata in the Lang *et al.* 2011 study. A range of mutation parameters were explored before setting the mutation parameter to 3.8×10^{-3} per generation, which produced measures of genetic diversity that were the most consistent with the observed data.

Carrying capacity (K) for the larger ENP population of gray whales was set to 20,000 animals, similar to the most recent abundance estimate (19,126 animals in 2006/2007; Laake *et al.* 2009). Carrying capacity for the PCFG was set to 200 in accordance with the estimated abundance of 194 animals in 2008 (Annex F, IWC 2011).

For all population trajectories, depletion due to commercial whaling was simulated as having occurred between 1846 and 1930. Attempts were made to utilize the catch history (Annex E, IWC 2011) with a multiplier to produce the desired level of depletion in 1930 (10% of K). However, when this modification was incorporated it resulted in a high number of simulation runs that failed due to the simulated population(s) going extinct. As such, the depletion per year was set to a constant proportion of K, such that the population was depleted by 7.1% of K in each year for the duration of the simulated whaling period. This level of depletion allowed the population to reach the desired level (0.10 of K, or ~2000 animals) by 1930. Examples of the population trajectories produced are shown in Figure 5.

Given that little is known about the origin of the PCFG, two different population histories were simulated. The first scenario ("post-whaling split") assumes that the PCFG split from the larger ENP population following depletion. After reaching equilibrium a single population was projected forward through the 1846-1930 whaling period with depletion occurring as described above. In 1930, 20 animals (10% of K_{PCFG}) were split from the larger population to represent the PCFG. The two populations were then allowed to increase until reaching K. *Rmetasim* employs a "hard ceiling" to restrict population growth to K, such that individuals are killed off randomly after reaching levels >10% higher than K.

The second scenario ("pre-whaling split") assumes that the PCFG split from the larger ENP gray whale population prior to the depletion of gray whales due to commercial whaling. In this scenario, the equilibrium population was split into two feeding groups to represent the northern feeding ground (K_{ENP}=20,000) and the PCFG (K_{PCFG} = 200). The split was presumed to occur at the start of the Little Ice Age (considered here to be at 1540), a period in which it seems plausible that ice conditions would have been favorable for gray whales to begin using more southern feeding grounds. Both populations were projected forward until 1846, when the depletion due to commercial whaling was simulated as described above. After reaching 1930, the simulated depletion ceased and the two populations were allowed to grow until reaching K.

Immigration rates ranging from 0 to 0.0008 were simulated. These migration rates correspond to the immigration of between 0 and 16 animals per year into the PCFG from the larger ENP population once it has reached K (Figure 6). In addition, each population history and migration rate combination was also simulated with a migration "pulse" of 20 individuals over two years. This pulse is reflected in the abundance of the PCFG in 2000 and in 2001. Examples of abundance trajectories for the PCFG under the different immigration scenarios are shown in Figure 7.

Additional simulations were performed in which the value of K_{PCFG} was increased from 200 to between 500 and 5000. These simulations incorporated a post-whaling split of the PCFG from the larger ENP, with the pulse migration of +20 animals over two years but no annual immigration into the PCFG. As in the "post-whaling split" scenarios described above, the split of the PCFG from the larger ENP was modeled such that the number of animals colonizing the PCFG in 1930 was 10% of K.

A final set of simulations were performed that incorporated a more recent split (between 1940 and 1990) of the PCFG from the larger ENP population. The number of animals splitting off to form the PCFG in a given year was derived by taking an average (over ten replicates) of the simulated abundance of the PCFG in each year when the abundance trajectories were modeled under the scenario of a post-whaling split of the PCFG in 1930 with no annual immigration.

A list of scenarios that have been simulated to date is included in Table 7. Of note, the simulations incorporating a pre-whaling split of the PCFG from the larger ENP are in progress and have not yet been completed.

Sampling and Genetic Analyses:

To generate the simulated dataset, the number of simulated animals sampled per year was set to match the number of animals sampled per year and per stratum in the Lang *et al*. (2011) study (Table 8). In the empirical study, some animals were sampled multiple times, and only one sample per individual was retained for the data analysis. For the simulated sampling, the year of sampling for such individuals was assigned as the first year that the animal was sampled. A total of 103 samples were collected from simulated ENP individuals and 71 samples were collected from simulated PCFG individuals.

These sampled individuals were used to generate summary statistics for each group. Genetic diversity was characterized by the number of mtDNA haplotypes, the mtDNA haplotype diversity, and the mtDNA nucleotide diversity. Differentiation between the two simulated groups was measured using F_{ST}, χ^2 (per degree of freedom), and ϕ_{ST}. The summary statistics generated from the simulated datasets were then compared to the observed summary statistics generated for the PCFG and the North strata in Lang *et al.* 2011.

To further evaluate how well the shape of the haplotype frequency distribution for the simulated ENP population matched the shape of the distribution for the North stratum in the empirical data, a χ^2 test was used to compare the two haplotype frequency distributions, and the number of significant tests ($p<0.05$) was calculated. In addition, the frequency of the most common haplotype in each replicate simulation was calculated and compared to the frequency of the most common haplotype in the empirical data for the North stratum. Given that the mtDNA summary statistics produced for the simulated ENP population under all scenarios was similar, these tests were only conducted using the data for the simulated ENP population produced under the model with a post-whaling split with pulse migration but no annual immigration.

In addition to showing the proportion of simulations that had higher and lower values for each statistic than the values generated from the empirical data, we used interpolation to calculate the "crossover point" at which the 50% probability (median) was reached (i.e. the point at which the proportion of simulated runs had values higher than the observed reached 50%). For the number of haplotypes, the crossover point was calculated as the point at which the lines representing the proportion greater than and the proportion less than crossed (as for the other statistics), but because some simulation replicates had values equal to (rather than less than or greater than) the observed value, this point was slightly lower than the 50% probability.

RESULTS

Although the goal is to produce 500 replicates of each scenario, currently only 100 replicates of each scenario are complete and are utilized in the results shown here.

Comparison of simulated and observed data for ENP

Table 9 includes a summary of the number of haplotypes, haplotypic diversity and nucleotide diversity for the simulated ENP population for the model incorporating the 9-stage matrices with a post-whaling split and pulse immigration. Results were similar under all scenarios tested (data not shown). Overall, median values for both the haplotypic diversity and the number of haplotypes were similar among the simulated and empirical datasets. The haplotypic diversity values generated in the simulated data were slightly lower than that in the observed data, with median values for the simulated data ranging from 0.948 to 0.950 (as compared to the observed haplotypic diversity of 0.952) and with 52-64% of replicates under the different immigration scenarios having lower haplotypic diversity than found in the empirical data. In contrast, the median number of haplotypes generated in the simulated datasets (33 to 34 haplotypes) was slightly higher than that found in the observed data (32 haplotypes). Between 62 and 75% of replicates for the different immigration scenarios generated values higher than the number identified in the empirical dataset. Although the nucleotide diversity calculated from the empirical data fell within the 90% range of the simulated values, nucleotide diversity in the simulated data was higher than that found in the observed data.

To evaluate whether the shape of our simulated haplotype distributions matched the shape of the observed distribution, we used a χ^2 test to compare the observed (North stratum) versus the simulated haplotype frequency distributions for the ENP population. The χ^2 test evaluates whether the haplotype distributions representing the empirical and simulated data could have been generated by random sampling of a single population. The χ^2 test is particularly sensitive to the frequencies of the most common haplotypes, as those haplotypes are the most likely to be represented in the random draws that represent immigration events. In our comparison, 12% of tests showed significant ($p<0.05$) differences (Figure 10), suggesting that the shape of the observed and simulated distributions were similar in most cases. We also compared the frequency of the most common haplotype in the empirical data with the frequency of the most common haplotype in the simulations. We found that the frequency of the most common haplotype was higher than that found in the empirical data for 47% of the simulation replicates. This finding is consistent with the expectation that if two samples are drawn from the same distribution, the frequency of most common haplotype would be expected to be greater in one sample than the other 50% of the time.

Comparison of simulated and observed data for the PCFG

Figure 11 shows a graphical representation of the proportion of simulated values for each statistic that are lower (shown in black) or higher (shown in gray) than the observed value generated from the empirical data for one of the scenarios tested (post-whaling split with pulse immigration, nine-stage matrices). Summaries of the number of mtDNA haplotypes (Table 12), mtDNA haplotype diversity (Table 13), mtDNA nucleotide diversity (Table 14), F_{ST} (Table 15), ϕ_{ST} (Table 16), and χ^2/df (Table 17) produced by the simulations under all completed scenarios are shown below.

With regard to comparisons between the observed and simulated data, the statistics based on haplotype frequencies (haplotypic diversity, $F_{ST,}$ and χ^2/df) and haplotype numbers were the most informative. For all four of these statistics, scenarios based on annual immigration of one animal or less per year (at K) produced values that were inconsistent with the empirical data. The comparisons were less informative with regard to the highest level of immigration that could be occurring, although comparison of F_{ST} and χ^2/df values suggested that levels of immigration including > 8 animals/year (along with the pulse immigration) would produce values inconsistent with those produced by the empirical data.

Similar to the pattern seen in comparison of the observed and simulated data for the larger ENP population, the nucleotide diversity identified among the simulated datasets was higher than that seen in the empirical data. In the ϕ_{ST} comparisons, the value generated in the empirical comparison was more consistent with the lower range of values for annual immigration and indicated that more than 8 immigrants per year into the PCFG would produce values of ϕ_{ST} lower than that observed. Caution should be applied when interpreting this pattern, however, given the lower nucleotide diversities identified in the observed data when compared to the simulated datasets.

Table 18 shows the results of simulations evaluating scenarios in which the PCFG splits from the larger ENP population between 1940 and 1990. The results shown suggest that for no annual immigration into the PCFG to be plausible, the PCFG would have had to split from the larger population after 1950.

Table 19 shows the results of simulations evaluating scenarios in which the carrying capacity for the PCFG was set to between 500 and 5000. The results indicate that the carrying capacity for the PCFG would need to be higher than 500 animals for the simulated results to be consistent with the empirical data under a scenario of no annual immigration. Examples of the abundance trajectory of the PCFG for the K values tested are shown in Table 20. For all K values simulated, the abundance of the PCFG was close to carrying capacity by 2010 (Table 21).

DISCUSSION:

Comparison of the simulated and empirical datasets for the larger ENP population suggests that the simulations represent the empirical data reasonably well with regard to the number of haplotypes and their distribution. Although the simulations predict that we would find slightly higher number of haplotypes and a slightly lower haplotypic diversity than is present in the empirical data, the differences are small and the χ^2 test suggests that the two samples would be interpreted as being drawn from the same population in the majority (88%) of cases. The results of these comparisons suggest that similar frequency-based comparisons of the simulated and empirical data representing the PCFG should be informative.

The level of nucleotide diversity in the simulated data representing the larger ENP population is higher than that found in the empirical data, indicating that there are some aspects of the population's history that are not being captured by the simulations. It is likely that the gray whales in the North Pacific have experienced numerous fluctuations in abundance due to changing ice conditions in the past, and historic K may have been substantially larger than we have simulated here (e.g., Alter *et al*. 2007). Our simulations incorporate only a simplified version of the recent history of gray whales, and our results suggest that the statistics relying on nucleotide differences (e.g., nucleotide diversity and ϕ_{ST}) may be more sensitive to violations of our assumptions about past (pre-commercial whaling) population size and equilibrium. As such, the results derived from the comparisons of nucleotide diversity and ϕ_{ST} warrant further investigation and should be interpreted with caution.

The comparison of frequency-based statistics between the simulated and empirical datasets representing the PCFG suggests that annual immigration into the PCFG is likely to be higher than 1 immigrant per year under the scenarios tested. The simulations were less informative with regard to the upper bound on annual immigration that could be occurring. Although the F_{ST} and χ^2/df comparisons indicated that immigration of >8 animals/year would be inconsistent with the empirical data, the proportion of simulations with higher than the observed values for the number of haplotypes and the haplotypic diversity never exceeded 84% and 63%, respectively. For all four statistics, the proportion of simulations with higher (for the number of haplotypes and haplotypic diversity) or lower (for F_{ST} and χ^2/df) values than the observed appears to level off at the higher (8 -10 or more per year) levels of immigration. This pattern is particularly evident in the comparisons utilizing haplotypic diversity, where the proportion of simulations with higher or lower values than the observed levels off at ~50% for immigration of 8 or more animals per year. Haplotypic diversity is calculated based on the sum of squared allele frequencies. Given that relationship, as the number of haplotypes in a population increases, the addition of another haplotype, particularly one found in low frequencies as would be expected to be brought in by an immigrant, has little impact on diversity. As such, this statistic, and to a lesser extent the others, appear to have limited power to differentiate between the higher levels of immigration.

Although these statistics were limited in their ability to distinguish an absolute upper bound on how much immigration could be occurring, the calculation of the number of immigrants per year which corresponds to the "crossing point" provides some information on what the most plausible values of immigration could be (Table 22). The estimated number of migrants ranged from ~2 to 8 for the scenarios with pulse immigration under the updated matrices. For the reasons discussed above, the calculations based on ϕ_{ST} and haplotypic diversity may not provide the best estimates. Comparisons between the observed and simulated values for the number of haplotypes, F_{ST}, and χ^2/df, suggest that immigration of approximately 4 animals per year is most plausible. If the current abundance of the PCFG is approximately 200 animals, this represents immigration of ~ 2% per year. Of note, this estimate does not include the +20 animals which were simulated to immigrate into the PCFG in 2000 and 2001.

Although the simulation results could be sensitive to other parameters incorporated in the models, a limited evaluation of the effects of increased carrying capacity for the PCFG or a more recent founding time was conducted. These simulations suggested that to obtain the empirical results presented in Lang *et al.* 2011 under a scenario of no annual immigration, the abundance of the PCFG would have to be larger (>500 animals) than currently estimated. Gray whales have been observed feeding off of Kodiak Island, Alaska since at least 1999, with ~350-400 individuals counted during a single day in July 2000 (Moore *et al.* 2007). Approximately 20% of the animals photographically identified in this area between 2002 and 2005 are known to be animals that have also been photographed in the Pacific Northwest from northern California to southeast Alaska (Gosho *et al.* 2011). However, the median "crossing point" calculated from these comparisons suggest that values of K between 2000 (based on F_{ST}) and 3000 (based on the number of haplotypes) animals produce values that are most consistent with the empirical data, indicating that additional explanation may be needed.

The simulations exploring more recent founding times suggest that under a scenario with no annual immigration, the PCFG would have to have been founded after 1950, and more plausibly between the mid-1960s to mid-1970s, to produce simulated results that are consistent with the empirical data. Small numbers of gray whales have been sighted within the seasonal range of the PCFG since at least 1926 (Howell & Huey 1930, Gilmore 1960, Pike and MacAskie 1969, additional references in Rice & Wolman 1971), but photo-identification studies did not start until the 1970s, when the repeated return of individuals to the area was first documented (Hatler & Darling 1974, Darling 1984). Our simulations model an instantaneous colonization of the PCFG, such that for the scenarios modeling colonization in 1960 or later at least 60 whales become part of the PCFG in a given year. This aspect of our simulations is clearly an oversimplification. Given both the limited information available on use of the PCFG seasonal range prior to the 1970s and the limitations of our model, it is difficult to evaluate how the simulation results fit in with past records.

The simulations incorporating a pre-whaling split of the PCFG from the larger ENP population are in progress and are expected to be completed by the 2012 SC meeting. Future work will also include integrating the genetic data representing ENP gray whales in LeDuc *et al*. 2002 and Lang 2010 with the data represented in Lang *et al.* 2011 to ensure that the diversity values utilized here are as representative as possible of the larger ENP population. Simulations will also be performed to explore the effect of incorporating lower MSYR rates for the PCFG into the life history matrices underlying the models.

Table 1. The proportion of birth events in the simulated data that resulted in multiple offspring for the same female in a given year.

	5-stage TOSSM matrices	9-stage matrices
Proportion of single offspring births:	64%	92%
Proportion of multiple offspring births:	36%	8%
Range of multiple offspring births:	2-7	2-3

Table 2. Calving intervals in the simulated datasets.

Measure	5-stage TOSSM matrices	9-stage matrices
Median	3	2
Mean	5.1	3.2
Variance	27.08	16.50
stdev	5.20	4.06
Min	2	1
Max	35	38

Table 3. Vital rates for gray whales. Generation time shown here is calculated based on a maximum age of 40 years (as in previous work).

	5-stage TOSSM matrices		9-stage matrices	
Vital Rate	At K	Near ZPD	At K	Near ZPD
Juvenile survival	0.925	0.94	0.905	0.935
Adult female survival	0.946	0.946	0.982	0.982
Adult male survival	0.954	0.954	0.982	0.982
Calf survival	0.925	0.94	0.732	0.732
Age of first reproduction	10	5	10	7
Rate of increase (λ)	1.003	1.072	1.000	1.064
Generation Time*	19.5	16.9	21.10	20.60

Table 4. The updated stage-based matrices for use at a) zero population density and b) carrying capacity are shown below.

ABSTRACT
The western population of North Pacific gray whales (WGW), once thought extinct, is now estimated at 130 individuals and feeds primarily off northeastern Sakhalin Island, Russia, during summer. The population is critically endangered, facing anthropogenic threats throughout its range from nets, ships, and oil development, but present migration routes and wintering areas remain unknown. On 4 October 2010, a subcutaneous Argos tag was applied following protocols established by the International Whaling Commission to a 13-year-old male (named "Flex") in good body condition off Piltun Lagoon, northeastern Sakhalin Island. Flex was first seen as a calf off Sakhalin in 1997. State-space modeling of fall near-shore movements for 68 days post-tagging identified a small home range foraging area within 45km of the tagging site. These data are unique as local weather conditions during this time generally prevent other forms of whale observation. On 11 December, Flex departed Sakhalin and began migrating across the Okhotsk Sea, Bering Sea, and Gulf of Alaska. By 5 February, Flex was within 20 km of the central Oregon coast, overlapping spatially and temporally with the last few weeks of the usual eastern gray whale southbound migration. Flex's migration segments were linear, high speed (averaging 6.5 km/h), and included deep water far offshore, suggesting open-water navigation skills not previously attributed to gray whales, who are considered coastal and shallow-water oriented. State-space modeling (considering directionality and speed) identified the basin-wide movements as "migration" rather than "wanderings" associated with foraging behavior. Flex's movements do not preclude other migration routes or winter destinations for WGWs. Additional WGW tagging is needed to identify other areas of use. The resulting data will have high conservation value and be useful in potential mitigation of anthropogenic activities.

BACKGROUND

The western population of North Pacific gray whales (Eschrichtius robustus, WGW) once thought to be extinct was re-discovery off northeastern Sakhalin Island, Russia and is critically endangered (IUCN, 2008). The population is estimated to contain about 130 individuals age one or older, of which only about 25 are reproductive females (Cooke et al., 2008), and it faces a number of anthropogenic threats throughout its range, including fatal interactions with coastal net fisheries off Japan (Weller et al., 2008; Bradford et al., 2009) along its presumed migration route(s) and oil development in and near its principal summer feeding area (IUCN, 2009). The wintering area of the present population is unknown but, based on the limited available information, has been suggested as south of Honshu, Japan, off the coast of southern China in the South China Sea and the Gulf of Tonkin (Weller et al., 2002), or possibly off North America (Ilyashenko, 2009).

Satellite telemetry has been proposed repeatedly as an efficient way to investigate the migratory routes and wintering grounds of western gray whales and scientists have been cautious about tagging because of the population's very low numbers. After considerable discussion by the IWC Scientific Committee from 2006-10 and various panels convened under the auspices of IUCN from 2006-8 (summarized for the U.S. Marine Mammal Commission and IUCN by Weller, 2008), the research tagging effort reported here was undertaken to tag and track up to 12 of whales during the late summer of 2010 to ascertain winter migration route(s) and reproductive area(s).

METHODS

We used Wildlife Computers Spot-5 Argos transmitters epoxy-cast in Stainless steel cylinders for nearly complete implantation. Insertion blades and attachments for WGWs were similar to those used on 18 eastern NP gray whales (EGW) in 2009/10 (Mate, 2010). The latter field study was an efficacy test prior to using the tags on WGWs. The tags were applied by using a modified air-powered ARTS applicator and specialty pushrods (Mate et al. 2007).

The research was based from the 50 m M/V Igor Maximov, which was at sea from 3 September to 7 October 2010. Although we encountered technical difficulties with the supplied small tagging vessel and significant weather problems (including remnants of two typhoons and two gales), we tagged a whale on the last field-operational day of the extended cruise.

We followed the protocols established by the IWC special steering committee on western North Pacific Gray whale telemetry, which required tagging only known adult males in good body condition. On 4 October 2011, we tagged a13 year old male known as Flex off the northeast coast of Sakhalin Island, Russia (Figure 1 inset), where the whale had first been seen as a calf in 1997. Although the tag was not completely deployed, it provided location data for 124 days.

RESULTS

Flex stayed along the Sakhalin Island coast within 45 km of the tagging site and within 5 km of shore for 68 days (Figure 1). These near shore movements suggest foraging behavior. In mid-December Flex crossed the Sea of Okhotsk to the west side of the Kamchatka Peninsula, went around the southern end of the peninsula and departed the east coast in early January. The tagged whale crossed the western and central Bering Sea in one week to arrive at the shallow shelf break near a major canyon and then proceeded south passed the Pribilof Islands and through the eastern Aleutian Islands before crossing the Gulf of Alaska and heading south 20-25 Km off the Washington and Oregon Coasts (Figure 2). He was last located by satellite 20 Km off Siletz Bay, Oregon (~45*N) on 5 February, which over-lapped with the last few weeks of the usual ENP gray whale southbound migration through this same area.

Despite ambiguities in the accuracy of many Argos location classes, the course heading across the western Bering Sea varied within just a few degrees for a week. Such linearity in the Argos track makes significant errors in the actual distance traveled unlikely compared to the Argos-derived path. The Argos track length may actually be a conservative estimate, but still resulted in sustained swimming speed estimates for various segments of travel (Table1) substantially higher than those normally observed for EGWs during their southbound migration (Herzing and Mate, 1989; Granite Canyon ref).

CONCLUSIONS AND DISCUSSIONS

The very liner movement of Flex so far from shore suggests good open water navigation skills not previously attributed to gray whales. ENP gray whales have been considered more coastal or shallow-water oriented. State-space modeling suggests the long-range movements of Flex across the Sea of Okhotsk, Bering Sea, and Gulf of Alaska are directed migration movements rather than “wanderings", usually indicative of foraging behavior. During the Bering Sea and North Pacific travel segments, the whale's average speeds were >6.5 km/h, 50% higher than average speeds observed for six 2009-tagged EGWs migrating south in 2010 (Mate, 2010).

Flex has previously visited the eastern North Pacific, confirmed by photo matching (Weller et al., IWC/SC63/BRG6) and two other WGWs have been genetically matched to southern California (Lang et al., IWC/S63/BRG10). The results demonstrated by this whale do not preclude other migratory destinations for other WGWs or even this whale during other winters. The possibilities identified from the tagging, genetics, and the photo-ID papers suggest additional WGW taggings would be useful to identify other possible winter migratory routes and/or destinations. We took 13 tags to Russia in anticipation of tagging 12 whales in 2010. The remaining 12 tags are still in Russia. We suggest tagging 12 more WG whales to increase the total sample size to 10% of the estimated population. The use of a mother ship would help assure our ability to move more widely if necessary to find adequate candidate whales for tagging. An improved tagging boat would increase the probability of success. An earlier tagging season would avoid seasonally predictable bad weather. Being able to tag both males and females would dramatically improve the probability of successfully deploying additional tags and develop information about possible sexual differences in: winter migratory routes; foraging area departure timings; reproductive destinations; wintering area arrival timings; the amount of time spent in wintering areas; turnover rates in wintering areas, and spring migration re-entry routes and timing back into the summer feeding areas. All of these issues might identify areas or specific anthropogenic activities that could be risks to WGWs, as well as mitigation possibilities.

ACKNOWLEDGEMENTS

This research was conducted under a permit issued to V. Rozhnov, Deputy Director of the A.N. Severtsov Institute of Ecology and Evolution of the Russian Academy of Sciences and funded via an IWC contract with support from Exxon Neftgas Limited, Sakhalin Energy Investment Company, and IUCN. We thank assistants C. Hayslip, L. Irvine, Y. Poltev, and the crew of the Maximov for their preparations and field work; O. Tyurneva for photo analyses; and Tomas Follett for data archiving and graphics preparations.

ABOUT THIS DOCUMENT

The mission of the National Oceanic and Atmospheric Administration (NOAA) is to understand and predict changes in the Earth's environment and to conserve and manage coastal and oceanic marine resources and habitats to help meet our Nation's economic, social, and environmental needs. As a branch of NOAA, the National Marine Fisheries Service (NMFS) conducts or sponsors research and monitoring programs to improve the scientific basis for conservation and management decisions. NMFS strives to make information about the purpose, methods, and results of its scientific studies widely available. NMFS Southwest Fisheries Science Center uses the **NOAA Technical Memorandum NMFS** series to achieve timely dissemination of scientific and technical information that is of high quality but inappropriate for publication in the formal peer-reviewed literature. The contents are of broad scope, including technical workshop proceedings, large data compilations, status reports and reviews, lengthy scientific or statistical monographs, and more. NOAA Technical Memoranda published by the Southwest Fisheries Science Center although informal, are subjected to extensive review and editing and reflect sound professional work. Accordingly, they may be referenced in the formal scientific and technical literature.

A **NOAA Technical Memorandum NMFS** issued by the Southwest Fisheries Science Center may be cited in following manner:

ACKNOWLEDGEMENTS

We are grateful to the Alaska Fisheries Science Center, Cascadia Research Collective, International Whaling Commission, National Marine Mammal Laboratory, NOAA Northwest Regional Office, Southwest Fisheries Science Center for their contributions and support of this work. We thank Jeff Laake for providing data and significant insight and advice on how to approach the analysis. We also extend our appreciation to John Brandon, Bob Brownell, John Calambokidis, Greg Donovan, Aimee Lang, Andre Punt and Jon Scordino for their input.

EXECUTIVE SUMMARY

Recent observations of gray whales (*Eschrichtius robustus*) identified in the western North Pacific (WNP) migrating to areas off the coast of North America (Alaska to Mexico) raise concern about the possibility of the small western population being subjected to the gray whale hunt proposed by the Makah Indian Tribe in northern Washington, USA. To address this concern, we estimated the probability of striking (i.e. killing or seriously injuring) a WNP whale during the Makah hunt using six models from 4 model sets that varied based on the assumptions and types of data used for estimation. Model set 1 used WNP and ENP abundance estimates. Model set 2 used these abundance estimates, as well as sightings data from the proposed hunt area. Model sets 3 and 4 used only the sightings data. Within model sets 1 and 2, two models (A and B) differed based upon whether migrating ENP and WNP whales were assumed to be equally available to the hunt per capita (A) or whether this assumption is relaxed (B). We consider Model 2B the most plausible of all models because model set 2 makes use of all available information and 2B contains fewer assumptions than 2A. Based on model 2B, the probability of striking ≥1 WNP whale in a single season ranges from 0.007 to 0.036, depending on if the median or upper 95th percentile estimate is used and on which maximum is used for the total number of whales struck. The probability of striking ≥1 WNP whale out of 5 seasons ranges from 0.036 to 0.170 across the same scenarios. The expected number to be struck in a single year ranges from 0.01 to 0.04 and from 0.04 to 0.19 across 5 years. For context, these strike estimates were compared to different possible values of Potential Biological Removal (PBR). We also summarized analogous estimates for the number of WNP whales that would be "taken" non-lethally, in terms of the number of attempted but unsuccessful strikes as well as the number of animals approached and pursued during the hunt.

INTRODUCTION

Gray whales (*Eschrichtius robustus*) are recognized as comprising two populations in the North Pacific Ocean. Significant mitochondrial and nuclear genetic differences have been found between whales in the western North Pacific (WNP) and those in the eastern North Pacific (ENP) (Lang *et al*., 2011). The ENP population ranges from wintering areas in Baja California, Mexico, to feeding areas in the Bering, Beaufort, and Chukchi Seas (Fig. 1). An exception to this generality is the relatively small number (100s) of whales that summer and feed along the Pacific coast between Kodiak Island, Alaska, and northern California (Calambokidis *et al*. 2012). These whales are collectively called the Pacific Coast Feeding Group (PCFG). U.S. domestic policy defines the PCFG as gray whales observed between 1 June and 30 November from Northern California through Northern British Columbia. The International Whaling Commission (IWC) has refined this definition to be: PCFG whales are those observed between 1 June and 30 November from 41°N to 52°N in two or more years (IWC, 2012). The WNP population feeds in the Okhotsk Sea off Sakhalin Island, Russia (Weller *et al*., 1999; Weller *et al*. 2012), and in nearshore waters of the southwestern Bering Sea off the southeastern Kamchatka Peninsula (Tyurneva *et al*., 2010).

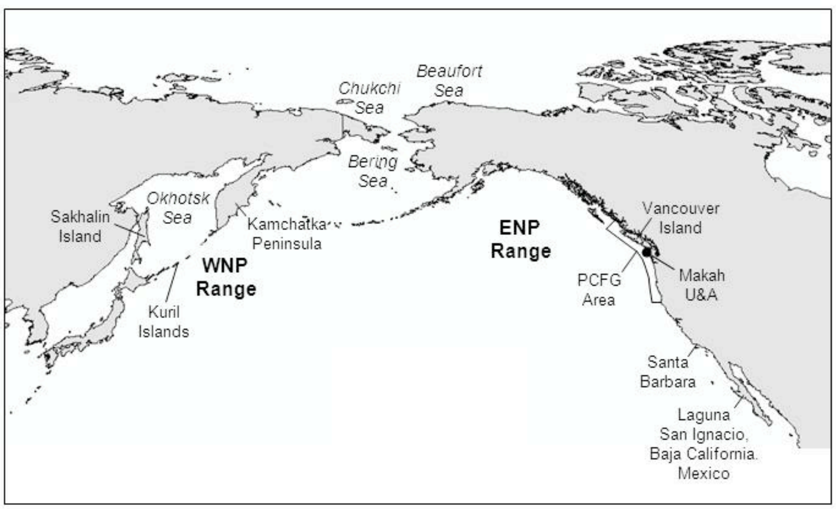

Figure 1. Areas in the western and eastern North Pacific mentioned in the report.

The historical distribution of gray whales in the Okhotsk Sea greatly exceeded what is found today (Reeves *et al*., 2008). Whales associated with the Sakhalin feeding area can be absent for all or part of a given feeding season (Bradford *et al*., 2008), indicating they use other areas during the summer and fall feeding period. Some of the whales identified feeding in the coastal waters off Sakhalin, including reproductive females and calves, have also been documented off the southern and eastern coast of Kamchatka (Tyurneva *et al*., 2010). Whales observed off Sakhalin have also been sighted off the northern Kuril Islands in the eastern Okhotsk Sea and Bering Island in the western Bering Sea (Weller *et al*., 2003).

Recently, mixing of whales identified in the WNP and ENP has been observed (Weller *et al*., 2012). Lang (2010) reported that two adult individuals from the WNP, sampled off Sakhalin in 1998 and 2004, matched the microsatellite genotypes, mtDNA haplotypes, and sexes (one male, one female) of two whales sampled off Santa Barbara, California in March 1995. Mate and colleagues (Mate *et al*., 2011) satellite-tracked three whales from the WNP to the ENP (Mate *et al*., 2011; IWC, 2012). Finally, photographic matches between the WNP and ENP, including resightings between Sakhalin and Vancouver Island and Laguna San Ignacio, have further confirmed use of areas in the ENP by whales identified in the WNP (Weller *et al*., 2012, Urbán *et al*., 2012). Despite this level of mixing, significant mtDNA and nuclear genetic differences between whales in the WNP and ENP have been found (Lang *et al*., 2011).

Observations of gray whales identified in the WNP migrating to areas off the coast of North America (Alaska to Mexico) raise concern about placing the WNP population at potential risk of being harmed or killed incidental to the ENP gray whale hunt proposed by the Makah Indian Tribe off northern Washington, USA (IWC, 2012). Given the ongoing concern about conservation of the WNP population, in 2011 the Scientific Committee of the International Whaling Commission (IWC) emphasized the need to estimate the probability of a western gray whale being killed during aboriginal gray whale hunts (IWC, 2012). Additionally, NOAA is required to prepare an Environmental Impact Statement (EIS) pertaining to the Makah's request for a waiver under the U.S. Marine Mammal Protection Act (MMPA) in order to hunt gray whales (NOAA, 2008). The EIS will include an estimate of the likelihood of Makah hunters approaching, pursuing, and attempting to strike a WNP whale in addition to the likelihood of actual strikes (assumed to result in death or serious injury).

The objective of this analysis was therefore to estimate the probability that one or more whales identified in the WNP might be lethally or non-lethally "taken[1]" during the hunt proposed by the Makah Indian Tribe. This report updates the analysis of mortality risk provided by Moore and Weller (2012), by incorporating feedback from the IWC Scientific Committee on that report and by including an analysis of the likelihood of non-lethal as well as lethal take.

METHODS

The probability of striking or taking a WNP whale during the proposed Makah hunt was estimated using four different sets of models (6 models total). Models were based on the following information: (1) the most recent estimates of WNP and ENP population abundance; (2) sightings data from spring 1999-2010 off the coast of northern Washington (NWA) in the Makah Usual and Accustomed (MUA) fishing grounds, where the proposed hunt would take place; and (3) minimum estimates of the proportion of the WNP population that migrate to ENP areas along the North American coast.

Data

Abundance estimates

The most recent WNP abundance estimate (for 2012) is 155, with 95% CI = 142 – 165 (IUCN, 2012). The most recent ENP estimate (for 2007) is 19,126, with CV = 0.071 (Laake *et al*., 2009). In the models, these estimates were expressed as log-normally distributed random variables with parameters $\mu_{WNP} = 5.043$, $\sigma_{WNP} = 0.0387$, and $\mu_{ENP} = 9.856$, $\sigma_{ENP} = 0.0709$.

[1] Under the U.S. Marine Mammal Protection Act, "take" is defined as "harass, hunt, capture, kill or collect, or attempt to harass, hunt, capture, kill or collect."

Sightings in the Makah Usual and Accustomed (MUA) Fishing Grounds
During spring surveys (1 March to 31 May) in 1999-2009, there were 118 "whale-days" in the MUA off the NWA coast (Calambokidis *et al*., 2012), where all sightings of an individual on a particular day collectively count as 1 "whale-day" (e.g., multiple sightings of the same individual on the same day count as just 1 whale-day, but the same individual seen the next day would count as a second whale-day). There were 9 gray whale sightings in March. All other sightings were in April or May. None of the 118 whale-days observed included WNP whales[2]; 35 (29.7%) were considered "Pacific Coast Feeding Group" (PCFG) whales; and the rest (83, or 70.3%) were assumed to be migrating ENP whales. The photo-identification catalog for whales identified in the WNP off Sakhalin Island is characterized by extremely high (> 95%) resighting rates since 2002 (Burdin *et al*., 2012). Therefore, we assumed in this analysis that the absence of WNP sightings is not likely due to false negative identification (although it is possible that WNP whales were missed during days when MUA surveys were or were not conducted).

Proportion of WNP whales migrating with ENP whales
The proportion of the WNP population that migrates along the North American coast is unknown but based on recent photo-identification, telemetry, and genetic matches of WNP whales to ENP areas, we estimate the value to be at least 0.15, based on there being 23 known matches out of an estimated population size of 155 (Mate *et al*., 2011; IWC, 2012; Urbán *et al*., 2012; Weller *et al*. 2012).

Models
Model set 1
Model set 1 makes use of the ENP and WNP abundance estimates but ignores information obtained from sightings in the MUA off the NWA coast. The potential justification for ignoring the sightings data is that these may not be representative of the whale compositions that would be encountered by hunters, perhaps because of a timing mismatch (if hunt does not occur in April/May) or if whales approached by field researchers in motorized boats behave fundamentally differently than those approached by hunters in non-motorized boats.

Model 1A - All whales migrating through the MUA area -- WNP and ENP -- are assumed to be equally available to the hunt, so that the probability of taking a WNP whale is:

$$P_{WNP} = mN_{WNP}/N_{ENP}$$
$$m \sim \text{uniform}(0.15, 1)$$
$$N_{WNP} \sim \text{log-normal}(\mu_{WNP}, \sigma_{WNP})$$
$$N_{ENP} \sim \text{log-normal}(\mu_{ENP}, \sigma_{ENP}),$$

where m is the proportion of WNP whales that migrate with ENP whales along the North American coast and abundance parameters are as above (see Data section). The lower limit for m, 0.15, is based on genetic and photo-identification matching data (see Data section). The upper limit of 1 for m is precautionary, as the true value is unknown but could be high. We used Monte Carlo simulation based on drawing 100,000 random samples from the above distributions to estimate the distribution for P_{WNP}.

Model 1B – Rather than assuming P_{WNP} to be directly proportional to the ratio of abundances (N_{WNP}/N_{ENP}), we express our uncertainty in P_{WNP} as a uniform distribution with the upper limit

[2] Although not in the MUA, Weller *et al*. 2012 report observing three WNP whales on 2 May 2004 and three more on 25 April 2008 near Barkley Sound off the west coast of southern Vancouver Island, British Columbia, Canada.

for P_{WNP} based on the maximum (99^{th} percentile) estimate for the number of WNP whales available to the hunt divided by a minimum (1^{st} percentile) estimate for the ENP population, i.e.,

$$P_{WNP} \sim \text{uniform}(0, P_{max})$$
$$P_{max} = m \cdot N_{99,WNP}/N_{01,ENP}.$$

The interpretation of this model is that, within some plausible upper bound (defined as P_{max}), we have no information about the per capita probability of taking a WNP whale, given unknown differences in migration patterns between WNP and ENP animals. Just as for Model 1A, we use a Monte Carlo approach (100,000 samples) to estimate a distribution for P_{WNP}. For each sample, P_{WNP} is drawn from the uniform distribution specified by P_{max}. P_{max} varies with each sample based on the draw for m, while the ratio $N_{99,WNP}/N_{01,ENP}$ is fixed. Analysis for Model set 1 was conducted in R.

Model set 2

Model sets 2, 3, and 4 differ from Model set 1 in that they use the information from the sightings data in the MUA. In these models, it is assumed that the sightings data from the MUA are representative of the composition of whales (three groups: ENP, WNP, PCFG) that would be available to the hunt. In other words, whales that are most likely to be photographed (i.e., approachable in a small boat) are also the most likely to be approached by hunters.

Model set 2 makes use of the MUA sightings data, as well as WNP and ENP abundance estimates. WNP whales are assumed to be moving with the ENP migrants, so that the marginal probability of a WNP whale being taken is the probability of being a migrant, P_{mig} (i.e., probability of not being a whale from the PCFG), multiplied by the conditional probability of being a WNP whale given that it is a migrant ($P_{WNP|mig}$), i.e., $P_{WNP} = P_{mig}P_{WNP|mig}$. P_{mig} is estimated using Bayesian MCMC methods assuming that $n_{mig} \sim$ Binomial (N, P_{mig}), where n_{mig} is the number of non-PCFG migrants (83) out of N (118) sightings in the MUA sightings data set. Models 2A and 2B differ in how the conditional probability $P_{WNP|mig}$ is estimated.

<u>Model 2A</u> - The distribution for $P_{WNP|mig}$ is given by the estimator for P_{WNP} in Model 1A. Thus, it is assumed the per capita probabilities of an ENP or WNP whale being taken are the same.

<u>Model 2B</u> - The distribution for $P_{WNP|mig}$ is given by the estimator for P_{WNP} in 1B. Thus, this model asserts that we have no information (apart from specifying a reasonable upper bound) about the per capita likelihood of a WNP whale being killed relative to that of an ENP whale.

Model 3

This uses the MUA sightings data but does not make use of information about WNP population size or the proportion of WNP whales that migrate with ENP whales. Thus, P_{WNP} estimates are solely based on the proportion of animals in the MUA sightings data set that are from the WNP. The posterior distribution for P_{WNP} is estimated using MCMC methods assuming that $n_{WNP} \sim$ Binomial (N, P_{WNP}), where $n_{WNP} = 0$, and N = 118. The justification for this model (i.e., for ignoring information about WNP abundance) would be that the relative per capita probability of taking WNP vs. ENP animals is totally unknown apart from the information contained in the sightings data set. For example, WNP whales could be much more (or less) available to the hunt than ENP whales due to differences in migration timing or behavior, such that our knowledge about the WNP population being very small is irrelevant to the estimates.

Model 4
Model 4 is a variant of Model 3, explained below.

Bayesian estimation
Analyses for Models 2, 3, and 4 were conducted in WinBUGS. Posterior distributions for parameters were summarized from two MCMC chains, each 50,000 samples in length (100,000 samples total) following a burn-in of 20,000 samples. These simple models converged quickly and clearly (chains well mixed) in all cases (Fig. 2). A uniform [0, 1] prior was used for P_{mig} in model set 2 and for P_{WNP} in model 3 and 4; these are the only parameters for which the prior is updated by data (the MUA sightings data) to obtain a new posterior. The posterior distributions for $P_{WNP|mig}$ in Models 2A and 2B were not informed by the sightings data and thus are essentially determined by informative priors given by the above estimators for these parameters.

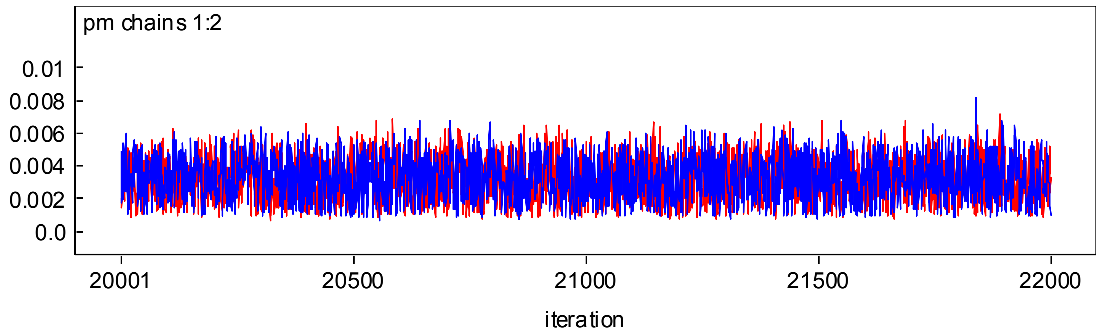

Figure. 2. Example from Model 2A of two MCMC chains (red and blue) mixing for the parameter P_{WNP}.

Estimated parameters
Based on estimates of P_{WNP} for each model, we calculated the probability of striking at least one WNP whale (i.e., P(x>0)) out of X total strikes (strikes are treated as lethal takes), the probability of non-lethally taking at least one WNP whale out of Y strike attempts (P(y>0)), or the probability of non-lethally taking at least one WNP whale out of Z approaches (P(z>0)). We also estimated the expected number of WNP takes out of X, Y or Z total takes. These are calculated as follows:

$$P(x > 0) = 1 - (1 - P_{WNP})^X$$
$$P(y > 0) = 1 - (1 - P_{WNP})^Y$$
$$P(z > 0) = 1 - (1 - P_{WNP})^Z$$
$$E(x) = P_{WNP}X$$
$$E(y) = P_{WNP}Y$$
$$E(z) = P_{WNP}Z$$

For model sets 1, 2, and 3, let X = X* = 5, 7, 20, and 35 gray whale strikes. These were based on the description of the Makah Tribe's proposed gray whale hunt (IWC, 2012 Annex D), which states the following: 5 is the maximum allowable number of landed whales per year; 7 is the maximum number of struck whales allowed per year; 20 is the maximum number allowed to be landed over a 5-year period; and 35 is the maximum number that could be struck over a 5-year period.

For model sets 1, 2, and 4, let X = X** = 3 or 4 strikes in one year and 15 or 20 strikes in 5 years of *non-PCFG whales*. The justification for considering this scenario is that, given other management measures within the Makah plan – most importantly the provision to cease the annual hunt if a certain number of PCFG whales are struck – it may be unlikely that the maximum strike limits in the proposal will be achieved. Implementation trials conducted by the Aboriginal Whaling Management Procedure (AWMP) subgroup of the IWC scientific committee suggest that, when management measures are considered, the expected number of strikes per year *to non-PCFG whales* would typically be between 3 and 4 (J. Scordino, pers. comm.).

For Model set 1, estimates for when X = X** are calculated the same as for when X = X*. For Model set 2, since it is given that X** are for *non-PCFG* whales (i.e., migrant whales), then it follows that P_{mig} = 1, so the model 2 estimators for P_{WNP} reduce from $P_{mig}P_{WNP|mig}$ to just $P_{WNP|mig}$, which are the same estimators as for Model set 1. When X = X**, we use Model 4 as a variant of Model 3 (which is for X = X*). In Model 3, n_{WNP} ~ Binomial (N_{tot}, P_{WNP}), where n_{WNP} = 0, and N_{tot} = 118 total whale-day sightings, 35 of which were PCFG whales and 83 of which were migrating ENP whales. In Model 4, n_{WNP} ~ Binomial (N_{mig}, $P_{WNP|mig}$), where N_{mig} = 83 whale-day sightings of non-PCFG migrant whales (i.e., we are only evaluating conditional probability of being a WNP whale given being migrant whale.

Values of Y for each model were calculated as 4X, and values for Z were calculated as 20X. In other words, for every struck whale, there are an estimated 4 strike attempts and 20 whales approached in attempt to strike. These numbers are based on the Makah tribe's experience in the 1999 and 2000 hunts, for which they stated that for every struck whale, there would be approximately 4 attempted strikes and 10 individuals pursued, which are assumed to affect 20 whales, given an average pod size of two whales (NOAA, 2008).

Comparison to Potential Biological Removal (PBR)
To contextualize the Table 1 estimates of lethal takes, we provide 5-year estimates of PBR[3]) for comparison. PBR is conventionally calculated as $0.5R_{max}N_{min}F_R$, where R_{max} is the maximum productivity rate estimate for the population (we used 0.062 based on the 2012 Draft Stock Assessment Report; NMFS, 2012), N_{min} is the 20th percentile abundance estimate (we used 150 based on WNP abundance parameters), and F_R is a recovery factor. We provide PBR estimates for F_R = 0.1, 0.5, and 1.0. F_R = 0.1 is typically used for stocks of endangered species, noting that the WNP gray whale stock is listed as Endangered under the U.S. Endangered Species Act and Critically Endangered on the IUCN Red List. F_R = 0.5 is a recommended default for most stocks (NMFS 2005), whereas F_R = 1.0 may be appropriate for stocks with known and favorable population status. The PBR estimate is also supposed to take into the account (be discounted by) the proportion of the stock using US waters and the proportion of time it is there (NMFS, 2005). The proportion of the WNP migrating in the ENP range is unknown but characterized in our models by a uniform (0.15, 1) distribution. The proportion of time spent in US waters is difficult to estimate for migratory animals but is probably on the order of 3 months or 0.25 years. Thus, for each value of F_R, we calculated a distribution for the 5-year PBR estimate, by multiplying the standard equation by 0.25 and by a uniform (0.15, 1) distribution.

[3] Under the U.S. Marine Mammal Protection Act, PBR level is defined as "the maximum number of animals, not including natural mortalities, that may be removed from a marine mammal stock while allowing that stock to reach or maintain its optimum sustainable population."

a b

RESULTS

Take estimates

Estimated parameters from all model sets are in Tables 1 – 3. Table 1 presents estimates for the probability of striking a WNP whale during a single strike event (P_{WNP}), and of striking at least one WNP whale (P(x>0)) and the expected number of WNP whales (E(x)) that would be struck given X = X* (number of gray whales struck) or X** (number of *non-PCFG* whales struck). Table 2 presents the analogous estimates for the number of attempted strikes (Y = Y* or Y**), and Table 3 presents the analogous estimates for the number of whales approached (Z = Z* or Z**). We present median estimates and, for precautionary purposes, 95th percentile estimates from the Monte Carlo or Bayesian posterior distributions.

For X = X*, Y = Y*, and Z = Z* (i.e., out of the total number of events affecting gray whales, irrespective of the putative stock affected), parameter estimates were higher for Model set 1 than Model set 2. Within these models sets, median parameter estimates were higher for version A than B, although upper (95th percentile) estimates were similar. Estimates for Model 3 were higher than for the other models, particularly when looking at upper bound (95th percentile) estimates, because of the highly skewed and unconstrained posterior for P_{WNP} (Fig. 3).

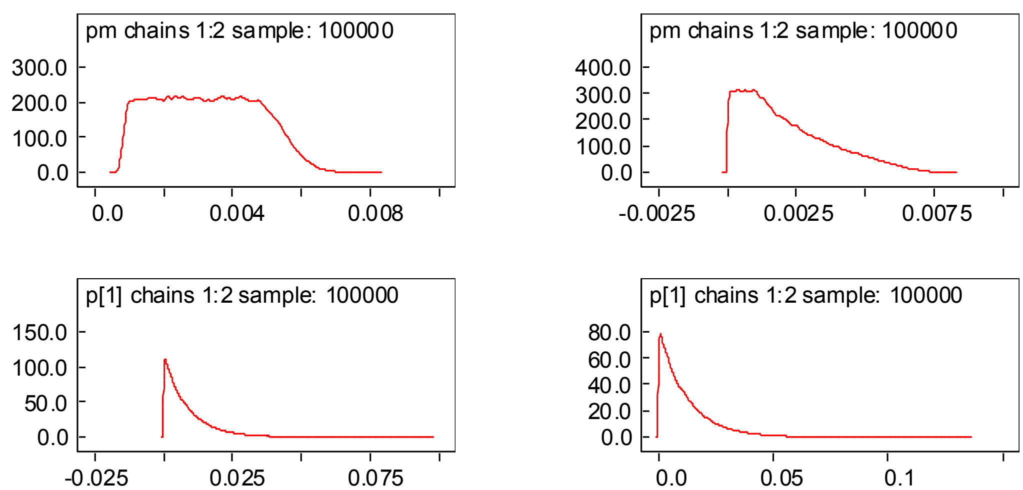

Figure 3. Comparison of Bayesian posterior distributions for P_{WNP} for Models 2A (a), 2B (b), 3 (c), and 4 (d).

For X = X**, Y = Y**, Z = Z** (i.e., out of the total number of events affecting *non-PCFG* whales), model set 1 and model set 2 results are the same (because the estimators are the same), but median estimates were higher for version A than B in these model sets (although 95th percentile estimates were similar). Estimates for Model 4 were higher than for the other models.

In Tables 1 – 3, we highlight (bold) estimates from Model 2B because Model set 2 makes the greatest use of available information (i.e., uses all datasets), and model 2B is based on fewer assumptions than 2A, and thus we favor Model 2B estimates as the most plausible (see Discussion). Estimates from this model for the proposed 5-year hunt period are as follows. The median (and 95th percentile) probability of striking a WNP whale within the 5-year permit period ranged from 0.036 (0.107) to 0.058 (0.170) as X increased from 15 *non-PCFG* whales to 35 whales of any putative stock, and the expected number of whales that would be struck ranged from 0.04 (0.11) to 0.06 (0.19). The probability of an attempted strike on a WNP whale ranged from 0.136 (0.365) to 0.212 (0.524), and the expected number of attempts on WNP whales ranged from 0.15 (0.45) to 0.24 (0.74). Finally, the probability that a WNP whale would be pursued or approached by a hunter ranged from 0.519 (0.897) to 0.697 (0.976), and the expected number of WNP whales that would be approached ranged from 0.73 (2.26) to 1.19 (3.70).

In summary, we estimate based on Model 2B a fairly high probability that at least one WNP would be taken in the broadest sense of being pursued or approached by Makah hunters (i.e., $P(z>0) = 0.52 – 0.98$, depending on Z and whether the median or upper estimate is used). The probability of an attempted strike on least one WNP whale in 5 years was relatively moderate (i.e., $P(y>0) = 0.14 – 0.52$). The probability of actually striking at least one WNP whale during the 5-year period was relatively low but non-trivial (i.e., $P(z>0) = 0.04 – 0.17$).

Table 1. Summary statistics for six models from four model sets. P_{WNP} is probability of taking (striking) a WNP whale during a given take event. $P(x>0)_X$ are probabilities of striking at least 1 WNP whale out of X events. $E(x)_X$ is the expected number of struck WNP whales out of X total events. X=X** indicates that events are known to affect *non-PCFG* whales (otherwise X = X*, the number of events to gray whales in general). Cell entries are median and upper (95th percentile) probabilities.

Table 3. Summary statistics for six models from four model sets. P_{WNP} is probability of taking (approaching) a WNP whale during a given take event. $P(z>0)_Z$ are probabilities of approaching at least 1 WNP whale out of Z events. $E(z)_Z$ is the expected number of approached WNP whales out of Z total events. Z=Z** indicates that events are known to affect *non-PCFG* whales (otherwise Z = Z*, the number of events to gray whales in general). Cell entries are median and upper (95th percentile) probabilities.

Comparison to PBR

Table 4 provides 5-year estimates of PBR based on F_R = 0.1, 0.5, and 1.0. Uncertainty in the estimates (e.g., 95% CI) reflects uncertainty in the proportion of the WNP stock that migrates with the ENP stock. For F_R = 0.1, striking one WNP whale in the 5-year period would exceed PBR. For F_R = 0.5, one WNP strike could exceed PBR, depending on how many WNP individuals migrate with the ENP stock. Fewer WNP whales in U.S. waters would mean higher chance that one strike would exceed PBR, but it would also translate into lower probability of there being a WNP strike in the first place (i.e., lower than reflected in the Table 1 estimates). For F_R = 1, striking one WNP whale in the 5-year period would not exceed PBR.

Table 4. Estimates of PBR (5-year total) for the WNP gray whale stock under three different values of F_R. Uncertainty in the estimates reflects uncertainty in the proportion of the WNP that uses U.S. waters; the lower estimate corresponds to a little more than 0.15 of the WNP stock migrating in ENP areas, whereas the upper estimate corresponds to nearly all WNP animals migrating in ENP areas.

	F_R = 0.1	F_R = 0.5	F_R = 1.0
2.5%	0.10	0.50	0.99
median	0.33	1.67	3.35
97.5%	0.57	2.85	5.69

DISCUSSION

In general, we consider Model set 2 the most plausible of the model sets used, because it makes use of information from sightings in the MUA from the NWA coast area as well as relative abundance of the WNP vs. ENP. In contrast, Model set 1 ignores the MUA sightings information, and Models 3 and 4 ignore our knowledge of the WNP being small relative to the ENP. We also feel that, within Model sets 1 and 2, the B-versions of each model are more appropriate than A-versions, because the B models make fewer assumptions. The B models assume no prior knowledge about $P_{WNP|mig}$, except to specify a reasonable upper bound, whereas the A models assume that WNP and ENP migrants are equally available to the hunt on a per capita basis. Therefore, Models 2A and 2B, but especially 2B, may be considered the most useful estimates.

Models 3 and 4 are probably the least justifiable, since by ignoring information about the WNP population size they allow for upper parameter estimates that are likely implausible. For example, if we assume that WNP and ENP animals are equally available to the hunt and there are 16,000-22,000 ENP animals, then the upper estimate for Model 4 of P_{WNP} = 0.035 corresponds to a WNP population estimate of nearly 560-770 animals, which far exceeds existing estimates. Alternatively, WNP animals would need to be far more available to hunters on per capita basis than ENP animals for behavioral reasons, and there is no reason presently to expect this is the case.

Estimates from our analysis are considered precautionary since they assume that the Makah will achieve their proposed maximum strike limits. That being said, the results herein offer a conservative initial step in assessing the potential risk of WNP gray whales incurring mortality incidental to the proposed hunt on the ENP population by the Makah Indian Tribe.

About the NOAA Technical Memorandum series

The National Oceanic and Atmospheric Administration (NOAA), organized in 1970, has evolved into an agency which establishes national policies and manages and conserves our oceanic, coastal, and atmospheric resources. An organizational element within NOAA, the Office of Fisheries is responsible for fisheries policy and the direction of the National Marine Fisheries Service (NMFS).

In addition to its formal publications, the NMFS uses the NOAA Technical Memorandum series to issue informal scientific and technical publications when complete formal review and editorial processing are not appropriate or feasible. Documents within this series, however, reflect sound professional work and may be referenced in the formal scientific and technical literature.

SWFSC Technical Memorandums are available online at the following websites:

SWFSC: https://swfsc.noaa.gov

NOAA Repository: https://repository.library.noaa.gov/

NTIS National Technical Reports Library: https://ntrl.ntis.gov/NTRL/

Accessibility information

NOAA Fisheries Southwest Fisheries Science Center (SWFSC) is committed to making our publications and supporting electronic documents accessible to individuals of all abilities. The complexity of some of SWFSC's publications, information, data, and products may make access difficult for some. If you encounter material in this document that you cannot access or use, please contact us so that we may assist you.

ACKNOWLEDGEMENTS

We extend our gratitude to the NOAA Fisheries West Coast Regional Office and Southwest Fisheries Science Center for their contributions to, and support of, this work.

EXECUTIVE SUMMARY

Observations of gray whales (*Eschrichtius robustus*) from the western North Pacific (WNP) migrating to areas off the coast of North America (Alaska to Mexico) raised concerns that this small population could be encountered during a hunt of eastern North Pacific (ENP) gray whales proposed by the Makah Indian Tribe in northern Washington, USA. In 2013, an analysis was conducted to estimate the probability of striking (i.e. killing or seriously injuring) a WNP whale under the Makah Tribe's hunt proposal (Moore and Weller 2013). NOAA Fisheries is considering a draft proposal that would govern ENP gray whale hunts by the Makah for up to 10 years. Under the draft proposal, hunting seasons would alternate between winter-spring hunts in even-numbered years and summer hunts during odd-numbered years. It is presumed that only in even-numbered years (thus, for 5 of the 10 years) would WNP whales potentially be encountered during the hunt. In each of these years, the draft proposal would allow for up to 3 gray whales to be struck. Based on this alternative hunting scheme and the availability of updated gray whale data, this report re-estimates the probability of striking a WNP whale reported earlier (Moore and Weller 2013). One of the models from the 2013 analysis (Model 2A) was used to generate new estimates. We estimate that for an individual strike on a gray whale, the expected probability of it being a WNP whale is 0.004 (95% CRI: 0.002 – 0.007). For a single year's hunt (3 strikes), the expected probability of striking ≥1 WNP whale would be 0.012 (0.006 – 0.019). Across the 10-year hunt period (15 strikes), the probability of striking ≥1 WNP whale would be 0.058 (0.030 – 0.093).

INTRODUCTION

Two gray whale (*Eschrichtius robustus*) populations are recognized in the North Pacific Ocean. Significant mitochondrial and nuclear genetic differences have been found between whales in the western North Pacific (WNP) and those in the eastern North Pacific (ENP) (LeDuc *et al*., 2002, Lang *et al*. 2010, Lang *et al*., 2011). The ENP population ranges from wintering areas in Baja California, Mexico, to feeding areas in the Bering, Beaufort, and Chukchi Seas (Fig. 1). An exception to this generality is the relatively small number (100s) of whales that summer and feed along the Pacific coast between Kodiak Island, Alaska, and northern California (Weller *et al*., 2013). These whales are collectively called the Pacific Coast Feeding Group (PCFG). The International Whaling Commission (IWC) has defined PCFG whales as individuals observed between 1 June and 30 November from 41°N to 52°N in two or more years (IWC, 2012), and NOAA Fisheries has adopted this definition in recent assessments (Weller *et al.*, 2013). The usual and accustomed (U&A) fishing grounds of the Makah Indian Tribe are off the coast of northern Washington, USA, and overlap with a portion of the PCFG summering area (Fig. 1).

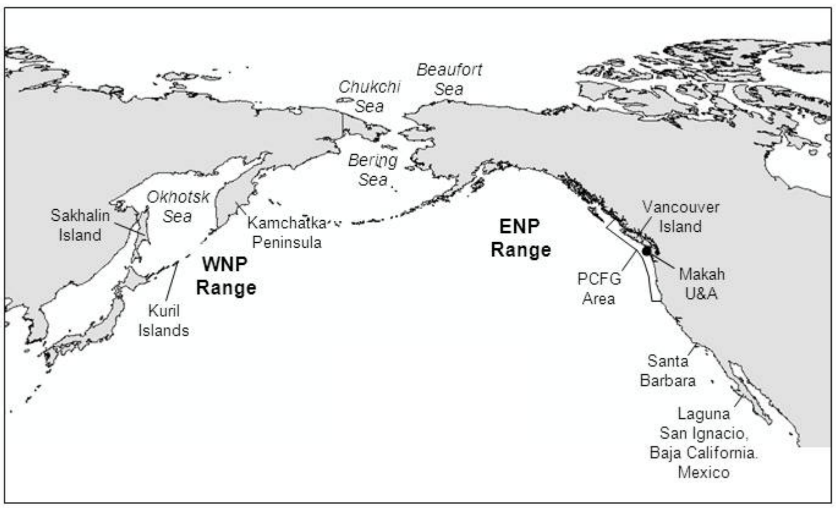

Figure 1. Areas in the western and eastern North Pacific mentioned in the report.

The WNP population feeds in the Okhotsk Sea off Sakhalin Island, Russia (Weller *et al*., 1999; Weller *et al*. 2012), and in nearshore waters of the southwestern Bering Sea off the southeastern Kamchatka Peninsula (Tyurneva *et al*., 2010). The historical distribution of gray whales in the Okhotsk Sea greatly exceeded what is found today (Reeves *et al*., 2008). Whales associated with the Sakhalin feeding area can be absent for all or part of a given feeding season (Bradford *et al*., 2008), indicating they use other areas during the summer and fall feeding period. Some of the whales identified feeding in the coastal waters off Sakhalin, including reproductive females and calves, have been documented off the southern and eastern coast of Kamchatka (Tyurneva *et al*., 2010). A small number of whales observed off Sakhalin have also been sighted off the northern Kuril Islands in the eastern Okhotsk Sea and Bering Island in the western Bering Sea (Weller *et al*., 2003).

Mixing of whales identified in the WNP and ENP has been observed (Weller *et al*., 2012). Lang (2010) reported that two adult individuals from the WNP, sampled off Sakhalin in 1998 and 2004, matched the microsatellite genotypes, mtDNA haplotypes, and sexes (one male, one female) of two whales sampled off Santa Barbara, California in March 1995. Between 2010 and 2012 three whales outfitted with satellite transmitters were tracked moving from Sakhalin in the WNP to the ENP (Mate *et al*., 2015). Finally, photographic matches between the WNP and ENP, including matches between Sakhalin, Vancouver Island and Laguna San Ignacio (Fig. 1), have further confirmed use of areas in the ENP by whales identified in the WNP (Weller *et al*., 2012, Urbán *et al*., 2012). Despite this level of mixing, significant mtDNA and nuclear genetic differences between whales in the WNP and ENP have been found (LeDuc *et al*. 2002, Lang *et al*., 2011).

In 1995, following the 1994 delisting of ENP gray whales under the U.S. Endangered Species Act, the Makah Indian Tribe notified NOAA Fisheries of its interest in re-establishing limited ceremonial and subsistence whale hunting. The decision-making history on this issue is complex and not described here except to note that in 2005, the Makah Tribe submitted a detailed proposal for hunting ENP gray whales in the coastal portion of its U&A off northern Washington, USA, as part of a request for a waiver of the U.S. Marine Mammal Protection Act's (MMPA) take moratorium (16 USC 1371(a)(3)(A)). Subsequently, observations of WNP gray whales migrating through areas off the coast of North America (Alaska to Mexico) emphasized the need to evaluate the probability of a WNP gray whale being encountered in aboriginal hunts for ENP gray whales (IWC, 2012). Following recommendations of the Scientific Committee of the International Whaling Commission (IWC), analyses were conducted to estimate such probability in the context of the Makah Tribe's hunt proposal (Moore and Weller, 2013). These analyses informed a draft Environmental Impact Statement (DEIS), completed in 2015 (NMFS, 2015), pertaining to the Makah Tribe's MMPA waiver request.

NOAA Fisheries is presently considering a MMPA waiver and associated draft proposal that would govern a modified version of the Tribe's hunt proposal. The objective of the analysis reported here was to provide updated estimates of the probability that one or more WNP whales might be subjected to strikes[1], unsuccessful strike attempts (i.e., harpoon throws that do not penetrate), and vessel approaches during hunts and hunt training exercises considered in the draft proposal. This report is based on the methods used by Moore and Weller (2013) and incorporates updated information about the population sizes of ENP and WNP gray whales and their occurrence within the proposed hunt area.

METHODS

Hunt proposal

NOAA Fisheries' draft proposal would govern a Makah Tribe hunt of ENP gray whales in the coastal portion of the U&A (i.e., the "hunt area") over a 10-year hunt period. In odd-numbered years, the hunt would take place from 1 July through 31 October, a period when no sightings of WNP whales have been recorded in the ENP, and when gray whales generally (apart from PCFG

[1] As described in NOAA Fisheries' DEIS (NMFS, 2015), the term "strike" is interpreted to be consistent with the IWC Schedule definition as meaning "to penetrate with a weapon used for whaling."

animals) are in northern feeding areas. Thus, hunted animals in these odd-numbered years would presumably belong to the PCFG and it is assumed that WNP whales would not be at risk from proposed hunt operations. In even-numbered years, the hunt would take place from 1 December through 31 May. This period coincides with both the southward (December to mid-February) and northward (mid-February to late May) migration of ENP whales and overlaps with the time when WNP gray whales have been sighted in the ENP. Thus, in even-numbered years there is a potential risk to WNP whales from proposed hunt operations. In each of the even-numbered years, a maximum of 3 gray whales per year could be struck (including "struck and lost" animals). Over the 10-year period of the proposed hunt, a maximum of 15 whales could be struck (in even-numbered years) that would have some probability of being WNP whales. We therefore evaluate the probability of striking at least one WNP whale per even-numbered year (out of 3 strikes) and for the 10-year period (out of 15 strikes). We also evaluate associated rates of WNP whales being subjected to aforementioned "unsuccessful strike attempts" (i.e., harpoon throws that do not penetrate) and "approaches" (i.e., whales approached by vessels during hunts and hunt training exercises).

Data

Abundance estimates - The most recent ENP abundance estimate (for 2015/2016) is 26,960 (CV = 0.05) (Durban *et al.*, 2017). The most recent WNP abundance estimate (for 2015) is 200 (CV = 0.03) for the 1+ population (i.e., excluding calves) (Cooke 2018). We then multiplied the WNP estimate by 1.099 to account for calves. This multiplier is based on the ratio of the population size with and without calves in 2012 (IUCN, 2012).

Mixing proportions based on sightings in the Makah Hunt Area - During spring surveys (March to May) in 1996-2012 there were 181 observed whale-days in the Makah hunt area (Calambokidis *et al*., 2014). To clarify the term "whale-day" – all sightings of an individual on a particular day collectively count as 1 whale-day (e.g., multiple sightings of the same individual on the same day count as just 1 whale-day, but the same individual seen the next day would count as a second whale-day). None of the 181 whale-days observed included WNP whales[2]; 73 (40.3%) were considered PCFG whales; and the rest (108, or 59.7%) were assumed to be migrating ENP whales.

However, rather than use 40.3% as the expected PCFG proportion in the hunt area during an even-year hunt, we use 28% for this mixing proportion (i.e. 72% of animals encountered during an even-year hunt are likely to be non-PCFG animals). This value is based on analyses summarized in a 2018 IWC workshop (IWC, 2018).

Proportion of WNP whales migrating with ENP whales - The proportion of the WNP population that migrates along the North American coast is unknown but estimated to be at least 0.37 based on analysis by Cooke (2015) and reported to a 2015 IWC workshop on gray whale population structure (IWC, 2016).

[2] Although not in the Makah hunt area, Weller *et al.* (2012) report observing three WNP whales on 2 May 2004 and three more on 25 April 2008 near Barkley Sound off the west coast of southern Vancouver Island, British Columbia, Canada.
