The Committee noted that while the data available for breeding stocks D and E dominate updates of prior inputs for growth rate in the Bayesian assessment of these populations, this is not the case for breeding stocks A, B, C and G. Estimates of future trends for all four of these and of the current status for B, C and G are heavily dependent on extrapolation of growth rate information for stocks D and E through the use of a posterior distribution from the latter as a prior for the former. This process could be improved by the use of hierarchical meta-analysis for stocks B, C and D, but nevertheless that would be based on as few as two estimates for the growth rate parameter r from stock D and stock E if only other Southern Hemisphere humpback whale populations are taken into account. For this reason, the Committee cautions that estimates given above for stocks B, C and G should not be regarded as very reliable.

SC/57/O21 described a multi-species model based on feeding ground information (from IDCR/SOWER population estimates) for absolute abundance rather than the breeding stock-based estimates used in the models presented above. The model's results suggested that the population growth rate would slow sooner in the future than is suggested by the single species models. Details on the discussion of this paper are to be found in Annex G, item 3.3.3.

The Committee welcomed the presentation of these papers and **suggests** that further work be done to refine the input data for the models and the modelling framework.

10.3.1.5 ANTARCTIC HUMPBAC WHALE CATALOGUE

SC/57/SH7 summarises the progress of the Antarctic Humpback Whale Catalogue (AHWC). During the 2004/5 contract period, the AHWC catalogued 445 photo-identification images representing 315 individual humpback whales, including 50 previously known individuals. These submissions bring the total number of catalogued whales to 2,238. Matches made during the contract period to previously sighted individuals include resightings between the Antarctic Peninsula and Ecuador (7) and Colombia (1); between Ecuador and Colombia (2); between Chile and Ecuador (2); the first documented re-sighting of an individual between Brazil and the Scotia Sea (1); and between Eastern Australia and Antarctic Area V (1). Trans-equatorial migration is confirmed by some of these resightings. It was noted that the website has been revised in accordance with IWC policy, and users may now choose to search a public database or log in as a contributor. It was noted that the IDCR/SOWER cruise was one of the very few contributors of Antarctic photographs outside of the Antarctic Peninsula and the Committee **recommends** continued collection of photographs to establish ties between the feeding and breeding grounds.

The Committee stressed the important contribution the catalogue makes to its work and **recommends** that it be continued. Financial implications are discussed under Item 21.

10.3.2 Assessment of Southern Hemisphere blue whales

10.3.2.1 NEW INFORMATION

A number of papers on blue whales (*B. musculus*) were presented to the Committee. They included reports of projects on blue whales off Southern Chile, where there is increasing research on the species (SC/57/SH5, SC/57/SH14, SC/57/O19). The Committee welcomed the presentation of these papers and **recommends** that these studies be continued.

The Committee considered the report of the intersessional group to summarise the state of knowledge of Southern Hemisphere blue whales. This was in a similar format to the humpback whale summary table referred to under Item 10.3.1.1. It was noted that available information was limited and that continued submission of abundance, trend estimates and stock structure information was welcomed. A number of sources of further information were identified and these have been incorporated into the table. The Committee **recommends** that the work of the intersessional group continue to complete this table.

10.3.3 Work plan

The Committee **agrees** that completion of the Comprehensive Assessment of Southern Hemisphere humpback whales is a high priority and that it should proceed as described in Annex H, item 6.8. This will

include an intersessional Workshop that will be partly funded by the government of Australia (for details see Annex H, Appendix 7¹⁰) and will focus on:

- (1) advancing the Comprehensive Assessment of Southern Hemisphere humpback whales to near completion using the best available data; and
- (2) reviewing the abundance, population structure and status of Southern Hemisphere humpback whales breeding populations and their relationship to feeding grounds in the Southern Ocean.

This will facilitate the completion of the assessment by the end of the next annual meeting. The Committee **recommends** that the Workshop take place and thanked the Government of Australia for its offer. Financial implications are discussed under Item 21.

Completion of the Comprehensive Assessment also requires the finalisation of a final catch series for Southern Hemisphere humpback whales. The Committee **recommends** that this work be undertaken at an intersessional meeting in Cambridge.

The Committee **agrees** that the Comprehensive Assessment of blue whales should be initiated in 2006, as previously recommended (IWC, 2005g, p.244). In this regard, Branch will try to:

- (1) provide new abundance estimates from recent IDCR/SOWER cruises;
- (2) provide an updated catch series split by sub-species and area;
- (3) collate positional data from sighting, catch, acoustic sources, and satellite tags;
- (4) revise the assessment by Ichihara and Doi (1964) of pygmy blue whales; and
- (5) examine the feasibility of using IDCR/SOWER cruises to estimate the proportion of blue whales outside the Antarctic survey region.

Financial implications of the work plan are discussed under Item 21.

10.4 Other small stocks – bowhead, right and gray whales (see Annex F)

10.4.1 Small stocks of bowhead whales

SC/57/BRG11 described molecular genetic relationships among bowhead whales in eastern Canadian Arctic and West Greenlandic waters. The objective of the study was to investigate whether or not the Hudson Bay/Foxe Basin (HB-FB) bowhead whales are genetically distinct from the Baffin Bay/Davis Strait (BB-DS) animals. The ultimate goal will be to provide information for the management of the subsistence harvest of bowhead whales in the eastern Canadian Arctic. On the basis of the microsatellite analyses, Igloodik (HB-FB) samples were significantly differentiated from the Pangnirtung and Disko Bay (BB-DS) samples. Several mechanisms could have contributed to these results, including: geographic partitioning, age and reproductive status segregation, temporal segregation, selective mating strategies/success, or some combination of these factors. The subsequent discussion of SC/57/BRG11 on the relationship between bowhead whale stocks in the Arctic is given in Annex F (item 4.2.1).

SC/57/BRG8 described temporal changes of the genetic structure of the Spitsbergen stock of bowhead whales based on bones collected on raised beaches on Svalbard. The authors were unable to detect any temporal haplotype structure in the historical Svalbard population. In the future, they plan to extend the dataset with 200 additional samples from Svalbard and the Norwegian mainland. Rosenbaum indicated that a plan had been established to merge historical and current data sets from the eastern Canadian Arctic stocks with the data presented in SC/57/BRG8.

10.4.2 North Atlantic right whales

North Atlantic right whales are among the most endangered of all the large whales, with a remaining population of around 300 individuals. The population appears to be in decline, largely due to anthropogenic impacts such as ship collision and entanglement (IWC, 2002d). SC/57/BRG13 summarised recent research and management activities for this species. Reproductive rates have improved substantially in recent years and a total of 27 calves have already been identified in 2005. However, the status of this population continues to be a major concern in light of the high anthropogenic mortality. The Committee **repeats its previous recommendation** on this population (e.g. IWC, 2005c, p.32), i.e. that it is **a matter of absolute urgency** that every effort be made to reduce anthropogenic mortality in this population to zero. There were eight deaths in the past year, including six since November 2004. A precise cause could not be attributed in all cases, but four were known or suspected ship strikes and one was the result of entanglement. The USA has developed a strategy to address ship strikes through new operational measures for the shipping industry and education and outreach programmes.

Although calf counts have been high in recent years, survival rates have not been updated since the 2002 Workshop on right whale survival estimation (Clapham, 2002; IWC, 2003c, p.247). The Committee noted the importance of updated survival estimates and **recommends** that such an analysis be performed.

As noted in previous years, some North Atlantic right whales are only seen on their breeding ground, suggesting that some potential feeding areas remain unidentified.

SC/57/BRG7 described efforts to estimate the age of North Atlantic right whales based on allometric relationships visible in lateral photographs of their heads. Changes in the curvature of the rostrum and the height of the dome were the best predictors of age in the external anatomy of the head of right whales. The accuracy of age prediction decreased with age: it was maximal for calves and minimal for whales older than 8yrs. Mean coefficients of variation of repeated measurements ranged from 0.31 to 4.11%. The Committee commends the authors on this useful study and notes that now the technique has been developed on a group of known-age animals, it can potentially be applied to other right whale populations.

SC/57/BRG20 evaluated the results of Rastogi *et al.* (2004), which explored the impact that Basque whaling had on historical population sizes of North Atlantic right whales and bowhead whales. Both species had been severely hunted and, with the exception of one of the bowhead populations, neither has shown signs of recovery. The topic presented by Rastogi *et al.* (2004) was of considerable importance given that present management of North

¹⁰ Although the proposal was first presented to the Plenary session, it is included as an Appendix to the Annex at which it was first discussed.

Atlantic right whales is focused on recovery to estimated pre-exploitation population sizes. The Committee considered that SC/57/BRG20 illustrated a number of errors in the work ranging from study assumptions and study design to analysis and interpretation. It concluded that Rastogi *et al.* (2004) have drawn inappropriate conclusions about pre-exploitation and 16th century right whale populations based upon genetic data from a single individual right whale.

The Committee **agrees** that the results of Rastogi *et al.* (2004) should not be used to estimate pre-exploitation size, recovery targets and levels of pre-exploitation genetic diversity for North Atlantic right whales.

10.4.3 Southern Hemisphere right whales

SC/57/BRG2 presented updated estimates of demographic parameters for Southern right whales on the south coast of South Africa. Aerial counts of right whale cow-calf pairs between 1971 and 2003 indicate an annual instantaneous population increase rate of $0.069/\text{year}^{-1}$ over this period. Observed calving intervals ranged from two to 23 years, with a principal mode at three years. The model of Payne *et al.* (1990) produces an estimate for adult female survival rate of 0.990 with a 95% confidence interval of (0.983, 0.997). First year survival rate was estimated as 0.734 (0.518, 0.95). The current population is estimated as some 3,400 animals.

The Committee welcomed the results of this study, which illustrates the great value of long-term monitoring. As it has in previous years, it **recommends** that this extensive programme be continued.

SC/57/BRG12 reviewed published catch data and the sighting distribution of southern right whales in the eastern South Pacific, off the coasts of Chile and Peru. The primary goal was to address a gap in knowledge identified in the 1998 Workshop on the status of right whales (Best *et al.*, 2001). Historical winter catches were primarily near central Chile (30°S), between Coquimbo and Valparaíso. Feeding grounds have not been well established for this population.

SC/57/ProgRep Australia described inshore aerial surveys for southern right whales off southern Australia in the winter and spring of 2004. Two 'short' flights on the southern Western Australia coast and one 'long' flight along the coast into South Australia were performed. The latter was used for the yearly comparison of the 'Australian' population. The number recorded on the 'long' flight in 2004 was not as high as expected given the previous strength of that three-year cohort in 2001. Nevertheless, significant positive increase rates were obtained for 'all' animals and cow-calf pairs in that data series. For cow-calf pairs, the increase rate for the period 1993-2004 was 6.4% ($p=0.004$) and the 95% CI remained wide (1.71-11.23%). The Committee welcomed this report and **recommends** that this monitoring programme and other long-term monitoring programmes be continued.

SC/57/O5 reported southern right whale sightings during the 2004/05 JARPA survey in Area V. Three individuals were sighted in three groups.

10.4.4 Other small stocks of right whales

SC/57/O3 reported North Pacific right whale sightings during the 2004 JARPN II survey. Four individuals were sighted in two groups, southeast of the Kamchatka Peninsula.

10.4.5 Western North Pacific (WNP) stock of gray whales

SC/57/BRG23 summarised the distribution and abundance of western gray whales off the northeast coast of Sakhalin Island, Russia in 2004. Aerial, vessel and shore-based surveys were carried out by the Russian programme during summer and autumn. There was a higher inshore distribution of gray whales compared to 2003, with sightings in the 'offshore' area having declined from 12 to three animals in aerial surveys, and from 50 to nine animals in vessel-based surveys. In the near-shore Piltun feeding area, the number of sightings increased from 27 to 49 sightings (aerial), from 47 to 63 (vessel-based) and from 70 to 122 (shore-based). The cause of observed gray whale redistribution is unclear but was most likely a reflection of prey availability. The main feeding season lasted two months, from the third 10-day period of July through to the end of September.

SC/57/BRG25 summarised efforts to study benthic communities in the two primary feeding grounds off the northeastern Sakhalin coast. Although some previous preliminary data were available for the benthic fauna at Piltun, the 'offshore' area had not previously been studied. Whales feeding at Piltun were found mainly within a shallow-water benthos complex dominated by amphipods and isopods. Mobile, deposit-feeding amphipods were dominant and distinguished by their eurybiotic nature, short life cycle and high growth rates. The 'offshore' feeding area was characterised by the seston-feeder amphipod, *Ampelisca eschrichti*.

SC/57/BRG9 described Russian efforts to photo-identify western gray whales on the northeastern Sakhalin shelf, 2002-2004. Photo-identification studies were conducted from the vessel *Nevelskoy* in 2002-03 and *Oparin* in 2004. Over the three years, 121 individuals had been identified. There was an apparent increase in the number of large groups in 2004 relative to the previous year.

SC/57/BRG1 presented the 2004 results of the on-going Russia-USA research programme on the western gray whale population summering off northeastern Sakhalin Island. A total of 92 whales (including seven calves and two previously unidentified non-calves) were identified from photographs leading to a 1994-2004 catalogue of 140 photo-identified individuals. Between 1995 and 2004, 23 known reproductive females had been documented. However, over the course of this study six calves had already been weaned by the time they were first encountered. Therefore, if all six of these 'independent' calves had mothers other than the 23 known reproductive females, the maximum number of calf bearing females could be as high as 29 individuals. Genetic samples collected from these whales will be used to determine the identity of the mothers. There are plans to produce and publish a western gray whale photo-identification catalogue (140 animals) before next year's meeting.

SC/57/BRG22 presented an analysis of western gray whale photo-identification data collected in the Piltun feeding ground, Sakhalin, during 1994-2003. This analysis had also been presented to the World Conservation Union (IUCN) independent scientific review panel (ISRP) for western gray whales in 2005 (Reeves *et al.*, 2005), discussion of which is provided below. An individually-based, stage-structured model was fitted to the data, to estimate vital parameters and to project the population forward under different assumptions. The population was estimated at 102 animals aged 1+ in 2004 (90% CI 94-110).

The 1+ survival rate was estimated as 0.97 (0.96-0.98), while the 'yearling' survival rate (i.e. from the first to the second summer of life) was estimated at 0.73 (0.61-0.83). The population is estimated to have been increasing at approximately 3% (90% CI 1-5%) per annum during this period. Projections forward to 2050 indicate that if the current situation continues, the population is very likely to continue to increase as long as there are no additional deaths. However, projections under the assumption of one additional female death per year indicate that the population would decrease and quite likely become extinct by 2050.

To date, Piltun and the 'offshore' area are the only two feeding areas known in the Okhotsk Sea. All photographs of western gray whales found outside of the Sakhalin Island feeding ground have been successfully matched to the animals using the Piltun area.

SC/57/BRG18 described the sighting and ultimate entanglement death, of a juvenile female gray whale in Tokyo Bay. The animal was sighted repeatedly from mid-April until its recovery in a coastal set net on 11 May 2005. This was despite the fact that central and local authorities had given instructions to fisheries operating in the vicinity of Tokyo Bay not to disturb the animal and to try to release it if it became entangled. The whale was 7.81m in length and estimated at 1.5 years and was thought to be a recently weaned animal on its second northbound migration from the wintering ground to the northeast coast of Sakhalin.

SC/57/BRG14 provided an update on the genetic analysis of western gray whales. Western gray whales have been shown to be significantly different from the eastern population using mtDNA analysis and nuclear markers. However, the differentiation between the populations is greater for females than it is for males. This finding, coupled with the high number of mtDNA haplotypes in the western population, especially among males, raises the possibility of low levels of male dispersal from the east into the west.

Sohn summarised the second year of shore-based surveys on western gray whales off the coast of Korea. Five researchers participated in the survey in 2004, with three individuals on watch at all times, rotating through three observation stations. Surveys were conducted 21-30 December 2004, however no gray whales were sighted.

The Committee welcomed the news that the Russia-USA programme has produced a catalogue of individuals identified to date that is near to publication. It noted that the catalogue would be available to all interested parties (contact R.L. Brownell). It **agrees** that the Russian scientists working on photo-identification as part of the oil companies' research work should compare their photographs with those in the catalogue, and that potential new whales should be reviewed by a group of experts (including scientists from both programmes) before being added to the catalogue. After the publication of the catalogue, the Committee **strongly recommends** that researchers from the two programmes work as quickly as possible to share and compare all their photographs, agree on a single catalogue that is updated regularly and collaborate on future data collection and analyses. As has been found elsewhere for other species, the Committee believes that conservation efforts for the western gray whale can be best achieved by collaboration rather than by completely separate photo-identification programmes.

The modelling work in SC/57/BRG22 has emphasised the critically endangered status of this population and in

particular the potentially detrimental effect of the death of even one additional female per year. Given this, the Committee **recommends** that every effort be made to ascertain whether the animal that died recently in Tokyo Bay was a previously identified animal. This could be achieved by:

- (1) comparison with the photo-identification catalogues; and
- (2) comparison with the DNA catalogue held at the Southwest Fisheries Science Center (SWFSC), California on behalf of the Russia-USA programme.

Given the difficulties in standardising microsatellite loci between laboratories, the Committee **recommends** that arrangements be made for a sample from the Tokyo Bay animal to be sent to the genetic archive of the joint Russia-USA programme (i.e. the SWFSC). It **urges** the appropriate CITES authorities to facilitate this.

The Tokyo Bay entanglement illustrated the need for an education campaign for fishermen and others throughout the gray whales' potential range, to provide information on the need for every effort to be made to release incidentally caught whales and how this might best be achieved and the importance of taking photographs and/or collecting a sample from stranded or bycaught whales and providing them to the appropriate authorities. The Committee **urges** relevant Governments to try to implement these ideas.

Similarly, the Committee **recommends** that efforts be made in all of the range states to organise stranding networks, aerial surveys and beach surveys, particularly during the period of the northern migration (animals migrating north alone for the first time are probably the most vulnerable).

Finally, the Committee welcomes and supports the report of the ISRP (Reeves *et al.*, 2005) that had included five members of the IWC Scientific Committee (Brownell, Cooke, Donovan, Moore and Reeves). It commended SEIC¹¹ for requesting this review and IUCN for facilitating the process. Despite some difficulties, it believes that this process represented an important step forward for western gray whale conservation.

The Committee strongly supports efforts to build upon this in the future and to develop a framework for collaborative research, monitoring and mitigation efforts between oil companies, independent experts, national programmes and authorities and the IWC and other intergovernmental organisations. In this regard, it **strongly urges** that other companies in the area co-operate with this process.

An important addendum to the ISRP report (Reeves *et al.*, 2005) was the need for a comprehensive strategy to save western gray whales. The panel noted that while their review had necessarily focussed on the Sakhalin feeding region in Russian waters, gray whales spend approximately half their time in other waters in eastern Asia (Japan, the Republic of Korea, the Democratic People's Republic of Korea and China). The results from SC/57/BRG22 emphasise the need for mitigation measures for the many potential threats to the western gray whale throughout its range. There are a number of groups that already play a role in discussing and reviewing the population status and management and research needs for this population,

¹¹ Sakhalin Energy Investment Corporation, a consortium of companies developing oil and gas reserves in the region.

including the IWC Scientific Committee, the Russian Group for Strategic Planning of Gray Whale Research, the joint Russia-US programme, the IUCN Cetacean Specialist Group and other national programmes that may form the basis for developing a strategy. The importance of involving scientists, authorities and other stakeholders in the range states was recognised. The Committee **recommends** that the IWC plays an active and facilitating role in the process.

10.4.6 Work plan

The work plan for the coming year is to review new information on the WNP stock of gray whales, right whales and the small stocks of bowhead whales.

10.5 Future SOWER cruises (see Annex G)

10.5.1 Report from Intersessional Workshop

Last year, the Committee agreed that the objective of any future programme should be:

to provide information to allow determination of the status of populations of large whales that feed in the Antarctic waters. The programme will primarily contribute information on abundance and trends in abundance (including of Antarctic minke whales), learning from both the successes of past IDCR-SOWER cruises and the difficulties in interpreting previous results (IWC, 2004b, p.35).

A Workshop (SC/57/Rep1) held in October 2005 continued work on the development of a future SOWER research programme. The Workshop agreed that the long-term goal for a future programme is to provide circumpolar estimates of abundance and trends in abundance for large whales that feed in Antarctic waters. It also agreed that the short term goal for a future programme is to undertake research on priority species including to: (a) undertake experimental surveys to provide information useful in developing optimal survey design and methodology and addressing problems with previous IDCR/SOWER surveys; and (b) provide estimates of abundance for smaller areas (in conjunction with stock structure studies), which will be potentially useful in investigating long term trends.

The Workshop agreed that the following species priorities should be assigned in order from highest to lowest:

- (1) Antarctic minke and blue whales;
- (2) fin whales;
- (3) humpback whales;
- (4) sei and right whales; and
- (5) sperm whales.

The Workshop recommended that the Scientific Committee should consider its report as a set of guidelines for the development of an initial proposal for a future programme and that Scientific Committee members should provide papers to allow for efficient progress to be made on the development of a proposal for the long term programme.

The Committee **agrees** with the Workshop's long and short term goals for a future programme. In addition, the Committee **recommends** that the sightings surveys, as conducted previously, should not immediately be continued, and that in the short term the goals of the cruises should address questions and problems that have arisen during the previous CP surveys and should investigate different data collection and analysis methodologies that could be used to collect abundance and trend data for the large whale species that feed in Antarctic waters.

10.5.2 Recommendations for future SOWER cruises

10.5.2.1 2005/06 SEASON

For the practical purposes of planning, the Committee assumed that the Japanese Government would continue to provide vessels and assistance at the present level, even though it was recognised that no decision has been taken and that this represents a major investment from the Japanese Government. After evaluating potential experiments to address problems with previous analyses, new methods to collect less biased future data and other data needed to complete assessments of large whales in the Antarctic (Appendix 2 of Annex G), the Committee **agrees** the priority of research for the 2005/06 cruise is as follows (with highest priority assigned to the first item):

- (1) Antarctic minke whales: Experiments designed to address problems with analysis and interpretation of CPII and CPIII Antarctic minke whale abundance estimates (BT mode, satellite tagging, collaborative research with icebreaker);
- (2) a fin whale survey feasibility study north of 60°S;
- (3) humpback biopsy and photo-identification studies; and
- (4) continuation of blue whale research.

It was noted that the priority rankings of several experiments were conditional, for example, because of the uncertainty of being able to acquire the necessary equipment such as satellite tags and user-friendly high power binoculars. The research to be completed during the 2005/06 cruise is dependent on the completion of a number of tasks (listed in Appendix 2 of Annex G). The Committee **recommends** that these tasks be completed and the Tokyo planning meeting:

- (1) facilitate a full evaluation and possible review of its relative priority ranking; and
- (2) finalise the research to be conducted on the 2005/06 cruise.

The Committee **recommends** the IWC/SOWER Steering Group (Annex P(12)) complete the planning of the 2005/06 SOWER cruise.

Morishita stated that due to current budget difficulties, it now should not be assumed that the Japanese Government will be able to continue to provide vessels and assistance at the previous level. A decision will be made later.

10.5.2.2 LONG TERM

There was insufficient time available for the Committee to develop firm long term plans to fulfil the objectives of the SOWER programme. It was noted that feedback from the fin whale feasibility study planned for this year's cruise would provide information useful for the next step of designing a long-term plan for SOWER research. To promote discussion next year, the Committee **recommends** that, time allowing, the Planning Meeting produce an outline of a potential long-term plan and present this to the next year's meeting. In addition, the Committee **recommends** that members also submit proposals on this to next year's Committee meeting. Together these could be used to develop a proposed long-term plan for the SOWER research.

10.6 Other

10.6.1 Report from a non-IWC sponsored workshop on sperm whales

Bannister presented SC/57/IA8, Summary of Report of Cachalot Assessment Research Planning Workshop, Woods

Hole, Massachusetts, USA, 1-3 March, 2005¹². Thirty six scientists from nine countries had participated. At its 2005 meeting, the Committee had accepted the initiative to begin preparing the background for an eventual in-depth assessment of sperm whales, noting that considerable progress is being made on improving basic knowledge of sperm whales; at that time it looked forward to the report as a useful way of integrating current understanding of the species.

The Workshop had three terms of reference, developed by a Steering Group within the IWC Scientific Committee:

- (1) identify and evaluate new methods, identify critical tests of such methods, and describe how these might be conducted, especially using combinations of new methods simultaneously;
- (2) identify relevant spatial scales and formulate plans for regional field studies to address key uncertainties relevant to an eventual in-depth assessment; and
- (3) develop a research programme that would be necessary and sufficient as the basis for an in-depth assessment of sperm whales, including research coordination and funding mechanisms.

The Workshop's context was set by an overview of Whitehead's global assessment (Whitehead and Planck, 2002). Recent research was reviewed under the headings: population structure and movements, abundance and distribution, life history, population ecology, human interactions, field studies and future work. In addition to developing a systematic list of research topics and priorities, several items were identified as highest priority. These included: developing provisional hypotheses about population structure; obtaining information on female survival rates; improving historical catch data; exploring further the effects of differential exploitation by sex; improving methods to correct abundance survey data to account for bias; and refining population modelling approaches. The need for regular and substantive interaction between modellers and field researchers was emphasised. Three coordinating tasks were identified, including the need for a second Workshop in two years time.

The Committee thanked the organisers for providing the report, and **agrees** that it should consider sponsoring the second Workshop.

10.6.2 Consideration of proposals for further in-depth assessments

North Pacific sei whales and Southern fin whales were suggested as candidates for future in-depth assessments. North Pacific sei whales were suggested because the IWC has not conducted an in-depth assessment on this species in over 30 years and takes of this species have resumed under JARPN II. Southern fin whales were suggested because they may be an important predator in the Antarctic ecosystem, takes of this species may be resumed (SC/57/O1) under JARPA II and there is some reason to believe that historical assessments may have underestimated the extent of depletion at the time of protection (SC/57/IA13). It was noted that new data on North Pacific sei whales are currently being collected under JARPN II and it is noted that new data on Southern fin whales will be

collected during the 2005/06 SOWER survey. To evaluate which species should be considered for future in-depth assessments, the Committee **recommends** papers be presented at future meetings that discuss the reasons why an in-depth assessment should be conducted and the status of the necessary data (distribution and abundance, stock structure, biological parameters, total takes and assessment methods).

10.6.3 Historic abundance estimation: genetic methods

Last year, the Committee discussed a study by Roman and Palumbi (2003) which used genetic diversity in mtDNA to infer historical levels of abundance of 240,000 humpback, 360,000 fin and 265,000 common minke whales in the North Atlantic. The Committee agreed that these figures, which greatly exceeded previously reported estimates of pre-whaling abundance for at least humpback and fin whales, had considerable uncertainty associated with them and could not be considered reliable estimates of immediate pre-whaling population size. A Working Group listed a series of questions that needed to be addressed in order to resolve this discrepancy (IWC, 2005i) and an intersessional e-mail group was established to continue discussion of this issue.

Although some progress was made on a few of these issues (see below), this has not been sufficient to reconcile the genetic estimates with those from analysis of catch data.

10.6.3.1 GENETIC ISSUES: CORRELATING GENETIC DIVERSITY WITH EFFECTIVE POPULATION SIZE

Palsbøll summarised a report on progress in Palumbi's laboratory in the last year. New analyses of the mitochondrial control region mode of mutation based on multiple models of mutation and new data on baleen whale phylogeny and divergence times had revealed no significant change in their abundance estimates. Estimates of genetic diversity obtained from the cytochrome *b* locus (also in the mitochondrial genome) were compared to the original estimates obtained from mtDNA control region sequences. The cytochrome *b* locus was estimated to evolve about 5-7 times slower than the mtDNA control region, which is consistent with the 5-7 times lower estimates of diversity at this locus. The estimates of abundance are thus similar to that obtained for the mtDNA control region. These data were collected from Antarctic minke whales and may be biased by the large genetic variation in this population and the long branches leading to highly divergent control region lineages. Palumbi's lab is working on a phylogenetic estimate of the control region mutation rate based on overlaying the control region data on the cytochrome *b* genealogy; this should correct for multiple mutations in the mtDNA control region by using the cytochrome *b* sequences as a base line. A limited data set collected from humpback whales detected very low levels of variation among cytochrome *b* sequences compared to the mtDNA control region. The importance of additional cytochrome *b* sequences from humpback whales to make more headway with regard to the discrepancy between common minke and humpback whales was stressed.

Palumbi's laboratory was also collecting data from the mtDNA control region, mtDNA cytochrome *b* and nuclear data (10 loci) in 142 gray whale samples. They were likely to have preliminary estimates ready in the near future. They were undertaking new analyses on non-equilibrium estimates of population fluctuation based on genetic data. The data show long-term increases of population size in

¹² A final version of the workshop report is currently being prepared and will be available through the principal sponsor, the US Marine Mammal Commission (www.mmc.gov), or through the convenor, Dr. T. Smith (tsmith@whsun1.wh.who.edu).

Antarctic minke whales but with no signal of Ice Age fluctuations. The analyses revealed a steady population size in North Atlantic fin whales and population expansion in North Atlantic common minke whales. However, Palsbøll commented that the former conclusion is not reliable given the strong signal of expansion that he and his collaborators have observed in their fin whale data set from this ocean.

Humpback whales appear to have mainly stable population sizes over time but the estimates are highly variable. Palumbi had felt that this might reflect pulses of gene flow rather than pulses of population size. A Bayesian version of this latter analysis will be implemented to obtain confidence limits. There is no evidence of historic population crashes and that the analyses suggest that long-term average population size is lower than recent effective population size, at least in the case of the Antarctic minke whale.

Palsbøll commented that Palumbi's observations that the population expansions were pre-Pleistocene in origin, would mean that Roman and Palumbi's estimates would be, if anything, negatively biased (i.e. there would need to have been even more whales in the North Atlantic to explain the observed level of diversity). This analysis depended critically upon an estimate of mutation rate. If the true rate is significantly higher than that used in Palumbi's analysis (as many people believe), then the resulting estimates would drop sharply.

10.6.3.2 STATISTICAL RELIABILITY OF CATCH RECORDS

SC/57/O7 revisited the problem of estimating the pre-exploitation sizes of the two populations of North Atlantic humpback whales. Several sources of uncertainty in the underlying data and in population models were considered. One factor considered was the uncertainty in the estimated catches of North Atlantic humpback whales given by Smith and Reeves (2003). The sensitivity of the results from the model to this uncertainty was explored by considering extreme scenarios for the historical catches created by considering four sources of uncertainty:

- (1) the effect of interpolating landings between years because of incomplete data series;
- (2) statistical uncertainty associated with the estimate of barrels of oil per whale;
- (3) statistical uncertainty with the ratio of numbers struck but lost; and
- (4) the possibility that catch estimates for the years prior to 1850 were grossly underestimated because of limitations in data sources.

Upper bounds on catches considering each of the four factors ranged up to 43,000, and considering all factors simultaneously led to upper bounds of the order of 69,000. This value is 135% of the best estimate of historical catches of 29,000 whales, and implies a notional upper limit on pre-whaling abundance of 80,000, the present abundance plus total catches.

These upper bounds on catches and other uncertainties with the data for these populations were used to estimate pre-whaling abundance using different sets of data and model assumptions. As expected, the pre-whaling abundance estimates for both populations were below the 'notional upper limit'. For all models considered, including those that explored the extreme scenarios of catches, total pre-whaling abundance was still substantially below the estimate of average abundance over evolutionary time scales given by Roman and Palumbi (2003).

10.6.3.3 OTHER ISSUES

There was no reported progress on any of the other issues outlined last year.

The Committee **agrees** that this Working Group should continue during the coming year (see Annex P(32)). It noted that there are a number of new genetic analyses that are being undertaken that *inter alia* will provide considerably better estimates of mutation rate, one of the most critical (and uncertain) factors in the Roman and Palumbi article. It looks forward to receiving this information next year.

10.7 Work plan and budget request

10.7.1 Sub-committee on in-depth assessments

The Committee acknowledged the heavy workload of the sub-committee this year. There was considerable discussion on how best to relieve this workload. It was agreed that the highest priority next year is to try to finalise abundance estimates of Antarctic minke whales from the CPI to CPIII time series. The Committee therefore **agrees** that sufficient time should be allocated to achieve this. Consideration should be given to work on the North Pacific common minke whale in-depth assessment, to occur outside the sub-committee, at least for next year. The best way to achieve this will be discussed by the Convenors after the meeting (and see Item 19).

The priority topics under this Agenda Item will thus be in priority order:

- (1) produce agreed abundance estimates of Antarctic minke whales;
- (2) continue development of the catch-at-age analyses of the Antarctic minke whales;
- (3) continue preparation for an in-depth assessment of WNP common minke whales, with a focus on J stock;
- (4) develop recommendations for future SOWER cruises, both for the short- and long-term; and
- (5) continue to examine and then attempt to agree on reasons for differences between minke abundance estimates from CPII and CPIII.

Annex G (Appendix 6) details tasks identified to produce estimates of abundance of Antarctic minke whales. Annex G (Appendix 4) details tasks to continue development of the catch-at-age analyses, where the goal is to complete these analyses at the 2007 meeting. The financial implications are discussed under Item 21. Annex G (Appendix 5) details tasks to continue preparations for an in-depth assessment of WNP common minke whales, with a focus on J stock.

11. STOCK DEFINITION (SEE ANNEX I)

11.1 Review progress on the Testing of Spatial Structure Models (TOSSM) project

In 2003, the Committee instigated the TOSSM project (IWC, 2004b, pp.27-8; IWC, 2004f, pp.469-85). The main aim of this project is to develop simulation tools that can be used to examine the performance of current and future genetic population structure techniques. The focus is on management implications, where the genetic techniques are used to suggest management boundaries, which in turn are used to set or subdivide catch limits according to some rule; the performance of different genetic methods is ultimately to be assessed in terms of how well a simulated management regime performs if the suggested boundaries are used. The Committee's experience of studying population structure, e.g. in developing *Implementation*

Simulation Trials (ISTs) for common minke whales in the North Pacific, has shown that genetic data do not usually provide unequivocal evidence of specific boundaries for use in management. Furthermore, few boundary-placement techniques have been subject to simulation testing. Even those that have, cannot be considered to have undergone the level of extensive simulation testing to incorporate uncertainty that has been a feature of, for example, the IWC's work on the RMP and AWP. This is perhaps not surprising, given the scope and complexity of developing suitable genetically-specified simulation datasets.

The Committee has identified the following six work modules, each of which has to be completed before the simulation performance testing can actually begin:

- (i) genetic simulation;
- (ii) biology and population dynamics;
- (iii) sampling;
- (iv) catch strategy;
- (v) adaptation of boundary-settings methods for testing; and
- (vi) integrating all of the above to allow a complete test to be run.

The chosen vehicle for *Implementation* is the freely-available software RMETASIM developed as a result of the Workshop, which required some modifications to cope with whale-specific life history patterns and with harvesting. By the 2004 meeting, much progress had been made on those modifications and on the detailed specification of the above modules. Three technical priorities were identified last year, and following intersessional work by the TOSSM Core Group (Martien, Tallmon, Tiedemann), all three are expected to be complete by 1 July 2005. This will essentially complete modules (i), (ii), and (iii), at least for the simple demographic archetypes that are to be considered initially. It will then be possible to generate simulated genetic datasets suitable for boundary-setting methods; some further work will be required on (iv)-(vi) before the methods' performance can be tested. Although it was hoped last year that some such datasets would be ready for this year's meeting, delays beyond the Core Group's control have prevented this.

The Committee welcomed the progress made, and thanked the Core Group for their efforts. Future plans for the project are presented under Item 11.4.

11.2 Review of statistical and genetic issues relating to population structure (including DNA quality issues)

A number of methodological papers were discussed (see Annex I). SC/57/SD1 described the initial development of an allele-matching model for analysing population structure, for use when the existence of subpopulations is uncertain and *a priori* assignment of samples to hypothesised subpopulations is problematic. The total genetic correlation is partitioned between a subpopulation component and a covariate-linked component unrelated to population structure. The authors plan to apply the method to B-C-B bowhead whales in the coming year. The Committee noted the promise of the approach, made a variety of methodological suggestions and **strongly encourages** its continued development and application for the 2006 meeting.

SC/57/SD2 presented further results of close-kin analyses, using new data in the North Atlantic common

minke whale DNA register. The register was screened for pairs of apparently closely related individuals. The most closely related pairs were then screened at 15 additional microsatellite loci, and these loci were used to test the hypothesised relatedness. Preliminary results showed that the distances between parents and offspring were often large, and that the number of confirmed parent-offspring pairs was higher than expected given the estimated abundance and assumed mortality rate. Further work is required to investigate the statistical significance of this finding, and its sensitivity to demographic assumptions. The Committee noted the power and cost-effectiveness of the approach (expensive extra genotyping is only needed on those animals most likely to be informative) and **strongly encourages** its further development.

SC/57/SD5 reported further investigations into the extent of bias in the Boundary Rank procedure when applied to unevenly-sampled clines. The Committee noted that the TOSSM/RMETASIM framework is approaching the point at which it can be used for testing the full management implications of boundary-setting procedures, and **recommends** that this framework be considered for future simulation tests.

Genetic data quality

At the 2004 meeting, the Committee's discussions on bowhead whales had highlighted a number of issues related to quality of microsatellite data and caveats about its interpretation, ranging from DNA handling issues to e.g. ascertainment bias and mis-scoring, to the implications for population structure analyses. A review was proposed for 2005, and the preparation of a review paper was encouraged. Although work began on this intersessionally, it proved to be too large a task. The Committee noted, however, that several review papers have appeared in recent published literature. Palsbøll offered to compile a list of appropriate references for the 2006 meeting.

11.3 Definition of unit-to-serve and the implications for management

The point of this item is to allow consideration of various possible definitions of unit-to-serve, and their corresponding implications for management (see IWC, 2002c, p.49). No papers were received this year, but the Committee received a verbal summary of recent thinking in the academic literature about definitions of 'population'. Two paradigms can be identified: the evolutionary paradigm which is concerned with levels of gene flow, which scales with the *absolute number* of effective migrants per generation; and the ecological paradigm, which is concerned with the *per capita* rate of migration per generation. A number of proposed definitions of 'population' within each paradigm are shown in Annex I but few if any of the definitions are operational, in the sense of providing a quantitative criterion for separating 'populations' in a management context. This emphasises the importance of a process such as TOSSM to bridge the gap between empirical data related to population structure, and management objectives such as avoiding local depletions. Despite the absence of an operational definition of 'population', a number of possible criteria might be used to make the definitions in Annex I quantitative and operational; some suggested criteria may be found in Annex I.

The Committee noted that these or similar criteria might prove valuable in:

- (1) adapting existing methods for analysing population structure to TOSSM;
- (2) actually applying such methods; and
- (3) aiding experimental design and sample size calculations.

From the IWC perspective, there are a wide variety of possible temporal and spatial scales that could be of interest for management. In addition, there are some population structures that are persistent in space and/or time, but that do not correspond to breeding stocks: for example, matrilineal philopatry as exhibited by 'feeding stocks' of humpback whales. The Committee's aim has therefore been to get to a point where it can provide advice to the Commission about likely levels of depletion on a range of different temporal and spatial scales, and for different types of population structure. This has been the principle underlying TOSSM. By experimenting with different criteria during the adaptation of existing methods to TOSSM, the Committee will gain experience about which criteria tie in best with management objectives.

In recent years, new analytical methods (and increases in available data) have allowed for considerable increases in the power for detecting population structure. Given large enough sample sizes and numbers of loci, there is now a realistic possibility for some whale species of detecting significant genetic differences that, while genuine, are actually not important in demographic terms: i.e. where the migration rate is too high to warrant separate management. This is a considerable change from a few years ago, when the available data and methods very typically were not powerful enough to detect a migration rate that is low enough to warrant separate management, but high enough to blur the genetic signal.

High power to detect very weak population structure has another potential downside: care must be taken not to confuse small artefacts (e.g. non-random sampling, family structure, data errors) with a true signal of population differentiation. This emphasises the need for careful attention to experimental design, sampling protocols, and data quality control, as well as the importance of understanding the biology of the target species.

Finally, the Committee noted the importance of regular and repeated communication with population geneticists, to bridge the evident gap between academic methods development and the practical conservation/management issues that the IWC faces.

11.4 Work plan and draft agenda for 2006

11.4.1 Further work on TOSSM

The IWC has extensive experience of complex simulation exercises similar to TOSSM, such as the development of Management Procedures for the RMP and AWMP. To avoid costly back-tracking, it is important to do some 'full runs' early on - that is, to make sure that the entire set of steps can be completed together for a fairly simple scenario - before spending too much attention on polishing individual details. Although some background work is still needed, TOSSM has now reached the 'full run' stage. Once initial 'full run' results are in hand, it will be time to discuss preliminary results with non-IWC developers of population structure methods, who form an essential part of the TOSSM process.

The Committee believes that the most efficient way forward is to hold an intersessional Workshop after completing the background work and some 'full runs'. Preparatory work will include adapting about four existing population structure methods to TOSSM, as well as one or more methods developed by Committee members. The Workshop will also involve non-IWC population geneticists who have developed population structure methods, and will present feedback on preliminary tests of those methods, along with development of further datasets and simulation scenarios. The Workshop objectives are:

- (1) present results of preliminary runs using existing adapted methods;
- (2) discuss adjustments to the first sets of simulated data;
- (3) discuss how to better adapt existing boundary-setting methods;
- (4) discuss other boundary-setting methods that might be tested in TOSSM; and
- (5) decide on priorities for further simulated datasets (e.g. more complex population archetypes, more realistic genetics, simulation of physical tags).

A date sometime in March 2006 would leave enough time to:

- (1) complete the background work beforehand; and
- (2) implement some of the Workshop recommendations before the next annual meeting, so that a more useful set of test results can be considered.

Tiedemann offered to host the meeting at the University of Potsdam, including free meeting facilities and the provision of computing power for generating extra datasets during the meeting. The Committee thanked Tiedemann for his offer and **strongly endorses** the proposal for a Workshop. The full proposal is given in Appendix 2 of Annex I, along with a timetable and lead personnel for pre-Workshop preparations. Financial implications are discussed under Item 21.

11.4.2 Draft agenda for 2006

The priority issues for next year's meeting are:

- (1) review statistical and genetic issues relating to stock definition;
- (2) review progress on TOSSM;
- (3) unit-to-convert; and
- (4) review of genetic data quality issues.

12. ENVIRONMENTAL CONCERNS (SEE ANNEX K)

12.1 Sea ice and whale habitat Workshop

As agreed last year, a Workshop entitled 'High Latitude Sea Ice Environments: Effects on Cetacean Abundance, Distribution and Ecology' was held in Ulsan, South Korea from 28-29 May 2005. The aim of the Workshop was to review information on sea ice environments in the Arctic and Antarctic, and to develop means of incorporating sea ice and similar data into analyses and models used by the Scientific Committee in its work.

The report of the Workshop is given as SC/57/Rep5. The Workshop provided an excellent opportunity for scientists who typically work at either pole to meet and exchange information on sea ice variability with respect to whale habitats. The three invited talks provided information on the present understanding of decadal changes and current conditions at both poles. Common themes included:

- (1) the extreme variability in sea ice conditions at both poles;
- (2) the complexity of both polar ecosystems; and
- (3) the great dearth of sea ice data, especially at scales relevant to cetacean habitat assessment, with regard to retrospective and forward-looking investigations.

Research tools are now available that can augment future studies including:

- (1) passive acoustic recorders, both short and long-term instruments (i.e. sonobuoys and moored recorders);
- (2) satellite telemeters for attachment to cetaceans, augmented with oceanographic instrumentation (e.g. CTDs, fluorometers); and
- (3) sea ice analytical tools to provide routine application at the temporal and spatial scale of whale habitats (i.e. days to months; 1 to 1,000s km).

The Committee **recommends** the application of these tools to future cetacean research in the Arctic and Antarctic and **encourages** researchers to continue the collaborative exchanges initiated at the symposium.

The Workshop identified a number of high priority intersessional projects targeted at issues in polar regions. Two Arctic projects were proposed. The first focuses on retrospective analyses of sea ice conditions, using both satellite-derived data and traditional ecological knowledge (TEK) to collate with extant records of B-C-B bowhead and ENP gray whale population dynamics. The second project seeks to investigate health status in both populations with regard to variability in sea ice. The Antarctic projects focus on:

- (1) areas of high Antarctic minke whale density;
- (2) shelf break position correlation with whale distribution;
- (3) data-rich regional comparison of variables affecting distribution;
- (4) analysis of Antarctic minke whale distribution and relative proportions inside and outside the pack ice;
- (5) integration of historical and recent whale catch/sighting data; and
- (6) support for the completion of the Southern Ocean Collaboration Database.

Finally, it was noted that the Integrated Analysis of Circumpolar Ecosystem Dynamics (ICCED) initiative in the Southern Ocean and the International Polar Year (IPY) afford unprecedented opportunities for collaborative multi-disciplinary research in polar regions. The aforementioned tools provide the means to fully integrate cetacean studies into broad-scale programmes of marine ecosystem research in ways not imagined only a few years ago. For these reasons, the Committee **strongly recommends** the integration of cetacean research into these two programmes.

The Committee expressed its deep appreciation to Thiele and Moore for their hard work in organising and convening the Workshop. The Committee **endorses** the findings and recommendations in the report of the Sea Ice Workshop. Financial implications are considered under Item 21.

12.2 Review of the report of the Habitat Degradation Workshop

The Committee was pleased to receive the report (SC/57/Rep2) of the IWC Workshop on Habitat Degradation which was held at the University of Siena, 12-15 November 2004. The Workshop was financed by the Government of Austria, the Environmental Investigation

Agency, ASMS-Ocean Care and the World Wide Fund for Nature.

The main discussion of the Workshop report took place in the SWG on environmental concerns and the reader is referred to Annex K for a more detailed summary of the Workshop. This summary presents the main conclusions of the Workshop and its recommendations.

In its conclusions, the Workshop had stressed the importance of undertaking work relating habitat conditions to cetacean status in the context of conservation and management. It recognised that this is a particularly complex area of study, requiring both theoretical developments in modelling approaches and a commitment to long-term interdisciplinary data collection programmes.

The Workshop noted that the framework it had developed (see fig. 3 of SC/57/Rep2) provided the basis for a long-term approach to investigating the significance of habitat degradation for cetaceans. However, general application of the framework will require a much longer-term view to be taken by management and research bodies. This would eventually result in major improvements in advice to resource managers for conservation and management of cetaceans with respect to predicting the effects of habitat degradation and the effects of many anthropogenic activities, as well as the development of appropriate mitigation measures. The Workshop noted that the continuation of the present *ad hoc* and usually insufficient processes (such as 'Environmental Impact Assessments' based on short-term limited datasets) would be unsatisfactory.

In order to facilitate the development process, the Workshop agreed that the primary focus should be on populations for which it was believed there was the most chance of success, i.e. those for which good information is available on both cetaceans and their habitat over a reasonable time period. The Workshop recognised that overall there are few cetacean populations studied with broad sampling programmes covering sufficiently long time frames.

The Workshop also stressed the value of long-term monitoring of both cetaceans and key aspects of their habitat at appropriate temporal and geographical scales. Baseline data on natural variability in cetacean populations and their habitat are a prerequisite to determining whether anthropogenic changes in the habitat are important to the conservation of cetacean species. Obtaining suitable information on the biotic and abiotic features of habitat will require interdisciplinary efforts and co-operation. It agreed that where possible, collection of cetacean data, as well as data on their environment, should be conducted simultaneously. It also noted that spatial modelling approaches are particularly valuable in integrating data on cetacean distribution and abundance with data on their habitat.

The Workshop also stressed the need to better understand the feeding and reproductive behaviour of cetaceans. With respect to the former, this particularly includes the relationship of cetacean distribution with their prey. As suggested in the report of the SOWER 2000 Workshop (IWC, 2000e, pp.319-46), this will include fine-scale research on feeding strategies and prey selection. It also requires much better knowledge of the distribution, behaviour and abundance of prey species which will require better cooperation with other disciplines, especially physical and biological oceanographers and fisheries scientists.

Newer technologies such as satellite tagging (including environmental sensors), remote sensing and new initiatives for developing ocean-based observing systems (e.g. in the USA and Europe) have the potential to provide broad-based data sets on both cetaceans and their habitat.

The Workshop also made a number of recommendations (see item 12.2 of SC/57/Rep2); the key recommendations are summarised below.

The Workshop strongly recommended that effort be put into further consideration of the framework including:

- (1) linking of the different types of models, e.g. through data on vital rates;
- (2) developing ways to model how stressors affect features of the habitat or individuals directly; and
- (3) developing ways in which spatial modelling approaches can better incorporate dynamic variables.

Attention must also be given to trying to determine the relative importance of natural versus anthropogenic environmental changes on the dynamics of cetacean populations.

The Workshop also strongly recommended the continuation (and where necessary, initiation) of long-term studies, both of cetaceans as well as key biotic and abiotic features of the environment. In this regard, the Workshop recognised that this may require a change in emphasis of both management and research agencies. In the present climate there is often reluctance to invest in long-term programmes. The Workshop stressed that the issue of cetaceans and habitat degradation will only be resolved by long-term multidisciplinary datasets. This will also require a change in the way many institutes evaluate scientists. At present, this is often on the basis of the number of publications. It is often a feature of long-term monitoring programmes that they do not result in several publications per year despite the fundamental importance of the work. This may discourage high calibre scientists from committing to such programmes to the detriment of cetacean conservation.

The Workshop also recognised the difficulties in developing (and measuring) suitable indices both of habitat quality and response in cetaceans. It recommended that further work be undertaken in this regard, particularly with respect to:

- (1) identifying key features of cetacean habitat;
- (2) reviewing methods used to assess cetacean nutritive status in both live and dead specimens, with a view to future standardisation of techniques; and
- (3) developing indices of cetacean response to various stressors.

Other recommendations concerned the importance of interdisciplinary research, the development of standard necropsy protocols, the importance of considering the representativeness of information collected via strandings programmes; appropriate long-term preservation of tissues; the use of metadatabases to improve collaborative research and data/information sharing and the development of habitat restoration science and technology.

The Committee thanked Simmonds, the Convenor, and the Workshop participants for their report and **endorses** its conclusions and recommendations. The Committee **agrees** that it will review progress on habitat degradation recommendations in 2008.

There was considerable discussion of aspects of the report in the SWG and this can be found in Annex K (item 7). Issues discussed included: the value of properly archiving older studies and datasets (including searching the grey literature); the choice of case studies to which to apply the framework; the integration of noise into habitat models; the value of strandings schemes; the need for standardised protocols for pathology (particularly with respect to possible acoustic trauma); and the need for 'control' datasets from 'normal strandings' for comparisons to suspected acoustic traumas.

The Committee recognised that pathology should not be examined only in cases where acoustic trauma is suspected. Therefore the Committee **agrees** that management agencies and pathologists should follow equally rigorous, standardised pathology protocols in fresh, natural strandings as they do in atypical mass stranding events when acoustic trauma is suspected, especially in those areas identified as 'controls'.

12.3 Habitat related issues

12.3.1 Steering Group report on POLLUTION 2000+
SC/57/E12 presented an interim report on POLLUTION 2000+. Three papers have now been published (Tornerio *et al.*, 2005; Tornerio *et al.*, 2004; Wells *et al.*, 2004) and another is in review (Hall *et al.*, in press).

With respect to the bottlenose dolphin sub-project, the Steering Group has made progress on the process of identifying a relatively highly polluted area inhabited by bottlenose dolphins. Unfortunately, sampling bottlenose dolphins in the initially proposed area, the Mediterranean, proved to be impractical in terms of both sample size and costs, after considering the results of a feasibility study. However, samples from bottlenose dolphins from Biscayne Bay, Florida, USA and New Brunswick, Georgia, USA have been collected by US scientists, and the Steering Group will evaluate whether one of these provides a suitable alternative.

Progress on the remaining analyses required under the harbour porpoise sub-project has been very slow due to administrative and logistical issues (e.g. in obtaining permits) that obstructed the shipping of samples from the USA to Europe. Although it seems that these problems have now been overcome, the results from the analyses will not be available until next year.

The Steering Group is also examining the possibility of extending the sample size of harbour porpoise tissues collected under POLLUTION 2000+, by investigating retinoid levels in harbour porpoises from the UK and/or from the northeast Atlantic.

The Steering Group has developed an intersessional workplan to finalise Phase I of the project and report the results to the Committee and the Commission next year. The Steering Group will also evaluate whether it believes Phase II of the project should proceed, and if so, will bring a workplan and associated budget to the Committee for consideration next year.

The Committee **endorses** the POLLUTION 2000+ programme and the intersessional workplan. It **strongly recommends** continuation of the programme and **agrees** that the work of Phase I should be completed by next year's Scientific Committee meeting.

12.3.2 Progress report of the Southern Ocean Collaboration Working Group

The IWC Southern Ocean Collaboration Working Group (IWC SOC) conducted field work and analysis during the intersessional period. The IWC SOC commenced field work with Southern Ocean Global Ecosystem Dynamics (SO-GLOBEC), Commission for the Convention on Antarctic Marine Living Resources (CCAMLR) and other research programmes in 2000, and the benefits from this ecosystem-focused research are now being realised. The field collaboration has given the IWC an important role in the synthesis and analysis phase of these programmes, with IWC SOC members now participating in ecosystem modelling and analysis projects that should improve the understanding of the links between whales and the environment in this region.

Six papers from IWC SOC were presented at this year's meeting, using data from the IWC SOC Database. A spatial analysis of sea ice habitat for whales and seasonal availability of sea ice habitat types was presented in SC/57/E1; SC/57/E2 provided an update of the progress made with the completion of the SOC database; and SC/57/E3 provided a summary of field and analysis work conducted intersessionally, including the group's involvement in the development of the science planning for the Integrated Analysis of Circumpolar Ecosystem Dynamics (ICCED) initiative (long term follow on to SO-GLOBEC) and a number of collaborative analysis projects, including circumpolar modelling and analysis of whale and seabird time series with environmental variables. In addition, SC/57/E4 provided an update on field work carried out under the IWC SOC (international collaboration on multidisciplinary ecosystem research cruises); SC/57/E10 presented a preliminary analysis of whale presence in the Ross Sea from acoustic instruments, one of the first along-track acoustic surveys in sea ice; and SC/57/SH4 provided important new data from year-round acoustic monitoring instruments on seasonal patterns in blue whale distribution off East Antarctica. The Committee welcomed this updated information, and **strongly encourages** continued collaboration in the Southern Ocean. Financial implications are considered under Item 21.

12.3.3 State of the Cetacean Environment Report (SOCER)

SC/57/E8 (SOCER 2005) provided information on issues of environmental concern for the polar regions, as well as globally. The editors noted that the Arctic and Antarctic papers summarised in the SOCER provide evidence for global warming-induced melting of sea ice and oceanographic and ecosystem changes. Pollutant data emphasised that the polar regions are not pristine and the toxicity of some pollutants may even be enhanced in these low-temperature regions. Global issues included growing international concern about effects of noise on marine life, including cetaceans; concerns about potential threats posed by diseases in the marine environment; and changes in the distribution of cetaceans and their prey resulting from global warming. Next year, the Indian Ocean is the SOCER's priority region. The SOCER report can be seen in full in Annex K, Appendix 2.

12.3.4 Arctic issues

The SWG had considered a number of papers on Arctic issues and details of those discussions can be found in Annex K (item 8.4).

Two papers (SC/57/E13 and SC/57/E5) addressed the potential effect of variability in sea ice cover on B-C-B bowhead whales. In the first, a preliminary examination of bowhead whale body condition with reference to sea ice coverage showed a positive correlation of body condition with reduced sea ice, perhaps because a reduction of sea ice enhances feeding opportunities for bowhead whales. In the second, an examination of trends in sea ice cover over 24 years (1979-2002) for four large (~100,000km²) and 12 small (~10,000km²) habitats used by bowhead whales revealed significant changes in sea ice cover for three of the large and five of the small areas. This evaluation of sea ice cover at spatial and temporal scales linked to bowhead whale natural history provides a basis for research on specific regions critical to investigation of the effects of climate change on this pagophilic species. However, the biophysical links between reduction in sea ice, primary production and availability of food for bowheads in the Arctic requires investigation.

SC/57/BRG3, in conjunction with Moore (1999), provided provisional results of a passive acoustic monitoring study northeast of Barrow, Alaska. Results indicated that gray whales remained in the western Beaufort Sea through early winter 2004, with calls detected again less than three months later. This unusual occurrence of gray whales in the western Beaufort Sea may indicate a shift in seasonal migration and habitat use that could result in competition between bowhead and gray whales.

Anon. (2005) described coordination of International Research Programmes in the Arctic. The International Polar Year (IPY 2007-2008) and the Second International Conference on Arctic Research Planning (ICARPII) provide unprecedented opportunities for cetacean researchers to collaborate on multi-disciplinary projects in the Arctic. Research plans evolving from these programmes seek to address priority gaps in knowledge from the Arctic Climate Impact Assessment (ACIA) (see also SC/57/Rep5). The Committee **recommends** that the IWC pursue formal ties to these international research programmes, and that participation from their oceanographers and ecologists be encouraged in whale research.

12.3.5 Anthropogenic noise

SC/57/E9 presented the latest in a series of updates on noise pollution and the limitations of mitigation measures, as well as alternative technologies (e.g. marine vibrators instead of airguns). After discussion, the Committee **strongly encourages** producers of high intensity noise (e.g. sonar and seismic operators) to share information on noise source characteristics and to work with cetacean scientists to investigate the impacts of these activities. The Committee was informed of a workshop (entitled 'A Workshop to Identify Potential Impacts and Mitigation Strategies for Offshore Hydrocarbon Industry Activities with Respect to Marine Mammals and Other Marine Fauna in the Gulf of Guinea (Central West Africa)') that will be convened by the Wildlife Conservation Society (WCS) and the hydrocarbon industry. It will take place at the end of June 2005, where data and information about industry activity will be shared, and mitigation strategies will be discussed. One of the reasons this meeting is being convened is because of the extensive oil and gas development in West Africa, potentially overlapping with numerous critical habitats for marine mammals (e.g. the coastal waters of Gabon and the

Gulf of Guinea are important humpback whale breeding, calving, and nursing grounds).

The Committee welcomed this information, **endorses** the workshop and looks forward to receiving its report, which is directly related to next year's work plan.

The SWG also considered SC/57/E16 which examined the use of sound in drive fisheries and whaling operations. SC/57/E16 noted that fishermen in different parts of the world have used sound to herd various species of small cetaceans to mass strand, or into harbours to be killed. This supports the growing body of evidence that anthropogenic noise can affect cetaceans. The paper also reviewed the use of ASDIC (Anti-Submarine Detection Investigation Committee) sound (i.e. sonar) by whalers to hunt large whales (baleen and sperm whales). The reported reaction to ASDIC by baleen whales was consistent with reactions observed by Nowacek *et al.* (2004) when they played a synthetic alerting stimulus to North Atlantic right whales.

The Committee **agrees** that detailed information on acoustic sonars be obtained whenever possible; all sonars do not have the same acoustic characteristics. This holds true for seismic surveys as well. Detail on the type, number and configuration of airguns is needed to evaluate source capabilities and the potential impact on cetaceans.

The Committee noted that mass strandings are often preceded by 'milling' events, where a group of normally pelagic small cetaceans enter shallow water and circle continually or move haphazardly in a tightly packed group. Touhey (2003) reported using the combination of herding with small vessels and acoustic deterrents to prevent milling events from becoming stranding events. It was suggested that this approach be expanded to other regions where 'milling' events are known to occur. In addition, efforts are needed to document such attempts by a scientific team independent of the rescue team. The Committee **agrees** that this work is important and **recommends** that it be expanded.

Following last year's recommendations, a two day pre-meeting Workshop assessing the potential for seismic surveys to impact cetaceans was proposed for next year. The Workshop should review and characterise information on seismic sound sources, attenuation and their effects on cetaceans as well as review relevant case studies and current mitigation and monitoring strategies. A Steering Group was formed (Annex P(18)) and Rosenbaum was appointed as Convenor (Annex K, Appendix 3). The Committee **endorses** the pre-meeting Workshop and **agrees** to the terms of reference.

12.3.6 Other

The SWG also discussed three other habitat-related papers. The first (SC/57/E7) described the use of biopsy samples to investigate the feeding ecology of ENP killer whales; the second (SC/57/E11) reported on predicting concentrations of elements (e.g. mercury, arsenic) in tissues (e.g. liver, kidney) using epidermal samples; and the third (SC/57/E15) presented information on metal concentrations in common minke whales from Korean waters. These are summarised in Annex K (item 9).

12.4 Work plan

12.4.1 SOCER

SOCER will summarise information from publications related to cetacean ecology, life history and other biological

and management issues globally and will focus on the Indian Ocean for 2006.

12.4.2 Sea ice

The Committee proposed emphasis on the high priority intersessional projects identified during the Sea Ice Workshop. Financial issues are considered under Item 21.

12.4.2.1 ARCTIC

The Arctic projects focus on:

- (1) retrospective analyses of sea ice conditions, using both satellite-derived data and traditional ecological knowledge (TEK) to collate with extant records of B-C-B bowhead and ENP gray whale population dynamics; and
- (2) investigation of health status in B-C-B bowhead and ENP gray whale populations with regard to variability in the extent of sea ice coverage.

12.4.2.2 ANTARCTIC

The Antarctic projects focus on:

- (1) areas of high Antarctic minke whale density;
- (2) correlation between shelf break position and whale distribution;
- (3) data rich regional comparison of variables affecting distribution;
- (4) analysis of Antarctic minke whale distribution and relative proportions inside and outside the pack ice;
- (5) integrating historical and recent whale catch/sighting data; and
- (6) support for the completion of the SOC Database.

12.4.3 Seismic Workshop

The SWG proposed a two-day Workshop in advance of the 2006 Annual Meeting to assess the potential impact of seismic surveys on cetaceans. The rationale, initial terms of reference, draft agenda and suggested invited participants are provided in Annex K, Appendix 3. The Committee **endorses** these plans.

12.4.4 Disease

Last year, the SWG proposed that the topic of disease be the focus of the 2007 meeting. The Committee **agrees** that the focus in 2007 should be the emerging issue of biotoxins produced by harmful algal blooms and their potential impact on cetaceans. Harmful algal blooms have been documented as the cause of numerous mass mortalities in marine mammal populations and have been increasing in frequency and expanding to global geographic distribution. It was noted that ICES is developing plans for a workshop on diseases.

13. SMALL CETACEANS (SEE ANNEX L)

13.1 Review of the status of the finless porpoise (marine populations)

In recent years there has been concern about the status of finless porpoises (*Neophocaena phocaenoides*) with evidence for a localised decline in abundance, fragmentation and degradation of habitat and high bycatch levels.

13.1.1 Distribution and stock structure

Marine populations of the finless porpoise are restricted to shallow, tropical and temperate waters (Annex L, fig. 1). Currently, three subspecies are recognised: *N.p.*

phocaenoides (the tropical marine form, distributed from the Persian/Arabian Gulf eastward to at the least the Taiwan Strait area), *N.p. asiaeorientalis* (the Yangtze River form, which some researchers believe may extend outside the river into estuarine and even marine waters of the East China Sea) and *N.p. sunameri* (the northern temperate marine form, which occurs in waters of Japan, Korea, and northern and central China). There is morphological variation (including variation in dorsal ridge size and shape) amongst the three subspecies, leading some authors to suggest species level differentiation. The subspecies of finless porpoise that occurs in the Yangtze River was reviewed in 2000 (IWC, 2001b, pp.274-5) and was not considered during this meeting.

Geographically localised studies of the distribution, cranial morphology and genetics of finless porpoises have suggested that there are at least five distinct populations in Japanese coastal waters and despite limited coverage and sample sizes, studies elsewhere in the species' range provide evidence for additional populations. The Committee concluded that finless porpoises may exhibit multiple populations over relatively small distances (as occurs off Japan), and that there are likely to be numerous small and vulnerable populations along their coastal range. The Committee **recommends** that genetic and morphometric studies of finless porpoises be conducted to assist in clarifying taxonomy and population structure in the genus *Neophocaena*. The Committee **agrees** that predictive habitat models which recognise potential variability among populations will help to better target resources for field surveys and sample collection. In this regard, the collection of detailed environmental variables during field surveys will be valuable. It further **recommends** that fine-scale surveys be carried out with particular emphasis on targeting effort to areas where the least is known (e.g. the northern rim of the Indian Ocean (including the Arabian/Persian Gulf) and the Indo-Malay Archipelago).

13.1.2 Abundance

The Committee reviewed the results of recent boat-based and aerial line-transect surveys to estimate abundance carried out in five areas, Japan, Korea, Hong Kong, Bangladesh and the Arabian/Persian Gulf. The Committee welcomed estimates from two new areas and noted the apparent decline in abundance in two other areas (Inland Sea of Japan and Persian Gulf). Given certain methodological concerns, the Committee **agrees** that most of the abundance estimates were minimum estimates (see Annex L). The Committee also noted that combined visual and acoustic surveys may result in improved estimates in the future. Given the complexity of the inshore habitat in many parts of this species range and the difficulty in surveying small cetaceans in these areas, the Committee **recommends** that a workshop be carried out to try to develop and standardise survey methodology, including the use of passive acoustics. There is long term merit in training and involving local scientists to conduct studies such as this.

13.1.3 Life history

Information on the life history parameters of finless porpoises derives primarily from stranded and bycaught animals from Japanese and Chinese waters, although new studies have begun in Korea. Growth parameters are generally similar to those of other phocoenids. Males appear to reach longer asymptotic lengths than females. Calving in finless porpoises occurs seasonally and the duration of this

period differs between areas. Continued collection of data to allow estimation of life history parameters in other areas, using standardised methodology will allow more rigorous inter-population comparisons. Given the issue of inter-individual variation in reading and interpreting Growth Layer Groups (GLGs) for age determination, the Committee **recommends** that inter-calibration exercises occur between the different researchers working on this species.

13.1.4 Ecology and habitat

Finless porpoises are almost exclusively found in shallow continental shelf waters, particularly nearshore but also in offshore areas if waters depths are sufficiently shallow (i.e. <50m). Habitats include mangrove swamps, estuaries, sheltered bays and open waters with sandy, muddy or rocky bottoms. Some limited evidence indicates that local distribution patterns may be modulated by the occurrence of other small cetacean species in the same area. Finless porpoises consume a wide variety of prey species that include fish, cephalopods and crustaceans (SC/57/SM1, SM3, SM6, SM17), with some evidence of ontogenetic variation. As these porpoises have a range that includes a narrow coastal strip over a long coastline, they are exposed to a wide diversity of anthropogenic activities. Although potential threats have been identified, their impacts at the population level remain unknown. The Committee **encourages** further work to assess the potential impacts of contaminants and other anthropogenic influences on finless porpoises in all parts of their range.

13.1.5 Directed and incidental takes

No large scale commercial hunts for this species have been recorded. Some local hunting has occurred in the past and probably continues to some extent today. Furthermore, a few tens of finless porpoises have been live-captured for public display and research in Japan, China and Thailand.

Incidental mortality is probably substantial throughout the species' range. Catches are known to occur in a broad range of fishing gears including both active (trawls, beach seines) and passive (e.g. gillnets) fishing gear and also as a result of fishing with explosives and (in the Arabian/Persian Gulf) nets set for dugongs (*Dugong dugon*). There is generally little or no bycatch monitoring of these fisheries and coupled with the limited information on the size of their source populations it is difficult to quantify the population level impacts. A recommendation on bycatches is given under Item 13.1.6.

13.1.6 Consideration of status

The finless porpoise is listed as 'data deficient' by the IUCN. The species is in no immediate danger of extinction, but some populations for which the status has been assessed (such as in the Inland Sea of Japan) are apparently declining. Incidental mortality in fisheries is likely to be the biggest source of direct mortality but other anthropogenic influences such as chemical pollution, depletion of prey species and loss of habitat may all have impacts. Throughout most of the species' range, human populations are increasing and becoming more industrialised, suggesting that anthropogenic pressures will continue and intensify. Given the possibility of population structuring over relatively small geographical regions, the Committee **re-iterates its recommendation** that genetic and morphometric studies of finless porpoises be conducted to assist in clarifying taxonomy and population structure. It also noted that the range of this species includes areas that

support intensive coastal gillnet fisheries and that large bycatches have been documented in some fisheries. The Committee **recommends** that the magnitude and effects of such bycatches be investigated as a matter of priority.

The Committee recognises that inadequate information exists on the distribution of this species throughout much of its range and **recommends** that surveys be carried out with particular emphasis on targeting effort to areas where the least is known. The Committee **agrees** that the northern rim of the Indian Ocean (including the Arabian/Persian Gulf) remains an extensive area where our knowledge of the status and biology of finless porpoises is extremely poor.

13.2 Progress on previous recommendations

IWC Resolution 2001-13 (IWC, 2002a, p.60) directs the Scientific Committee to review progress on recommendations and resolutions relating to critically endangered stocks of small cetaceans on a regular basis.

13.2.1 Baiji

The baiji (*Lipotes vexillifer*) is the world's most endangered cetacean. Its range is restricted to the Yangtze River and the population size is believed to number in the low tens of individuals. The Commission has requested that the Government of China report progress on the conservation of the species to the Scientific Committee on an annual basis. No new information was received this year. However, it was noted that an international Workshop on the conservation of the baiji and Yangtze finless porpoise took place in late 2004 in Wuhan, China (workshop report available from www.baiji.org). The Workshop operated under the assumption that the Chinese authorities had decided to proceed with capture operations to remove some baiji from the Yangtze River into the ox-bow reserve and/or into a dolphinarium. The Committee was also informed that Yangtze finless porpoises would not be removed either before or after baiji were introduced into the reserve.

The Committee noted the news from the Workshop but also recalled that recommendations made at previous international workshops and those made by the Committee (IWC, 2001c) had not commonly been followed, including the recommendation to remove Yangtze finless porpoises from the Shishou Tian-e-Zhou oxbow semi-natural reserve before introducing baiji into it, because of concerns of inter-species interactions. The Committee did not discuss the pros and cons of *ex situ* versus *in situ* approaches but **agrees** with the conclusion of the Workshop that any captured dolphins should be placed in the oxbow under soft-release (i.e. temporarily monitored in a holding-pen (or pens) prior to their release) conditions. The Committee also **agrees** that the recommendation for a range-wide baiji survey should be implemented as a matter of urgency and any capture efforts be targeted on the most threatened areas while concomitant *in situ* conservation work should be pursued in areas ostensibly subject to lower levels of risk.

13.2.2 Vaquita

The Committee has followed with great interest the progress on conservation efforts on behalf of the vaquita (*Phocoena sinus*), an IUCN listed 'critically endangered' species endemic to the upper Gulf of California, Mexico. Several members of the Committee are members of the International Committee for the Recovery of the Vaquita (CIRVA). This year, the Committee received information on the use of passive acoustics to study habitat use and a brief review of progress on conservation actions recommended in the third

report of CIRVA (Rojas-Bracho *et al.*, 2004) presented at last year's meeting, including the establishment of a closed area for gillnetting. The Committee welcomed progress with acoustic research on vaquita distribution and on promotion of the CIRVA recovery plan and noted that results of the acoustic study provide additional evidence of the need for urgent implementation of the plan. The Committee was informed that on 5 June 2005, the President of Mexico stated that it had been agreed to declare the highest vaquita concentration area as a refuge for this species. The Committee wholeheartedly **welcomes** this news and thanked the President of Mexico for this important conservation measure.

13.2.3 Harbour porpoise

The Committee had reviewed the status of harbour porpoises (*P. phocoena*) in the North Atlantic in 1995 and agreed that reported bycatch levels justified concern about sustainability. In 2001, a joint IWC/ASCOBANS Working Group had provided scientific advice to ASCOBANS on a simulation modelling approach that might allow ASCOBANS to develop algorithms to meet their conservation objectives (IWC, 2002c, p.59). The Committee then considered and endorsed an alternative approach for developing a relatively simple, but spatially explicit, model or models with the objective of determining bycatch levels that would allow small cetaceans to recover to, or be maintained at above, 80% of carrying capacity. This approach has now been incorporated as part of the current EU funded SCANS-II (Small Cetaceans of the European Atlantic and North Sea) Project which will advise the European Community and ASCOBANS. The Committee **agrees** that it may be appropriate to re-instate the joint IWC-ASCOBANS Working Group, as suggested by the observer from ASCOBANS, when the results from the modelling work become available. SC/57/SM13 describes a planned project as part of SCANS-II to determine appropriate limits for small cetacean bycatch (concentrating initially on harbour porpoises) in the European Atlantic and North Sea. The Committee **welcomes** this development and looks forward to receiving updates at subsequent meetings.

13.2.4 Humpback dolphin (*Sousa spp.*)

The genus *Sousa* was the subject of an extensive review in 2002 (IWC, 2002c). Jefferson reported that substantial progress had been made on implementing the recommendation for a global study on the systematics of the genus using molecular techniques. The Committee **welcomes** news of a workshop on conservation and research needs in early 2004 and encourages efforts to assess the status of *S. chinensis* in China, Taiwan.

13.2.5 Irrawaddy dolphin

The Committee addressed the status of Irrawaddy dolphins (*Orcaella brevirostris*) in 2000 (IWC, 2001c). It concluded that densities appeared to be low in most areas and that several populations were believed to be seriously depleted and threatened with extirpation, particularly in freshwater areas of their distribution. Subsequently, five geographically isolated populations have been classified in the IUCN Red List as 'critically endangered' due to small population sizes and continuing declines in abundance. In 2000, the Committee recommended that all live captures should cease 'until affected populations have been assessed using accepted scientific practices' (IWC, 2001b, p.266). The Committee noted that the proposal to transfer Irrawaddy

dolphins from CITES Appendix II to Appendix I was approved at the 13th CITES Conference of Parties in October 2004.

The Committee welcomed new information on opportunistic and dedicated surveys in two previously unsurveyed regions – northwest Australia and the mangrove channels of the inner Sundarbans Delta in Bangladesh. It noted that other unknown populations almost certainly exist within the range of the species and **expresses concern** about observations reported in SC/57/SM4 of potentially unsustainable bycatches in a drift gillnet fishery for elasmobranchs.

13.2.6 Other recommendations

The Committee welcomed a preliminary attempt at compiling a global review of interactions between cetaceans and longline fisheries (SC/57/BC3). Although longline fishing has generally been viewed as being benign to cetaceans, a large variety of species have been incidentally hooked or entangled by this fishery. Small and medium sized cetaceans appear to be more vulnerable. The Committee noted that a large number of additional cetacean species and countries could be added to the existing compilation and it **commends** plans by the authors of the paper to conduct a more comprehensive review in the future.

The Scientific Committee has been unable to complete a full assessment of the status of Dall's porpoise (*Phocoenoides dalli*) populations as directed by IWC Resolution 2001-12, in the absence of necessary information. The last reviewed abundance estimates in 1991 for Dall's porpoises affected by the Japanese harpoon fishery were 217,000 ($CV=23\%$) for the Central Okhotsk Sea (*truei*-type) and 226,000 ($CV=15\%$) for the Southern Okhotsk Sea (*dalli*-type). Catch statistics from the Japanese Fisheries Agency website for January-December 2003 were 7,412 individuals for the *dalli*-type and 8,308 individuals for the *truei*-type, which represent 3.4% and 3.7% of the 1991 abundance estimates for both types, respectively. Directed takes of Dall's porpoise have exceeded the Scientific Committee's recommended anthropogenic mortality limit of 2% of abundance (IWC, 2002c, p.58) for over 15 years, and the fishery remains the largest directed hunt for small cetaceans in the world. The Committee **repeats its previous recommendation** that directed takes be reduced to a sustainable level as soon as soon as possible.

13.3 Consideration of revision of IWC cetacean list

The present IWC list of recognised species of cetaceans does not include two very recent changes in cetacean taxonomy, specifically the description of a new beaked whale species (*Mesoplodon perrini* sp. n., Dalebout *et al.*, 2002) and the replacement of *M. bahamondi* (Reyes *et al.*, 1995), on the basis of morphological features of the skull, mandible and teeth and phylogenetic analysis of mtDNA sequences (van Helden *et al.*, 2002) with the senior synonym *M. traversii* (Gray, 1874). The Committee **recommends** that the list (presented in full in Annex L, Appendix 2) be updated as follows:

- (i) Bahamonde's beaked whale (*M. bahamondi*) (change to *M. traversii*, recognise common name spade-toothed whale); and

- (ii) Perrin's beaked whale (*M. perrini*) (recognise species).

13.4 Takes of small cetaceans

Information on small cetacean catches in 2001-04 is given in Annex L (Appendix 3) and it was noted that the data were incomplete. The Committee **urges** member governments to ensure that complete figures are reported to the Commission in a timely manner. The Committee **recommends** that the bycatch reporting tables for small cetaceans in the Progress Reports include the responsible fishing gear type, as is the case with large whales. The Committee also noted that the species identity of small cetaceans (directed take or bycatch) may be determined by genetic analysis of samples obtained during market surveys. The Committee recognised the potential of this approach to supplement official bycatch reports and agreed on the need to address potential biases of the technique.

An increase in strandings associated with a marked increase in fisheries entanglement of a small population of bottlenose dolphin (estimated to contain 80 individuals based on mark-recapture photo-identification studies) in Rio Grande do Sul, Southern Brazil is of concern, with model predications indicating a likely decline (SC/57/SM8). The Committee **recommends** that the status of this population be assessed as a matter of urgency.

13.5 Work plan

The Committee reviewed its work plan and schedule of priority topics. The work plan for the coming year includes as a priority a review of the status of small cetaceans of the Caribbean and western tropical Atlantic. Full details are given under Item 19 and in Annex L. A minority statement is given in Annex S.

14. WHALEWATCHING (SEE ANNEX M)

14.1 Report of the intersessional Working Group

Based on the work of an intersessional group, a number of definitions were developed to help clarify discussions on whalewatching activities. A glossary of types and categories of whalewatching, recommended by the Committee, is presented in Annex M, Appendix 2.

The intersessional Working Group on further development of precautionary approaches as a science-based framework for management of whalewatching was not convened during the intersessional period. The Committee **agrees** that this issue remains a high priority. Recognising the importance of the Workshop on Science for Sustainable Whalewatching held in South Africa in 2004 and of continued progress in the development of a scientifically based framework for the management of whalewatching, the Committee **agrees** that the report be made available through a link on the IWC website¹³.

14.2 Biological impacts of whalewatching on whales

SC/57/WW3 summarised several studies on the impacts of whalewatching activities on cetaceans (Scheidat *et al.*, 2004; Goodwin and Cotton, 2004; Buckstaff, 2004; Orams, 2004; Bejder and Samuels, 2003; Bejder, 2005). The studies are summarised in Annex M, item 6. Parsons agreed to provide a review of relevant papers next year.

¹³ <http://www.iwcoffice.org/conservation/whalewatching.htm>.

SC/57/WW5 reviewed recent key research and considered implications for future whalewatching research and management (Lusseau, 2003; Lusseau, 2004b; Constantine *et al.*, 2003; Constantine *et al.*, 2004; Williams *et al.*, 2002; Erbe, 2002; Bejder and Samuels, 2003). The studies are summarised in Annex M, item 6.

Given the innovative, quantitative methodologies in the papers reviewed, particularly those that examine linkage between short and long-term impacts, the Committee noted that the presence of key invited participants would have greatly enhanced the work of the Committee. The Committee therefore **recommends** that Invited Participants (such as Bejder, Lusseau and Samuels, who were invited but unable to attend this year) with this level of expertise be invited and funded to attend next year's meeting.

SC/57/WW7 described the increase of whalewatching efforts on humpback whales along the Bahia and Espírito Santo State coast, an area encompassing the main breeding ground of this species in Brazil. Edict 117/96 (modified by Edict n° 024-08/02/2002) regulates whalewatching in Brazilian waters. Article n°4 foresees restrictions on whalewatching only inside Marine Protected Areas (MPAs); Article n°5 states that any commercial tour vessel operating inside MPAs where cetaceans regularly occur must provide interpretative information on these animals and their conservation needs to passengers on a permanent basis. Due to the increase in the occurrence of humpback whales along the Bahia State coast outside of the MPAs, the authors suggest the Edict be changed to encompass the full range of the breeding area. The Committee welcomed this report and **supports** the proposal for revised legislation. In addition, the importance of presenting data on impact studies at next year's meeting was noted. Details of the study and discussions are in Annex M, item 6.

A land-based study to assess vessel impacts on Risso's dolphins (*Grampus griseus*) in the Azores, an important feeding, breeding and nursery area for the species, is nearing completion. Results indicated that Risso's dolphins significantly decreased their resting behaviour when the number of boats in the area increased, responding to the presence of boats as soon as they were present in the bay. In addition, their resting period shifted to midday, when the average number of boats in the area was relatively low, possibly adapting to a less favourable situation.

14.3 Review of published whalewatching guidelines and regulations

SC/57/WW2 detailed the present state of whalewatching regulations in Argentina. The first whalewatching regulations for Península Valdés were created in 1984 by adapting laws from other countries and several aspects of the regulations presently are not applicable. In 2004, Instituto de Conservación de Ballenas/Whale Conservation Institute (ICB/WCI) organised a meeting with whalewatching company owners, boat captains, government officials and researchers to discuss ways to improve the current laws and to minimise the impact on the animals. Participants at the workshop agreed that the process to update the law could take years and proposed to create a Voluntary Code of Conduct that would be in effect for the short term. The Committee **welcomes** this approach to reducing the impacts of whalewatching since it integrates the stakeholders involved in whalewatching activities. Details of the code and discussions are in Annex M, item 7.

SC/57/WW3 presented studies on the effectiveness of whalewatching guidelines and regulations (Lusseau, 2004a; Scarpaci *et al.*, 2003; Scarpaci *et al.*, 2004). The studies are summarised in Annex M, item 7.

SC/57/E8 addressed concerns about tourism in Antarctica. As whalewatching may be an added stressor in the region and treaty nations are interested in developing a regime for tourism management, it was suggested that the Committee consider collecting data on whalewatching activities in the area. The Committee **agrees** that information on whalewatching activities and research conducted from whalewatching vessels in Antarctica should be presented at next year's meeting and that members should actively solicit papers for review.

The compendium on whalewatching guidelines and regulations around the world (Carlson, 2004) is being updated and will be posted on the IWC's website when complete. It was noted that the Instituto de Conservación de Ballenas/Whale Conservation Institute had translated the compendium to Spanish. The author thanked the group for this enormous and very useful work and suggested that the Spanish version be linked to the IWC website.

14.4 Development of the scientific foundation of whalewatching guidelines

SC/57/WW1 reviewed 48 scientific peer-reviewed and grey literature articles involving impacts of whalewatching on cetaceans, characterised by species, location, methods and potential sources of impact, including vessel distance, speed, direction and noise. The aim of the review was to highlight available research results that could facilitate the development of scientifically based regulations. Results indicate that the majority of cetacean reactions appear to be elicited by the speed and direction of whalewatching vessels and that noise appeared to play an important role. The authors concluded that there is a body of evidence, varying by species and location, that can provide important information about cetacean reactions to whalewatching vessels and guidance for a science-based formulation of new regulations or the revision of current ones. The authors further suggested that areas where extensive whalewatching research has been conducted, in particular those where long-term studies exist, can provide research models for locations looking to develop a whalewatching research programme.

SC/57/WW3 summarised Goodwin and Cotton (2004). The authors suggested that guidelines incorporate speed restrictions and distances between boats and animals due to significant behavioural responses to fast-moving, planning-hulled vessels, but not other categories of boats studied.

It was noted that the majority of authors cited in SC/57/WW5 provided management advice, linking it to their research (Williams *et al.*, 2002; Constantine *et al.*, 2003; Constantine *et al.*, 2004; Lusseau, 2004a; Simmonds, 2004). The studies are summarised and discussed in Annex M, item 8.

In principle, all human activities in proximity to cetaceans will impact the animals. Therefore, it is critical to identify management objectives and then develop a management procedure that links the knowledge base to regulation. This management procedure should include an assessment of risk associated with anthropogenic disturbance in proximity to cetaceans, and describe the relation between level of disturbance and effect on the cetaceans. As a precautionary approach, whalewatching activities should be regulated well within the levels that

have no significant, detrimental effect on cetaceans. The level of whalewatching activities that will be allowed might differ between areas and countries, taking into account *inter alia*, socio-economic conditions, and will reflect the level of risk the respective managers are willing to take.

It was noted that one of the recommendations of the Workshop on Science for Sustainable Whalewatching was to conduct risk assessment analyses. The Committee **agrees** that terms of reference be developed for an intersessional Working Group to correspond on this subject and present a report at next year's meeting (see Annex P(28)).

14.5 Other topics

14.5.1 Review of risk to cetaceans of high-speed whale-watching boats

SC/57/WW8 presented a review of known collisions between whalewatching boats and whales worldwide. Thirty-two records were identified between 1984-2003. Results indicate the need for caution as whalewatching industries increase the use of larger, faster whalewatching boats. However, risks from whalewatching boats may not be substantively higher than any other transiting vessel in the same area. Details of the study are given in Annex M, item 9.1.

The Committee expressed an interest in receiving more information on this issue next year. Based on the evidence presented in SC/57/WW8, the Committee **agrees** to provide the following scientific advice for whalewatching management: whalewatching vessels, as well as other vessels, are at an increased risk of striking a whale within a set distance (2km or 4km) of the sighting of another individual and whales that are struck will often not be sighted prior to the strike. The severity of injury from a strike will increase as a function of the force of the strike. Since a key component of force is the speed at which the animal is struck, reducing speed in the vicinity of a sighted whale is likely to reduce the severity of a strike, and may have the auxiliary benefit of allowing operators increased time to avoid a strike altogether. This may be especially important in cases where relatively large whalewatching boats are used, since their size could also lead to increased force and therefore, injury if a strike were to occur.

14.5.2 Review of potential impacts of 'swim-with' programmes on populations of cetaceans

SC/57/WW3 reviewed studies on swim-with-cetacean tourism (Courbis, 2004; Samuels and Bejder, 2004; Orams, 2004; Scheer *et al.*, 2004). The studies are summarised in Annex M, item 9.2.

SC/57/WW6 presented an update to Rose *et al.* (2003) on the occurrence of swim-with-whale operations worldwide. Fifty-one specific commercial operations were identified, an increase of 43% from 2003. Humpback and dwarf minke whales remained the main species targeted, although swims were also offered with sperm, bowhead and blue whales. There was a decrease from 2003 in the number of web sites that mentioned conservation, human safety and research. The results reported are still only an imprecise estimate for the frequency of this activity as web searches were only conducted in English. The Committee **concurs** with steps recommended by the authors for presentation at the 2007 meeting, with an update next year, including: revising the world-wide review of swim-with-whale programmes; using additional methods; reviewing

published and ongoing studies of swim-with-whale programmes; and identifying data gaps that would be necessary to fill in order to allow an assessment of the effects of such programmes on target individuals and/or populations.

The Committee **agrees** that this work be addressed by an intersessional Working Group (see Annex P(29)).

14.5.3 Other

Mayr and Ritter (2005) reviewed photo-identification research and behavioural observations of rough-toothed dolphins (*Steno bredanensis*) conducted from 2000 to 2003 on board whalewatching vessels off La Gomera (Canary Islands). The dolphins were found to have several distinct features suitable for individual identification. Identification and resighting data indicate a resident population and higher vulnerability towards anthropogenic activities. The study highlights the importance of longitudinal data collection and the value of platforms of opportunity for this type of research.

Published studies, based on data collected on whalewatching vessels, have addressed a wide range of management-relevant topics, including: distribution; stock identity; reproduction and survival rates; abundance; population composition; migratory destinations; behaviour and anthropogenic impacts (Robbins, 2000a). Some of these studies have contributed to the work of the Scientific Committee, such as in the 2001 Comprehensive Assessment of North Atlantic humpback whales. However, logistical and financial limitations can slow the pace at which whalewatching-based research emerges in the published literature (Robbins, 2000b). There also may be areas where useful data could be collected from opportunistic platforms, but no programme is underway.

It was proposed that the sub-committee on whalewatching make a dedicated effort to identify opportunistic sources of cetacean data of potential value to the work of the Scientific Committee. Committee members have detailed knowledge of the locations of whalewatching operations worldwide and so can identify areas, operations and/or data that are potentially relevant to upcoming Scientific Committee needs. Furthermore, members have expertise in the scientific use of opportunistic data sets, which have their own limitations and biases (Robbins, 2000b). The Committee could therefore provide a valuable service by scrutinising existing data collection programmes and archives, providing guidance to data collectors, seeking access to data that might address its scientific needs, and encouraging new data collection in key areas. It was noted that the ultimate value of this work within the whalewatching sub-committee would depend upon close co-ordination with other sub-committees.

The formation of an intersessional Working Group with membership from other relevant sub-committees to examine overlap between whalewatching activities, existing data collection programmes and upcoming Scientific Committee priorities was proposed and a request was made that the sub-committee solicit and review scientific information derived from opportunistic data sources and analytical techniques appropriate to such data. The Committee **agrees** that this would be of value to its work and should be a priority item for next year. It further **establishes** an intersessional Working Group to forward this work (Annex P(27)).

14.6 Work plan

The discussion of the work plan is given in Annex M, item 10. This is taken into account under Item 19.

15. DNA TESTING (SEE ANNEX N)

15.1 Progress on genetic methods for species, stock and individual identification

SC/57/SD3 presented an update on improved methods for DNA extraction and Polymerase Chain Reaction (PCR) amplification from small, old, and degraded tissue samples (including bone and dried soft tissue). Discussion of this can be found in Annex N, item 5.

SC/57/SD4 presented the results of a validation exercise for cetacean species identification using the curated reference dataset of mtDNA control region and cytochrome *b* sequences implemented in the Web-based species identification program, *DNA Surveillance* (Ross *et al.*, 2003) and the non-curated sequences available in the international repository GenBank. The purpose of the exercise was two-fold:

- (1) to evaluate the potential for taxonomic mis-identification of sequences in the non-curated collection in GenBank; and
- (2) to evaluate the reliability of *DNA Surveillance* to identify cetacean sequences and to recognise non-cetacean sequences.

Overall agreement between GenBank and *DNA Surveillance* in the attribution of species identity was high and there was little evidence that non-cetacean sequences in GenBank have been mislabeled as cetaceans. Discussion of this can be found in Annex N (item 5).

The Committee **agrees** that validation such as that described in SC/57/SD4 should be carried out routinely for cetacean sequences in GenBank and other such repositories and the Committee established an intersessional Working Group to develop and implement a protocol for routine validation for cetacean sequences in GenBank and other repositories. The question arose of what action could be taken when an identification is found to be erroneous, in view of the fact that the database entries are the responsibility of the original submitter. One possible solution suggested was that a new field could be added to the database where a challenge to the identification could be noted.

Kanda summarised a recent paper on the use of single nucleotide polymorphisms (SNPs) as markers in population genetics (Morin *et al.*, 2004). SNPs are genetic variation resulting from single-point mutations that produce single base-pair differences among DNA sequences.

A lengthy discussion on the advantages and disadvantages of SNPs took place in the Working Group and details can be found in Annex N (item 5). It was noted that the relevant issue for DNA registers is the potentiality of this marker for individual identification. The Committee **agrees** that SNPs offer considerable promise for application in the genetics of whale management, in particular because of the ease of standardisation of data across laboratories.

15.2 Collection and archiving of samples from catches and bycatch

A total of 638 and 537 common minke whales were landed in Norway in 2003 and 2004, respectively. Genetic analysis of these samples is in progress.

SC/57/O14 reported that samples of skin and muscle have been collected for 36 common minke whales taken in 2003 and 25 in 2004 in the Icelandic scientific whaling operations.

Regarding collection of samples in Japan, the Committee was informed that for the scientific whaling for the Antarctic (JARPA) programme, samples stored as of April 2005 were: Antarctic minke whale since 1987/88, $n=6,794$; common minke whale, $n=16$. For the western North Pacific (JARPN II) programme, samples stored as of December 2004 were: common minke whale since 1994, $n=1,097$; Bryde's whale since 2000, $n=243$; sei whale since 2002, $n=189$, and sperm whale since 2000, $n=31$. The samples from bycatch stored as of December 2004 were: North Pacific common minke whale, $n=403$; North Pacific Bryde's whales, $n=3$; North Pacific right whale, $n=1$, and North Pacific humpback whale, $n=9$. Genetic samples were stored for the following stranded whales as of 1 December 2004: North Pacific humpback whale, $n=1$; North Pacific common minke whale, $n=1$ and North Pacific fin whale, $n=1$.

15.3 Reference databases and standards for a diagnostic register of DNA profiles

Skaug reported on the status of the Norwegian register. Genetic analyses on samples of common minke whales landed in 2003 and 2004 have not yet been completed.

Annex N (Appendix 3) provided information on procedures, standards and status for the Japanese register for large whales. All whales taken under special permit in the western North Pacific (up to 2003) and most of those taken in the Antarctic (up to 2003/04) have been incorporated into the register. All bycaught and stranded whales (up to 2004) have been incorporated into the register.

As in the case of Norway, the Japanese register uses three kinds of genetic markers: mtDNA control region sequences for species identification; a set of nuclear DNA markers (microsatellites) for individual identification, and Y chromosome DNA for gender determination. A total of 17 microsatellite loci are used in the case of North Pacific common, Bryde's and sei whales. In the cases of the Antarctic minke whale and North Pacific humpback whales, six loci are used. Since the sex of the animals is determined by experienced researchers, molecular sexing is not conducted for samples taken under JARPA and JARPN II. In the case of bycatches, sex is determined molecularly.

The Committee **agrees** that it is important that a uniform procedure for estimating error rates be used by the several nations with DNA registers and **recommends** that this be done.

The Committee expresses its gratitude to the three nations (Japan, Norway and Iceland) for supplying information on their collections and registers.

15.4 Work plan

The terms of reference for the Working Group for the next year will remain the same as for this year, unless the Commission requests other information in the interim (and see Item 19).

16. SCIENTIFIC PERMITS (SEE ANNEX O)

16.1 Review of results from existing permits

16.1.1 Japan-Antarctic minke whales

SC/57/O5 presented the results of the eighteenth and final year of the JARPA programme. Research was conducted in the western part of the Area VI and Area V over a 92-day period between 7 December 2004 and 8 March 2005. Furthermore, the first co-operative survey with the RV *Kaiyo Maru* was conducted in the Eastern part of Area V. This was a meso-scale survey for the elucidation of the Antarctic marine ecosystem based on recommendations from the JARPA mid-term review meeting in 1997. Details of this cruise were reported in SC/57/O16.

One sighting vessel, three sighting and sampling¹⁴ vessels and one research base ship were engaged in the research. A total of about 4,120 n.miles was covered in the western part of Area VI, and 14,460 n.miles in Area V. The total searching distance of the four research vessels was about 18,700 n.miles, which was similar to the totals in previous JARPA cruises.

Eight large whale species were seen during this cruise. Antarctic minke whales were the most numerous species in the research area overall and were also widely distributed throughout most of the area except for the West-North stratum of Area V. There were numerous sightings of four other species (in decreasing order of occurrence, humpback whales, sperm whales, fin whales and southern bottlenose whales (*Hyperoodon planifrons*)) in the whole research Area except for the East-South stratum in Area V.

The total number of sightings of Antarctic minke whales by the four research vessels was 4,400 individuals in 1,711 schools. Primary sightings of Antarctic minke whales made by the three sighting and sampling vessels amounted to 3,045 individuals in 1,049 schools. A total of 467 schools (consisting of 1,167 animals) was targeted for sampling of one whale from each school. On some occasions the chase was interrupted, e.g. by adverse chasing conditions or animal movements. One whale was struck and lost. A total of 440 individuals were sampled. The rate of success in sampling targeted individuals was therefore 94%.

Mature females dominated the samples in the East-South stratum, whereas mature males dominated the samples in the North strata in Area V and Area VI-W. Pregnant females were most numerous in the East-South stratum where a few immature individuals of both sexes were also sampled. There were 182 individual pregnant females with 182 foetuses in the whole research area.

Two Discovery tags were collected from a mature female that was 8.87m in length. This animal was captured at 72°59'S, 172°12'E on 5 February 2005. The Discovery tags had been attached at 66°16'S, 140°57'E on 4 January 1981 by the IDCR cruise and the visually estimated body length at that time had been 29ft (8.84m).

Particular features of this research cruise were:

- (1) the East-South stratum in Area V (Ross Sea) was more extensive than in previous research cruises;
- (2) relatively warm SST (1-4°C) was widely distributed in the western part of Area V; and
- (3) a cooperative survey with RV *Kaiyo Maru* was conducted in the Eastern part of Area V for the

elucidation of structure and function of the Antarctic marine ecosystem.

The survey indicated that the feeding migrations and segregation pattern of cetaceans were strongly influenced by yearly changes in oceanic environmental conditions such as SST and ice-pack distribution. It was stated that this indicated that long-term monitoring is therefore necessary to elucidate the structure and function of the Antarctic marine ecosystem.

The sampling regime has remained unchanged and the Committee did not enter into any detailed discussion of the results of this survey as the opinions of proponents and critics of this work within the Committee as expressed in previous years' meetings (e.g. see IWC, 2005c, pp.45-6) have remained unchanged.

16.1.2 Japan-North Pacific common minke, Bryde's, sei and sperm whales

SC/57/O3 outlined the offshore component of the 2004 full-scale survey under JARPN II. The objectives of the full-scale research were:

- (1) to investigate the feeding ecology of common minke and other whales and to further ecosystem studies, involving studies of prey consumption by cetaceans, prey preferences of cetaceans and ecosystem modelling;
- (2) to monitor environmental pollutants; and
- (3) to study stock structure, particularly for common minke whales.

Target species were the common minke whale, Bryde's whale, sei whale and sperm whale. The research area covered sub-areas 7, 8 and 9 in the western North Pacific. The survey covered the four whale species as well as their prey. A total of six research vessels were used: one dedicated sighting vessel, three sighting and sampling vessels, one research base vessel and one trawl survey vessel equipped with a scientific echo sounder. A total of 10,695 n.miles was surveyed over a period of 96 days. During that period, 119 common minke, 180 Bryde's, 385 sei and 523 sperm whales were sighted by the sighting and sampling vessels. A total of 100 common minke, 50 Bryde's, 100 sei and 3 sperm whales were sampled. The co-operative survey on ecosystem research was conducted in a part of sub-area 9, 15-17 September. All whales sampled were examined on board the research base vessel. Stomach contents of the common minke whales consisted mainly of Pacific saury (*Cololabis saira*), minimal armhook squid (*Beryteuthis anonychus*) and Japanese anchovy (*Engraulis japonicus*). Bryde's whale stomachs contained mainly Japanese anchovy and Chub mackerel (*Scomber japonicus*). Sei whale stomachs contained mainly Japanese anchovy, copepods and Pacific saury. Dominant prey items in the stomach of three sperm whales were various kinds of mid- and deep-water squid.

The coastal component of the ongoing JARPN II work was described in SC/57/O4. Based on the results of the two-year feasibility study conducted in 2002 and 2003, the coastal component has been revised to be conducted twice a year, with 60 common minke whales being sampled in the spring and autumn seasons respectively. The first of the JARPN II revised coastal surveys was conducted 13 September-31 October 2004, off Kushiro, northeast Japan (i.e. the northern part of sub-area 7), using four small-type

¹⁴ Under Special Permit research, sampling implies lethal sampling of whales unless otherwise specified.

whale catcher boats, one echo-sounder trawl survey vessel and one dedicated sighting survey vessel. An additional dedicated sighting survey using one small-type whale catcher boat was also attempted. The sampling was conducted in coastal waters within 50 n.miles of the port of Kushiro and all whales sampled were landed at the land station at the port of Kushiro.

During the survey, the total search effort for whale sampling was about 6,920 n.miles (635 hours), 151 schools and 156 individual common minke whales were sighted and 59 whales were sampled. The average body length of the sampled whales was 6.87m (SD=0.80, $n=47$) for males and 6.00m (SD=1.09, $n=12$) for females. Dominant prey species found in the forestomach were Japanese anchovy (62.1%) and Pacific saury (31%). The concurrent prey survey revealed the distribution of those prey species in the research area, and the dedicated sighting survey sighted 17 schools (18 individuals) of common minke whales within some 810 n.miles searched. Compared with the results of the 2002 survey off Kushiro, the length frequency of the whales inclined towards larger males, while the species composition of the prey species found in the forestomach was similar.

These results revealed yearly changes in the migration and feeding habits of common minke whales in the coastal waters off Kushiro in the autumn season, and it was suggested that those changes might be related to yearly variation in environmental factors such as the oceanographic conditions or the distribution of prey species. To evaluate the potential for long-term competition between whales and fisheries in the local area and to clarify the role of whales in the marine ecosystem, the proponents stated that further surveys should be conducted on a yearly basis.

The relevance of the reported collection of oocytes from female common minke whales for *in vitro* fertilisation (SC/57/O5) was questioned. The Committee was referred to the work of Prof. Y. Fukui, of the Obihiro University of Agriculture and Veterinary Medicine, who has published several papers in international journals on his work on oocyte development and whale reproduction, some of which are detailed in SC/57/O15.

There remained divided views on the validity of the JARPN II research programme and its results, as expressed in previous years (e.g. see IWC, 2005c, p.46; IWC, 2004d, p.364).

16.1.3 Iceland-North Atlantic common minke whales

The Icelandic Research Programme on common minke whales was reviewed in SC/57/O14. The original plan had called for a sample of 200 common minke whales in the two years after the review by the Committee in June 2003. The programme began in August 2003, with takes of 36 whales that season, followed by 25 in the 2004 season. Progress has therefore been much slower than anticipated. The reasons for this were political rather than scientific, with the Icelandic Ministry of Fisheries deciding the rate of sampling. This should not present a problem in scientific terms, so long as the total expected take of 200 is achieved and the original seasonal and geographical distribution is retained. The present expectation is that 39 whales will be taken in 2005 and the remaining 100 in 2006.

The 2004 season was 3 June-6 July. Three catching boats had been employed with search effort distributed all around Iceland. The 2004 season had taken more females than males (15 out of 25) than in the previous year (13 out

of 36). This year seven animals were taken ashore for a full veterinary post mortem examination. Aerial surveys were also conducted during the period April to September 2004 and the resulting maps of survey effort and sightings were shown in SC/57/O14 and SC/57/O8.

Satellite telemetry was attempted on seven animals and data were received from one of these for several months, until 5 December 2004, at which time the animal was off the coast of West Africa (SC/57/O9). A summary of other projects within the overall programme was also given in SC/57/O14. Some members commended the work on satellite telemetry.

In response to questions about the criteria used to select animals for toxicological studies, it was stated that from the animals taken under the Special Permit, five animals had been selected under domestic legislation for marketing purposes. Another 25 animals had been selected over the two years for toxicological studies in order to obtain a representative sample from both sexes and different age classes from the whales taken under Special Permit. Some of these samples needed to be sent abroad for full analysis, and there had been some delays in obtaining the relevant permits.

In order to address the question of how effectively faecal samples collected at sea might be used to study diet, faecal matter was also being collected from the posterior end of the rectum of some common minke whales in order to make comparisons with stomach contents. This might then be compared with results from an International Fund for Animal Welfare (IFAW) project that had collected faeces under a research permit issued by the Icelandic authorities in 2004. The project will shed light on the feasibility of collecting common minke whale faecal samples at sea to study their feeding habits.

Childerhouse welcomed the increase in attention to non-lethal methods. Vikingsson welcomed a proposal from Hatanaka for collaboration with Japanese scientists.

The Committee noted the lower than expected sampling rate. As for the preceding programmes, opinions were divided on other aspects of the work, and reference was made to earlier statements on this programme by proponents and opponents respectively (IWC, 2005c, pp.46-7).

16.1.4 Review report from non-IWC meeting on JARPA results

A JARPA Review Meeting called by the Government of Japan was held at the Institute of Cetacean Research, Tokyo, on 18-20 January 2005, and is summarised in SC/57/O6. The JARPA research objectives and its work tasks were first reviewed. The JARPA survey procedure, the data collected and the results were also reviewed in the light of the JARPA objectives. The meeting agreed that:

- (1) JARPA has collected a very large and consistent database over a 16-year period, which provides a basis for time series analyses relating whales to the Antarctic environment and the beginning of an ecosystem approach to the management of whale resources in the region;
- (2) JARPA has contributed to the elucidation of biological parameters of Antarctic minke whales, and improved the understanding of the Antarctic marine ecosystem; and
- (3) JARPA has revealed the changes that have occurred in the ecosystem since the 1970s suggesting competition among Antarctic minke and other large whales and data

obtained through this monitoring will contribute to the development of ecosystem models, which are necessary for ecosystem-based management of whales.

The review meeting considered that JARPA had made good progress in addressing its objectives, and also agreed that tasks identified in the IWC mid-term review meeting in 1997 (see section 5 of SC/57/O6) had been appropriately addressed.

Some members of the Committee noted that the meeting to review JARPA hosted by Japan had been attended largely by representatives of nations that supported whaling, and thus they questioned the objectivity of this non-IWC review. In response it was noted that the review meeting had been widely made known, and that all members of the Scientific Committee had been invited, although it had been agreed that this review meeting would not be considered an IWC sponsored meeting (IWC, 2005c, p.46).

16.1.5 Preparations for JARPA review

The JARPA Review Planning Steering Group worked intersessionally to prepare for a full review of the JARPA programme by the Scientific Committee when the complete set of results of the 18 year programme is available. It had been agreed that the review would not be limited simply to results relating to Antarctic minke whales, but that research areas not covered in the original plan, and later adopted by JARPA, such as the work on blue and humpback whales, would also be considered. Abundance estimates and sightings survey work are also part of JARPA and need to be considered in full. The Group agreed that this review should be carried out by an Intersessional Working Group to Review Data and Results from Special Permit Research on Minke Whales in the Antarctic. This would be done during an intersessional meeting, most likely in Tokyo in late 2006. Progress in planning for this review was summarised, and a draft Terms of Reference and a draft Agenda were provided as appendices to the progress report (given as Annex O2 to this report).

The Steering Group had agreed on most aspects of the proposed review except for the draft Terms of Reference numbers 3 and 4, and proposed agenda item 9. There was some disagreement over how to address Resolutions made by the Commission with respect to the review, including issues surrounding the utility of lethal or non-lethal methods (proposed agenda items 9.1 and 9.2). It was **agreed** that a group led by Zeh (Annex P(30)) would reconsider this issue by re-examining the Commission's Resolutions in detail.

Noting the differences of opinion between members over interpretation of the Commission's Resolutions, the Committee nevertheless **agrees** that only scientific and not ethical issues should be considered by the review. However, a discussion of the scientific aspects of the respective merits of lethal and non-lethal methodologies was important. In view of the fact that some experts from outside the Scientific Committee would be invited to the review meeting, the Committee **agrees** that some discussion of the respective merits of lethal and non-lethal methodology (proposed agenda items 9.1 and 9.2, and Proposed Terms of Reference 3 and 4) is necessary to allow the Invited Participants to the Review to contribute to this debate. However, the main focus of the review would be on the remaining agenda items, and these more contentious issues would mainly be discussed at the subsequent Scientific Committee meeting by the full Committee. The Committee

accepts the proposed terms of reference and proposed agenda with this qualification.

16.1.6 Responses to previous Scientific Committee reviews

Childerhouse asked what changes had been made to each of the research programmes as a result of extensive comments received from the Scientific Committee in previous years. In response it was noted that the meso-scale surveys had been added to the JARPA research programme as a direct result of recommendations made at the mid-term review of JARPA in 1997. It was noted, however, that no modifications to the JARPN II work plan had been implemented as a result of any comments or suggestions made by the Committee in previous years. In reply it was stated that all comments on JARPN II research plans had been studied and considered but that few if any were constructive while others were difficult to accommodate.

With regard to Icelandic common minke whale research, it was noted that SC/57/O14 states that no major changes had been made to the original proposal, but that some new non-lethal components had been added in response to Scientific Committee comments made on the original proposal. Specifically, the Committee was informed that additional prey sampling was being conducted by taking samples from the posterior end of the rectum of sampled animals to compare with stomach contents and potentially with faecal samples collected at sea.

Although there is no formal requirement for Special Permit holders to report on what changes have been made to their research plans as a result of any comments or suggestions received from the Scientific Committee, the Committee **agrees** that it would be good practice to do so. This would help to speed up future reviews and would constitute an act of good faith.

16.2 Review of new or continuing proposals

16.2.1 JARPA II

The Plan for the Second Phase of the Japanese Whale Research Programme under Special Permit in the Antarctic (JARPA II) was presented in SC/57/O1.

JARPA was conducted between the 1987/88 and 2004/05 austral summer seasons, under Article VIII of the International Convention for the Regulation of Whaling. The IWC Scientific Committee conducted an interim review of JARPA results in 1997. In January 2005, a non-IWC JARPA review meeting called by the Government of Japan was held.

Based on its stated desire to take into account species-interaction (ecosystem) effects in understanding the dynamics of the baleen whale species in the Antarctic ecosystem, and predicting future trends in their abundance and population structure, the Government of Japan will launch a new comprehensive study under the Second Phase of the Japanese Whale Research Programme under Special Permit in the Antarctic (JARPA II), combining lethal and non-lethal methods, starting from the 2005/06 austral summer season. The first two seasons (2005/06 and 2006/07) will be dedicated to feasibility studies. The practicability and appropriateness of sighting methods in the enlarged area and sampling procedures given the increased sample size and number of species to be sampled, will be examined. Methods for catching, flensing and taking biological measurements of the larger species will be tested. The full-scale JARPA II will start from the 2007/08 season.

It will be a long-term research programme with the following objectives:

- (1) monitoring of the Antarctic ecosystem;
- (2) modelling competition among whale species and developing future management objectives;
- (3) elucidation of temporal and spatial changes in stock structure; and
- (4) improving the management procedure for the Antarctic minke whale stocks.

JARPA II will focus on Antarctic minke, humpback and fin whales and possibly other species in the Antarctic ecosystem that are major predators of Antarctic krill. Annual sample sizes for the full-scale research (lethal sampling) are 850 (with 10% allowance) Antarctic minke whales (eastern Indian Ocean and western South Pacific stocks), 50 humpback whales (D and E stocks) and 50 fin whales (Indian Ocean and the western South Pacific stocks). During the feasibility study, a maximum sample of 850±10% Antarctic minke whales and ten fin whales will be sampled in each season. Humpback whales will not be taken during the feasibility study.

The research methods for the JARPA II are basically the same as the previous JARPA with some modifications. The programme also includes non-lethal research techniques such as sighting surveys, biopsy sampling, acoustic surveys for prey species and the collection of oceanographic data.

The research proposal for JARPA II as described in SC/57/O1 was elaborated upon in an audio-visual presentation. In response to subsequent questions of clarification from members of the Committee, it was made clear that there will be six vessels involved in the JARPA II survey. Two of these will be dedicated sighting vessels and these will cover the entire area independently of the sighting and sampling vessels, but their tracklines have not yet been determined. Three of the vessels will be sighting and sampling vessels (the sixth vessel being the research base vessel). In response to a query as to how the same vessels could double the catch rate achieved under JARPA within the same seasonal sampling period, the Committee was informed that in previous seasons about 1,000 schools had been encountered, but that not all schools had been sampled and that whereas previously one animal per school had been taken, the plan for JARPA II was to take two animals per school. It was stated that sampling just one animal might lead to bias, and that sampling two animals per school would therefore be less biased. It was also stated that a larger area would be covered by JARPA II. The objective in JARPA II was to sample sufficient animals to achieve statistically significant results, and this required more animals to be taken.

There are as yet no plans to use trawls to validate acoustic estimates of krill abundance, although the independent meso-scale surveys of the area using another vessel may employ trawls to monitor krill at a later date. None of the vessels used in the JARPA II survey will be ice-breakers, so pack ice areas will be avoided, but some sightings survey work may occur in the marginal ice areas, so long as ice conditions permit the vessels to maintain speeds of 11 knots. This condition will define the ice-edge for these surveys. It is also intended to include sightings data from other expeditions involving ice-breakers working in the pack-ice if these are available. The issue of collaboration with CCAMLR was also brought up, as the removal of 850 Antarctic minke whales might impact

ongoing CCAMLR studies of the Antarctic ecosystem, so it was questioned whether or not collaboration with CCAMLR had been sought. It was stated in response that under JARPA, meso-scale surveys had included the participation of a Japanese CCAMLR scientist, and that collaboration with CCAMLR was therefore already happening.

In answer to the question of whether or not an ethical review process had been implemented it was stated that Japanese domestic legislation on animal welfare had recently been updated, and that although there was no formal process in terms of inter-agency consultation, the Fisheries Agency of Japan had considered the JARPA II plan in relation to the revised legislation and no conflict had been found between the planned research and the revised legislation. In response to a question on the issue of humane killing, it was stated that in previous JARPA surveys the time-to-death had been recorded, and that this practice would be continued.

Regarding the rationale for having an allowable error of 10% of the sample size of 850 animals, it was stated that tracklines are set according to previously observed densities, taking account of catchability by area, but it was not always possible to guarantee that the target would be attained.

Following these points of clarification, the proposal was reviewed by the Committee in accordance with the relevant guidelines for reviewing proposals for scientific permits. However a group of 63 members objected to a review of the JARPA II proposal because the Committee has had no opportunity to conduct a formal review of the results of the original JARPA programme; these members submitted a statement to this effect (SC/57/O22). This statement is included in Annex O, Appendix 2. These members further stated that they had substantial concerns about all aspects of the JARPA II proposal, but that it would be inappropriate to provide a detailed critique until after a JARPA review had been conducted by the IWC.

Accordingly, they stated that the lack of comments and criticisms of JARPA II in the Scientific Committee report should in no way be construed as consensus within the Committee regarding the objectives and methodology proposed by the JARPA II programme.

In response to this, the proponents tabled a working paper (Annex O, Appendix 3) that rebutted the assertions of SC/57/O22. Specifically these members stressed that the Scientific Committee was obliged to review the JARPA II proposal, according to paragraph 30 of the Schedule. These members also asserted that Japan was not trying to abandon the RMP, but rather was trying to strengthen it by addressing a multi-species approach. Concerning the lack of peer-reviewed results in international journals, it was stated that there has been a number of publications but that many western journals refuse to publish results from JARPA for ethical reasons. It was also asserted that the proposed sample sizes would not have an adverse impact on the recovery or status of any whale populations.

Following this exchange of views, the Committee continued to review the research plan in accordance with the relevant guidelines, but without the participation of the authors of SC/57/O22.

A. The Proposal

The current relevant guidelines for review are as follows:

1. A statement as to whether the permit proposal adequately specifies the four sets of information required under paragraph 30 of the Schedule (IWC, 1986, p.133).
2. Objective of the research (Schedule Paragraph 30).
3. Number, sex, size and stock of the animals to be taken (Schedule Paragraph 30).

Summary of proposal

The proposal provides the information required under Paragraph 30 of the Schedule.

Comments and discussion

Some members expressed the opinion that the JARPA research programme had made a major contribution to the knowledge of the biology of Antarctic minke whales, and that in the face of changing environmental conditions the value of this work would increase. They stressed the importance of preserving the continuity of the research programme, provided the research does not hamper the development of the stocks. Some other members stressed the importance of JARPA II as an approach towards ecosystem management of the Antarctic.

One member also expressed the view that many of the important results of JARPA have been presented to the Scientific Committee during the past few meetings, and that large parts of the proposed JARPA II have objectives that are virtually independent of the JARPA objectives and results. For these reasons he felt that the Committee has more than sufficient information to conduct a review of the JARPA II research plan. He also stated that it was reasonable to expect a continuation of scientific whaling in Antarctica, because of the need to keep ships and personnel employed with the task, and also the need to maintain markets for the whale meat, which helped to fund the entire programme. In reply it was noted that these logistical and economic considerations should be outside the purview of the Scientific Committee, and that the validity and necessity of such research programmes should be considered on their scientific merits alone.

B. Objectives

The current relevant guidelines for review are as follows:

1. comments on the objectives of the research to be carried out under the proposed scientific permit, including in particular how they might relate to research needs identified by the Scientific Committee (IWC, 1986, p.133);
2. the proposed research is intended and structured accordingly to contribute information essential for rational management of the stock (IWC, 1987, p.25);
3. is required for the purposes of management of the species or stock being researched (IWC, 2000a);
4. the research addresses a question or questions that should be answered in order to conduct the comprehensive assessment or to meet other critically important research needs (IWC, 1988, pp.27-8); and
5. the number, age and sex of whales to be taken are necessary to complete the research and will facilitate the conduct of the comprehensive assessment (IWC, 1987, p.25).

Summary of proposal

The proponents stated that JARPA has revealed evidence that the Antarctic ecosystem is changing and therefore, it is necessary to understand the dynamics of interactions between whale species in order to achieve rational management and sustainable use of whale resources. Based on the results of JARPA, JARPA II was planned with the following four objectives:

- (a) monitoring of the Antarctic ecosystem;
- (b) modeling competition among whale species and future management objectives;

- (c) elucidation of temporal and spatial changes in stock structure; and
- (d) improving the management procedure for Antarctic minke whale stocks.

JARPA II will provide information on abundance trends, biological parameters and stock structure, which will contribute to comprehensive/in-depth assessments of Antarctic whale stocks. An ecosystem model will be developed based on data collected under JARPA II, which will contribute to the testing of hypotheses concerning changes in the Antarctic ecosystem as well as the establishment of an ecosystem-based management scheme for whale resources.

Comments and discussion

Responses from the Committee to the listed objectives were limited in view of the opinions expressed in SC/57/O22. Some members stressed the importance of continued monitoring of biological parameters of Antarctic minke whales, not least in the light of global environmental changes, but also to supplement other ongoing research into Antarctic ecosystem dynamics. The failure of several baleen whale stocks to recover was also a matter that required an ecosystem level analysis, and while JARPA represented a significant step in addressing this question, JARPA II would provide a framework for multi-species modelling of the Antarctic marine environment. Other members also stressed the need to develop an ecosystem-based approach to managing the Antarctic marine environment and commended the objectives of JARPA II in this respect.

One member questioned the assumption expressed in SC/57/O1 that the population of Antarctic minke whales had increased after the cessation of whaling on the larger baleen whale species and in response to the depletion of these whale populations, noting that there had been no assessments of Antarctic minke whale stocks in the early 20th century.

C. Methodology

The current relevant guidelines are as follows:

1. 'comments on the methodology of the proposed research and an evaluation of the likelihood that the methodology will lead to achievement of the scientific objectives. These comments may also include evaluation of the methodology in terms of current scientific knowledge' (IWC, 1986, p.133);
2. 'the objectives of the research are not practically and scientifically feasible through non-lethal research techniques' (IWC, 1987, p.25);
3. '...whether the information sought could be obtained by non-lethal means' (IWC, 2000a, p.51);
4. 'the research addresses a question or questions that can not be answered by analysis of existing data and/or use of non-lethal research techniques' (IWC, 1988, pp.27-8);
5. 'whales will be killed in a manner consistent with the provisions of Section III of the Schedule, due regard being had to whether there are compelling scientific reasons to the contrary' (IWC, 1987, p.25); and
6. 'the research is likely to yield results leading to reliable answers to the questions being addressed' (IWC, 1988, pp.27-8).

Summary of proposal

The proponents stated that JARPA II will involve both lethal and non-lethal sampling. In general the research methods established by JARPA will be used in JARPA II. Monitoring of food consumption, blubber thickness, and age at maturity are important because these parameters are indicators of food availability and competition for a major food species in the Antarctic, krill. These data cannot be obtained through non-lethal sampling. Age, which can only be obtained by lethal sampling, is essential for detecting

recruitment trends by VPA and for studies of pollution on whales. All whales are taken using explosive grenades. If instantaneous death is not achieved, a suitable secondary method is applied.

Comments and discussion

Again, responses from the Committee were limited. Some members agreed that lethal sampling was the only way to collect the necessary data to achieve the stated research objectives and suggested furthermore that in order to elucidate ecosystem interactions sampling should be expanded to include other krill predators such as penguins and seals. Other members also noted the two-year feasibility phase and suggested that this would be valuable in refining the methodology. They agreed that while some biological data could be collected using non-lethal methods, the overall objectives would require lethal sampling.

Polacheck noted, in relation to guideline C1, and not withstanding the concerns raised in SC/57/O22 concerning the difficulty and validity of reviewing the JARPA II proposal prior to the completion of the review of JARPA, three additional general concerns with methodological aspects of the proposal, as listed below.

- (1) The level of details in the proposed survey and sampling designs is insufficient to adequately review the proposal – particularly with respect to the consideration of sample size, the relative effort devoted to sighting activities and the representativeness of coverage and sampling.
- (2) Monitoring of the Antarctic ecosystem and testing of hypotheses for changes in whale abundance through ecosystem modelling are two of the stated primary objectives of JARPA II. As noted in the proposal, krill play a central role in the Antarctic ecosystem and is a critical hypothesis underlying the proposal is that ‘the carrying capacity of the whale species depends on available biomass of krill’. The abundance of krill is seen as the dominant factor controlling changes in whale abundance. As such, estimation of the abundance of krill, monitoring trends in their abundance and understanding krill dynamics are critical for achieving the above two primary objectives of the proposal and would have been expected to have been a central component in the proposal. However, the proposal appears to recognise this but contains no commitment or specific survey plans for such work.
- (3) Monitoring of Antarctic minke whale abundance and biological parameters are a central focus of the proposed research programme. Substantial numbers of Antarctic minke whales appear to occur within the pack ice and the pack-ice is a potentially important habitat for this species. The current Scientific Committee review of Antarctic minke whale abundance and trends has found that lack of information on the abundance of Antarctic minke whales within the pack-ice, possible differential distributions with age and/or sex is an important uncertainty that confounds the interpretation of past research efforts (including those of JARPA). In designing a future research programme, it is critical to learn from the past results. JARPA II contains no plans to survey within the pack-ice, but will simply repeat this past deficiency of previous research. Similarly, as in (2), addressing the question of Antarctic minke whales in the pack-ice through direct monitoring would have been expected to be a central component of the

research if the proposal were serious about achieving its objective. The lack of this will likely compromise the interpretation of the Antarctic minke whale results and the likelihood of the programme achieving its stated objectives.

In response to these criticisms, the proponents of JARPA II stated firstly that the sampling design is still not finalised, but that the same approach as was used in JARPA will be used to lay down the specific tracklines that will be used in JARPA II. Secondly, and with respect to the issue of krill sampling, acoustic survey methods will be used to determine krill abundance, as was the case in JARPA, whilst simultaneously surveying cetacean distribution. Data collected in this way will promote the development of an ecosystem-modelling framework for the Antarctic marine environment. Finally, and with respect to Antarctic minke whales in the pack-ice, data on Antarctic minke whale distribution in the pack-ice have been collected gradually using ice-breakers, and this data collection will continue. Previous pack-ice work under JARPA has shown, for example, that there was a high proportion of mature females in the pack-ice and if enough time is spent collecting such data in future years, then these issues will be investigated.

Polacheck responded that he would still expect both krill sampling and Antarctic minke whale sampling in the pack-ice to be central components of any research projects with the stated objectives of JARPA II, rather than the adjunct exercises they appeared to be from both the proposal and the explanation given. Hatanaka replied that krill abundance estimates would certainly be carried out routinely every year.

D. Effects on stocks

The current relevant guidelines are:

1. a review of the most recent information on the stock or stocks concerned, including information on any exploitation, stock analysis and recommendations by the Scientific Committee to date (including, where appropriate, alternative analyses and conclusions and points of controversy) (IWC, 1986, p.133);
2. an evaluation of the specification in the permit proposal of ‘possible effect on conservation of the stock’. As appropriate, the Scientific Committee may carry out its own analysis of the possible effects (IWC, 1986, p.133); and
3. the research can be conducted without adversely affecting the overall status and trends of the stock in question or the success of the comprehensive assessment of such stocks (IWC, 1988, pp.27-8).

Summary of proposal

Based on the most recent information on stock structure and abundance in the Antarctic minke and humpback whale as well historical information in the case of the fin whale, the effect of JARPA II catches on the stocks has been evaluated by the proponents. They reported that the FITTER methodology used for Antarctic minke whales showed no negative effect on the stocks. In the case of humpback whales, they had applied the population dynamics model developed by Johnston and Butterworth (SC/57/SH16). The results showed that the proposed take of 50 animals per year would probably not delay the recovery of stocks to pristine level. The abundance estimate of fin whales does not cover their entire range and therefore is greatly underestimated. The planned sample size of fin whale is less than 1% of the underestimated abundance, and therefore the planned catch was considered by the proponents to have no adverse effect on the stocks.

Comments and discussion

Some members believed that the takes of Antarctic minke whales would not pose any threat to the population. They also asserted that sample sizes of the larger whale species were also small and unlikely to affect the stocks involved. The proposed takes of humpback whales in particular, are well below recruitment levels judging from recent evidence of a population growth of at least 10%. Abundance of fin whales has also increased so that the proposed catches should not have a negative effect on these stocks.

Leaper reminded the Committee that when the effect of research programme time-scales on catch quotas had been addressed at the 2000 meeting, the Scientific Committee had expressed concerns that open-ended special permit programmes initially proposed as feasibility studies had become ongoing programmes. Consequently the Committee **agreed** that when addressing the effects of special permit catches on stocks it would examine such effects as if the takes were ongoing. The continued increase in special permit takes since that time would seem to make that agreement in 2000 (IWC, 2001d, pp.57-8) even more pertinent for the present discussions.

In response, Hakamada pointed out that in Appendix 9 of SC/57/O1, simulation trials had been run in which continued catches at the levels proposed in JARPA II had little effect on the populations of Antarctic minke or humpback whales even when extended for as long as 30 years. However, the duration of the research programme is independent from the period of the research assumed in the trial.

E. Research co-operation

The current relevant guideline is:

1. comments on the adequacy and implications of specific arrangements for participation by scientists of other nations (IWC, 1986, p.133).

The proponents offered the usual invitation for suitably qualified foreign scientists to join the cruises.

16.2.2 JARPN II

Last year a revised JARPN II plan had been submitted, and the research in 2004 had been conducted according to those plans. There were no changes to the current research plans, on which the Committee had divided views. The Committee therefore refers back to previous statements made by proponents and critics of this research programme (IWC, 2003a, pp.66-77; IWC, 2005c, pp.47-9).

16.2.3 Iceland

The initial Icelandic proposal has been changed with respect to the rate of sampling, and this year's sample size has yet to be determined, although the Marine Research Institute's proposal was for 39 common minke whales. Once again, in the absence of any significant change to the planned research, the Committee refers back to previous statements by members (IWC, 2004b, pp.40-7; IWC, 2005c, p.49).

16.3 Proposals to facilitate the review process of scientific permits

Last year, (IWC, 2005c, pp.44-5; Bjørge and DeMaster, 2004) efforts were made to prepare a proposal to the Commission on restructuring the guidelines for scientific permits but no agreement was reached on any proposal for changes. This included a proposal to use independent reviewers, as had been done for the Southern Ocean Sanctuary review. Therefore, the Committee agreed at last year's meeting that, lacking further guidance from the

Commission, the Committee would not be able to agree any recommended changes and that this item should be removed from the agenda. Following a short discussion of several aspects of scientific permit whaling the Committee agreed that little had changed regarding the two disparate positions described in last year's Committee Report and the disparate positions described in Annex O (SC/57O22 and Appendix 2). For example, some members again questioned whether the scientific content of the proposal was sufficient to justify taking whales, while others believed it was. When reviewing scientific permit proposals, the Committee recognises the chronic difficulties it faces in separating purely scientific issues from those issues that are more appropriate for discussion in other fora and notably the Commission. However, **it draws to the Commission's attention** the fact that the integral nature of the scientific and non-scientific issues surrounding expanding scientific permit programmes makes it extremely difficult for the review process within the Committee to function effectively, since it wishes to limit its discussions to purely scientific aspects of the proposals.

Nonetheless, two specific proposals were raised concerning the review process.

Holders of special permits provide annual progress reports on the activities conducted under the special permit during the previous year. The Scientific Committee is required to review these reports and provide advice to the Commission. This year, the Committee was required to review reports from two Japanese permits (JARPA and JARPN II), the Icelandic permit and a new permit proposal by Japan (JARPA II). In all cases the scientific merit and value of the programs are highly controversial with entirely polarised views being expressed.

Some members believe that a major problem with the review process in the Scientific Committee is its lack of independence. They pointed at the proponents defending their own reports and proposals, participating in the review of these and in the drafting of the resulting reports. This is in contrast to a process that leads to the review being undertaken by scientists without conflict of interest, and they felt that this has created a scientific deadlock and an ineffective review process within the Committee. They suggested that an external, transparent review of these progress/mid-term/final reports and proposals should take place by submitting these for review to an international body representing independent scientists with marine mammal expertise e.g. the Society of Marine Mammalogy (SMM). The Journal of this Society publishes peer-reviewed scientific reports irrespective of lethal or non-lethal sampling protocols. They believed that by submitting the reports to the board of SMM, the IWC can expect an external independent review of the science of the work conducted under special permits.

Other members doubted that any independent and objective review of such proposals would be possible, as the issue of scientific whaling has polarised opinions in the wider scientific community as well as in the Scientific Committee. It was also noted by some members that a review of scientific permits is a mandated responsibility of the Committee under the Convention, the Schedule, and the Rules of Procedure. Therefore, it did not seem appropriate for the Committee to abrogate this responsibility to another organisation.

A second proposal for an alternate approach to how the Committee reviews scientific permits was to require the

country responsible for the proposal to subsequently submit a revised proposal that incorporates comments received from the Committee. It was also suggested that under this alternative approach, delegates from the country preparing the proposal would not participate in the review. There is no consensus within the Committee for this proposal.

As noted above, some members did not believe it was reasonable to expect a meaningful review by independent experts, given the controversy that exists over lethal sampling in general in the scientific community, and lethal sampling of large whales in particular.

Polacheck suggested in any case, review of the methodological aspects of proposals relative to evaluation of whether the methodology would likely lead to achievement of the scientific objectives (including survey design, lethal and non-lethal sampling methods and sampling sizes) was one component of the review process that should be feasible and for which it would be useful to seek independent review. Walløe commented that in his experience it is impossible to separate validation of methodology from other aspects of the research plan, such as costs, logistics and questions such as lethal versus non-lethal sampling.

The Committee **concludes** that there is no agreement on any of the suggestions raised during the meeting. It **notes** two issues that emerged that might be given further consideration at next year's meeting:

- (1) the possibility of an independent and objective review panel; and
- (2) the debate over whether or not the proponents of a proposal should participate in a review of their own proposal.

It further **concludes** that any new review process must be consistent with the Convention and with established Rules of Procedure.

17. WHALE SANCTUARIES

The only agenda item related to whale sanctuaries this year was in response to a request from Palazzo and the Government of Brazil to review a proposal to establish a South Atlantic Whale Sanctuary (SAWS) (IWC/57/4).

Palazzo summarised the proposal. It was noted that this document was not prepared *only* for the Scientific Committee. It was written to be discussed in several fora, including *inter alia* the Scientific Committee, the Conservation Committee, and the Commission Plenary. In the author's opinion, the proposal for a South Atlantic Sanctuary has not received proper time or consideration by the Scientific Committee. The Committee's previous reviews are summarised under Item 17.1.

The author stressed that the proposal for a SAWS presented jointly by Argentina, Brazil and South Africa has a very clear stated goal: that of promoting and consolidating a non-lethal management regime for cetacean resources in the area it encompasses. The author pointed out that the most relevant parts of the proposal for review by the Scientific Committee were contained in parts 6 and 7 of the proposal.

The author also noted that the proposed Sanctuary is to serve the stated goal of promoting non-lethal use of whales. The author pointed out that in this context, the proposed Sanctuary should not be judged in relation to the RMP, nor should its establishment be constrained by the possible future existence of RMP-based management regimes in

other areas. It was noted that in the author's opinion, the management decisions concerning the best way of appropriating whale resources are not to be dictated globally only on the basis of lethal harvests.

Finally, it was recognised by the author that the Committee was deeply divided about the issue of sanctuaries and its role in cetacean management. Nevertheless, Palazzo noted that this discussion would be a valuable exercise for the Commission as it attempts to craft a way out of the current deadlock in whale management alternatives.

The issue was raised whether coastal range states had been contacted, as it was desirable for their consent before going forward with this proposal. Palazzo stated that they had and noted that while the Convention applies to 'all waters in which whaling is prosecuted' (Article I (2)), the authors of the proposal understand that nothing in the proposal was intended to imply any restrictions to the sovereign rights of coastal States.

17.1 Background information regarding reviews of sanctuary proposals

Proposals similar to IWC/57/4 have been reviewed in the past by the Scientific Committee. A summary of the most recent comprehensive review was published in IWC (2002c, pp. 65-67; 2002e, pp. 404-7). During its annual meeting in 2001, the Committee 'was unable to reach a consensus view'.

At the 2001 meeting of the Commission, the Scientific Committee received further instructions from the Commission regarding reviews of sanctuaries (IWC, 2002c, p.65). The general guidance was that the Committee 'should give primary attention to considering the scientific feasibility of meeting the scientific aspects of the stated objectives, and, if necessary, recommend amendments to the objectives, or changes to the proposal to better meet its objectives.' Specific guidance included *inter alia*:

- (1) assess whether the sanctuary distinguishes between species and stocks that are depleted and apparently slow to recover, those that are increasing rapidly, and those that are abundant and not threatened and assess the present and potential threats to whale stocks and their habitats in the area of the proposed sanctuary and how the proposed sanctuary addresses these;
- (2) assess the anticipated effects of the proposed sanctuary in terms of:
 - (i) improving protection of whales, in breeding areas, feeding grounds, or migratory routes;
 - (ii) improving the conservation of breeding sites, migratory routes or feeding grounds; and
 - (iii) complementing existing or potential protection;
- (3) provide advice on whether the proposed boundaries of the sanctuary are ecologically appropriate;
- (4) provide advice on whether the sanctuary addresses the issue of critical habitat and non-critical whale habitat;
- (5) evaluate whether the sanctuary may contribute to or impede the conduct of scientific research useful for meeting IWC objectives and facilitate coordinated and integrated research and monitoring programmes; and
- (6) provide advice on whether the sanctuary is consistent with the precautionary approach.

At the 2002 meeting of the Scientific Committee 'it was noted that a proposal for a South Atlantic Sanctuary would

be submitted to the Commission this year and that its supporting document remains the same as that presented to the Committee in 2001' (IWC, 2003a, p.81). There was therefore, no substantive discussion of this proposal during the 2002 meeting.

In 2003, the Scientific Committee discussed an evaluation of the SAWS Proposal based on the instructions from the Commission and the review criteria. As in previous years, there was no consensus regarding recommendations to the Commission (IWC, 2004b, p.50). A summary of the perspectives both for and against the proposal to establish a SAWS is reported in Appendices 2 and 3 of Annex P (IWC, 2004e, pp.372-4).

At the 2004 meeting of the Scientific Committee, no review of the SAWS was undertaken. However, the Committee endorsed the recommendations listed below that were to be implemented generically to the review of sanctuary proposals (IWC, 2005c, p.50).

- (1) The purpose(s) of the SOS [Southern Ocean Sanctuary] (and other IWC Sanctuaries) should be better articulated through a set of refined overall objectives (e.g. preserving species biodiversity; promoting recovery of depleted stocks; increasing whaling yield). In particular, the relationships between the RMP and the Sanctuary programme should be articulated.
- (2) Appropriate performance measures both for Sanctuaries in general, and the SOS in particular, should be developed. These performance measures should link the refined objectives of the SOS with monitoring programmes in the field.
- (3) Systematic inventory and research programmes should be established or further developed so as to build the required information base for a Sanctuary management plan and subsequent monitoring programmes.
- (4) A Sanctuary management plan should clearly outline the broad strategies and specific actions needed to achieve Sanctuary objectives (e.g. how to protect x% of a given feeding area for stock y).
- (5) A monitoring strategy that measures progress toward achieving the Sanctuary objectives should be developed and subsequently implemented. A key component of this monitoring strategy would be the development of tangible indicators to monitor progress.
- (6) Review criteria that reflect the goals and objectives of the Sanctuary (as described above) should be established.
- (7) The Sanctuary management plan should be refined periodically to account for ecological, oceanographic and possible other changes in an adaptive fashion.

17.2 Instructions from the Commission to the Scientific Committee for reviews of sanctuaries

As noted above, the Scientific Committee undertook a review of the SAWS proposal at its 2003 meeting following the instructions received from the Commission at their 2001 annual meeting (IWC, 2002b, pp.18-9). After some discussion, there was general agreement that the information presented in IWC (2004e, pp.367-374) remained a reasonable summary of the two primary viewpoints of the Scientific Committee regarding this proposal relative to the most recent guidance from the Commission. However, both proponents and opponents agreed to provide additional comments to update the material provided in Borsani *et al.* (2004) and Hatanaka *et al.* (2004). Their summaries are provided below under Items 17.2.1 and 17.2.2.

17.2.1 Proponents section

Committee members supporting the SAWS proposal noted that the issues presented in Borsani *et al.* (2004) are relevant to the current review. In addition to those, it was further noted by these members that the proposal:

- (a) addresses threats to cetacean populations other than whaling in the region encompassed by the SAWS, and considers ways of dealing with these in light of current international law and the sovereign rights of coastal States as expressed in The United Nations Convention on the Law of the Sea (UNCLOS) (pp. 11-15 and 23-24 of IWC/57/4);
- (b) fully complies with the list of anticipated effects provided in (2) of the Commission instructions in terms of providing adequate protection of whales in breeding areas, feeding grounds and/or migratory routes, as well as the conservation of vital habitats through international coordination and cooperation, and complements effectively the Commission's current management regimes by proposing non-lethal management in the ocean basin level;
- (c) is ecologically justifiable as regards the SAWS proposed boundaries (IWC/57/4, pp.6-8; 18-21);
- (d) will contribute to the co-ordination and promotion of research as outlined in IWC/57/4 (pp.22-9), by providing for further involvement of the IWC in fostering cooperation; and
- (e) is consistent with Principle 15 of the United Nations Conference on Environment and Development (UNCED) 1992 Declaration, the Precautionary Principle, as it strives for attaining the natural carrying capacity levels and promoting use through exclusively non-lethal means (IWC/57/4, p.30).

17.2.2 Opponents section

Committee members opposing the SAWS proposal noted that the evaluation based on the instructions provided by the Commission presented in Hatanaka *et al.* (2004) also applies to the current review. In addition to that evaluation, these members also noted the points listed below.

In the context of the conservation and management of a living resource, a sanctuary means a limited land or sea area where harvesting activities of the resource is prohibited in order to achieve sustainable utilisation of the resource outside the area. This area is expected to provide a 'refuge' for a certain part of the migration, distribution, and/or life stage of the resource so that the resource is not over-harvested. Conservation measures that are totally prohibitive over a large area when the status of stocks allows for sustainable utilisation or when a management regime in effect is sufficiently precautionary can not be scientifically justified and negate the principle of sustainable utilisation.

A whale sanctuary in the South Atlantic is unnecessary for whale conservation given the application of the moratorium on commercial whaling to that area. Further, the proposal undermines almost a decade of work by the Scientific Committee to develop the risk-averse RMP. Once the RMP is implemented, it will only provide safe quotas for abundant stocks meaning that a sanctuary would be unnecessary and contrary to the purpose of the Convention even after the moratorium is no longer in place. The proposal is also contrary to Article V (2) of the International Convention for the Regulation of Whaling (ICRW) since it ignores the fact that the stock status of some of the large whale species is well above exploitable level.

Table 2

Proposed Workshops and pre-meeting meetings for the intersessional period. Financial implications are dealt with under Item 21.

Subject	Agenda item	Venue	Dates	Steering group
Finalise Soviet catch data	3.3.2	Cambridge	Before January 2006	P1
SOWER cruise: planning meeting and future	10.5	Tokyo	Mid-September (5 days)	P12
Bryde's whale <i>Implementation</i> workshop	6.1	Tokyo	25-29 October 2005 (5 days)	P15
SH humpback whale assessment workshop	10.3.1	Hobart	Spring 2006 (5 days)	P25
Fin whale stock structure and catch history	6.2	Reykjavik	Spring 2006	n/a
POLLUTION 2000+ workshop	12.3.1	?Boston	Spring 2006	P20
Bowhead <i>Implementation Review</i> workshop	8.4	La Jolla or Seattle	March 2006	P2
TOSSM workshop	11.1	Potsdam	March 2006 (5 days)	P9
Seismic pre-meeting	12.4	St Kitts and Nevis	May 2006 (2 days)	P18
Pre-meeting AWMP (early start)	8.1	St Kitts and Nevis	2 days prior to start of meeting	P2
Pre-meeting RMP (early start)	6.3	St Kitts and Nevis	May 2006	n/a

The opponents of the SAWS proposal noted that the conclusions of the external reviewers which highlight major flaws in the IWC's approach to sanctuaries are also applicable to the proposed sanctuary for the South Atlantic. A summary of these conclusions (IWC, 2005c, pp. 49-51; IWC, 2004a; Zacharias *et al.*, 2004) follows:

- (1) the SOS and IWC sanctuaries in general are not ecologically justified;
- (2) the SOS is based on vague goals and objectives that are difficult to measure;
- (3) the SOS lacks a rigorous approach to its design and operation and does not have an effective monitoring framework to determine whether its objectives are being met;
- (4) the SOS represents a 'shotgun' approach to conservation, whereby a large area is protected with little apparent rationale for boundary selection and management prescriptions within the sanctuary; and
- (5) the SOS is more prohibitive than precautionary.

17.2.3 Recommendations from the Commission for reviews of sanctuaries

In discussion, with respect to the instructions from the Commission to the Committee, there was no agreement within the Committee regarding the proposal to establish a SAWS.

17.3 Recommendations from the 2004 Scientific Committee meeting for reviews of sanctuaries

Regarding the recommended approach for reviewing sanctuary proposals, the Committee agreed to use the seven topics reported in IWC (2005c, p.50) in evaluating the SAWS proposal under this Agenda Item. Summaries of the positions against and for the proposal are provided in Annexes R1 and R2.

18. RESEARCH AND WORKSHOP PROPOSALS AND RESULTS

Table 2 lists the proposed intersessional meetings and Workshops.

18.1 Review results from previously funded research proposals

Results from IWC funded projects are dealt with under the relevant agenda items.

18.2 Review proposals for 2005/2006

No unsolicited research proposals were received.

19. COMMITTEE PRIORITIES AND INITIAL AGENDA FOR THE 2006 MEETING

19.1 Committee priorities for SC/57 (2005)

At this year's Scientific Committee meeting, 13 sub-committees (including standing Working Groups and *ad hoc* Working Groups) were established. As was the case last year, the annual meeting of the Committee was conducted over a 12-day period of which two days were allocated to Plenary. The number of sessions for sub-committee deliberations was therefore limited to 90. This is based on three concurrent sub-committee meetings for each of five work sessions per day, starting at approximately 08:30 and ending typically at 21:30, for a period of six days. At this year's meeting, because of our inability to schedule certain sub-committees opposite other sub-committees we were only able to schedule 85 meetings of sub-committees and Working Groups.

Some members were disappointed that insufficient time in sub-committee meetings was available to adequately discuss certain agenda items or issues, as reflected in some sub-committee reports. However, it was recognised by all members of the Committee that there was insufficient time to fully address all of the issues of relevance to the Commission. Therefore, difficult choices had to be made about which issues to assign priority during the 2005 meeting.

Table 3

Number of sessions by subgroups in 2005.

Sub-committee	Sessions	Sub-committee	Sessions
RMP	6	SM	8
AWMP	5*	SD	4
BRG	7**	SH	8
IA (+SOWER/NPM)	18**	Sanctuaries	2
BC	6*	Scientific Permits	5
E	10**	DNA	2
WW	4	Total	85

*Had pre-meeting; **had joint pre-meeting.

19.2 Committee priorities for SC/58 (2006)

As in recent years and with the Committee's agreement, the Convenors met after the close of the Committee meeting and drew up the following as the basis of an initial agenda for the 2006 meeting. The same criteria as previous years were taken into account (IWC, 2004b, p.51). The Committee recognises that priorities may have to be reviewed in light of decisions made by the Commission at IWC/57.

As last year, the Convenors agreed a provisional number of sessions per sub-committee. It was agreed that the

number of sessions allocated to each sub-committee will have to be strictly followed, as with only six days for sub-committee meetings there will be a maximum of 90 sessions available. The provisional number of sessions per sub-committee is indicated in Table 3. Items of lower priority on sub-committee agendas will only be discussed as time allows. The Committee **stresses** that papers considering anything other than priority topics will probably not be addressed at next year's meeting.

Based on comments received during Plenary, the Convenors agreed to form an *ad hoc* Working Group under IA to handle discussions related to North Pacific common minke whales. In addition, an *ad hoc* Working Group under Environmental concerns will be formed to handle discussions related to ecosystem modelling (e.g. interspecific competition). At this stage, the Convenors were not aware of the need to create a Working Group to evaluate the scientific merits of any sanctuary proposals at next year's meeting.

In addition, it was agreed that three pre-meeting meetings will be proposed to the Commission for:

- (1) AWMP;
- (2) RMP; and
- (3) E (Seismic Noise Workshop).

The proposal is that AWMP and RMP will share 2 days.

Table 4
Proposed allocation of sessions for 2006.

Sub-committee	Sessions	Sub-committee	Sessions
RMP	11*	SM	9
AWMP	8*	SD	5
BRG	8	SH	7

WW	6	Ecosystem modeling	3
		Total	90

*Plus pre-meeting; **plus workshop.

Revised Management Procedure (RMP)

As last year, this Committee will concentrate on general issues as well as preparations for *Implementation*. The Committee **agrees** on the following priority items (in order).

General issues

Evaluation of the criteria developed to determine whether the conservation performance of a RMP variant is 'acceptable', 'borderline' or 'unacceptable' (Item 5.1.1).

Implementation process

- (1) 'First Intersessional Workshop' for western North Pacific Bryde's whales; and
- (2) finalise the issues related to completing the *pre-Implementation assessment* for North Atlantic fin whales.

Aboriginal Whaling Management Procedure (AWMP)

The Committee **agrees** that the items below should be given priority:

- (1) review progress on the Greenlandic research programme (especially with respect to abundance, stock structure and the use of sex data in assessments) and attempt to provide management advice;

- (2) review progress on and refine design of trial specifications and coding for B-C-B bowhead whales (will include joint sessions with BRG on stock structure); and
- (3) review information on the St. Vincent and The Grenadines fishery and provide management advice.

Bowhead, right and gray whales (BRG)

The Committee **agrees** that the following item will be given highest priority:

- (1) review of new information on the stock structure of the B-C-B Seas stock of bowhead whales and on the progress of on-going research (joint meetings with the SWG on the AWMP).

It will also:

- (2) perform the annual review of catch information and new scientific information for the B-C-B Seas stock of bowhead and ENP gray whales; and
- (3) review new information on the western North Pacific stock of gray whales, right whales and the small stocks of bowhead whales.

In-depth assessment (IA)

The Committee **agrees** that the following item will be given highest priority:

- (1) produce agreed abundance estimates of Antarctic minke whales;

followed by (in priority order):

- (2) continue development of the catch-at-age analyses of the Antarctic minke whales;
- (3) develop recommendations for future SOWER cruises, both for the short- and long-term; and
- (4) continue to examine and then attempt to agree on reasons for differences between Antarctic minke abundance estimates from CPII and CPIII.

A separate Working Group will continue preparation for an in-depth assessment of western North Pacific common minke whales, with a focus on J stock.

Estimation of bycatch and other human-induced mortality (BC)

The Committee **agrees** on the following priority items:

- (1) further review of information and methods to estimate bycatch based on fisheries data and observer programmes:
 - (a) continue collaboration with FAO on collation of relevant fisheries data;
 - (b) progress on joining the FIRMS partnership;
 - (c) report back on EU bycatch monitoring schemes; and
 - (d) review modeling to determine observer coverage needed in a fishery to estimate bycatch; and
- (2) further consideration of methods to estimate bycatch based on genetic data;
 - (a) review progress on intersessional work related to market sampling; and
 - (b) report from Steering Group for follow-up Workshop on the use of market sampling to estimate bycatch.

In addition, the following items may be discussed if time allows (in priority order):

- (3) further review information and methods to estimate mortality from ship strikes;
 - (a) review results of data collected on vessels relevant to ship strikes;
 - (b) review report from planned ACCOBAMS workshop on ship strikes; and
- (4) consider methods for estimating additional human induced mortalities (e.g. from acoustic sources and marine debris).

Other Southern Hemisphere whales (SH)

The Committee **agrees** that the following item will be given highest priority:

- (1) completion of the Comprehensive Assessment of Southern Hemisphere humpback whales;
 - (a) completion of a final catch series; and
 - (b) an intersessional Workshop.

It will also:

- (2) initiate the Comprehensive Assessment of blue whales to the extent that time allows.

Environmental concerns (E)

The Committee **agrees** that the following items will be given high priority:

- (1) two day pre-meeting Workshop to assess the potential for seismic surveys to impact cetaceans; and
- (2) Working Group on ecosystem modelling.

The SWG will also receive progress reports on:

- (a) POLLUTION 2000+ (review of final report from Phase 1);
- (b) Southern Ocean Collaboration;
- (c) SOCER: focus on the Indian Ocean;
- (d) Sea ice: Arctic and Antarctic; and
- (e) Diseases: developing plans for a future workshop.

Stock definition (SD)

The Committee **agrees** that the following items will be given priority:

- (1) review statistical and genetic issues relating to stock definition; and
- (2) review progress on TOSSM (including the intersessional Workshop report).

The following items will be discussed if time allows (in priority order):

- (3) unit-to-serve; and
- (4) genetic quality issues and implications for population structure analyses.

Whalewatching (WW)

The Committee agrees that the two priority items will be:

- (1) assessing the biological impacts of whalewatching on cetaceans; and
- (2) identifying data sources from platforms of opportunity of potential value to the Scientific Committee.

In addition, the following items will be discussed if time allows:

- (3) reports from Intersessional Working Groups;
- (4) review of potential impacts of 'swim-with-whales' programmes on populations of cetaceans;
- (5) review of whalewatching guidelines and regulations; and
- (6) review of risks to cetaceans from whalewatching vessel collisions.

Small cetaceans (SM)

The Committee **agrees** that the following item will be given highest priority:

- (1) review of small cetaceans of the Caribbean and western tropical Atlantic.

The following items will also be discussed:

- (2) progress on previous recommendations; and
- (3) takes of small cetaceans.

Scientific permits (SP)

The Committee **agrees** that the following items will be given priority:

- (1) review proposals for other procedures for reviewing scientific permits;
- (2) review results from existing permits (including plans for the JARPA review); and
- (3) review of new or continuing proposals.

DNA

The Committee agrees that the following items (as directed by the Commission) will be given priority:

- (1) review genetic methods for species, stock and individual identification;
- (2) collect and archive tissue samples from catches and bycatches; and
- (3) reference databases and standards for diagnostic DNA registries.

20. DATA PROCESSING AND COMPUTING NEEDS FOR 2005/2006

The Committee identified and agreed the requests for intersessional work by the Secretariat given in Table 5.

Two items (WNP Bryde's whale trials and bowhead whale trials) cannot be specified in any detail until after the two intersessional Workshops (in late October 2006 and March 2006, respectively) so the time listed for these tasks is an estimated maximum. The work in coding the final bowhead trials is not scheduled to be completed until the 2nd intersessional Workshop in October 2006, whereas work resulting from the intersessional workshop for WNP Bryde's whales is required to be completed by the 2006 annual meeting, in order to comply with the agreed timetable for an *Implementation*. It is not expected that there will be conflict, but if there is any, higher priority will be accorded to the Bryde's whale work (which is required first) and urgent consideration should be given to determining ways to ensure that both tasks are completed on time.

Progress will be reviewed by Donovan, Bannister, Punt, Bjørge and Palka.

Table 5
Computing tasks/needs for 2005/6.

Task	Est. time
RMP – General issues	
Work with Punt to evaluate the criteria developed to determine whether the conservation performance of a RMP variant is 'acceptable', 'borderline' or 'unacceptable' (see Item 5.1.1).	<1 month
RMP – Preparations for Implementation	
Finish preparation of catch data for western North Pacific Bryde's whales.	<1 month
Work resulting from intersessional workshop for western North Pacific Bryde's whales: write code to implement the <i>ISTs</i> and do conditioning.	4-6 months ¹
Preparation of catch data for a North Atlantic fin whale <i>Implementation</i> (including collaboration with Dorete Bloch).	1 month
Encoding of Faroese data from 1902 on (as supplied by Dorete Bloch).	>6 months
AWMP	
Work resulting from intersessional workshop for the Bowhead <i>Implementation Review</i> : write code to implement the final stock structure hypotheses.	Up to 8 months ²
In-depth assessment	
Validation of the 2004/05 SOWER cruise data and incorporation into the sightings database.	6 months
Southern Hemisphere whale stocks	
Validation of basic individual records from the revised Soviet catch data and documentation of inconsistencies in the data.	6 months
Preparation of summaries of the revised Soviet Southern Hemisphere catch data and work towards creation of an interpolated dataset of missing data (including collaboration with former Soviet scientists at a workshop in Cambridge).	1 month
Finalise the Southern Hemisphere humpback whale catch series (by January 2006).	1 month
Investigate whether the historic blue whale catch data can be amended to distinguish between blue and pygmy blue whales.	1 month
Stock definition	
Development of interface between <i>CLA</i> and TOSSM programs (with Punt).	<1 month

¹This item will not be specified until the intersessional workshop in October 2005 and so a guessed maximum time has been entered. ²This item will not be specified until the intersessional workshop in March 2006 and so a guessed maximum time has been entered; the work is not scheduled to be completed until the 2nd intersessional workshop scheduled for October 2006.

All other tasks required for the Scientific Committee meeting in 2006 should be completed in timely fashion.

The Scientific Committee will be notified by e-mail when the Southern Hemisphere whale catch series has been finalised.

A Russian minority statement is presented in Annex S.

21. FUNDING REQUIREMENTS FOR 2005/2006

Table 6 summarises the complete list of recommendations for funding made by the Committee. The total required to meet its preferred budget is £409,400. The Committee **recommends** all of these proposed expenditures to the Commission.

However, it understands that the projected amount available for funding is £265,000. It therefore carefully reviewed the full list, taking into account its work plan, priorities and the possibility that some of the work requiring funding could be postponed to a future year or years. Such considerations are difficult and the Committee **stresses** that projects for which it has had to suggest reduced or no funding are still considered important and valuable. Should the Commission be unable to fund the full list of items in Table 6, the Committee **agrees** that the final column given in the table represents a budget that will allow progress to be made by its sub-committees and Working Groups in its priority topics. Progress will not be possible in some important areas, as outlined below and the Committee **requests** that the Commission or individual member governments provide additional funding in these areas. The Committee **strongly recommends** that at a minimum, the Commission accepts its reduced budget of £266,000, noting that this is only £1,000 more than the projected budget.

A summary of each of the items is given below, by sub-committee or standing Working Group. Full details can be found under the relevant Agenda Items and Annexes as given in the table.

(a) Items recommended for funding under the reduced budget

Revised Management Procedure

(1) NORTH PACIFIC BRYDE'S WHALE - INTERSESSIONAL WORKSHOP

The Commission has endorsed the process recommended last year by the Committee with respect to the time schedule if an *Implementation* begins (IWC, 2005e, pp.84-92); this requires two intersessional Workshops and thus another will be required after the 2006 annual meeting. The funding is required to cover the costs of invited participants; Japan has kindly offered to host the Workshop.

(2) NORTH ATLANTIC FIN WHALES - STOCK STRUCTURE

The Committee has outlined a programme to complete the *pre-Implementation* process for fin whales. This was agreed by the Commission last year. The money is required to allow two IWC scientists to participate in a joint workshop with NAMMCO in Reykjavik. The Workshop will not deal with management issues but will focus on the scientific aspects of stock structure and the development of an agreed catch series for North Atlantic fin whales.

Aboriginal Whaling Management Procedure

(3) AWMP DEVELOPERS FUND

The developers fund has been invaluable in the work of the AWMP trials and other essential tasks of the Standing Working Group. It has been agreed as a standing fund by the Commission. The two primary developing tasks facing the SWG are the bowhead whale *Implementation Review* (a requirement of the Committee and Commission) and issues relating to the Greenlandic fisheries. The task facing the SWG with respect to the Greenlandic fisheries is a major one and of high priority to the Committee which has expressed its great concern at its inability to provide management advice on safe catch limits (see Item 8.3, 8.4 and 8.5). The fund is essential to allow progress to be made.

(4) GREENLAND COMMON MINKE WHALES – GENETIC DATA AND ABUNDANCE

The Committee is unable to provide advice on the effects of aboriginal subsistence whaling on the common minke whale stocks off West Greenland. A major problem in terms of its ability to give management advice is that the total geographical area occupied by common minke whales potentially available to be harvested off West Greenland during summer is largely unknown and thus surveys consequently cover an unknown fraction of the range of the stock. Genetic methods may be able to provide a lower bound for the size of the total stock. This study will assess the statistical power of various genetic approaches to estimate abundance. It will be conducted intersessionally and if found to be appropriate, it will develop estimates of sample size and costs for an appropriate study. This would be seen as of very high priority by both the national authorities and the Commission.

*In-depth assessments***(5) SOWER CIRCUMPOLAR CRUISE**

The Committee and the Commission have both given high priority to obtaining agreed abundance estimates for

Antarctic minke whales and for explaining the differences between CPII and CPIII. The proposed plans for this year's survey are directed at experiments to address these problems as well as to conduct a pilot study to determine the best method to collect abundance data for fin whales (north of 60°S, acoustic survey, biopsy), and to continue research on blue whales and particularly humpback whales which are the subject of a comprehensive assessment. The funding is for equipment and participation by international scientists. The vessels are generously provided by the Government of Japan.

(6) FURTHERING ESTIMATION OF ANTARCTIC MINKE WHALE ABUNDANCE

As noted above, the Commission and the Committee have given high priority to obtaining agreed abundance estimates and trends for Antarctic minke whales and for explaining the differences between CPII and CPIII. To maintain the progress expected by the Commission requires that projects (i)-(iv) below are funded. The Committee notes that a considerable amount of in-kind support is included in these projects. Next year the Committee expects to receive abundance estimates from at least the standard method

Table 6

Summary of budget requests for the coming year. The number in parentheses after the short title refers to the number in the discussion below.

	Reference	Budget	
		Requested	Reduced
RMP (Annex D)			
North Pacific Bryde's whales <i>Implementation</i> . 1 st intersessional workshop (a1).	Item 6.1.1.2	£10,500	£10,000
North Atlantic fin whales. Participate at workshop (a2).	Item 6.2.2	£2,500	£2,000
AWMP (Annex E)			
AWMP developers fund (a3).	Item 8.	£10,000	£8,500
West Greenland common minke whales. Abundance estimation from genetic data (a4).	Item 8.2	£3,500	£3,500
Bowhead whale. Intersessional workshop to prepare for <i>Implementation Review</i> (b1).	Item 8.4	£7,700	£0
IA (Annex G)			
<i>Furthering estimation and interpretation of abundance estimates</i>			
SOWER cruise 2005/6 (a5).	Item 10.1.5	£95,900	£80,000
DESS maintenance (a6i).	Item 10.1	£7,500	£7,500
DESS standard analysis method (a6ii).	Item 10.2.3	£6,000	£4,000
Integrated model analysis (a6iii).	Item 10.2.3	£2,000	£2,000
CPII and CPIII explanation: VPA analysis (a6iii).	Item 10.1.2	£6,000	£5,000
CPII and CPIII explanation: catch-at-age analysis (a6iv).	Item 10.1.2	£20,000	£20,000
E (Annex K) – some with IA and BRG			
ICCED science planning and analysis/SO-collaboration. Cruise coordination (a7).	Item 12.3.2	£40,000	£13,000
German SO-GLOBEC, Weddell Sea. IWC participation (a8).	Item 12.3.2	£22,000	£17,500
Deakin University SOC database completion (a9).	Item 12.3	£30,000	£10,000
Whales and shelf break krill distribution (a10).	Item 12.3.2	£2,000	£1,000
Arctic sea ice – population dynamics (a11).	Item 12.1	£30,000	£14,500
Impact on cetaceans from seismic surveys. Workshop (a12).	Item 12.3.5	£6,000	£4,000
Arctic sea ice – body condition and health (b2).	Item 12.1	£20,000	£0
SOCER. Coordination, literature search and editing (b3).	Item 12.3.3	£3,000	£0

Co-ordination with FAO (a19).	Item 7.1.1	£2,500	£1,200
Estimation of bycatch. Simulation modelling (a20).	Item 7.2.1	£7,000	£1,000
Estimation of bycatch. Data collection and market pathways (a20).	Item 7.2.1	£5,000	£5,000
Scientific Committee			
Invited participants (a21).		£35,000	£30,000
Total		£409,400	£266,000

(Branch), the integrated model (Cooke) and the hazard probability method (Okamura). The IWC's DESS is vital to the Committee's work on abundance estimation, both with respect to providing estimates of abundance for past cruises and for future work on the abundance of Antarctic minke whales.

(i) DESS maintenance

(ii) DESS-standard analysis and integrated methods

(iii) and (iv) VPA analysis and catch-at-age analysis

This work has been recommended by the Committee and is essential in furthering the work on exploring the reasons for differences in Antarctic minke whale abundance from CPII and CPIII and working towards an in-depth assessment. The data have been generously made available by the Institute of Cetacean Research (Tokyo) under the Data Availability Agreement.

Environment (some with IA and BRG)

(7) ICCED SCIENCE PLANNING AND ANALYSIS/SO-GLOBEC COLLABORATION

This work will contribute to high priority analysis outlined in the sea ice Symposium (and see Annex K) and to ongoing collaboration with SO-GLOBEC. Research on Southern Ocean whales and their ecosystem is recommended by IWC Resolutions 1998-3 and 1998-6. Support for this activity complements the considerable in-kind support the IWC receives for the SO collaborative cruises. The Committee recognises that the funds available are less than those requested and **agrees** that allocation of the available funds should be the responsibility of the SOC Steering Group who must inform the Secretariat of their final decision on a spending plan.

(8) ANTARCTIC: GERMAN SO-GLOBEC. IWC PARTICIPATION

This is part of the field work programme previously funded in collaboration with SO-GLOBEC. The money is to fund a team of two observers on two cruises. The work will provide data to further elaborate the relationship between ice and cetaceans. It is the final year of a German Weddell Sea research programme. This work was given high priority at the Committee's recent sea-ice Workshop (SC/57/Rep5).

(9) DEAKIN UNIVERSITY – SOC DATABASE COMPLETION

The SOC database comprises data for all IWC/SO-GLOBEC/CCAMLR and other multidisciplinary survey data and sea-ice data under international collaborative programmes. This work will contribute to high priority analyses, outlined in SC/57/Rep5. The Committee has reluctantly recommended, as necessary, to reduce the funding for this proposal and thus priority should be given to coding data directly relevant to examining the questions related to the proportion of Antarctic minke whales in the pack ice. It is hoped that if external funding cannot be found this year, the remainder of the work can be completed next year.

(10) WHALES AND SHELF BREAK KRILL DISTRIBUTION

This work relates to possible differences between CPII and CPIII of the SOWER cruises. The funds will be used to pay for the travel and subsistence costs of Ensor (SOWER cruise leader) to attend a collaborative meeting to discuss spatial analysis and sea ice conditions on surveys.

(11) SEA ICE – POPULATION DYNAMICS

This work represents partial funding for one of the high priority Arctic projects identified in the sea ice Workshop. (SC/57/Rep5 and Annex K). It relates to a number of issues

potentially affecting the management and conservation of B-C-B Seas bowhead whales and eastern gray whales. The funds are for a student to work with a sea ice specialist to derive regional (meso-scale) analysis of changes in sea ice since 1979 and undertake projections into the future. This will feed into the project to be undertaken *gratis* by Wade, Punt, Breiwick and Brandon, to incorporate sea ice analyses into the population dynamics record of those two whale populations.

(12) IMPACT ON CETACEANS FROM SEISMIC SURVEYS WORKSHOP

Last year, the SWG on environmental concerns had recommended the holding of a Workshop on seismic exploration (including both industrial and academic activities) at the 2006 meeting. This proposal was developed further this year (Annex K, Appendix 3). It is timely as the hydrocarbon industry is expanding. Accelerating studies to assess potential impacts on cetaceans and examine ways to mitigate known and potential effects is thus particularly important. The funds are required to pay for IPs.

Southern Hemisphere whales (other than Antarctic minke whales)

(13) SH HUMPBACK COMPREHENSIVE ASSESSMENT - WORKSHOP

The Committee has been undertaking a comprehensive assessment of Southern Hemisphere humpback whales for several years and has given priority to its completion. The best way to finalise this work is to hold an intersessional Workshop. The Government of Australia have kindly offered to host this Workshop in Hobart, Australia. The funds are required for IPs (see Annex H, Appendix 7).

(14) SH HUMPBACK WHALE – POPULATION DYNAMICS MODEL

This project involves the coding and use of population dynamics models needed to finalise the Comprehensive Assessment referred to above. This work is essential for the success of the Workshop. The funds are to enable Johnston to complete this work.

(15) SH HUMPBACK WHALE - FINALISE CATCH SERIES

Similarly, the success of the Workshop referred to in (13) above depends on having a final catch series available. The funds will allow a scientist to travel to Cambridge to work with Allison, former Soviet scientists and others, to complete the historical catch data series and extract catches of humpback whales for the Comprehensive Assessment.

(16) ANTARCTIC HUMPBACK WHALE CATALOGUE

The Committee is already committed to funding this project, which represents only a partial cost of running the catalogue and is of great benefit to its in-depth assessment of Southern Hemisphere humpback whales. The work required to *inter alia* make the IWC/SOWER photographs more accessible is being carried out. The funds are mainly required for database management.

Stock definition

(18) TOSSM WORKSHOP

The Committee has noted the importance of stock structure issues to most of its Working Groups and sub-committees. For that reason it funded the first TOSSM workshop. Progress on the first stage of the process, developing simulated populations, has been excellent but for this to be of maximum value to the IWC, the next stage, i.e. the

incorporation of management related issues and the testing of methods to determine boundaries, must be undertaken. It was agreed that the only way to achieve this efficiently and appropriately is to hold another workshop. This will enable progress to be made at the 2006 Annual Meeting. The University of Potsdam has kindly agreed to host the Workshop. The funds are required for Invited Participants (IPs).

Bycatch

(19) CO-ORDINATION WITH FAO

The Committee has recommended that co-operation with FAO be continued with respect to information on fisheries, fishing gear and effort, as part of its work to try and estimate bycatch levels in terms of assessment and RMP related work to determine total removals. As a result of contacts made last year it is clear that increased cooperation can be of great mutual benefit. The collaboration will allow the IWC to become a partner agency in to FIRMS.

(20) ESTIMATION OF BYCATCH

In 2004, the Committee agreed to hold a Workshop to determine whether market sampling based methods can be used to provide adequate estimates of the number of bycaught animals. The initial Workshop was held this year and before deciding when the final Workshop should be held, the Committee identified work that needed to be completed. It was agreed that this year the following should be undertaken: (i) initial work to develop a modelling framework for sensitivity analysis and for testing market sampling design; and (ii) the collection of additional data on markets and market pathways. The initial modelling work will cost £1,000 and the data collection £5,000. After discussion of the results at the next Annual Meeting (2006), guidance on completing the development of a full simulation modelling framework can be given (the costs of completing this development is provisionally estimated at about £6,000 but this will be discussed next year).

Scientific Committee

(21) INVITED PARTICIPANTS FUND

The Committee **draws attention** to the essential contribution made to its work by the funded IPs. The IWC-funded IPs play an essential role in the Committee's work. They represent excellent value as they receive only travel and subsistence costs and thus donate their time, which is considerable. As was the case for previous meetings, where possible effort will be made to accommodate scientists from developing countries.

(b) Recommended items not included under the reduced budget (but still supported by the Scientific Committee)

(1) BOWHEAD IMPLEMENTATION REVIEW - INTERSESSIONAL WORKSHOP

This is a high priority item. The Commission has noted that we will have a bowhead *Implementation Review* in 2007. Due to the oddly named if not oddly derived 'Oslo bump', a major research programme has been initiated on bowhead whale stock identity. This has the potential to initiate a complex modelling exercise to test the performance of the *Bowhead SLA* with alternative stock hypotheses. The purpose of this Workshop is to specify the basic structure and types of simulation trials required. It is integral to the SWG workplan on this agenda item and will form an important contribution to its work at the next annual meeting and beyond. The USA has kindly agreed to host this meeting and it has been allocated no funding because

the USA has also indicated that it will make a donation to the research fund to cover the costs of the necessary IPs. Venue and dates will be determined when more information on progress becomes available but it will probably be in March 2006.

(2) SEA ICE – BOWHEAD WHALE BODY CONDITION AND HEALTH

This was identified as one of the priority items from the Sea Ice Workshop and was endorsed in Annex K. The Committee recognise the value of the work outlined in SC/57/Rep5 and hopes that this project will obtain outside funding.

(3) PREPARATION OF SOCER

The Commission (IWC, 2001a) has encouraged work in this area. A Working Group within the SWG again produced a SOCER this year that forms Appendix 2 of Annex K of the Committee's report. It is aimed at providing a non-technical report of some events and developments in the marine environment relevant to cetaceans to the Commission. The Committee hopes that this work will receive outside funding.

22. WORKING METHODS OF THE COMMITTEE

There was no substantive discussion under this Agenda Item. It was agreed to keep it on the agenda for next year.

23. ELECTION OF OFFICERS

The three-year terms of DeMaster as Chair and Bjørge as Vice-Chair end at the completion of IWC/57. The heads of delegations therefore met according to the new Rules agreed last year (IWC, 2005c, p.59). The Committee was delighted to welcome Bjørge as Chair and Palka as Vice-Chair by consensus.

24. PUBLICATIONS

2004 was another productive year with respect to the IWC's scientific publications and the Journal continues to attract increasing numbers of submissions. This year, in addition to the 500 page supplement, Volume 6 was completed. Volume 6 contained a total of 34 papers involving some 120 authors from 24 countries. Papers have been published on the full variety of subjects considered by the Committee. Donovan thanked the Publications staff for their hard work. In particular, he thanked Clare Last, who was Assistant Editor from the first issue, for her great contribution both to the Journal and to the work of the Scientific Committee. She left the IWC for pastures new in September 2004. The Committee members send her their best wishes for the future. He also welcomed the new Assistant Editor, Jemma Miller, who replaced Clare in January 2005.

Donovan reported that he and Hammond will finalise the third special issue (on development of the Revised Management Procedure) this autumn. With respect to ISI listing, he has been informed that the ISI listing is now complete.

Following discussions last year, the Guide for Authors has been modified as follows:

Welfare and legal policy

When submitting a manuscript for publication, the author(s) must state that all work conforms to the legal requirements of the country in which it was carried out, including those relating to conservation and animal welfare.

Sequence data

Authors submitting papers containing nucleic acid data must provide full primary sequences as Appendices for reviewing purposes. In addition it is expected that new DNA sequences are submitted to GenBank, and accession numbers cross-referenced throughout the text.

Finally, Donovan reiterated the importance of Committee members urging their respective institutes and colleagues to subscribe to the Journal and to submit high quality papers to it. The success of the Journal will be greatly increased as it becomes established in more institutional libraries.

The Committee welcomes this report and **stresses** the vital contribution the Journal makes to the work of the Committee and to the wider issues of the management and conservation of whales.

25. OTHER BUSINESS

On behalf of the Committee, the outgoing Chair expressed deep appreciation to the Government of Korea and the Mayor and people of Ulsan for the exceptional level of support and hospitality extended to the Committee during the meeting. The Committee also thanked the Secretariat for its major contribution to the smooth running of the meeting, as always carried out with great diligence and cheerfulness. The Committee gave DeMaster a standing ovation for his outstanding work as Chair of the Committee. In particular, he was praised for his unflinching efforts to reach consensus on as many issues as possible, his fairness and his great good humour. In reply he noted that he was handing over to an outstanding team in Bjørge and Palka. He also wryly noted that he was the only person to have faced competition in elections for both Chair and Vice-Chair – he hoped this was an ‘honour’ he alone would always retain!

26. ADOPTION OF REPORT

The report was adopted at 16:47hrs on 10 June 2005. As usual, final editing was carried out by the Convenors after the meeting.

Report of the Scientific Committee

Panama City, Panama, 11-23 June 2012

International Whaling Commission, Panama City, 2012

Scientific Committee Report

Contents

1-3 INTRODUCTORY ITEMS.....	3
4. COOPERATION WITH OTHER ORGANISATIONS.....	5
5. REVISED MANAGEMENT PROCEDURE (RMP) – GENERAL ISSUES (see also Annex D)	11
5.1 Complete the MSY rates review.....	11
5.2 Finalise the approach for evaluating proposed amendments to the <i>CLA</i>	11
5.3 Evaluate the Norwegian proposal for amending the <i>CLA</i>	11
5.4 Modify the ‘CatchLimit’ program to allow variance-covariance matrices.....	11
5.5 Update requirements and guidelines for conducting surveys and <i>Implementations</i>	12
5.6 Evaluate the optimisation method used when conditioning trials.....	12
5.7 List of abundance estimates and their recommended uses	12
6. RMP – PREPARATIONS FOR <i>IMPLEMENTATION</i>	12
6.1 Western North Pacific Bryde’s whales.....	12
6.2 North Atlantic fin whales	12
6.3 North Pacific common minke whales (continue <i>Implementation</i>).....	13
6.4 North Atlantic common minke whales	18
6.5 North Atlantic sei whales	19
7. ESTIMATION OF BYCATCH AND OTHER HUMAN-INDUCED MORTALITY (BC).....	19
7.1 Collaboration with FAO on collation of relevant fisheries data	19
7.2 Estimation of bycatch mortality of large whales	19
7.3 Estimation of risk and rates of entanglement.....	20
7.4 Review progress on including information in National Progress Reports	20
7.5 Ship strikes.....	20
8. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT PROCEDURE (AWMP).....	21
8.1 Complete <i>Implementation Review</i> of eastern North Pacific gray whales with an emphasis on the PCFG	21
8.2 Complete <i>Implementation Review</i> of Bering-Chukchi-Beaufort Seas bowhead whales.....	27
8.3 Continue work on developing SLAs for the Greenlandic hunts (Annex E, Item 4).....	28
8.4 Guidelines for Implementation Reviews	29
8.5 Scientific aspects of an aboriginal whaling scheme (AWS)	29
8.6. Conversion factors for edible products for Greenland hunts	30
9. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT ADVICE.....	30
9.1 Eastern Canada and West Greenland bowhead whales	31
9.2 Eastern North Pacific gray whales.....	32
9.3 Bering-Chukchi-Beaufort (B-C-B) Seas stock of bowhead whales.....	33
9.4 Common minke whales off West Greenland.....	34
9.5 Common minke whales off East Greenland	34
9.6 Fin whales off West Greenland	34
9.7 Humpback whales off West Greenland.....	34
9.8 Humpback whales off St Vincent and The Grenadines	35
10. WHALE STOCKS	35
10.1 Antarctic minke whales (Annex G).....	35
10.2. Southern Hemisphere humpback whales.....	40
10.3. Southern Hemisphere blue whales	43
10.4 Western North Pacific gray whales	45
10.5 Southern Hemisphere right whales.....	47
10.6 Other stocks of right whales and small stock of bowhead whales.....	50
10.7 Arabian Sea humpback whales.....	51
10.8 Cruises.....	52

10.9 Progress towards an in-depth assessment of North Pacific sei whales	54
11. STOCK DEFINITION.....	54
11.1 Guidelines for DNA data quality and genetic analyses	55
11.2 Statistical and genetic issues related to stock definition	55
11.3 Progress on the Testing of Spatial Structure Models (TOSSM).....	55
11.4 Terminology and unit-to-serve	56
12. ENVIRONMENTAL CONCERNS (E).....	56
12.1 State of the cetacean environment report (SOCER)	56
12.2 Pollution.....	56
12.3 CERD (Cetacean Emerging and Resurging Disease)	59
12.4 Anthropogenic sound	60
12.5 Climate Change.....	61
12.6 Interactions between MREDs and cetaceans	62
12.7 Other habitat related issues.....	63
13. ECOSYSTEM MODELLING	65
13.1 Review of ecosystem modelling efforts undertaken outside the IWC	65
13.2 Explore how ecosystem models contribute to developing scenarios for simulation testing of the RMP	66
13.3 Review of other issues relevant to ecosystem modelling within the committee	66
13.4 Review new information on ecosystem model skill assessment.....	67
14. SMALL CETACEANS (SM)	67
14.1. Review status of ziphiids whales in the North Pacific and northern Indian Ocean.....	68
14.2. Report on the voluntary fund for small cetacean conservation research.....	74
14.3. Progress on previous recommendations	74
14.4. Takes of Small Cetaceans.....	78
14.5. Local studies.....	78
14.6 Hector's dolphins	79
14.7. Workplan.....	79
15. WHALEWATCHING	79
15.1 Assess the impacts of whalewatching on cetaceans	79
15.2 Review whalewatching off Central America	80
15.3 Review reports from intersessional working groups	81
15.4. Other issues	82
15.5 Work plan.....	83
15.6 Other matters	84
16. DNA TESTING.....	84
17. SCIENTIFIC PERMITS	85
17.1 Review of results from existing permits.....	85
17.2 Review of new or continuing proposals	87
18. WHALE SANCTUARIES (S).....	87
19. SOUTHERN OCEAN RESEARCH PARTNERSHIP	87
19.1 Review of progress since IWC 63	88
19.2 Budget.....	93
19.3 Requirements for formalising participation in SORP and development of new projects.....	94
20. RESEARCH AND WORKSHOP PROPOSALS AND RESULTS	94
21. COMMITTEE PRIORITIES AND INITIAL AGENDA FOR THE 2013 MEETING.....	94
22. DATA PROCESSING AND COMPUTING NEEDS FOR 2011/12	96
23. FUNDING REQUIREMENTS FOR 2012/13	96
24 WORKING METHODS OF THE COMMITTEE.....	102
25. ELECTION OF OFFICERS	104
26. PUBLICATIONS	105
27. OTHER BUSINESS	105
28. ADOPTION OF REPORT.....	105

The meeting was held at El Panama Hotel and Conference Centre, Panama from 11 June to 23 June 2012 and was chaired by Debra Palka. A list of participants is given as Annex A

1. INTRODUCTORY ITEMS

1.1 Chair's welcome and opening remarks

The Chair welcomed the participants to the 2012 IWC Scientific Committee meeting noting that the Committee faced a long and complex Agenda this year. In particular, she thanked the Government of Panama for providing the facilities for this year's meeting and the IWC Commissioner for Panama, Tomas Guardia for his assistance. The Committee paused in silence for Alexandre de Lichtervelde, the previous Commissioner from Belgium who had been deeply involved in the issue of ship strikes, and Frank Hester, a long time Committee member, who had both sadly passed away since the last meeting. They both will be greatly missed.

Simon Brockington, the Secretary to the IWC, addressed the meeting on behalf of the Commission to convey a message of gratitude. He noted that the Scientific Committee is rightly regarded as one of the foremost international fora dedicated to cetaceans, and that this reputation stemmed from the quality of research conducted by the participants. He hoped that the meeting would be productive both in terms of providing advice to the Commission, but also in allowing knowledge to be gained and shared between participants so as to allow improved research in the future. He wished all participants a successful meeting.

On behalf of the Government of Panama Giovanni Lauri, the Administrator General of the Aquatic Resources Authority of Panama (ARAP) addressed the Committee and welcomed the participants to Panama. He hoped that everyone would enjoy their time in Panama City and wished the meeting every success.

1.2 Appointment of rapporteurs

Donovan was appointed rapporteur with assistance from various members of the Committee as appropriate. Chairs of sub-committees and Working Groups appointed rapporteurs for their individual meetings.

1.3 Meeting procedures and time schedule

Brockington summarised the meeting arrangements and information for participants. The Committee agreed to follow the work schedule prepared by the Chair.

1.4 Establishment of sub-committees and working groups

As intimated last year, (IWC, 2012f, p.59) and included in the draft agenda, a pre-meeting of the Standing Working Scientific Committee Report

Group on Environmental Concerns met from 9-10 June 2012 in Panama City to consider interactions between marine renewable energy developments and cetaceans. Its report is given as SC/64/Rep6.

A number of sub-committees and working groups were established. Their reports were either made annexes (see below) or subsumed into this report (see items 17 and 19).

Annex D – Sub-Committee on the Revised Management Procedure (RMP);

Annex D1 – Working Group on the *Implementation Review* of Western North Pacific common minke whales (NPM);

Annex E – Standing Working Group on an Aboriginal Whaling Management Procedure (AWMP);

Annex F – Sub-Committee on Bowhead, Right and Gray Whales (BRG);

Annex G – Sub-Committee on In-Depth Assessments (IA);

Annex H – Sub-Committee on Other Southern Hemisphere Whale Stocks (SH);

Annex I – Working Group on Stock Definition (SD);

Annex J – Working Group on Estimation of Bycatch and other Human-Induced Mortality (BC);

Annex K – Standing Working Group on Environmental Concerns (E);

Annex K1 – Working Group to Address Multi-species and Ecosystem Modelling Approaches (EM);

Annex L – Standing Sub-Committee on Small Cetaceans (SC);

Annex M – Sub-Committee on Whalewatching (WW);

Annex N – Working Group on DNA (DNA).

1.5 Computing arrangements

Allison outlined the computing and printing facilities available for delegate use.

2. ADOPTION OF AGENDA

The Adopted Agenda is given as Annex B1. Statements on the Agenda are given as Annex R. The Agenda took into account the priority items agreed last year and approved by the Commission (IWC, 2012a, pp.27-29). Annex B2 links the Committee's Agenda with that of the Commission.

3. REVIEW DATA, DOCUMENTS AND REPORTS

3.1 Documents submitted

Donovan noted that the pre-registration procedure, coupled with the availability of electronic papers, had again been successful. With such a large number of documents, pre-specifying papers had reduced the amount of photocopying and unnecessary paper dramatically. He was pleased to note that this year the percentage of people opting to receive their papers entirely electronically had continued to grow. As last year, the Secretariat provided participants with a memory stick with all of the papers

that had been received by the official deadline. Revised or new papers and reports were uploaded onto the IWC website. The list of documents is given as Annex C. The issue of electronic papers is discussed further under item 24.

3.2 National Progress Reports on research

The Committee is in the transition phase from receiving paper progress reports to online submission into a database (Skaug, 2012, pp.2). A working group was established to facilitate this process and its report is given as Annex O. The Committee **reaffirms** its view of the importance of national Progress Reports and **recommends** that the Commission continues to urge member nations to submit them following the new online system. It thanks the Secretariat and especially Tandy and Miller for their development work on the portal.

3.3 Data collection, storage and manipulation

3.1.1 Catch data and other statistical material

Table 1 lists data received by the Secretariat since the 2011 meeting. As requested last year, the Secretariat had contacted both Canada and Indonesia to request information on recent catches. The information received from Canada is included in Table 1, but no response has been received to date from Indonesia. The Committee requests that the Secretariat try again to obtain data on catches off Indonesia.

3.1.2 Progress of data coding projects and computing tasks

Allison reported that Version 5.2 of the catch databases was released in November 2011 and a new release was due shortly. Work has continued on the entry of catch data into both the IWC individual and summary catch databases, including data received from the 2010 season. Sightings data from the 2010 POWER cruise (see item 10.8) has been validated.

Programming work during the past year has focussed on amending the control program and datasets for use in the North Pacific common minke whale *Implementation* trials and is discussed further under Item 6.3.

4. COOPERATION WITH OTHER ORGANISATIONS

The Committee noted the value of co-operation with other international organisations to its work. The observers' reports below briefly summarise relevant meetings of other organisations but the contributions of several collaborative efforts are dealt with in the relevant sub-committees.

4.1 Convention on the Conservation of Migratory Species (CMS)

4.1.1 Scientific Council

The report of the IWC observer at the CMS Scientific Council meeting held in Bergen, Norway from 17-18 September 2011 is given as IWC/62/4E. With relation to cetaceans, their agenda included items on critical sites and ecological networks for migratory species, impacts of marine debris on migratory species and presentation of the report of the Working Group on Aquatic Mammals. It was agreed that the narwhal and the North Pacific killer whale populations be considered for cooperative action. A draft resolution on a programme of work for cetaceans (to implement the previous CoP resolution 'Adverse human-induced impacts on cetaceans') was endorsed. Note was taken of the recent split of the finless porpoise into two species, *Neophocaena brevirostris* and *N. asiaeorientalis* and both were recommended for inclusion in Appendix II of the Convention.

The Committee thanked Perrin for his report and **agrees** that he should represent the Committee as an observer at the next CMS Scientific Council meeting. Further information can be found at <http://www.cms.int>.

4.1.2 Conference of Parties

The report of the IWC observer at the 10th Conference of Parties for CMS held in Bergen 20-25 September 2011 is given as IWC/62/4E. The Convention now has 117 Parties. Three Resolutions related primarily to cetaceans: Resolution 10.14 *Bycatch of CMS-listed species in gillnet fisheries* called on Parties to *inter alia* assess the risk of bycatch arising from their gillnet fisheries and conduct research to identify and improve mitigation measures (including use of alternative fishing gear and methods) and instructed the Scientific Council to develop terms of reference for studies identifying the degree of interaction between gillnet fisheries and CMS-listed species;

- (1) Resolution 10.15 *Global programme of work for cetaceans* laid out tasks for the Scientific Council, Secretariat and Parties to advance the conservation of CMS-listed cetaceans, organised primarily on a regional basis; and

Resolution 10.24 *Further steps to abate underwater noise pollution for the protection of cetaceans and other migratory species* among other recommendations strongly urged the Parties to prevent adverse effects on cetaceans and other marine species by restricting the emission of underwater noise, understood as keeping it to the lowest necessary level with particular priority given to situations where the impacts on cetaceans are known to be heavy.

Table 1

List of data and programs received by the IWC Secretariat since the 2011 meeting.

Date	From	IWC ref.	Details
Catch data from the previous season:			
08-07-11	St Vincent: R. Ryan	E103 Cat2011	Information on the St Vincent and the Grenadines humpback harvest 2011 season
01-03-12	Canada: A. McMaster	E103 Cat2011	Information on the Canadian bowhead harvest 2011 season
30-03-12	Iceland: E. Thordarson	E103 Cat2011	Individual catch records from the Icelandic commercial catch 2011
22-05-12	Russia: R.G. Borodin	E103 Cat2011	Individual catch records from the aboriginal harvest in the Russian Federation in 2011
24-05-12	Norway: N. Øien	E103 Cat2011	Individual minke records from the Norwegian 2011 commercial catch. Access restricted (specified 14-11-00).
11-06-12	Japan: S. Hiruma	E103 Cat2011	Individual data for Japan special permit catch 2011 N.Pacific (JARPN II) & 2011/12 Antarctic (JARPA II).
Other catch data:			
10-4-12	Canada: J. Ford	E105	Comparison of N. Pacific catch data held by Canada with the IWC database, including 1,471 new individual records.
Sightings data:			
01-12-11	K. Matsuoka	E102	2011 POWER cruise sightings data
22-12-11	K. Matsuoka	E102	Data from the JARPN II sighting survey in the North Pacific 2011 (SC/63/RMP12); inc. sightings, weather, effort and distance and angle experiment data.
Other:			
30-11-11	USA: D. Palka	E101	List of data for the NP gray Implementation Review in June 2012
23-03-12	A. Punt	E104	Programs and data used in AWMP gray whale trials up to March 2012 workshop
23-06-12	A. Punt	E104	Programs and data used in AWMP gray whale trials at SC 2012

The resolutions can be seen in full on the CMS website (www.cms.int).

The Committee thanked Perrin for his report and **agrees** that he should represent the Committee as an observer at the next CMS Scientific Council meeting.

4.1.3 Agreement on Small Cetaceans of the Baltic and North Seas (ASCOBANS)

There was not a meeting of parties in the intersessional period. The next meeting of parties will take place 22-24th October 2012, Brighton, UK. The report of the observer at the 19th meeting of the Advisory Committee to ASCOBANS held in Galway, Ireland 20-22 March 2012 is given as IWC/64/4F. Topics covered included:

- (1) *Baltic Sea harbour porpoises*. Those in the Western Baltic, Belt Seas and the Kattegat form a different population to those of the Baltic proper and North Sea and since 2005 there has been a 60% decline in the population size of the former. A separate conservation plan for this area should be established.
- (2) *Working Group on a Conservation Plan for Harbour Porpoises in the North Sea*. A follow-up SCANS II survey was recommended, as was bringing smaller and recreational fisheries under the reformed Common Fisheries Policy.
- (3) *Working Group on Bycatch*. A review of the 1.7% removal rate was recommended.
- (4) *Dogger Bank surveys*. Independent surveys, both aerial and vessel-based, indicate that the harbour porpoise is the most common cetacean in the area, with most records on the slopes of the bank.
- (5) *Small cetacean hunt outside agreement area*. Tagging data indicates the pilot whale population subject to the Faroese hunt also occurs in the ASCOBANS

agreement area. Because of considerable uncertainties regarding the population ASCOBANS welcomes future studies (e.g. SCANS, CODA, T-NASS).

A working group on marine debris was established and in collaboration with ACCOBAMS, the ASCOBANS Secretariat is working to acquire satellite based data on shipping density to identify high risk areas and trends. A joint ECS/ASCOBANS/ACCOBAMS workshop on management of Marine Protected Areas for cetaceans will be held at the 2013 ECS conference.

The Committee thanked Scheidat for her report and **agrees** that she should represent the Committee as an observer at the next ASCOBANS Advisory Committee meeting and Meeting of Parties. Further information can be found at <http://www.ascobans.org>.

4.1.4 Agreement on the Conservation of Cetaceans of the Black Sea, Mediterranean Sea and Contiguous Atlantic Area (ACCOBAMS)

No meetings of ACCOBAMS occurred intersessionally, but a Scientific Committee meeting is scheduled for November 2012. The Committee **agrees** that Donovan should represent the IWC at this meeting.

4.1.5 Memorandum of Understanding (MoU) on the Conservation of the Manatee and Small Cetaceans of Western Africa and Macaronesia

There was no report related to the MoU on the Conservation of the Manatee and Small Cetaceans of Western Africa and Macaronesia. Perrin will represent the Committee at future activities.

4.1.6 Memorandum of Understanding (MoU) for the Conservation of Cetaceans and Their Habitats in the

Pacific Islands Region (MoU for Pacific Islands Cetaceans)

There was no report related to the *MoU for Pacific Islands Cetaceans*. Donohue will represent the Committee at future activities. Further information can be found at <http://www.pacificcetaceans.org>.

4.2 International Council for the Exploration of the Sea (ICES)

The report of the IWC observer documenting the 2012 activities of ICES is given as IWC/64/4A. The ICES Working Group on Marine Mammal Ecology (WGMME) met in February 2011. It conducted a review of the effects of tidal turbines on marine mammals and provided recommendations on research, monitoring and mitigation schemes. The working group recommended identification of sites of low risk for turbine deployments before consenting to further devices or upscaling in more sensitive sites. It also recommended extreme care when extrapolating environmental impacts between species and device types and caution when scaling up environmental lessons learned from studies of single turbines.

Marine spatial planning practices were considered by the working group. It recommended that data on cetacean presence and occurrence be incorporated at a very early stage of planning and it emphasised the importance of including information on seasonal changes in distribution. Due to the wide-ranging nature of cetaceans the relevance of 'important areas' outside MPAs should be assessed within marine spatial plans.

The working group discussed designation of MPAs. It recommended that the boundaries should be decided based on long-term data series (of at least five years). Creation of MPAs in response to public opinion without scientific evidence to support their selection risks providing false assurances and could reduce the pressure for targeted action on the most significant threats.

The Working Group on Bycatch of protected species (WGBYC) met in February 2011. It reviewed the status of information on recent bycatch estimates and assessed the extent of the implementation of bycatch mitigation measures. Reports from 15 member states indicated extrapolated estimates of bycatch for 2009 of 879 striped dolphins, 1,500 common dolphins, 11,000 harbour porpoises and at least 10 bottlenose dolphins in a variety of fisheries. Estimates are patchy and monitoring obligations not being met by several member states. Implementation of bycatch mitigation measures was also found to be poor, with few countries able to confirm that obligations for pinger deployment were being met.

The 2011 ICES Annual Science Conference (ASC) was held in Gdansk, Poland, 19-23 September 2011. Some sessions were designed with marine mammals included as Scientific Committee Report

an integral part. A number of sessions were of relevance to the Committee, including those describing:

- (1) integration of top predators into ecosystem management;
- (2) integration of multi-disciplinary knowledge in the Baltic Sea to support science-based management; and
- (3) Extraction of energy from waves and tides – consequences for ecosystems.

Butterworth advised that a World Conference on Stock Assessment Methods for sustainable fisheries will be held from 16-18 July 2013, in Boston, USA with Steve Cadrin, Mark Dickey-Collas and Rick Methot as Conveners, as part of the ICES SISAM initiative. A Scientific Steering Group (including Butterworth of the Scientific Committee), linked to SISAM, has been set up to assist the Conveners in planning the Symposium.

The symposium will be structured with presentation sessions, participatory workshops and open floor discussion groups. Further information can be found at <http://ices.dk/iceswork/symposia/wcsam.asp>.

The Committee thanked Haug for the report and **agrees** that he should represent the Committee as an observer at the next ICES meeting.

4.3 Inter-American Tropical Tuna Commission (IATTC)

The report of the observer at the 82nd meeting of the IATTC held La Jolla, USA 4-8 July 2011 is given as IWC/64/4C. The Antigua Convention came into force on 27 August 2010 and under this the IATTC is expected to give greater consideration to non-target and associated species, including cetaceans, in taking management decisions. A summary of ongoing work describing what is known about the direct impact of the fisheries on other species in the ecosystem and the environment. This ongoing work will shape future directions of AIDCP (see 4.4) and IATTC measures aimed at managing fisheries and conserving dolphins.

The Committee thanked Rusin for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next AIDCP meeting.

4.4 Agreement on the International Dolphin Conservation Program (AIDCP)

The report of the observer at the 24th Meeting of Parties to the AIDCP held in La Jolla, USA on 21 October 2011 is given as IWC/64/4C. The AIDCP mandates 100% coverage by observers of fishing trips by purse seiners of carrying capacity greater than 363t in the agreement area and in 2011 all trips by such vessels were sampled by independent observers.

The overall dolphin mortality limit (DML) for the international fleet in 2011 was 5,000 animals and the

unreserved portion of 4,900 was allocated to 86 qualified vessels that requested DMLs. In 2010 no vessel exceeded its DML. The number of sets on dolphin associated schools of tuna made by vessels over 363t has been increasing in recent years, from 9,246 in 2008 to 10,910 in 2009 to 11,645 in 2010, however fewer were made in 2011 – 9,604. This type of set accounted for 44% of the total number of purse-seine sets made in the ETP in 2011. While fewer dolphin sets were made in 2011, this remains a frequent practice and the predominant method for catching yellowfin tuna by purse-seine in the ETP. Assessment surveys scheduled for 2009 and 2010 have been delayed so it is unclear when abundance estimates for cetaceans in the ETP will be available to update the 2006 survey data.

The Committee thanked Rusin for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next AIDCP meeting.

4.5 International Commission for the Conservation of Atlantic Tunas (ICCAT)

No observer for the IWC attended the 2011 meeting of ICCAT.

4.6 Convention for the Conservation of Antarctic Marine Living Resources (CCAMLR)

The report of the IWC observer at the 30th Meeting of the CCAMLR Scientific Committee (CCAMLR-SC), held in Hobart, Australia from 23-27 October 2011 is given as IWC/64/4J. The main items considered at the CCAMLR meeting of relevance to the IWC included: (1) fishery status and trends of Antarctic fish stocks, krill, squid and stone crabs; (2) incidental mortality of seabirds and marine mammals in fisheries in the CCAMLR Convention Area; (3) harvested species; (4) ecosystem monitoring and management; (5) management under conditions of uncertainty about stock size and sustainable yield; (6) scientific research exemption; (7) CCAMLR Scheme of International Scientific Observation; (8) new and exploratory fisheries; (9) joint CCAMLR-IWC workshop with respect to ecosystem modelling in the Southern Ocean; and (10) the CCAMLR performance review.

The publication status of documents from the 2008 joint CCAMLR-IWC workshop on ecosystem modelling was discussed. Almost all expert groups have completed their review papers. The review process for the papers, which will be published in either *CCAMLR Science* or the *Journal of Cetacean Research and Management*, will begin soon.

Marine Protected Areas were discussed in detail. The area of the southern South Orkney shelf and the Seasonal Pack-ice Zone and part of the Fast Ice Zone south of the Shelf was the first MPA designated by CCAMLR. The following milestones were previously agreed: (1) by

2010, collate relevant data for as many of the 11 priority regions as possible;

(2) by early 2011, convene a workshop to review progress, share experience and determine a work programme for the identification of MPAs; (3) by 2011 identify candidate areas for protection in as many priority regions as possible;

(4) by 2011, submit proposals for areas for protection to the CCAMLR-SC; and (5) by 2012 submit proposals on a representative system of MPAs to the CCAMLR Commission.

The Committee thanked Kock for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next CCAMLR-SC meeting. In addition, Butterworth will act as an observer at meetings of the WG-EMM.

4.7 Southern Ocean GLOBEC (SO-GLOBEC)

The synthesis and analysis process under SO-GLOBEC has continued and has produced a number of papers relating cetacean distribution to prey and other environmental variables. There is no active work with respect to SO-GLOBEC at this time.

4.8 North Atlantic Marine Mammal Commission (NAMMCO)

4.8.1 Scientific Committee

The report of the IWC observer at the 18th meeting of the NAMMCO Scientific Committee (NAMMCO SC) held in Gjógv, Faroe Islands from 2-5 May 2011 is given as IWC/64/4I. The ICES-NAMMCO workshop on bycatch monitoring reviewed indirect and direct bycatch monitoring, data collection and fleet data needed for raising estimates to fleet level. It was noted that bycatch numbers could be high both in Norway and Iceland. The NAMMCO SC strongly encouraged Norway, Iceland and the Faroes to proceed with the implementation of their bycatch monitoring systems. The NAMMCO SC reiterated its recommendation to Greenland to investigate the degree to which bycatch is reported as catch.

Extensive biological sampling was conducted by Iceland from all fin whales landed in 2010. Analysis of all samples is complete and a DNA registry has been initiated.

The 2007 abundance estimates for humpback whales for all areas have now been provided to, reviewed and endorsed by the NAMMCO SC. For the first time since 1986 there was a quota for humpback whales in West Greenland and all nine whales were caught. The NAMMCO SC recommended eye sampling of the whales for age determinations, as well as tail photographs.

Corrected estimates for minke whales for the 2007 and 2009 Icelandic aerial surveys were endorsed. The best available estimate of abundance for 2007 was 48% of that

for 2001. Abundance in 2009 remains the lowest yet seen in all areas. The NAMMCO SC agreed that the new evidence presented strengthened the conclusion that the observed decline in abundance was not a result of error in measuring or analyses.

A conventional distance sampling abundance estimate of pilot whales for the Iceland-Faroes shipboard area was endorsed by the NAMMCO SC. They noted the difficulties in providing abundance estimates appropriate for management of this species given the absence of adequate data.

Observations of bowhead whales around Svalbard, Norway from 1940-2009 show an increase in abundance in the last decade. This could be due to an increase in the numbers of whales or increased tourism and a dedicated reporting system. An acoustic study that will continue through 2012 has shown that bowhead whales are present in the Fram Strait throughout the winter and generally during most of the year. A satellite tracked whale from the Spitsbergen stock moved from the so-called northern whaling ground to the southern whaling ground during summer and then back north again during winter. This is opposite of the general seasonal movement patterns for other bowhead whale stocks, but in accordance with reports from whalers in previous centuries.

An aerial survey in West Greenland was scheduled for spring 2012. The primary targets were planned to be narwhals and white whales, with bowhead whales and walrus secondary targets.

The Committee thanked Walløe for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next NAMMCO SC meeting.

4.8.2 Council

The report of the IWC observer at the 20th annual meeting of NAMMCO held in Oslo, Norway in September 2011 is given as IWC/64/4B. All requested stock assessments for large whale species in the North Atlantic have now been finalised based on sightings data from the Trans North Atlantic Cetacean Sightings Surveys (T-NASS) in 2007 and additionally in 2009. Management procedures applied have been derived from those already developed by the Scientific Committee of the IWC using the Revised Management Procedure (RMP) approach. An RMP-like approach has been recommended by the Scientific Committee of NAMMCO for some large whale stocks in their discussions on general models to be adopted by NAMMCO. These stock assessments by the constitute the main basis for catch limits set for some baleen whale stocks (fin and minke whales) in the North Atlantic.

Based on T-NASS data, an updated abundance estimate for pilot whales has been made in the areas surveyed in 2007. Although the combined area represented is small and not directly comparable with previous surveys, the Scientific Committee Report

available information gives no reason to amend previous conclusions on the sustainability of the Faroese catch. The next regular NASS is scheduled to take place between 2013 and 2015 and planning is already under way.

The working group on marine mammal-fisheries interactions continued its work on development of a large international ecosystem modelling project. A network has been established between several leading scientists in this field aimed at securing funding for the project which includes applying four different modelling approaches to two data rich areas, the Barents Sea and Icelandic coastal waters.

A training course for observers appointed under the NAMMCO joint control scheme for the hunting of marine mammals is to be organised this year.

The Committee thanked Katsuyama for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next NAMMCO Council meeting. Further information on NAMMCO can be found on their website.¹

4.9 International Union for the Conservation of Nature (IUCN)

Cooke and Reeves, the IWC observers, reported on the considerable cooperation with IUCN that had occurred during the past year and this is given as IWC/64/4K.

Western gray whales

The mandate of the IUCN Western Gray Whale Advisory Panel (WGWAP) has been renewed for a further five years, under the aegis of the IUCN Global Marine and Polar Programme. The Panel has expressed concerns about plans to install a third offshore platform for oil and gas extraction just offshore of the gray whale feeding ground, but this project has now been postponed. Analyses of the data collected during a 2010 seismic survey with respect of the effects on gray whales and the effectiveness of mitigation measures are still in progress. Similar mitigation and data collection arrangements are in place for a smaller seismic survey that is currently underway and further information is given in Annex F Appendix 9. The work of WGWAP is discussed further underwritten 10.4.2.

Red List updates

A current list of all cetacean species and populations that have been assessed for the Red List, and their current Red List classification, is maintained on the Cetacean Specialist Group site² with links to the assessments which are held on the Red List site www.redlist.org. Updates since the last Annual Meeting include separate assessments for the two recently recognised species of finless porpoises (*Neophocaena asiaeorientalis* and *N.*

¹ <http://www.nammco.no>

² www.iucn-csg.org/index.php/status-of-the-worlds-cetaceans

phocaenoides), both listed as Vulnerable. New assessments are underway for the dolphins in the genus *Inia*, which were recently split into two species, *Inia geoffrensis*, the Amazon River dolphin, and *I. boliviensis*, the Bolivian bufeo.

Cetacean Specialist Group

The website of the IUCN Cetacean Specialist Group (www.iucn-csg.org), contains regular updates of IUCN's cetacean-related activities and other work in which group members are involved. New items since last year relate to vaquita conservation efforts, Mekong River dolphins in Cambodia, Indus dolphins in Pakistan, new cetacean protected areas in Bangladesh.

World Conservation Congress

The IUCN 4-yearly World Conservation Congress will be held 6-15 September 2012 in Jeju, Korea with the theme 'Nature+'. The programme includes three cetacean-related events: a workshop on lessons learned from the IUCN western gray whale conservation initiative, a presentation on a local population of Indo-Pacific bottlenose dolphins found around Jeju Island, and a workshop on cetacean conservation and whale-watching in Africa³.

The Committee thanked Cooke and Reeves for their report. It thanks Larsen for his contributions in the past and has left IUCN and agrees that Cooke should continue to act as observers to IUCN for the IWC.

4.10 Food and Agriculture Organisation (FAO) related meetings – Committee on Fisheries (COFI)

No observer for the IWC attended the 2011 meeting of COFI.

4.11 Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES)

No observer for the IWC attended the 2011 meeting of CITES.

4.12 North Pacific Marine Science Organisation (PICES)⁴

The report of the IWC observer at the 20th annual meeting of PICES held 14-23 October 2011 in Khabarovsk, Russia is given as IWC/64/4H. The Marine Birds and Mammals Advisory Group (AP-MBM) recommended that PICES request the IWC Scientific Committee includes a seabird observer on the IWC POWER cruise survey vessel in the future.

Spatial ecology and conservation was selected as the basis of the new activity plan for the AP-MBM. The objectives are:

- (1) synthesise distribution data on marine birds and mammals and its temporal change in the North Pacific;
- (2) examine the physical and biological factors that correspond to the distribution and abundance of marine birds and mammals and their economic/ecological hot spots; and
- (3) provide information on ecological areas in the PICES regions to aid understanding and sustainable use of marine resources.

Two sessions at the 2012 AP-MBM workshop were of relevance to the IWC, these were: (1) environmental contaminants in marine ecosystems: seabirds and marine mammals as sentinels of ecosystem health; and (2) the feasibility of updating prey consumption by marine birds, marine mammals and large predatory fish in PICES regions.

The Committee thanked Kato for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next PICES meeting.

4.13 Eastern Caribbean Cetacean Commission (ECCO)

No information on the activities of ECCO was provided.

4.14 Protocol on Specially Protected Areas and Wildlife (SPA) of the Cartagena Convention for the Wider Caribbean⁵

The report of the IWC observer to SPAW is given as IWC/64/4D. The MSP LifeWeb Project was launched in October 2010, which aims to assist with the implementation of decisions from the Convention on Biological Diversity, as well as those of the Cartagena Convention and its SPAW protocol. Recent activities under this project include:

- (1) a workshop on integration, mapping and GIS analysis of marine mammal migration routes, critical habitats and human threats in the wider Caribbean region (May 2011);
- (2) assisting in the coordination of a conference on Marine Mammal Protected Areas (November 2011);
- (3) identifying marine mammal data sources within the wider Caribbean Region and collating information in an online database;
- (4) a workshop on broad-scale marine spatial planning (March 2012);
- (5) analysis of identified marine mammal data in order to develop data layers and maps on the critical habitats for marine mammals in the wider Caribbean; and
- (6) a workshop on broad-scale marine spatial planning and transboundary marine mammal management (May 2012).

³ www.worldconservationcongress.org

⁴ <http://www.pices.int>.

⁵ <http://www.cep.unep.org/cartagena-convention>.

In 2011 a project focusing on marine mammal watching was implemented. It aims to improve and centralise the level of information and knowledge on the status, distribution and threats of marine mammals in the region. A related workshop was held in October 2011. The Committee thanked Carlson for attending on its behalf and agrees that she should represent the Committee as an observer at the next SPAW meeting.

4.15 Indian Ocean Commission (IOC)⁶

No information on the activities of IOC was provided.

4.16 Permanent Commission for the South Pacific (CPPS)⁷

No information on the activities of CPPS was provided.

4.17 International Maritime Organisation (IMO)⁸

The report of the IWC observer to the IMO is given as IWC/64/4G. The IWC has contributed to IMO discussions on addressing ship strikes and the impacts of underwater noise from shipping. The IMO has established a correspondence group to develop non-mandatory draft guidelines for reducing underwater noise from commercial ships (Donovan is a member of this group). This group will report to the IMO's 57th session of the sub-committee on Ship Design and Equipment in early 2013.

The IMO is also working to develop a mandatory Polar Code to control the expected increase in ship traffic in polar waters (the Arctic and the Antarctic) that results from climate and other changes. The Polar Code is intended to function alongside existing IMO conventions and to augment existing measures to reduce the environmental impacts of shipping taking into account the greater environmental sensitivity of polar waters. An IMO Workshop on Environmental Aspects of the Polar Code was held in Cambridge in September 2011 where there was considerable discussion of ship strikes and underwater noise impacts on whales. The Polar Code work is also co-ordinated by the IMO Design Sub-committee on Ship Design and Equipment.

The Committee thanked Leaper for his report and **agrees** that the IWC Secretariat should represent the Committee at the next IMO meeting.

4.18 Conservation in the SE Pacific under the framework for the Lima Convention

No information on Conservation in the SE Pacific under the framework for the Lima Convention was provided.

4.19 International Committee on Marine Protected Areas (ICMMPA)⁹

At its 60th annual meeting in Santiago, Chile, the Committee endorsed support for the first International Conference on Marine Mammal Protected Areas, which was subsequently held in Hawaii, in 2009. The committee that formed to organize that conference has remained intact and is now a task force of the IUCN. It hopes to continue its constructive relationship with the IWC- SC/64/O1 is the summary report of the second International Conference on Marine Mammal Protected Areas (ICMMPA) meeting. Some 150 marine mammal protected area (MMPA) researchers and managers as well as government and conservation group representatives from 42 countries and overseas territories convened in Martinique in the French Caribbean from 7-11 November 2011 for the Second International Conference on Marine Mammal Protected Areas (ICMMPA 2). The goal: to seek solutions to shared problems related to marine mammal conservation and to MMPA network and site design, creation and management. A secondary goal was to orient those working in MMPAs to set those protected areas in the broader context of marine management. The conference was co-hosted by the French MPA Agency (*Agence des aires marines protégées*) and the US National Oceanic and Atmospheric Administration (NOAA). Fifteen other international and regional sponsors, as well as a dozen supporting organizations, were actively involved.

The conference theme of 'Endangered Spaces, Endangered Species' was explored in keynote talks, panels and workshops focusing on monk seals, sirenians, river dolphins and other small and large cetaceans. In several workshops and plenary talks, special attention was given to the *vaquita*, the most endangered, space-restricted marine mammal in the world. Plenary sessions were divided into panels, followed by discussions, focusing on:

- (1) special considerations for particularly endangered marine mammals and whether MPAs are the right tool;
- (2) refining our understanding of marine mammal critical habitat and hotspots to inform MMPA designation;
- (3) using marine spatial planning and ecosystem-based management to address broad threats to marine mammals;
- (4) managing MMPAs for localized threats and mitigation by spatial protection and other means;
- (5) development of MMPAs in the wider Caribbean region; and
- (6) regional cooperation for MMPA scientific and technical networking.

⁶ <http://www.coi-ioc.org>.

⁷ <http://www.cpps-int.org>.

⁸ <http://www.imo.org>.

⁹ www.icmmpa.org.

The workshops focused on marine mammals and oil spills, decision-making with limited data, best practices for whale watching in MMPAs, integrating marine mammal data in marine spatial planning, forging agreements to establish effective MMPA networks, and the widespread mortality attributed to fisheries bycatch.

Proceedings of this second ICMMPA meeting will be available and released briefly and a third ICMMPA meeting is planned to be held in about two years' time. A proposal was received from Australian scientists and decisions on exact location and date are yet to be taken.

5. REVISED MANAGEMENT PROCEDURE (RMP) – GENERAL ISSUES (SEE ALSO ANNEX D)

5.1 Complete the MSY rates review

Since 2007, the Committee has been discussing maximum sustainable yield rate (MSYR) in the context of a general reconsideration of the plausible range to be used in population models used for testing the *Catch Limit Algorithm (CLA)* of the RMP (IWC, 2008c; 2009b; 2010b; 2010h; 2011j). The current range is 1% to 7%, in terms of the mature component of the population. As part of its review, the Committee has been considering observed population growth rates at low population sizes. An important issue raised (Cooke, 2007) was that should variability and/or temporal autocorrelation in the effects of environmental variability on population growth rates be high, simple use of such observed population growth rates could lead to incorrect inferences being drawn over the lower end of the range of plausible values. In 2010, the Committee agreed a Bayesian approach (Punt, 2010) for calculating a probability distribution for the rate of increase for an 'unknown' stock in the limit of zero population size, once the inputs needed to apply it become available (IWC, 2011e).

Last year, the Committee had agreed that the review would be completed at this meeting (IWC, 2012f). However, given effectively no intersessional progress, the issue was furthered but not completed during the present meeting (Annex D, Appendix 2) as follows:

- (1) values of demographic parameters to be used for the calculation of the CV and autocorrelation of the rate of increase were agreed for the 15 populations for which estimates of growth rate at low population size were available if it is assumed that only fecundity is stochastic;
- (2) calculations were undertaken for the case where there is no variability in survival rate;
- (3) progress was made on the implementation of two approaches for specifying variability in survival rate; one which results in the same CV for the rate of increase for variability in survival rate as

the CV implied by the variability in fecundity, and another which is based on an approach involving optimal allocation of energy between reproduction and survival.

The Committee expressed serious concern that once again the process has not been completed and it carefully examined whether it was worth continuing the process. However, given the good progress during the meeting, and the workplan developed (Annex D, Item 2.1), the Committee **agrees** that no more than one further year would be allowed for this process. If the MSYR review cannot be completed at next year's meeting, the current range of MSYR rates (1% - 7% in terms of the mature component of the population) will be retained.

To ensure completion of these tasks, a three-day intersessional meeting is required, with at least five participants, ideally back-to-back with another intersessional meeting. An intersessional steering group (under Butterworth Annex R1) was appointed to co-ordinate the meeting and associated preparation. Any models related to variability in survival rate to be considered must be fully specified to the Steering Group at least one month before the intersessional meeting. The financial considerations are given under Item 23.

5.2 Finalise the approach for evaluating proposed amendments to the CLA

The Committee last discussed this issue in 2006 (IWC, 2007c) noting that it was originally intended that this work would occur in conjunction with the completion of the MSYR review (see Item 5.1 above). The Committee re-established a working group under Allison (Annex R1) to develop trials to examine the effects of possible environmental degradation in terms of trials in which *K*, and perhaps MSYR, varies over time. The Committee **stresses** that this work must be completed by the next Annual Meeting irrespective of the progress made under Item 5.1.

5.3 Evaluate the Norwegian proposal for amending the CLA

The Committee was unable to complete its evaluation of the Norwegian proposal given the discussions under Items 5.1 and 5.2 above. The Committee **agrees** that this task will be completed at the next Annual Meeting either using the revised values from the MSYR review or the existing values if the review is not completed.

5.4 Modify the 'CatchLimit' program to allow variance-covariance matrices

The 'CatchLimit' program implements the *Catch Limit Algorithm* and now allows variance-covariance matrices for the abundance estimates to be specified (IWC, 2012f). Allison noted that it includes some non-standard coding statements and she will be working with the Norwegian

Computing Center during the intersessional period to develop a final version of the program.

5.5 Update requirements and guidelines for conducting surveys and Implementations

The Committee's Requirements and Guidelines for Conducting Surveys and Analysing Data within the Revised Management Scheme (IWC, 2012v) were written when only design-based surveys were realistic. Subsequently, spatial modelling approaches have been developed as an additional realistic approach. In addition, many [quasi] design-based surveys do not formally meet design-based criteria, and there may be a question regarding on the adequacy of resultant estimates. The Committee has frequently considered model-based and quasi-design-based estimates (e.g., IDCR/SOWER and SCANS), but without explicit criteria and not necessarily in the context of the RMP. Two linked issues therefore arise: under what circumstances might approval from the Scientific Committee reasonably be given to surveys that are not design-based, and should the Guidelines should be amended to give more specific advice on the considerations for evaluating model-based estimates (including extrapolations) and/or quasi-design-based estimates.

The statistical issues involved are complex, both theoretically and in practice. A number of detailed starting points for discussion are noted in Annex D, Item 2.5, and sufficient experience with model-based methods has now accumulated to warrant a review. The Committee, also recognising the importance of this work for all sub-committees that consider abundance estimates in a conservation and management context, therefore **recommends** that such a review (covering model-based abundance estimation in theory and practice, and its relation to the design-based approach), be conducted. The review (Annex D, Appendix 4) will also provide draft text for inclusion in the Committee's Requirements and Guidelines for Conducting Surveys document. The financial considerations are given under Item 23.

5.6 Evaluate the optimisation method used when conditioning trials

Punt and Elvarsson (2011) developed and compared a number of ways to improve the performance of the optimisation algorithm underlying the conditioning process, as discussed in Annex D, Item 2.6. The Committee noted that the optimisation scheme used for conditioning the trials for the western North Pacific minke whales had been modified accordingly.

5.7 List of abundance estimates and their recommended uses

The list of accepted abundance estimates for those stocks that have been subject to RMP *Implementations* (and *Reviews*) are provided in Annex D, Appendix 2 along with references to discussions as to whether they are

acceptable for use in conditioning; acceptable for use in trials, and/or acceptable for use in applications of the *CLA*. The only exception was for western North Pacific common minke whales where evaluation is ongoing (see Item 6.3).

5.8 Work plan

The Committee's views on the workplan developed by the sub-committee on the RMP are given under Item 21 and financial matters are considered under Item 23.

6. RMP – PREPARATIONS FOR IMPLEMENTATION

6.1 Western North Pacific Bryde's whales

6.1.1 Prepare for 2013 Implementation Review

The Committee was informed that Japan wished to postpone the 2013 *Implementation Review* for North Pacific Bryde's whales until 2016 because:

- (1) Dedicated sighting surveys have been conducted in the western North Pacific since 2010 and additional surveys targeted towards Bryde's whales were planned for 2012 and beyond.
- (2) Lower latitudinal waters in the eastern North Pacific will be covered during the IWC/POWER research program during 2013- 2015.
- (3) There are currently no genetic samples for sub-area 2 (east of 180°). It is expected that biopsy samples will be collected from Bryde's whales during the IWC/POWER research programme.
- (4) New genetic samples have been obtained for sub-area 1 (west of 180°) during JAPRN II as well as other sources, but the data have yet to be analysed.

6.1.2 Recommendations

Implementation Reviews should normally be scheduled not later than six years after the completion of the previous *Implementation* (or *Review*) (IWC, 2012w). The western North Pacific Bryde's whale *Implementation* was completed in 2007 (IWC, 2008). However, the Committee **recommends** that the *Implementation Review* for western North Pacific Bryde's whales be delayed until 2016 given: (a) the *Implementation* completed in 2007 considered a range of hypotheses related to stock structure and productivity; (b) three more years of catches are unlikely to lead to conservation concerns given the results of the *Implementation*; (c) that it cannot conduct more than one *Implementation Review* at a time (see Items 6.2 and 6.3 below); and (d) allow additional sightings and genetics data to be available.

6.2 North Atlantic fin whales

In 2009, the Committee agreed (IWC, 2010d) that if the RMP is implemented for North Atlantic fin whales,

certain variants (see table 4 of IWC, 2010d, pp.122) could be implemented without a research programme. It also agreed that another variant would be acceptable only with an agreed research programme for the reasons given in IWC (2010d). A primary aspect of this related to whether or not a particular stock hypothesis, 'hypothesis IV', was appropriate.

SC/64/RMP3 responded to a recommendation from the Committee last year that further analysis of the Discovery Marking data should be carried out within the framework of the *Implementation Simulation Trials* as detailed in Annex D, Item 3.2. The Committee noted that SC/64/RMP3 provided evidence suggesting that stock structure hypothesis IV is inconsistent with existing data but recognised that making a final decision on its acceptability could also involve additional trials. This can best be achieved within the context of an *Implementation Review*.

Annex D, Table 1 summarises new information available for an *Implementation Review*. The Committee **agrees** that the available information is sufficient to warrant an *Implementation Review* in 2013. It noted that while the *Implementation Review* would be focused on providing advice for the Icelandic hunt, the discussions of stock structure would also be valuable in the context of the SWG's work to develop an *SLA* for the aboriginal hunt off West Greenland (Annex E).

6.2.1 Recommendations

The Committee **recommends** that the *Implementation Review* for the North Atlantic fin whales be brought forward to 2013. The *Review* should start during a pre-meeting immediately before the 2013 Annual Meeting to ensure that it is completed in one year. An intersessional email Steering Group (Vikingsson, Gunnlaugsson, Donovan (chair), Butterworth, Allison) was established to coordinate the work prior to the 2013 meeting.

6.3 North Pacific common minke whales (continue *Implementation*)

The Committee is conducting an *Implementation Review* for western North Pacific common minke whales and is following the schedule set out in its Requirements and Guidelines (IWC, 2012a). At last year's meeting, the Committee had been unable to complete the tasks required for the First Annual Meeting, primarily because it had not been possible to complete conditioning of the *Implementation Simulation Trials* a major task given their complexity. This meant that the 2 year schedule for the *Implementation Review* had been disrupted.

This year's meeting was effectively a repeat of the First Annual Meeting with the same list of tasks that had been initiated last year. There had been another Intersessional Workshop in December 2011 to facilitate the work necessary to ensure that all relevant tasks could be

completed at this year's meeting as described under item 6.3.1.1.

6.3.1 Report of the December 2012 Intersessional Workshop

Donovan presented a summary of the report of the Intersessional Workshop held 12-16 December 2012, kindly hosted by the Government of Japan (SC/64/Rep2). The primary objective of the Workshop was to ensure completion of the conditioning of trials in time for the 2012 Annual Meeting, although a number of other topics were addressed to assist the Committee in its work to complete the *Implementation Review*. Conditioning is the process of selecting the values for the parameters of the operating models that implement the trials such that the predictions from these models are consistent with the available data.

The Intersessional Workshop covered issues relating to: stock structure and mixing matrices; conditioning; abundance estimates for use in trials; specification of these trials; plausibility of stock structure hypotheses; and data/analyses to reduce the number of stock structure hypotheses in future *Implementations*. Considerable progress was made and details are given in Annex D1, Item 3 and SC/64/Rep2.

6.3.2 Conditioning

Following the Intersessional Workshop, a number of problems with the fits of the operating model to the data had been identified. Suggested changes to the trial specifications were developed, details of which are given in Annex D1, Item 4.1, which the Committee **endorses**.

The Committee reviewed the results for the six baseline trials (stock structure hypotheses A, B and C with MSY rates of 1% and 4%) given in Annex D1, Appendix 2 and **agrees** that the conditioning for these trials had been acceptably achieved. There was insufficient time to evaluate the results of the conditioning of all the sensitivity tests. However the Committee **agrees** that the results for trials for which 100 simulations were available suggested that it is possible to determine whether conditioning has been achieved successfully based on the fit of the operating model to the actual data.

The Committee received a summary report from a small group appointed to review the results of trials run to date. Allison reported that all trials for stock structure hypotheses A and C with MSYR = 1% had now been run with the actual data. Conditioning had been achieved for all these trials except two, for which the mixing matrices needed adjustment. Based on these results and on extensive past experience with reviewing the results of such trials, the Committee **agrees** that conditioning of the *Implementation Simulation Trials* of western North Pacific common minke whales had been acceptably achieved.

6.3.3 Update to standard datasets - abundance estimates

Abundance estimates play three roles in the *Implementation* process: (a) for use in conditioning trials; (b) for use when applying the *CLA* during *Implementation Simulation Trials*; and (c) for actual application of the *CLA*. The abundance estimates for use during conditioning were selected during the First Intersessional Workshop in December 2010 (IWC, 2012d). At this meeting, the Committee needed to select which abundance estimates to use when applying the *CLA* during *Implementation Simulation Trials*. The abundance estimates for use in actual application of the *CLA* will be finalised next year.

The Committee received a cruise report of a sightings survey in the Yellow Sea in May 2011 (SC/64/NPM6) and an estimate of abundance for minke whales from this survey (SC/64/NPM7); details are given in Annex D1, Item 5.1.1. The Committee expressed its appreciation to the Government of Korea for its continued commitment to surveys for minke whales in Korean waters, and to An for his role of oversight on behalf of the Committee. In discussion, the Committee raised a number of issues with the analysis that requires further work. Therefore this estimate was not accepted for use in implementation of the RMP at this meeting but the Committee looks forward to the presentation of a revised estimate in the future.

The Committee received SC/64/NPM2, an updated summary of the information on survey procedures for the Japanese dedicated sighting surveys conducted by the Institute of Cetacean Research (ICR) and the National Research Institute of Far Seas Fisheries (NRIFSF), in response to a recommendation from the December 2011 Intersessional Workshop (SC/64/Rep2). The authors concluded that sighting procedures for the ICR surveys follow the RMP requirements and guidelines for surveys, except that the surveys were not subject to Committee oversight, and that the survey procedures for the NRIFSF surveys met all these requirements and guidelines. The Committee also received SC/64/NPM3, which presented abundance estimates from JARPN II (see item 17) sightings data for minke whales in sub-areas 7CS, 7CN, 7WR, 7E, 8 and 9 collected during 2008 and 2009. Details are given in Annex D1, Item 5.1.2.

A number of issues were raised and discussed relating to survey design, survey direction relative to migration, survey protocol for responding to bad weather and achieved coverage; details are given in Annex D1, Item 5.1.2. One specific point was that the estimates of abundance for 2008 and 2009 use information from other years. The Committee therefore **recommends** that variance-covariance matrices be computed for the entire time-series of abundance estimates for sub-areas 7CS, 7CN, 8, and 9.

Whether and how to use estimates with low coverage or design concerns and the treatment of JARPN and JARPN II surveys (i.e. surveys that had not originally been intended to produce estimates for use in the RMP) that did not have Committee oversight raised issues beyond the specifics of the *Implementation Review* of western North Pacific minke whales. Accordingly, the Committee had a general discussion of these issues, the report of which is given under Item 5.8.

In light of that discussion, a small group reviewed all of the available abundance estimates to determine whether or not they were acceptable for use when applying the *CLA* during *Implementation Simulation Trials*. Each available estimate was categorized as ‘Yes’, ‘No’, ‘No agreement’, and ‘Yes*’ (see Annex D1, Appendix 3). The category Yes* indicates that they can be used in the trials but that further analysis needs to be considered for the estimate to become acceptable for application of the RMP. Surveys which had been accepted for use in the trials during the 2003 *Implementation* were automatically deemed acceptable. The Committee **endorses** the categorisations given in Annex D1, Appendix 3.

Regarding those estimates for which no agreement had been reached on whether or not they were acceptable for use in trials, the Committee **agrees** that the baseline trials should be conducted for the least and most aggressive RMP variants both using and not using the ‘No agreement’ estimates when applying the *CLA*. If the results of the trials are sensitive to the inclusion of the ‘No agreement’ estimates, the proponents would be requested to justify how the ‘No agreement’ estimates could become acceptable with further analysis. The final decision on whether further analysis is likely to allow ‘No agreement’ estimates to be acceptable will be made by the Intersessional Steering Group established under Butterworth (Annex R).

Annotation 21A to the RMP specifications (IWC, 2012w) states that ‘A part of an *Area* which is unsurveyed in a single year may count as surveyed when the data from several years are combined, provided that an appropriate multi-year regression analysis is used, and additional variance is taken into account’. In response to a recommendation in SC/64/Rep2, the Committee received SC/64/NPM5, which extrapolated abundance estimates to parts of sub-areas 8, 11, and 12NE which were not covered during some past surveys, to eliminate the bias in estimated abundance trend which arises due to variable coverage. Details are given in Annex D1, Item 5.1.2.

The Committee noted that blocks B11-2 and B12NE-2 had only been surveyed once which meant that there are insufficient data to inform additional variance. The Committee **agrees** that the information for sub-area 8 satisfied the requirements for applying annotation 21A.

6.3.4 Update to standard datasets – best catch series

The Committee **agrees** with the recommendation in Annex D of SC/64/Rep2 that the ‘Best’ catch series was appropriate for the direct catches.

The Committee noted that a single series of bycatches would be used for all of the trials when applying the RMP, irrespective of the true values for the bycatches, which differ among trials, and simulations within trials. The Committee **agrees** that the bycatches would be set to the averages of the predicted bycatches based on the fit to the actual data of the operating model for the six baseline trials (see Annex D1, Appendix 4).

Regarding the specification of future bycatches in the trials, the Committee **agrees** that this should be achieved by assuming that the bycatch rate in the future equals the bycatch rate estimated for the trial in question averaged over the previous five years (Annex D1, Appendix 9).

6.3.5 Final consideration of plausibility

A key step in the Committee’s Requirements and Guidelines for *Implementations* (IWC, 2012w) is assigning plausibility to hypotheses and, by extension, to all of the *Implementation Simulation Trials*. Trials are assigned ‘low’, ‘medium’ or ‘high’ weights, or are categorised as ‘no agreement’, which are treated as ‘medium’ weighted trials. Trials with ‘low’ weights are not considered further in the *Implementation*.

When the results of the trials are examined, for each management variant (see Item 6.3.1.5), ‘acceptable’ conservation performance is required for all ‘high’ weight trials but ‘borderline’ or ‘unacceptable’ conservation performance for a number of ‘medium’ weight trials, leads to further consideration of a possible ‘with research’ option, as detailed in IWC (2012w). Unacceptable performance of a management variant in any ‘high’ weight trial leads to that variant being eliminated from further consideration, including with respect to the ‘with research’ option.

The schedule for *Implementations* in the Committee’s Requirements and Guidelines for *Implementations* (IWC, 2012w) required final decisions on the plausibility of hypotheses to be made at this year’s meeting.

SC/64/Rep2 noted that the present meeting would decide whether analyses of CPUE data (or sighting per unit effort data, SPUE) could be used qualitatively to inform assignment of plausibility weights to the hypotheses (stock structure and MSYR) on which the trials are based (see Annex D1, Item 3.6). The Workshop had noted that a document outlining relevant operational factors needed to be developed for the Committee to make a decision in this regard, and it had made a number of recommendations regarding such a document.

SC/64/NPM4 summarised information pertaining to catch, sightings and effort data from Japanese small-type whaling during 1977–87 in relation to minke whales. The authors concluded that CPUE or SPUE data can be useful as an index of population trend if standardised.

The Committee thanked the authors of SC/64/NPM4, which covered most of the factors identified. It noted that there was considerable variation in where individual vessels operated during the year, and that if vessel movement reflects availability of whales, CPUE or SPUE may be biased as an index of relative abundance. It was suggested that focussing on April-May only may provide more consistency.

Following the presentation of the results of additional analyses, the Committee considered that further analysis and model diagnostics would need to be provided before the resultant SPUE trends could be used to assist the assignment of plausibility to hypotheses related to stock structure and MSYR. Given the time available, this was not feasible this year. It was noted that these data could be re-analysed and presented to the next *Implementation Review*, although some members considered that use of whaling SPUE data was inherently problematic and that no analyses of these data would lead to information which could inform plausibility.

6.3.5.1 STOCK STRUCTURE

In response to a request made intersessionally, the Committee received papers from the proponents of Hypotheses A/B (SC/64/NPM1) and of Hypothesis C (SC/64/NPM11) summarising their main features and supporting evidence. Details of these papers are given in Annex D1, Item 6.2. a graphical representation of these stock structure hypotheses is given in fig.1 of (IWC, 2012h, pp.103).

Two papers containing new genetic analyses were presented. SC/64/NPM9 used computer simulations to examine the effect of different sample sizes on the distributions of the correlations between θ and F_{IS} , following an analysis presented last year (SC/63/RMP7) in which it was proposed that, in a sample that contains individuals only from two distinct stocks, the largest departures from equilibrium (quantified as F_{IS}) should be seen at the loci that show the largest allele frequency differences between the two stocks (quantified as θ). Details are given in Annex D1, Item 6.2. given the considerable variability seen in the simulated data, the authors of SC/64/NPM9 suggested that further evaluation is required before the results of SC/63/RMP7 could be used as evidence against Hypotheses A and B.

In discussion, it was suggested that it would be useful to extend these analyses to the two-locus (linkage disequilibrium - LD) correlations that were also reported

in SC/63/RMP7. Additional discussion is given in Annex D1, Item 6.2.

SC64/NPM10 responded to a request from last year's meeting for follow-up analyses comparing the performance of two Bayesian clustering programs (STRUCTURE and HWLER) for detecting the number of gene pools represented in a sample. Details are given in Annex D1, Item 6.2. Both programs only detected one population when true panmixia was modelled, but both also failed to detect a second population at the weakest level of differentiation ($F_{ST} = 0.007$). STRUCTURE reliably detected two populations at $F_{ST} = 0.02$ but HWLER did not, but HWLER was more consistent in resolving mixtures for $F_{ST} > 0.03$.

In discussion, the Committee noted that the results provide additional confirmation that these Bayesian clustering methods cannot detect the weakest levels of population structure, at least using currently available numbers of genetic markers. Details of additional discussion are given in Annex D1, Item 6.2. Several more technical aspects of the performance of STRUCTURE at moderate levels of population differentiation ($F_{ST} = 0.045$ - 0.06) were also discussed; details are given in Annex I.

In response to a request in SC/64/Rep2, the summary information relating to key stock structure questions developed last year (Appendix 9 of Annex D1 of last year's report - IWC, 2012h) was reformatted and presented to the Committee. It was revised following discussion and a final version is given in Annex D1, Appendix 6. This table provided a useful starting point for final considerations of plausibility of stock structure hypotheses.

The Committee also received Annex D1, Appendix 7, which synthesised information relating to the relevance of departures from Hardy-Weinberg equilibrium at one and two gene loci, to distinguish between stock-structure hypotheses. The author's overall conclusion was that evidence from Hardy-Weinberg departures for more than two O+J stocks is only weak to moderate. Details of discussion are given in Annex D1, Item 6.2.

Following these presentations and discussions, the Committee considered a concise overall summary by the 'G5 group' of geneticists of their interpretation of the relative support for and against the five hypothesised stocks (JE, JW, OE, OW, Y), based on the cumulative genetic information presented and discussed during the last several years. This summary table is given in Annex D1, Appendix 8.

During the discussion, there was some attempt to reduce the number of stock structure hypotheses for consideration in the *Implementation Simulation Trials*. It was noted that the conclusion in Annex D1, Appendix 8

regarding Y stock did not depend on data on conception date, which some consider the strongest evidence for Y stock. Some members suggested that as a consequence, Hypothesis A be assigned 'Low' plausibility. This was not agreed to by the proponents of that hypothesis, who pointed out that reliability of the conception date data has been questioned (e.g. IWC, 2012h) and who argued that the genetic data are too limited to be considered strong support for existence of Y stock. Similarly, assigning 'High' plausibility to a 4-stock version of Hypothesis C that includes two O stocks but only one J stock, and 'Medium' plausibility to Hypothesis C did not receive agreement.

In the end, it was not possible to reach agreement on any of these alternatives and, as a consequence, all three main stock structure hypotheses (A, B and C) were 'no agreement'. The Committee **agrees** that they should therefore be treated as if they had been assigned 'Medium' plausibility and that the *Implementation Review* should proceed on this basis.

Pastene commented that although several types of data had been considered during the *Implementation* process thus far, he felt that the conclusions on plausibility were too heavily weighted to the genetic data. The Committee reaffirms the importance of using data from a suite of techniques.

Some members expressed their concern that, despite an enormous investment in research, no consensus had been reached on according low plausibility to the hypothesis of two J stocks. They noted the conclusion of five geneticists who were not proponents of any of the hypotheses (Gaggiotti, Hoelzel, Palsbøll, Tiedemann and Waples) that, based on existing genetic data and analyses, the evidence for the two J stock hypothesis is low and the evidence against it is medium or high (Annex D1, Appendix 8). They questioned whether it would ever be possible to agree, on the basis of genetic analyses, that a hypothesis be given low plausibility if such a statement was not considered by the Committee to be sufficient.

Other members considered that the genetic data were insufficient to evaluate any of the three stock structure hypotheses. They noted that genetic data do not provide information on annual mixing rates between *Small Areas*, which has been shown to be an important consideration in the application of the RMP (Martien *et al.*, 2008). They also noted the discussion under Item 6.1.3.8 on the lack of samples from the breeding grounds and recommendations for further research to determine the levels of demographic mixing between breeding populations in relation to management outcomes.

6.3.5.2 MSYR AND OTHER FACTORS

The previous *Implementation* assigned 'high' plausibility to $MSYR_{mat}=4\%$ and 'medium' plausibility to

$MSYR_{mat}=1\%$ (IWC 2005). It was noted that these whales are found in a region in which there are very large fisheries which might impact the prey base. However, the size of any such an effect on $MSYR$ cannot be quantified at this time. In addition, the review of MSY rates will not be completed during the current meeting so there is effectively no new information related to $MSYR$ for western North Pacific minke whales. The Committee therefore **agrees** to assign ‘high’ plausibility to $MSYR_{mat}=4\%$ and ‘medium’ plausibility to $MSYR_{mat}=1\%$, as in the previous *Implementation*.

The baseline trials are based on the hypothesis $g(0)=0.8$, based on the estimate of $g(0)$ by SC/62/NPM9 for the combination of top barrel and upper bridge. The December 2010 First Intersessional Workshop (IWC, 2012d) had noted that this estimate is conservative because the $g(0)$ value is to be applied identically to all surveys, including those by Korean vessels which have lower top barrels, and hence seem likely to miss a greater proportion of minke whales on the trackline. The Committee therefore **agrees** to assign ‘high’ plausibility to $g(0)=0.8$ and ‘medium’ plausibility to $g(0)=1$.

Regarding the full set of sensitivity trials, the Committee **agrees** to assign ‘medium’ plausibility to all of the trials except for the following three:

- (1) Trial 24, which is based on stock structure hypothesis C, but there is a single O-stock and two J-stocks. This trial was assigned ‘low’ plausibility given the results of the genetics analyses (see Annex D1, Appendix 8).
- (2) Trials 21 and 29, which are based on the abundance in sub-areas 5 and 6W, respectively, being set to the ‘minimum’ values. These trials were assigned ‘low’ plausibility because the Korean surveys in sub-areas 5 and 6W only cover a small fraction of the overall area of these sub-areas.

The Working Group noted that results of trials 21 and 29 might provide useful information regarding the behaviour of the trials, and **recommends** that these trials be conducted if time is available.

Annex D1, Appendix 5 lists the factors considered in the trials and the final plausibilities assigned by the Committee to each factor.

6.3.6 Specifications of operational features and management variants

In order to implement the *CLA* in trials, specifications of proposed whaling operations are required. Japan intends to conduct coastal whaling in sub-areas 7CS, 7CN and 11, and pelagic whaling in sub-areas 8 and 9. Coastal whaling will be restricted to 10 n.miles. from the coast and during August-October in sub-area 11 to minimise catches of J-stock animals. Whaling in sub-areas 8 and 9

will take place during April-October. Korea intends to conduct whaling using small-type catcher boats in sub-areas 5 and 6W from March to November. Operations will be conducted up to 60 n.miles. from the coast in sub-area 5 and up to 30 n.miles. from the coast in sub-area 6W.

It is also necessary to specify the management variants that will be implemented in the trials. A management variant defines the way the *CLA* is applied to *Management Areas*. This includes specifying *Medium Areas*, *Small Areas* and combinations of *Small Areas* (*Combination Areas*), specifying from which *Management Areas* catches are to be taken, and selecting *Catch-cascading* and/or *Catch-capping* options.

The **agreed** RMP variants and the associated *Small* and *Medium Area* definitions are given in Annex D1, Appendix 9.

The Committee noted that the trials will take longer to run than in previous *Implementations* because the *CLA* will be implemented using the Norwegian ‘CatchLimit’ program rather than the Cooke version of the *CLA*. The Committee **agrees** that priority should be given to running all RMP variants for the baseline trials as quickly as possible so that any of the RMP variants that are clearly likely to perform ‘unacceptably’ can be excluded from further consideration. The process of distributing and evaluating trials will be co-ordinated by the Intersessional Steering Group (see Annex R).

6.3.7 Specifications and classification of final trials

The final trial specifications are given in Annex D1, Appendix 9.

The Committee **agrees** that for running the trials it will be assumed that the proportional coverage of sub-areas will remain unchanged.

The planned future surveys and a proposal for how past surveys can be combined to calculate survey estimates for *Small Areas* are given in Annex D1, Appendix 9.

SC/64/NPM8 reported that a survey in the Yellow Sea will be conducted during spring 2013. Details are given in Annex D1, Item 8.2. The Committee was pleased to hear that additional surveys would continue to be conducted in the waters off Korea and appointed An to provide oversight on its behalf. In relation to survey design, the Committee had recommended some changes to the survey design, which was subsequently modified during the meeting (see Annex D1, Item 8.2).

SC/64/O9 reported on a sightings and satellite tagging survey for common minke whales in sub-area 7 in April-June 2011. Only two animals were encountered and efforts to deploy a tag were unsuccessful. SC/64/O10 reported on a sighting and biopsy sampling survey for common minke whales in the Okhotsk Sea, including the

Russian EEZ, in May-June 2011. Three schools of minke whales were targeted for biopsy sampling, but no samples were obtained because of difficulties closing on the animals. The Committee expresses its support for continued efforts to collect telemetry and biopsy data to help elucidate stock structure for minke whales in this region. More details are given in Annex D1, Item 9.

6.3.8 Consideration of data/analyses to reduce hypotheses in future

The Committee had a general discussion of the fact that, in spite of many years of concerted efforts and a great deal of genetic and non-genetic data, considerable uncertainties remain regarding stock structure of western North Pacific minke whales. This issue is particularly difficult because of the lack of any samples from breeding grounds. The Committee considered a number of types of genetic analyses that might help to reduce these uncertainties in the future. These included sensitivity analyses of recently-used methods and development and application of new analyses, details of which are given in Annex D1, Item 9. The importance of considering further work on non-genetic data was also noted. The Committee notes that plans for international collaborative work, including a workshop, to assist the Committee prepare for an *Implementation Review* under the RMP and the development of an AWMP SLA for the Greenland hunt for North Atlantic minke whales (Annex D, Appendix 6) could serve as a useful model for this.

In addition to proposed analyses specifically related to North Pacific common minke whales, the Committee considered an approach that would more broadly address core stock-structure problems that recur for many species in many areas. This general approach has two parts: (1) determining what levels of demographic mixing between breeding populations do and do not make a difference in terms of conservation goals or management outcomes; and (2) using genetic and other methods to determine whether actual levels of connectivity are above or below this threshold.

The Committee **agrees** that work towards this general approach should receive high priority. Suggestions to facilitate implementation of this approach are given in Annex D1, Item 9; further discussion is given in Annex I.

It was noted that the *Implementation Review* for North Atlantic common minke whales will undertake some of this work (see Annex D, Item 3.3) and that it would be desirable to coordinate efforts in that regard. It was also noted that similar work was being undertaken by scientists at the US Southwest Fisheries Science Center. Cumulative results of these analyses should make it apparent whether general rules of thumb about 'tipping point' levels of migration can be identified, or whether the outcomes are so diverse that each situation must be evaluated on its own merits.

As noted in SC/64/Rep2, in addition to issues of stock structure, other difficulties in conducting the present *Implementation Review* centred on abundance estimates, including their unavailability in some areas and the large CVs for some of the estimates that were available. The difficulties faced by the Committee in determining the acceptability of abundance estimates for use in trials (see Annex D1, Item 5.1.2) amplify this concern.

The Committee **agrees** that, to avoid such difficulties in future *Implementation Reviews*, it should consider taking a more active and collaborative approach to this issue. Examination of trial results will assist in identifying the key temporal and geographical areas where new/improved abundance estimates would be most valuable. The Committee should consider developing, in conjunction with the appropriate range states, a short-medium term survey strategy (including design and required effort) and analytical approach that would improve the availability of satisfactory abundance estimates with reasonable CVs at the appropriate geographical and temporal scale to facilitate future *Implementation Reviews*. This could follow a similar process to that used to develop the IWC-POWER programme (Annex G, Item 6.2).

6.3.9 Inputs for actual application of the CLA

The Committee **agrees** that the best estimates of the direct catches and the average predicted bycatch from the six baseline trial would be used for applications of the CLA.

The Committee did not have sufficient time to select abundance estimates for use in application of the CLA. This issue will need to be addressed at the Second Intersessional Workshop (see Item 20).

6.4 North Atlantic common minke whales

6.4.1 Review new information

SC/64/RMP4 summarised the results of aerial surveys covering most of the continental shelf waters of the Icelandic economic zone; the off season component was part of the Icelandic Research Programme of Common Minke Whales conducted during 2003-07. The Committee noted that SC/64/RMP4 will be considered during the review of this program in 2013 (see Item 17.1.3).

SC/64/RMP5 summarised a sighting survey conducted in the eastern Norwegian Sea in the *Small Management Area EW* during the summer 2011. Details are given in Annex D, Item 3.3.1 This was the fourth year in the ongoing six-year survey program 2008-2013. The Committee **welcomes** the information provided. The data will be included in developing a future abundance estimate for North Atlantic minke whales.

6.4.2 Prepare for 2014 Implementation Review

The Committee agreed last year (IWC, 2012i) to undertake an *Implementation Review* of common minke

whales in the North Atlantic in 2014. It has agreed that this will include a full review of stock structure and other issues, recognising that there has been substantial new information collected over the period since the original hypotheses were developed during the *Implementation* itself (IWC, 1993).

The Committee recognised that it was important to begin preparations for the review in sufficient time to allow for this thorough analysis. It therefore **recommends** the workplan (including a joint intersessional workshop with AWMP in 2014) as outlined in Annex D, Appendix 6, to consider stock structure hypotheses for North Atlantic common minke whales. It appointed a Steering Group under Palsbøll (Annex R).

6.5 North Atlantic sei whales

Vikingsson *et al.* (2010) represented a proposal to initiate a *pre-implementation assessment* of sei whales in the Central North Atlantic. As required (IWC, 2005), the paper provides a broad outline of the available data relevant to an pre-implementation assessment, including historical catches, distribution and abundance from dedicated and non-dedicated sightings surveys, stock structure (Discovery marking, genetics and satellite telemetry), biological parameters, feeding ecology and pathology. The authors concluded that the data are sufficient to warrant a pre-implementation assessment of sei whales in the North Atlantic.

The decision whether to initiate an *Implementation* is made by the Commission. The Committee **recommends** that an intersessional group convened by Vikingsson (Annex R) should be established with Terms of Reference to review the available data for North Atlantic sei whales in the context of a *pre-implementation assessment* and provide a report to the 2013 Annual Meeting. The Committee will review the report and any new information so that the Commission can be advised whether sufficient information is available to proceed with the *pre-implementation assessment*.

6.6 Work plan

The Committee's views on the workplan developed by the sub-committee on the RMP are given under Item 21.

7. ESTIMATION OF BYCATCH AND OTHER HUMAN-INDUCED MORTALITY (BC)

The report of the Working Group on Estimation of Bycatch and Other Human-induced Mortality is given as Annex J. This subject was introduced onto the Agenda in 2002 (IWC, 2003d) because under the RMP, recommended catch limits must take into account estimates of mortality due to *inter alia* bycatch, ship strikes and other human factors in accordance with Commission discussions at the 2000 Annual Meeting

(IWC, 2001a), although of course such mortality can be of conservation and management importance to populations of large whales other than those to which the RMP might be applied. Subsequently, the issue of ship strikes has become of interest to the Commission's Conservation Committee (e.g. IWC, 2011b) while entanglement response is being considered by the Commission's Working Group on whale killing methods and associated animal welfare issues (e.g. see IWC/64/WKM&AWI Rep1).

7.1 Collaboration with FAO on collation of relevant fisheries data

There has been an ongoing effort by the Secretariat and Sea Mammal Research Unit to consolidate data on entanglements submitted in the National Progress Reports into a single database to be shared with FAO. All bycatch records reported to the IWC for the period 1967-2010 have now been entered. The IWC is currently an observer to the FIRMS partnership (Fisheries Resources Management System), a collaborative partnership organised by the FAO, which enables fishery management bodies to share information. It was hoped that FIRMS may hold data on fishing effort that could be useful in estimating bycatch but FIRMS appears to have changed its focus somewhat since initial discussions. The Committee **recommends** that the Secretariat contact FIRMS to establish whether the partnership is still attempting to collate data on fishing effort in such a way that could be of use to the Committee in estimating bycatch.

7.2 Estimation of bycatch mortality of large whales

A long-term data set on entanglements and disentanglements off South Africa showed two centres of entanglement involving humpback or southern right whales, one off the coast of KwaZulu-Natal involving nets set to protect bathers from sharks and the second off the coast of the Western Cape involving traps and attached lines set for rock lobster. Interventions were successful in removing gear from 81% of whales entangled in shark nets off KZN (38 humpback, 17 right whales), while 11 humpback and 2 right whales were found dead. Off the Western Cape, whales were successfully disentangled in 23% of cases ($n = 90$) and partially disentangled in another 12%. The trend in humpback whale entanglement since 1990 was compatible with the recorded rate of population increase. Entanglement rates of southern right whales apparently increased from 1990 and this could also be attributed to an increase in the population (Meyer *et al.*, 2011).

Entanglement data from the coasts of Newfoundland and Labrador, Canada from 1979 to 2008 included 1,209 large whale entanglements, consisting primarily of humpback whales (80%) and minke whales (15%). Reported entanglements dropped from an average of 64 prior to the

moratorium on cod fisheries in 1992 to 19 afterwards (Benjamins *et al.*, 2011).

The Committee noted the value of the extensive data sets described in these studies and that they contributed to an understanding of the impacts, rates and trends over time in entanglement mortality. Both studies had been able to identify trends over time and relate these to either population size or fishing effort. The Committee **recommends** the continuation (or initiation) of these and similar studies and encourages the presentation of results at future Committee meetings.

7.3 Estimation of risk and rates of entanglement

Recent capacity building on entanglement response, conducted by the IWC working in conjunction with both national and regional authorities in Argentina, stimulated an analysis of entangled southern right whales in the province of Chubut. Of nine confirmed cases of entanglement, five involved moorings and four involved marine debris or fishing gear. Six of these whales were successfully released. Many of the mooring systems contained heavy chain and relatively thick diameter rope, but were still found to entangle whales. Whales were often seen ‘playing’ with mooring and anchor lines and this behaviour is believed to be a primary mechanism for entanglement in this region.

The primary focus of the second IWC workshop on Welfare Issues Associated with the Entanglement of Large Whales held in 2011 (IWC/64/WKM&AWI Repl) was on entanglement response and capacity building but several topics from the workshop were also relevant to estimating risk, including the mechanisms by which large whales become entangled. The Committee noted the value of data collected during entanglement responses and welcomed the efforts at the workshop to develop a data form to standardise the data now being collected around the world. The workshop participants had also proposed to form a ‘global network of entanglement response teams’ and seek the endorsement of the IWC as an expert panel to advise member nations on issues related to large whale entanglement including setting up response networks, methodologies for understanding scope and impact on local populations, and response capacity building. The Committee **supports** the call for the proposed group and a potential database noting that this will assist the work of the Committee. In many cases there are additional data available from entanglement incidents that could supplement the summary data currently requested in National Progress Reports. The IWC could become a repository for such data through a similar effort to the ship strike database.

7.4 Review progress on including information in National Progress Reports

Due to some delays with changing to electronic submission of Progress Reports, these were not reviewed

at the meeting. It was noted that, when complete, electronic submission will facilitate linking relevant data to the ship strike database. Suitable links within the submission system could also encourage the entry of data to the ship strike database where more detailed information is available.

7.5 Ship strikes

New information on ship strikes was received for the Arabian Sea region, South Africa and Sri Lanka. A preliminary summary of strandings, lethal entanglements and ship strikes of large whales in the Arabian Sea region, revealed seven documented ship strikes and four lethal entanglements between 2000 and 2012 and included three Arabian Sea humpback whales. The Committee has noted its concern over the status of this population and the increasing shipping traffic in this region (see Item 10.7 for further discussion).

Of 71 recorded mortalities of southern right whales on the South African coast between 1999 and 2010 five bore injuries consistent with a ship strike.

The southern coast of Sri Lanka has one of the busiest shipping routes in the world and overlaps with an area of high whale sightings. Two pygmy blue whales were struck and killed in Sri Lankan waters in early 2012. In the absence of any abundance estimates for the local population, the population impacts of ship strikes are unknown. The Committee **draws attention** to the urgent need for long-term monitoring of the blue whale population in Sri Lankan waters and elsewhere in the northern Indian Ocean. The Committee **recommends** that the Secretariat send a letter to the Sri Lankan Government, drawing their attention to its discussion of this topic and ways in which the Committee may assist.

There is a need to better understand the variables that will affect whether a ship struck whale will strand and predict where death may have occurred. A deterministic model that uses wind archives and outputs of tidal models to predict the drift of floating object has been developed by MétéoFrance. The model can make forward calculations to predict a stranding location or backward calculations to estimate the likely origin of an object. This model had been used to predict whether small cetacean carcasses in the Bay of Biscay would reach the coast (Peltier *et al.*, 2012). It was noted that some carcasses may ‘sail’ across the wind to variable degrees and a large whale carcass may also ‘swim’ after death, because of the action of swell on its tail flukes. The Committee **recommends** further study of carcass drift, detection and deterioration for large whales that could be used to establish the location of death from a ship strike or other sources.

A better understanding of the relationship between vessel speed and collision risk is needed to assess risk. A recent study (Wiley *et al.*, 2011) evaluated the relative risk

reduction that might be achieved by speed restrictions. Two studies based on the locations relative to the ship at which humpback whales were observed from cruise ships inferred greater collision risks with increases in speed (Gende *et al.*, 2011; Harris *et al.*, 2012).

A workshop focusing on ship strikes in the Bay of Biscay was held in London in April 2012 (Bull and Smith, 2012). It made a series of recommendations, mainly dealing with mitigation measures but also related to assessing risk. In particular, the workshop considered ways in which a large data set of observations from vessels may be used. The Committee **welcomes** the approach taken by the workshop to engage a wide variety of stakeholders, and noted that the report could also be relevant to work in other regions. The workshop had considered what could be inferred from observations of ‘near miss’ incidents. The difficulties in defining a ‘near miss’ have been discussed before and further analyses leading to papers for next year’s meeting were encouraged.

A proposal for a workshop of cetacean and shipping experts to agree on appropriate analytical and modeling techniques to assess ship strike risks arose out of the IWC-ACCOBAMS ship strike workshop in 2010 (IWC, 2011c). At the time there was some uncertainty about the availability and content of data on shipping density. Analysis approaches are likely to be most effective on a case by case basis and there are now commercial sources of raw data from Automatic Identification Systems (AIS). The Committee **agrees** that a dedicated workshop is not needed at this stage but **encourages** presentation of papers examining ship strike risks based on overlap of shipping and whale density.

7.6 Continue to develop global database of ship strike incidents

The IWC has been developing a global database of incidents involving collisions between vessels and whales since 2007*. A web based data entry system has now been in place for two years but there have been few new reports submitted. Most of the intersessional database related efforts were to promote awareness, including work by Mattila who has been seconded to the Secretariat to assist with work on mitigating conflicts between whales and marine resource users. As last year, the Committee **agrees** that a more pro-active approach is needed to encourage data to be entered and it **repeats its recommendation** for the appointment of a dedicated IWC ship strike data coordinator with the tasks described in Annex J Appendix II (and see Item 23). The Committee also **recommends** that the Guide for Authors for the IWC journal should encourage authors of papers containing data on ship strike incidents to report these to the database.

* www.iwcoffice.org/sci_com/shipstrikes.htm

Some members noted concern that ship strikes may increase in the Arctic as shipping begins to utilise increases in navigable waters resulting from reduced sea ice coverage. The Committee **welcomes** the offer to present new information on this issue at its next meeting.

7.7 Other issues

A number of papers concerning impacts of marine debris were considered under Item 12 (and see Annex K). The Committee **encourages** further activities that could help to quantify mortality related to marine debris, noting the difficulty in determining debris from actively fished gear.

7.8 Work plan

The Committees discussions on the sub-committee’s workplan (Annex J) are incorporated under Item 21.

8. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT PROCEDURE (AWMP)

This item continues to be discussed as a result of Resolution 1994-4 of the Commission (IWC, 1995a). The report of the SWG on the development of an aboriginal whaling management procedure (AWMP) is given as Annex E. The Committee’s deliberations, as reported below, are largely a summary of that Annex, and the interested reader is referred to it for a more detailed discussion. The primary issues at this year’s meeting comprised: (1) Implementation Review of eastern gray whales with special emphasis on the PCFG (the Pacific Coast Feeding Group); (2) undertaking an Implementation Review for BCB (Bering-Chukchi-Beaufort Seas) bowhead whales; (3) developing SLAs and providing management advice for Greenlandic hunts; and (4) review of management advice for the humpback whale fishery of St. Vincent and The Grenadines. This represented a significant workload.

8.1 Complete *Implementation Review* of eastern North Pacific gray whales with an emphasis on the PCFG

At the 2010 Annual meeting (IWC, 2011f), the Committee agreed that the information on stock structure and hunting presented, although some of it had not met the Data Availability Guideline requirements (IWC, 2004) for the 2010 review, warranted the development of trials as part of an immediate new *Implementation Review* to evaluate the performance of SLAs for hunting in the Pacific Northwest, with a primary focus on the PCFG. It had also agreed that the 2010 *Implementation Review* had shown that the population as a whole was in a healthy state, but that over the next few years, further work should be undertaken to investigate the possibility of structure on the northern feeding grounds, especially in the region of the Chukotkan hunts.

The Committee started the process of the new *Implementation Review* at an intersessional workshop in

2011 (IWC, 2012c) and followed that with work at the 2011 Annual Meeting (IWC, 2012g). A second workshop was held in March 2012 kindly hosted by the SWFSC in La Jolla California (SC/64/Rep3). At that Workshop, most of the effort centred on finalising the operating model and trial structure and completing conditioning. The present meeting reviewed progress made at and since the workshop and focussed on finalising the *Implementation Review*. This summary here incorporates work from the intersessional workshops and the present meeting.

8.1.1 Stock structure

The *Implementation Review* considers three geographic regions:

- (1) the 'north' area (north of 52°N i.e. roughly northern Vancouver Island);
- (2) the PCFG area (between 41°N and 52°N); and
- (3) the 'south' area (south of 41°N).

The trials consider two stocks ('PCFG' and 'north'). PCFG whales, which are treated as a separate management unit, are defined as gray whales observed (i.e. photographed) in multiple years between 1 June and 30 November in the PCFG area (IWC, 2011e, p.22). Not all whales seen within the PCFG area at this time will be PCFG whales and some PCFG whales will be found outside the PCFG area at various times during the year. However, this is not problematic since the historical catches north of 52°N occurred well north of 52°N and future catches will either occur in the Bering Sea or in the Makah U&A (Makah Usual and Accustomed Fishing Grounds). The remaining animals ('north') represent the large eastern North Pacific stock (the stock to which the whales taken during the Chukotkan hunt belong).

Several papers addressed stock structure and related issues (e.g. levels of immigration) at both the intersessional workshop (see SC/64/Rep3, item 2.4.2.2) and the present meeting (see Annex E, item 2.2.2). Notwithstanding the difficulties arising out of the complexities of the issue, the Committee was particularly pleased to see efforts to use the IWC's TOSSM framework (IWC, 2007) in SC/M12/AWMP4 and SC/64/AWMP4 (and see Item 11.3). In that context, it was recommended that future TOSSM analyses consider a broader range of parameter choices to explore the robustness of the conclusions to uncertainty. In concluding discussions on this issue, it was agreed that the trials (Table 3) covered a suitably broad range of immigration rates.

8.1.2 Abundance

The Committee reviewed the mark-recapture abundance estimates provided in SC/64/Rep3 and a new paper (SC/64/AWMP10). The agreed abundance estimates from a modified Jolly-Seber approach (Laake, 2012) are

provided in Table 2 for the OR-SVI region (Oregon to southern Vancouver Island ~42-49°N) and the NCA-NBC region (northern California to northern British Columbia ~41-52°N). Given the large bias in the first (1998) estimate, the estimates for this year out of conditioning.

Table 2

Abundance estimates (N) and standard errors in OR-SVI and NCA-NBC after exclusion of known calves from the year in which they were identified as calves.

Region	Year	N	SE(N)	Region	Year	N	SE(N)
OR-SVI	1998	63	4.1	NCA-NBC	1998	101	6.2
	1999	78	8.4		1999	135	12
	2000	89	11.9		2000	141	13.2
	2001	117	8.9		2001	172	12.6
	2002	133	15		2002	189	9.2
	2003	151	13.7		2003	200	16.4
	2004	157	15.5		2004	206	14.9
	2005	162	15.7		2005	206	22.6
	2006	154	15.3		2006	190	18.8
	2007	152	14.5		2007	183	23.1
	2008	150	12.5		2008	191	16.1
	2009	146	14.9		2009	185	23.2
	2010	143	16.8		2010	186	18.7

Abundance estimates for the total eastern North Pacific are those provided by Laake *et al.* (2012); they are given in Annex E, Appendix 2, Table 4a.

8.1.3 Catch data (direct and incidental)

The agreed catch series for the period of the trials (i.e. 1930 onwards) are given in Annex E, Appendix 2, Table 1. Following work at the intersessional workshop and further review by an intersessional group established in SC/64/Rep3, it was agreed that the average annual kills during 2000-09 were 2 for the PCFG (December-May), 1.4 for the PCFG (June- November) and 3.4 for the 'south' (December-May) and this information was used to forecast future incidental catches.

8.1.4 Mixing

Mixing relates to (1) mixing of stocks in the three areas and (2) the relative probability of whaling in the Makah U&A taking a PCFG whale given the number of PCFG and 'north' whales. The latter can be estimated as the proportion of PCFG whales to total whales in photographs during December - May from the outer coast of northern Washington (0.3; SC/64/Rep3). However, there are a number of uncertainties and assumptions surrounding such an analysis resulting in the need for sensitivity tests (i.e. alternative trials spanning a range of values).

8.1.5 Biological parameters and MSYR

Biological parameter values were agreed last year (IWC, 2012j). The priors, based on the 2004 *Implementation*, are given in the trial specifications (Annex E, Appendix 2).

The most likely value for $MSYR_{1+}$ for the north stock was agreed to be 4.5% i.e. the posterior median from the most recent assessment of this stock (Punt and Wade, 2012). The *Evaluation Trials* also consider a value for $MSYR_{1+}$ for the north stock of 2% (rounded lower 90% posterior bound from the Punt-Wade assessment). There are insufficient data to estimate $MSYR$ for the PCFG and so two scenarios are considered for the *Trials* as discussed last year (IWC, 2012j): (a) $MSYR_{1+}$ for the PCFG stock is the same as that for the north stock and there is no immigration (this is unlikely given the data but provides a conservative lower bound), and (b) three values of $MSYR_{1+}$ but with some immigration and emigration.

Table 3

SLA variants suggested by the Makah tribe used in the *Trials*.

Variant Number	PCFG Limit	Struck and Lost Count Toward APL
1	APL Formula	No
2	APL Formula	Yes
3	APL Formula	Yes
4	1	No
5	1	Yes
6	1	Yes
7	2	No
8	2	Yes
9	2	Yes
10	No limit	N/A
11	No limit	N/A

8.1.6 Variants

The management plan proposed by the Makah Tribe is given in Annex D of SC/64/Rep3 and a number of alternative *SLAs* were proposed for analysis in SC/64/Rep3 as given in Table 3. These variants explore:

- (1) how the allowable bycatch of PCFG whales level¹⁰ (APL) of PCFG whales is calculated (three options);
- (2) the time of year in which the hunt is modelled to occur and hence whether struck and lost animals are counted against the APL (two options); and
- (3) the effectiveness of the *SLA* if only PCFG whales are available for harvest (i.e. in effect a summer hunt).

Variants 1-3 use the APL¹¹ formula presented in the proposed plan, variants 4-9 have fixed bycatch limits, and variants 10 and 11 explore the impact of not having a limit on bycatch of PCFG whales (i.e. the hunt is only stopped if the total *Strike Limit* is reached, or the number

¹⁰ The Makah Tribe has proposed a hunt management plan with time and area restrictions to target migrating ENP whales, yet there is still a chance that PCFG whales are incidentally harpooned as bycatch to the targeted ENP gray whale hunt.

¹¹ The APL formula is provided in Annex E Appendix 2.

Table 4
Details of factors considered in trials

Factors	Other Levels (Reference levels shown bold)
$MSYR_{1+}$ (north)	2%, 4.5%
$MSYR_{1+}$ (PCFG)	1%, 2%, 4.5%
Immigration rate (annual)	0, 1, 2, 4, 6
Pulse immigration (1999/2000)	0, 10, 20, 30
Proportion of whales in PCFG area, ϕ_{fit}	0, 0.3, 0.6, 1
Struck and lost rate (PCFG area)	0, 50%, 75%
Northern need in final year (linear change from 150 in 2010)	340, 530
Historic survey bias	None , Increasing between 1967 to 2002 from 0.5→1 (North only), 50% (PCFG only)
Future episodic events	None , 3 events occur between yrs 1-75 (at least 2 in yrs 1-50) in which 20% of the animals die, Events occur every 5 years in which 10% of the animals die
Time dependence in K	Constant , Halve linearly over 100yr, Double linear over 100yr
Time dependence in natural mortality, M^*	Constant , Double linearly over 100yr
Parameter correlations	Yes, No
Probability of mismatching north whales, p_2	0, 0.01, 0.01-0.05
Probability of mismatching PCFG whales, p_1	0, 0.5
Frequency of PCFG surveys	Annual , 6-year
Incidental catch	Reference , double reference, half reference
Future sex ratio	0.5:0.5 , 0.2:0.8 (M:F)
Episodic events with future pulse events	None , 3 events occur between yrs 1-75 (with at least 2 in yrs 1-50) in which 20% of the north stock die and a pulse of 20 animals is added to the PCFG stock

of struck-and-lost animals reaches its limit, or the landing limit is reached).

8.1.7 Final trials and conditioning

The final trial structure was agreed in SC/64/Rep3. A summary of the factors considered in the trials is given as Table 4. The *Evaluation Trials* agreed are shown in Table 5 and the *Robustness Trials* are shown in Table 6. These trials were finalised at the March 2012 workshop (SC/64/Rep3). Conditioning the trials¹² began at the workshop and was evaluated after the meeting by an intersessional steering group (SC/64/AWMP11). Only three trials, B02C, I02C and P05A were eliminated after considering the conditioning results, leaving 72 *Evaluation Trials* in all.

¹² Conditioning is the process of selecting the values for the parameters of the operating model such that the predictions from this model are consistent with the available data.

Table 5

The *Evaluation Trials*. Values given in bold type show differences from the base case trial. The final three columns indicate which trials apply to which 'broad' hypotheses (P=pulse, B=bias, I=intermediate – see IWC, 2012). For 'broad' hypotheses B and I, the number given is the pulse in 1999/2000. Unless specified otherwise $\phi_{PCFG} = 0.3$, the struck and lost rate is 0.5, and there are no stochastic dynamics or episodic events. *Trials B02C, I02C and P05A removed after reviewing condition results – see text.

Trial	Need to condition	Description	$MSYR_{1+}$ North	$MSYR_{1+}$ PCFG	Final Need	Annual Immigration	Survey freq.	Survey Bias (North)	P	Hypothesis B	I
1A	Y	$MSYR_{1+} = 4.5\%/4.5\%$	4.5%	4.5%	340 / 7	2	10 / 1	1	20	Y	10

8.1.8 Review results of trials

Evaluation of *SLAs* is based on the objectives accepted by the Commission (IWC, 1983; 1995a) which are to:

- ensure that the risks of extinction to individual stocks are not seriously increased by subsistence whaling;
- enable aboriginal people to harvest whales in perpetuity at levels appropriate to their cultural and nutritional requirements, subject to the other objectives; and
- maintain the status of stocks at or above the level giving the highest net recruitment and to ensure that stocks below that level are moved towards it, so far as the environment permits.

Highest priority is accorded to the objective of ensuring that the risk of extinction to individual stocks is not seriously increased by subsistence whaling.

As their name implies, *Evaluation Trials* are used to examine the performance of the variant *SLAs* against the Commission's objectives. *Robustness Trials* are more extreme trials that are primarily to ensure whether an *SLA* performs as expected in such cases.

Table 6
The Robustness Trials.

Trial	Need to Condition	Description	MSYR ₁₊ North	MSYR ₁₊ PCFG	Survey freq.	Hypothesis P	B
1A		6 year surveys	4.5%	4.5%	10 / 6	20	Y
1B		6 year surveys	4.5%	2%	10 / 6	20	Y
2A		Linear decrease in K^{1+} [K halves over years 0-99]	4.5%	4.5%	10 / 1	20	Y
2B		Linear decrease in K^{1+} [K halves over years 0-99]	4.5%	2%	10 / 1	20	Y
3A		Linear decrease in PCFG K [K halves over years 0-99]	4.5%	4.5%	10 / 1	20	Y
3B		Linear decrease in PCFG K [K halves over years 0-99]	4.5%	2%	10 / 1	20	Y
4A		Linear increase in M [M halves over years 0-99]	4.5%	4.5%	10 / 1	20	Y
4B		Linear increase in M [M halves over years 0-99]	4.5%	2%	10 / 1	20	Y
5A		Linear increase in PCFG M [M halves over years 0-99]	4.5%	4.5%	10 / 1	20	Y
5B		Linear increase in PCFG M [M halves over years 0-99]	4.5%	2%	10 / 1	20	Y
6A		Perfect detection; $p_1=0$; $p_2=0.01-0.05$	4.5%	4.5%	10 / 1	20	Y
6B		Perfect detection; $p_1=0$; $p_2=0.01-0.05$	4.5%	2%	10 / 1	20	Y
7A		$p_1 = 0.5$	4.5%	4.5%	10 / 1	20	Y

GP10B	0.475	0.536	0.476	0.538	0.556	0.619	0.557	0.621

The results of all of the trials, expressed in tabular and graphical form (see examples in Annex D, Appendices 3-5) for all agreed performance statistics (conservation and need related) are available from the Secretariat.

The SWG (Annex E, Item 2.5.1) screened the trials for conservation performance to focus on those that required more detailed examination. The criteria used were:

- (1) The lower 5%ile of the final depletion distribution < than 0.6 (the MSYL level) and the lower 5%ile of the rescaled final depletion is lower than 0.6 for any of variants 1-10.
- (2) The trial involved episodic events.
- (3) The lower 5%ile of the trend in 1+ population size indicated a decline in population size of 5% or larger over the final 20 years of the 100-year projection period for any of variants 1-10.

After this initial evaluation a number of features became apparent (see Annex E, Items 2.5.1 and 2.5.2)), primarily related to conservation performance (apart from variant 5 which had poor need satisfaction) that led the Committee to eliminate further consideration of all but variants 1 and 2.

8.1.9 Conclusions and selection of SLAs

In order to minimise the risk of taking PCFG whales, the management plan developed by the Makah Tribe restricts the hunt both temporally (to the migratory season for gray whales i.e. 1 December – 31 May) and geographically (to the Pacific Ocean region i.e. the Makah U&A except the Strait of Juan de Fuca). Some PCFG whales are present during the migratory season and thus the plan proposes an allowable PCFG limit (APL) during hunts that are targeting eastern North Pacific migrating whales with the aim of ensuring that accidental takes of PCFG whales do not deplete the PCFG. Whales struck in May might have a higher probability of being PCFG whales since they feed in this area in June. The management plan thus proposes an additional requirement that all animals struck-and-lost in May are assumed to be PCFG whales (i.e. count against the APL), whereas whales struck between December and April are not.

Weather conditions and availability of whales makes it likely that most hunting will occur in May. However, there are insufficient data to assess the number of strikes by month. Thus, it is not possible to reliably estimate the proportion of struck-and-lost whales that would count towards the APL. Given this uncertainty about how the plan would respond to failing to take into account struck-and-lost PCFG whales, the Tribe had proposed two *SLA* variants (1 and 2) spanning the options as to when the hunt might occur.

SLA variant 1 proposes that struck-and-lost whales do not count towards the APL i.e., there is no management

response to PCFG whales struck but not landed. *SLA* variant 2 proposes that all struck-and-lost whales count to the APL irrespective of hunting month. i.e., the number of whales counted towards the APL may exceed the actual number of PCFG whales struck. A number of other *SLA* variants were proposed by the Tribe to explore additional management options. However, none of the variants precisely mimicked the final management plan proposed.

The *Trial* results revealed:

- (1) *SLA* variants 1 and 2 were potentially satisfactory and performed well in nearly all 72 *Evaluation Trials*;
- (2) *SLA* variants 1 and 2 performed acceptably for all *Robustness Trials*.

Given this, the Committee focussed on those few trials for which conservation performance required further consideration. Trials with 1% $MSYR_{1+}$ are the most challenging and the conservation performance for some of these trials for both variants was not satisfactory (see Table 7). However, given the available information for the eastern North Pacific population as a whole (the observed recovery rate from severe historical depletion, as well as the current recovery rate from the 1999/2000 mortality event), the most recent assessment (Punt and Wade, 2012) resulted in an estimated $MSYR$ rate of 4.6% [90% posterior interval 2.2%, 6.4%]. Therefore, the $MSYR_{1+}=1\%$ trials are at the lower bounds of plausibility and the Committee **agrees** that the conservation performance for these trials alone was not reason to preclude the conclusion that both variants have overall satisfactory conservation performance.

The Committee then focussed on certain trials within the 2% $MSYR_{1+}$ set for which conservation performance might be considered questionable. Trial 8b (pulse and bias) involved 10% declines in abundance every five years as a proxy for random biological, environmental or anthropogenic events (e.g. disease or contamination). As noted in Annex E, Item 2.5.1, these trials are in effect trials with lower $MSYR_{1+}$ than the nominal 2% of the trial. Given this, it **agrees** that both variants 1 and 2 had acceptable performance for these two trials.

Trial 10b (pulse and bias) involves an assumption that the relative probability of harvesting PCFG whales in the Makah U&A is double the observed ratio of PCFG whales to migrating whales observed in the available photo-identification studies. The conservation performance of *SLA* variant 2 was considered acceptable for this trial but that for variant 1 was considered marginal (Table 7). In discussing the results of this trial, the Committee noted that the ratio of PCFG whales to migrating whales could be monitored directly from data collected during the hunting period allowing this assumption to be evaluated.

In conclusion, the Committee **agrees**:

- (1) *SLA* variant 2 performed acceptably and met the Commission's conservation objectives for conservation while allowing limited hunting;
- (2) *SLA* variant 1 performed acceptably for nearly all the trials and could be considered to meet the Commission's conservation objectives provided that it is accompanied by a photo-identification programme to monitor the relative probability of harvesting PCFG whales in the Makah U&A, and the results presented to the Scientific Committee for evaluation each year.

The Committee **endorses** these conclusions and commends them to the Commission. It also **agrees** that the *Implementation Review* is completed. Management advice is discussed under item 9.2.3.

However, the Committee noted that the *SLA* variants tested did not correspond exactly to the management plan proposed by the Makah to the IWC. The Committee **agrees** to test such a variant intersessionally and examine the results at the next Annual Meeting.

8.1.10 Other business

Spatial mixing between eastern and western North Pacific gray whale stocks along the Pacific coast of North America outside the feeding season raises issues about the population structure within the Sakhalin feeding area (see SC/64/BRG 10 and IWC, 2012). The broad issue of stock structure of North Pacific gray whales is being addressed through a basinwide research programme (see item 10.4). However, as noted last year, this finding raises concern about the possibility of whales feeding in the Western North Pacific being taken during the proposed Makah Tribe hunt in northern Washington.

Last year (IWC, 2012f p.16) the Committee had stressed three points.

- (1) The new information on movements of gray whales highlighted the importance of further clarification of the stock structure of North Pacific gray whales. In particular, the matches of animals from the Sakhalin feeding grounds with animals seen in the PCFG area and other areas along the west coast emphasised the need for efforts to estimate the probability of a western gray whale being taken in aboriginal hunts for Pacific gray whales (noting that this did not require incorporation of western gray whales into the *Implementation Review*).
- (2) It had strongly endorsed the basinwide research programme, noting that the results of the research may require further trials for future *SLA* testing; this would be a matter for

consideration at the next *Implementation Review* if not before.

- (3) The Committee will continue to monitor the situation and was willing to respond to any guidance or requests for further information from the Commission.

SC/64/BRG9 provided an initial modelling approach to address point (1) above. It was discussed extensively in Annex E, Item 2.6 and although welcoming this work, a number of questions were raised and further work identified before any conclusions could be agreed. The Committee **recommends** that a revised document be developed for further review at next year's meeting, noting its potential importance for the provision of management advice. An Advisory Group (Annex Q) was appointed to provide guidance to the authors of SC/64/BRG9.

8.2 Complete *Implementation Review* of Bering-Chuckchi-Beaufort Seas bowhead whales

The procedure and purpose of *Implementation Reviews* for aboriginal whaling *SLAs* is summarised under Item 8.4. The Committee's task is to assess whether there is any new information that would suggest that the range of trials used to evaluate the *Bowhead SLA* is no longer sufficient to ensure that the *SLA* meets the Commission's conservation and user objectives.

8.2.1 Consideration of new information with a focus on whether this implies a need for new trials

A number of papers were submitted presenting new information on a variety of scientific matters relevant to *Implementation Review*. Full discussion of these papers is given in Annex E Item 3. The summary of discussions in the following sections is somewhat brief as it only focusses on the SWG's deliberations as to whether additional trials are required.

8.2.1.1 STOCK STRUCTURE

Four papers were relevant to stock structure issues.

SC/64/BRG1 reported on a satellite telemetry study of 57 BCB bowhead whales tagged during 2006–2011. The Committee commended the authors for providing relevant data on bowhead migration patterns, and recognised the cooperation of native hunters who were closely involved in all aspects of this study and deployed most of the tags. It **recommends** that such tagging and telemetry efforts continue.

SC/64/AWMP3 compared the use of SNPs and microsatellites for studying population structure, assignment and demographic analyses of bowhead whale populations in the Sea of Okhotsk, BCB and eastern Canada. SC/64/AWMP9 presented sequences from 3 mtDNA genes from 350 bowhead whales from the BCB, eastern Canadian Arctic and the Sea of Okhotsk and discussed methods to calculate gene and site specific mutation rates, while SC/64/AWMP1 investigated the demographic history the BCB

population of bowhead whales using a variety of analytical methods.

The Committee thanked the authors and **agrees** that the information in these papers provide no evidence to suggest that the trials evaluated during the previous *Implementation Review* (IWC, 2007b; 2008a; 2008d; 2008g) did not adequately address stock structure concerns.

8.2.1.2 ABUNDANCE AND RATE OF INCREASE

A new agreed abundance estimate is not required for completion of the BCB bowhead *Implementation Review*. When a new estimate becomes available it can be incorporated into the *Bowhead SLA* calculations to provide management advice.

SC/64/AWMP5 incorporates the 1985 and 2004 abundance estimates from aerial photography by Schweder *et al.* (2010) into the ice-based survey estimates to obtain an updated ROI for 1978-2004 (Fig. 1). The Committee **endorses** this estimate (3.5% with 95% CI of (2.2%, 4.8%)) as the best available estimate of annual rate of increase for the BCB bowhead population. It also **agrees** that the best estimate of current abundance is 12,631 (95% bootstrap percentile CI 7,900 -19,700; 5% lower limit 8,400) for 2004 (Schweder *et al.*, 2010).

The Committee was pleased to receive information from recent ice-based surveys (2011) that count whales migrating past Barrow, Alaska (SC/64/AWMP7). Full discussion of these surveys will occur in conjunction with the presentation of new abundance estimates within the next two years.

SC/64/BRG4 presented estimates of visual detection probabilities from the spring 2011 ice-based survey of bowhead whales migrating near Barrow, Alaska. The same methods will also be applied to similar data from the 2010 survey. These estimates are highly relevant since they constitute one foundation upon which a future population abundance estimate will be calculated from the 2011 survey counts. This abundance estimate will then be used as input to the *Bowhead SLA*. The authors intend to estimate 2011 abundance using detection probability estimates based only on the new independent observer data. The Committee **endorses** this approach, while also recognising that any possible implications of the shift to the superior IO method might merit future consideration in the context of long term trends. It **encourages** Committee members interested in abundance estimation to contact the authors of SC/64/BRG4 intersessionally with comments and suggestions so that the future abundance estimate for use in the *Bowhead SLA* can be based on an approved estimate of detection probabilities.

SC/64/BRG3 described an aerial photographic survey for BCB bowheads conducted from 19 April to 6 June, 2011. The field season was very successful, both in

terms of total flight days and the very large number of whale images (approximately 6,800) obtained. These photographs are a significant contribution to the bowhead whale photographic catalogue. The Committee recognised the importance of this work as potentially providing an estimate of population abundance for use with the *Bowhead SLA* that is entirely independent of the ice-based survey estimate described in SC/64/BRG4. Analyses of the photo-id data may also provide better precision in estimates of bowhead whale life-history parameters such as adult survival rate. A detailed discussion of this paper is provided in Annex F.

8.2.1.3 CATCH DATA

SC/64/AWMP8 provides a preliminary summary of subsistence harvest of bowhead whales in Alaska from 1974 to 2011. Further discussion of the paper can be found in Annexes E and F. The Committee welcomes this information and noted that strikes have remained within the need envelope tested during development of the *Bowhead SLA*. It therefore **agrees** that no additional trials are warranted in this regard.

8.2.2 Discussion of new trials

In consideration of the evidence described above, the Committee **agrees** that there is no need for new trials or further simulation testing of the *Bowhead SLA*.

8.2.3 Conclusions and recommendations

The Committee thanked US scientists, the North Slope Borough, Alaska, and the native communities for continuing to provide a considerable body of high-quality scientific work which facilitated the SWG's *Implementation Review* process. The Committee **agrees** that the *Bowhead SLA* continues to be the most appropriate way for the Committee to provide management advice for the BCB population of bowhead whales. This completes the *Implementation Review* for the BCB bowhead whales. Management advice itself is provided under item 9.3.2.

8.3 Continue work on developing SLAs for the Greenlandic hunts (Annex E, Item 4)

In Greenland, a multispecies hunt occurs and the expressed need for Greenland is for 670 tonnes of edible products from large whales for West Greenland; this involves catches of common minke, fin, humpback and bowhead whales. The flexibility among species is important to the hunters and satisfying subsistence need to the extent possible is an important component of management for the hunters. For a number of reasons, primarily related to stock structure issues, development of *SLAs* for Greenland aboriginal hunts (especially for common minke and fin whales) will be more complex than previous *Implementations* for stocks subject to aboriginal subsistence whaling. The Committee has endorsed an interim safe approach to setting catch limits for the Greenland hunts in 2008 (IWC, 2009c), noting that this should be considered valid for two

blocks i.e. the target will be for agreed and validated *SLAs*, at least by species, for the 2017 Annual Meeting (assuming that the Commission sets 5-year block quotas in 2012 as scheduled).

The Committee noted the benefits in previous *CLA* and *SLA* developments of a co-operative competition amongst more than one developer. Several members of the SWG indicated that they may be interested in proposing *SLAs*. The Committee noted the multi-species nature of the Greenland hunts and Greenland's desire for flexibility amongst species in meeting its subsistence needs. It **reiterates** that its approach will first be to develop *SLAs* for individual species before considering whether and how to address multispecies considerations (e.g. IWC, 2010a; IWC, 2011i).

In response to a request made at the intersessional workshop (SC/64/Rep3), the Committee was pleased to receive four papers by Witting (SC/64/AWMP12-15) that summarised the available information on common minke whales, fin whales, humpback whales and bowhead whales off Greenland in the context of developing *SLAs* (summarised in Annex E, Appendix 6). In order to progress essential *SLA* development work, the Committee **agrees** that an intersessional workshop (to be held in winter 2013, probably in Copenhagen) was essential to maintain progress. As in previous years, the Committee also recommends maintenance of the AWMP Developer's Fund. Financial matters are discussed further under Item 23.

8.3.1 Common minke whales

The Committee notes that the SWG on the AWMP and the sub-committee on the RMP both have interest in North Atlantic common minke whales. It **endorses** the planned co-operative and collaborative process (Annex D, Appendix 6) developed that will culminate in a joint workshop on the stock structure of this species in the North Atlantic in early 2014. This is planned to inform the RMP *Implementation Review* process for common minke whales in the North Atlantic scheduled for 2014 as well as the *SLA* development process. The operating models developed for the RMP *Implementation* (perhaps with minor adjustment to take account of focus on different populations) will also serve as the basis for the *SLA* development process. The Committee also notes that aspects of the work to be undertaken by Punt described in Annex E Appendix 7 will assist developers of candidate *SLAs* for the Greenlandic hunts for common minke whales.

8.3.2 Fin whales

The Committee notes that the SWG on the AWMP and the sub-committee on the RMP both have interest in North Atlantic fin whales. A pre-meeting for a North Atlantic fin whale RMP *Implementation Review* is scheduled before the 2013 Scientific Committee meeting. The stock structure discussions at this meeting will provide useful input to the fin whale *SLA*

development process. The operating models developed for the RMP *Implementation* (perhaps with minor adjustment to take account of focus on different populations) can also serve as the basis for the *SLA* development process. The Committee notes that aspects of the work to be undertaken by Punt described in Annex E Appendix 7 will also assist developers of candidate *SLAs* for the Greenlandic hunts for fin whales.

8.3.3 Humpback whales and bowhead whales

Development of *SLAs* for these hunts is relatively simple compared to the common minke whale and fin whale cases. The Committee **agrees** that it should be possible to develop an appropriate trial structures and operating models for the humpback and bowhead whale hunts before the next Annual Meeting to enable potential *SLAs* to be evaluated in the future. It **endorses** the proposal outlined in Annex E Appendix 7 to support this work.

8.4 Guidelines for Implementation Reviews

An integral part of the AWMP process is the undertaking of regular or 'special' *Implementation Reviews*, as noted for example during the development process of the *Bowhead Whale SLA* (IWC, 2003b).

The first BCB bowhead whale *Implementation Review* took place over two years and was completed in 2007 with most focus being on the issue of stock structure (IWC, 2007b; 2008a; 2008d; 2008g). No changes needed to be made to the *Bowhead SLA* after the review. The first *Implementation Review* for gray whales was completed in 2010 and the *Gray Whale SLA* was not changed with respect to providing advice on the Russian hunt off Chukotka (IWC, 2011f). However, as discussed above, during that review, information was received that led to the need to call for an immediate *Implementation Review* before providing advice for a potential hunt of gray whales by the Makah tribe on the west coast of the USA. That review is now complete (see item 8.1)

The Committee had agreed that it would be useful to develop guidelines for *Implementation Reviews*, given the experience gained thus far. The proposed guidelines are provided in Annex E, Appendix 8 and cover the following issues: (1) Objectives; (2) Timing of regular and special *Implementation Reviews*; (3) Outcomes; (4) Data Availability; (5) Computer programs.

The Committee **adopts** these guidelines.

8.5 Scientific aspects of an aboriginal whaling scheme (AWS)

In 2002, the Committee strongly recommended that the Commission adopt the Aboriginal Subsistence Whaling Scheme (IWC, 2003a). This covers a number of practical issues such as survey intervals, carryover, and guidelines for surveys. The Committee has stated in the past that the AWS provisions constitute an important

and necessary component of safe management under AWMP SLAs and it **reaffirms** this view. It noted that discussions within the Commission of some aspects such as the 'grace period' are not yet complete.

8.6. Conversion factors for edible products for Greenland hunts

In 2009, the Commission appointed a small working group (comprising several Committee members) to visit Greenland and compile a report on the conversion factors used by species to translate the Greenlandic need request which is provided in tonnes of edible products to numbers of animals (IWC/62/9). At that time the group provided conversion factors based upon the best available data, noting that given the low sample sizes, the values for species other than common minke whales should be considered provisional. The group also recommended that a focused attempt to collect new data on edible products taken from species other than common minke whales be undertaken, to allow a review of the interim factors; and that data on both 'curved' and 'standard' measurements are obtained during the coming season for all species taken.

Last year the Committee had welcomed an initial report, recognising the logistical difficulty of collecting these kinds of data. However, it had noted that considerably more detail was needed, and requested that a detailed report be presented for consideration at the present meeting.

This year, a further report was received from the Greenlandic authorities that provided information on the data collected thus far (Annex E, Appendix 9).

The Committee **welcomes** this report and the provision of data. A comparison of these values and the Recommended Conversion Factors Per Animal (RCPFA) from IWC/62/9 showed reasonable agreement for humpback and bowhead whales (within 1 SD), but the yield for fin whales was lower than expected. It was not possible to examine this difference *inter alia* because no lengths of the animals included in the analysis were provided.

Although welcoming the report, the Committee expressed some concerns over the insufficient level of detail provided, some inconsistencies within the report, the efficiency of the sampling regime (relatively poor sample sizes) and the extrapolation procedure in which only one meat tote or bin is weighed.

In response to the concern over the lack of samples, it was noted that the Greenland Institute of Natural Resources (GINR) has been asked to investigate this and is working with the hunters and authorities to improve the sample size in the future. The Committee greatly **encourages** this and looks forward to a report on progress made. It also **encourages** the GINR to develop improved protocols including weighing as many of the meat, mattak, and qiporaq bins as possible.

Providing a breakdown of products from bowheads would be valuable both for conversion factors and biological information.

Given these concerns, the Committee **reiterates** its recommendations from 2011 and 2011:

(1) the provision of a full scientific paper to the next annual meeting that details *inter alia* at least a full description of the field protocols and sampling strategy (taking into account previous suggestions by the Committee); analytical methods; and a presentation of the results thus far, including information on the sex and length of each of the animals for which weight data are available;

(2) the collection and provision of data on Recommendation No. 2 of IWC/62/9 comparing standard vs curvilinear whale lengths. This should be done for all three species on as many whales as possible. Guidelines and protocols are suggested in IWC/62/9.

8.7 Workplan

The Committee's views on the workplan developed by the SWG on the AWMP are given under Item 21.

9. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT ADVICE

The Commission is considering a change from annual to biennial meetings. This has raised the issue within two Commission working groups as to whether there are any scientific implications for the Commission moving to setting block quotas for an even number of years rather than the present five-year intervals. This issue was addressed at the intersessional AWMP workshop (SC/64/Rep3) and that report is endorsed by the Committee and the conclusions incorporated below

The Committee recalled that trials for the B-C-B bowhead and Eastern North Pacific gray whale SLAs had shown satisfactory performance for surveys at intervals of 10 years (and even for some *Robustness Trials* for 15 years). The Committee **agrees** that there are no scientific reasons for the Commission not to set catch limits for blocks of even numbers of years up to 8-years for these stocks. However, it draws attention to its discussions of the AWS where it noted that despite the trial results it would not be appropriate for catches to be left unchanged if new abundance estimates were not available after 10 years (IWC, 2004).

The Committee notes that it does not require changing its regular process of *Implementation Reviews* approximately every five years (with the provision for 'special' reviews should circumstances arise) or an annual examination of new information and provision of advice if requested.

The Committee also notes that the interim safe *SLA* for the Greenland hunts (see Items 9.1 and Items 9.4 – 9.6 below) had also been tested for surveys at 10-year intervals and shown satisfactory performance and had been adopted by the Commission in 2008 (IWC, 2009a). However, as noted at the time, those tests had been for a restricted number of scenarios than the wider range of hypotheses customarily considered for such trials. It had thus been agreed that this *SLA* was appropriate for the provision of advice for up to two blocks or approximately 2018. The Committee **agrees** that there are no scientific reasons why the next quota block for the Greenland hunts could not be for a 6-year period, noting that the long-term *SLAs* will be available for implementation for the following block quota.

9.1 Eastern Canada and West Greenland bowhead whales

9.1.1 Review new information on Eastern Canada and West Greenland bowhead whales

Discussion within the Committee in recent years has focussed on stock structure and associated abundance estimates. The present working hypothesis is that bowhead whales in eastern Canada - West Greenland comprise a single stock; the alternative hypothesis assumes two stocks: one in Hudson Bay - Foxe Basin and another in Baffin Bay - Davis Strait. However, the Committee agreed on the need for further genetic analyses last year (IWC, 2012k), recognising the complications arising out of the fact that existing data pertinent to the question of stock structure are held by a non-member nation, Canada.

The Committee was pleased to receive several papers on Eastern Canada and West Greenland bowhead whales and details can be found in Annex F Item 2.2.

Alter *et al.* (in press) presented a study on genetic diversity and differentiation across all five putative stocks of bowhead whales, including Baffin Bay-Davis Strait (BBDS), Hudson Bay-Foxe Basin (HBFB), Bering-Beaufort-Chukchi, Okhotsk, and Spitsbergen. Ancient specimens (500-800 years old) from Prince Regent Inlet (PRI) in the Canadian Arctic were also compared with modern stocks. Results show low differentiation between Atlantic and Pacific, consistent with high gene flow between these areas in the recent past. No difference was observed between the two putative/hypothesized Canada-Greenland populations (HBFB/BBDS), which differ from previous results with more samples and a longer fragment of mtDNA. Significant genetic differences between ancient and modern populations were observed, which suggests that PRI harbored unique maternal lineages in the past that have been recently lost, possibly due to loss of habitat during the Little Ice Age and/or whaling. Unexpectedly, samples from this location show a closer genetic relationship with modern Pacific stocks than Atlantic, supporting high gene flow between the central Canadian Arctic and Beaufort Sea over the past

millennium despite extremely heavy ice cover over much of this period.

The Committee **welcomes** this work, and noted that this type of collaborative effort across research groups is valuable in advancing the understanding of bowhead whale stock structure.

Spatial overlap of the extreme summer range of bowhead whales was identified from the eastern and western Arctic in the Canadian High Arctic (Heide-Jorgensen *et al.*, 2011). In the summer of 2010, one satellite tagged bowhead whale from West Greenland and one from Alaska entered the Northwest Passage from opposite directions and spent approximately 10 days in the same area but not at the same time.

Wiig *et al.* (2011b) updated on an abundance estimate for bowhead whales in the Disco Bay area of West Greenland. The study employed multi-locus genotype and sex to identify individual bowhead whales at 4 localities in eastern Canada (Foxe Basin, Pelly Bay, Repulse Bay, and Cumberland Sound) and at one locality in West Greenland (Disko Bay).

9.1.2 Review recent catch information

In 2011, one female bowhead whale was landed in West Greenland and none were struck and lost (SC/64/ProgRepDenmark). Two bowhead whales were found dead in West Greenland in 2011, entangled in fishing gear for crabs.

During 2011, three bowhead whales were taken in Canada. More detailed information (e.g. sex, size) was made available by Canada to the Secretariat. The Committee is pleased to receive this information including catch as well as struck/lost data. It requests that in the future Canada also provides information on any strandings, entanglements and ship strikes of bowhead whales.

9.1.3 Management advice

In 2007, the Commission agreed to an annual strike limit of 2 animals (for the years 2008-12) with a carryover provision (IWC, 2008). The Committee agreed an approach for providing interim management advice in 2008 and this was confirmed by the Commission IWC (2009). The Committee recalled that the agreed abundance estimate for Eastern Canada / West Greenland is 6,344 (95% CI: 3,119-12,906; IWC, 2009d) for 2002. The most recent agreed estimate (IWC, 2012k; Wiig *et al.*, 2011b) for the spring aggregation in the West Greenland area is 1,747 (95% CI: 966-2,528) for 2010.

Using the agreed interim safe approach and the 2010 estimate for West Greenland, the Committee **repeats its advice** that an annual strike limit of 2 whales in West Greenland will not harm the stock.

The Committee **agrees** that it will review the updated analysis for the 2010 West Greenland (Wiig *et al.*,

2011a) at next year's meeting, noting that although slightly lower, if adopted it does not alter the management advice. The Committee is also aware that catches from the same stock have been taken by a non-member nation, Canada. Should Canadian catches continue at a similar level as in recent years, this would not change the Committee's advice with respect to the strike limits agreed for West Greenland. Given the importance of this issue, the Committee **recommends** that the IWC Secretariat continues to contact Canada requesting information about catches and domestic catch limits for bowhead whales.

9.2 Eastern North Pacific gray whales

9.2.1 New information

SC/64/AWMP2 presented the results of comparison of the genetics of gray whales sampled off Vancouver, Canada (i.e., PCFG whales), and San Ignacio Bay, Mexico. Results supported the conclusion that PCFG and the larger population are from the same breeding group. However results from other studies of photo-identification and mtDNA indicate that during the summer, whales of the PCFG represent a seasonal subpopulation driven by maternally directed site fidelity. The Committee's work (Item 8.1) is based on treating PCFG as a separate management stock.

There are at least two sets of genetic samples for PCFG whales, one is possessed by the research group in Canada, and the other by the Southwest Fisheries Science Center in La Jolla, USA. The Committee **recommends** that the two groups consider merging these data sets as this will result in a more robust evaluation of PCFG gray whales. The Committee also **suggests** that future work uses a greater number of microsatellites and increased mtDNA length.

The Committee received two papers on photo-identification studies undertaken in Mexican waters. SC/64/BRG14 provided information about the number of eastern North Pacific gray whales using Laguna San Ignacio, Baja California during the 2011 and 2012 winter breeding season. High counts of female-calf pairs in 2011 and 2012 suggest that more females whales are using the Laguna San Ignacio region as a winter aggregation area than during the 2007-2010 period. SC/64/BRG23 presented information on a new photographic identification programme in the Bahía Magdalena lagoon complex of gray whales in 2012 (there is little recent information from there). A total of 275 individual whales photographically identified, of which 234 were single whales and 41 were mother-calf pairs. 83% of the mother-calf pairs were sighted in waters around the López Mateos, and the majority of singles (89%) were sighted in waters near to mouth of Bahía Magdalena.

The Committee **thanks** the authors for these studies in Mexican waters which are discussed further in Annex

F, Item 4.3.1, It noted the value of long-term datasets and **encourages** updates in future years.

SC/64/BRG18 presented results from a linear model relating the average ice cover over the Bering Sea during the first 15 days of May with estimates of northbound gray whale calves the following spring for the years 1994-2010 (ice years 1993-2009) and further used to predict calf estimates for 2011 to 2013. There is a negative relationship between the area of the Bering Sea covered by seasonal ice during the first two weeks of May and the number of gray whale calves estimated by shore-based counts off central California the following spring (Perryman *et al.*, 2011; Perryman and Rowlett, 2002). It is not clear whether an ice-shortened feeding season has a significant impact on overall population condition or health. Measurements of southbound gray whales in vertical aerial photographs collected in 2012 indicated that overall population condition was comparable to that in previous years when the observed strandings were about average.

The Committee **thanks** the authors for this analysis of data from an extremely valuable long-term dataset. The Committee **recommends** that continued annual shore-based counts be accorded high priority. It also recommends aerial photogrammetric body condition studies be continued next year, and results compared to existing data to test the hypothesis that ice conditions in May influence gray whale body condition and reproductive output. The Committee also **encourages** a more integrated analysis using ice cover data for spring in the Chukchi Sea and spring and autumn for the Bering and Chukchi seas.

Last year (IWC, 2012k) the Committee had encouraged the undertaking of a more quantitative integrated analysis for the lagoon counts in Baja California, Mexico and the northbound calf counts in California, given the length of the time series. It was also suggested that correlations between calf production in western and eastern gray whales be examined. The Committee **reiterates** its advice from last year.

SC/64/BRG21 provided information about coastal counts of gray whales off Chukotka Peninsula, Russia, and monitoring of the harvest. The Committee was pleased to see a variety of biological information collected from the harvested whales and **recommends** the collection of additional data and samples, such as tissue for genetic analyses, tissue samples for understanding the cause of 'stinky whales' (and see Item 12), and photographs for comparison with catalogues. Catch data are discussed further below.

9.2.2 Review of recent catch information

Russian Federation reported that a total of 128 gray whales were struck in Chukotka, Russia in 2011¹³; two

¹³ This updates the information in SC/64/BRG21 for 2011
03/07/2012

were lost and 126 were landed. Of the landed whales, two were stinky and not used for human consumption.

9.2.3 Management advice

In 2007, the Commission agreed that a total catch of up to 620 gray whales was allowed for the years 2008-2012 with a maximum of 140 in any year. No new data were presented this year to change the advice for the large eastern North Pacific population and therefore the Committee agrees that the *Gray Whale SLA* remains the appropriate tool to provide management advice for eastern North Pacific gray whales apart from the consideration of the PCFG and the Makah hunt (see Item 8.1). The Committee **reiterates** that the current strike limits will not harm the stock.

With respect to the management plan variants provided by the Makah Tribe, the *Implementation Review* was completed this year (Item 8.1) and the Committee **agrees**:

- (1) hunt variant 2 performs acceptably;
- (2) hunt variant 1 performs acceptably provided that it is accompanied by a photo-identification programme to monitor the relative probability of harvesting PCFG whales in the Makah U&A, and the results presented to the Scientific Committee for evaluation each year.

Matters related to the possibility of an animal feeding in the western North Pacific being taken in the PCFG area are discussed under Item 8.

9.3 Bering-Chukchi-Beaufort (B-C-B) Seas stock of bowhead whales

9.3.1 New information

SC/64/BRG1 provided results of seasonal movements of the BCB stock of bowhead whales from a satellite telemetry study of 57 tagged whales during 2006–2011. All but one tagged whale migrated past Point Barrow in spring and went to Amundsen Gulf. That remaining whale was tagged at Barrow in summer, wintered in the Bering Sea and then summered along the Chukotka coast in the Chukchi Sea. While most whales summered within the Canadian Beaufort Sea, extensive summer movements included travel far to the north and northeast. Fall movements coincided in space and time with oil and gas activities and potentially with shipping activities. Likely important feeding areas included Amundsen Gulf in spring and summer; Barrow in summer and fall; Wrangel Island (some years) in fall; the northern Chukotka coast in fall; and the western Bering Sea in winter.

Full discussion of this paper can be found in Annex F Item 2. It was noted that this work indicates that earlier estimates of bowhead whales off Cape Pe'ek on the Chukchi Peninsula (Melnikov and Zeh, 2007) were probably BCB bowheads, and not a separate smaller stock. The Committee **encourages** the continuation of

this work, including the future analysis of other environmental covariates (e.g. physical oceanography) relating to BCB bowhead migration and distribution.

Results of a year-long acoustic study of B-C-B stock of bowhead whales were reported (Moore *et al.*, 2012). Calls from bowhead whales were recorded in October 2008, and from March-August 2009, on a recorder deployed on an oceanographic mooring near the Chukchi Plateau (ca. 75°N, 168°W). The rate of bowhead whale call detection was highest from May through August, when sea ice diminished from nearly 100% surface cover to zero and corresponded to a period of very high zooplankton backscatter signal from June through August.

SC/64/BRG3 reported the results of aerial photographic surveys of bowhead whales near Point Barrow, Alaska during 2011. Aerial surveys have periodically been flown in this area since 1984. Sufficient photo recaptures from the 2011 surveys are expected to calculate a mark-recapture abundance estimate with reasonable precision. SC/64/AWMP7 provided details about a successful ice-based survey in 2011 (see Item 8.2.1.2 AWMP Chair's summary). An ice-based estimate of abundance is expected in 2014 and the photo-id estimate thereafter. This would provide a rare opportunity to compare two independent large-whale abundance estimates in the same season.

SC/64/BRG4 presented estimates of visual detection probabilities from the spring 2011 ice-based survey of bowhead whales migrating near Barrow, Alaska, based on a new method first discussed last year (Givens *et al.*, 2011). This paper is also discussed under Item 8.2. In discussion, it was noted that the estimates in SC/64/BRG4 were slightly lower but generally consistent with those from earlier surveys, and the precision of the new estimates was better due to the new experimental design and a larger dataset. The Committee **agrees** that the estimation approach and application of the resulting detection probabilities to applicable years of survey data represents a methodological improvement over previous efforts. As noted under Item 8.2, it **encourages** Committee members with any detailed comments to submit those to the authors intersessionally.

SC/64/BRG8 reported on progress being made to sequence the bowhead whale transcriptome. It was noted in discussion that this research has the potential to provide insights into the life history, ecology, evolution and genetics of bowhead whales, with broader implications for other great whales.

9.3.2 Management advice

SC/64/BRG2 presented information on the 2011 Alaskan hunt. A total of 51 bowhead whales were struck resulting in 38 animals landed. No bowhead whales were reported struck and lost at Chukotka.

In 2007, the Commission agreed that a total of up to 280 BCB bowhead whales could be landed in the period 2008-2012, with no more than 67 whales struck in any year and up to 15 unused strikes being carried over each year. In the light of the *Implementation Review* completed this year (see Item 8.2), the Committee **agrees** that the *Bowhead SLA* remains the most appropriate tool for providing management advice for this harvest. It **reiterates** that the present strike and catch limits are acceptable.

9.4 Common minke whales off West Greenland

9.4.1 New information

In the 2011 season, 174 minke whales were landed in West Greenland and 6 were struck and lost (SC/64/ProgRepDenmark). Of the landed whales, there were 133 females, 39 males, and two whales of unreported sex. Genetic samples were obtained from 90 of these whales. The Committee **re-emphasises** the importance of collecting genetic samples from these whales, particularly in the light of the proposed joint AWMP/RMP workshop (see Annex D).

9.4.2 Management advice

In 2007, the Commission agreed that the number of common minke whales struck from this stock shall not exceed 200 in each of the years 2008-12, except that up to 15 strikes can be carried forward. In 2009, the Committee was for the first time ever able to provide management advice for this stock based on a negatively biased estimate of abundance of 17,307 (95% CI 7,628-39,270) and the method for providing interim management advice which was confirmed by the Commission. Such advice can be used for up to two five year blocks whilst *SLAs* are being developed. Based on the application of the agreed approach, and the lower 5th percentile for the 2007 estimate of abundance, the Committee **repeats** its advice of last year that an annual strike limit of 178 will not harm the stock.

9.5 Common minke whales off East Greenland

9.5.1 New information

Nine common minke whales were struck (and landed) off East Greenland in 2011, and one was struck and lost (SC/64/ProgRepDenmark). All landed whales were females. Catches of minke whales off East Greenland are believed to come from the large Central stock of minke whales. No genetic samples were obtained from minke whales caught in East Greenland. The Committee **re-emphasises** the importance of collecting genetic samples from these whales, particularly in the light of the proposed joint AWMP/RMP workshop (see Annex D).

9.5.2 Management advice

In 2007, the Commission agreed to an annual quota of 12 minke whales from the stock off East Greenland for 2008-12, which the Committee stated was acceptable in 2007. The present strike limit represents a very small

proportion of the Central Stock – see Table 8). The Committee **repeats** its advice of last year that the present strike limit would not harm the stock.

Table 8
Most recent abundance estimates for minke whales in the Central North Atlantic.

<i>Small Area(s)</i>	<i>Year(s)</i>	<i>Abundance and CV</i>
CM	2005	26,739 (CV=0.39)
CIC	2007	10,680 (CV=0.29)
CG	2007	1,048 (CV=0.60)
CIP	2007	1,350 (CV=0.38)

9.6 Fin whales off West Greenland

9.6.1 New information

A total of five fin whales (all females) were landed, and none were struck and lost, in West Greenland during 2011 (SC/64/ProgRepDenmark). No genetic samples were obtained from caught fin whales in 2011. The Committee **re-emphasises** the importance of collecting genetic samples from these whales, particularly in the light of the proposed work to develop a long-term *SLA* for this stock.

9.6.2 Management advice

In 2007, the Commission agreed to a quota (for the years 2008-12) of 19 fin whales struck off West Greenland. This was subsequently modified and at the 2010 Annual Meeting Greenland voluntarily reduced the limit to 10 until 2012 (IWC, 2011). The Committee agreed an approach for providing interim management advice in 2008 and this was confirmed by the Commission. It had agreed that such advice could be used for up to two blocks whilst *SLAs* were being developed. Based on the agreed 2007 estimate of abundance for fin whales (4,539 95%CI 1,897-10,114), and using this approach, the Committee **repeats** its advice that an annual strike limit of 19 whales will not harm the stock.

9.7 Humpback whales off West Greenland

9.7.1 New information

A total of eight (three males; five females) humpback whales were landed (none were struck and lost) in West Greenland during 2011 (SC/64/ ProgRepDenmark). Genetic samples were obtained from three of these whales. The Committee **re-emphasised** the importance of collecting genetic samples and photographs of the flukes from these whales, particularly with respect to the YoNAH and MoNAH initiatives (Clapham, 2003; YoNAH, 2001).

9.7.2 Management advice

In 2007, the Committee agreed an approach for providing interim management advice and this was confirmed by the Commission. It had agreed that such advice could be used for up to two five year blocks

whilst SLAs were being developed (IWC, 2009a, p.16). Based on the agreed estimate of abundance for humpback whales (3,039, CV 0.45, annual rate of increase 0.0917 SE 0.0124) and using this approach, the Committee **agrees** that an annual strike limit of 10 whales will not harm the stock.

9.8 Humpback whales off St Vincent and The Grenadines

9.8.1 New information

Last year the SWG noted that it had received no catch data from St Vincent and The Grenadines for 2010-11. This year the Secretariat received information from the government that a 35-foot whale was taken on 18 April 2011 (IWC/63/18) and a 33.75 foot female taken on 14 April 2012. 2.). After the meeting it was also informed of a struck and lost animal during the 2011 hunt. The Committee was pleased to hear that genetic samples and photographs were taken and that the United States and St Vincent and The Grenadines are discussing the transfer of tissue samples from this whale for analysis and storage at SWFSC (the IWC archive where *inter alia* SOWER samples are stored). Iñiguez reported information on a hunt on the 11 April 2012 and a struck and lost animal on the 22 March 2012.

It also repeats its previous strong **recommendations** that St Vincent and The Grenadines:

- (1) provide catch data, including the length of harvested animals, to the Scientific Committee; and
- (2) that genetic samples be obtained for any harvested animals as well as fluke photographs, and that this information be submitted to appropriate catalogues and collections.

9.8.2 Management advice

In recent years, the Committee has agreed that the animals found off St. Vincent and The Grenadines are part of the large West Indies breeding population (11,570 (95% CI 10,290-13,390) – (Stevick *et al.*, 2003). The Commission adopted a total block catch limit of 20 for the period 2008-12.

The Committee **repeats** its advice of last year that this block catch limit will not harm the stock.

10. WHALE STOCKS

10.1 Antarctic minke whales (Annex G)

The Committee is in the process of undertaking an in-depth assessment of the Antarctic minke whale. The primary abundance data are those collected from the 1978/79 to 2003/04 IWC-IDCR/SOWER cruises (e.g Matsuoka *et al.*, 2003) that had been divided into three circumpolar series (CPI, CPII and CPIII). Two different methods for estimating minke whale abundance from the last two circumpolar data series have been developed in recent years. Although they gave different estimates of abundance, both were consistent in

estimating a decline in circumpolar abundance between CPII and CPIII (IWC, 2012l). The Committee has been working to resolve the differences between the estimates for some time and last year believed that it would be possible to present an agreed abundance estimate at this year's meeting. The Committee has also been discussing uncertainties about stock structure, especially in the Indian Ocean and Pacific sectors, which are the sectors where catches have been taken in recent years (IWC, 2008b).

10.1.1 Stock structure

Two genetically distinct populations of Antarctic minke whales have been identified in the Area III-E-VI-W feeding grounds (IWC, 2008b). There is no sharp boundary between them, only a "soft" boundary; the two populations overlap, but one predominates in the East, called the Pacific or P-stock, and the other in the West, called the Indian Ocean or I-stock. The extent and location of overlap is an important issue for assessment.

SC/64/IA4 presented a new integrated analysis of three different sources of data: morphometrics, microsatellites and mitochondrial DNA. The goal is to estimate longitudinal segregation of the breeding populations on the Antarctic feeding grounds. The model is intended to allow the location of the soft boundary to move from year to year. The method was applied to the extensive data for the Antarctic minke whales taken by the JARPA and JARPA II surveys. The results indicated that the spatial distribution of the two populations have soft boundary in Area IV-E and V-W, which does vary clearly and significantly by year. The results also suggest that the boundary is sex-specific.

The Committee noted that the approach used is simple and potentially powerful. Aside from the general relevance of the results to understanding Antarctic minke whale dynamics, it might in the future prove useful in allocating historical catches to stocks. The Committee **endorses** the specific investigations for further statistical analysis given in Annex G Item 5.1.

10.1.2 Abundance estimation of Antarctic minke whales

In order to reach its goal of having agreed abundance estimates by the 2012 Annual Meeting, an intersessional workshop was held in Bergen, Norway, in May 2012 (SC/64/Rep4). It made substantial progress in identifying reasons for the large differences between earlier 'trackline conditional independence' and 'hazard probability based' estimates of Antarctic minke whale abundance (the 'SPLINTR' model, Bravington and Hedley, and the 'OK' model, Okamura and Kitakado, respectively). It also identified aspects of the OK model that needed adjustment related to plausibility of mean dive-time estimates from fits of the model and the resultant effects on $g(0)$, compared to independent estimates of $g(0)$. A work programme was

agreed for completion by the 2012 Annual Meeting which resulted in three papers - SC/64/IA2, SC/64/IA12 and SC/64/IA13. The Committee thanked the authors for completing the workplan. Detailed discussions can be found in Annex G Item 5.3.

SC/64/IA12 analysed data from the IWC/SOWER 2004/05 video dive time experiments. The Committee was pleased to receive these estimates, which after discussion within the intersessional steering group became key inputs for the OK method. SC/64/IA2 presented a revision of the 'Norwegian Product' formulation of the OK model and investigated sensitivity to a number of factors. The abundance estimates were lower than previously estimated by versions of the OK model, after incorporating the new mean dive-times and the resultant lower $g(0)$ values. SC/64/IA3 presented a 'Norwegian Product' version of SPLINTR, also using the externally-estimated dive-times. The authors noted that their fits showed some problems and counterintuitive results but also noted that they had insufficient time to investigate the model. They thus considered that although the framework of the model therein seemed reasonable, the actual estimates were not ready for consideration.

Based on considerable experience from previous years, the intersessional workshop had identified a core set of diagnostics most capable of revealing important model deficiencies when modelling IDCR/SOWER minke whale data (SC/64/Rep4). The main issue for SC/64/IA2, the OK model, was that the observed proportion of near-simultaneous compared to delayed duplicates was considerably lower than the predicted; this is potentially important in terms of estimating $g(0)$ and thus overall abundance, because of the close link to mean dive-time. The likely cause of the misfit is the aggregation-over-time that is required in order to deal with rounding and measurement errors in timing and distance estimates in IDCR/SOWER, in conjunction with the clumped nature of real whale dive patterns (in contrast to the independence of successive dive-times assumed by OK models). For the reasons discussed in Annex G, however, the Committee **agrees** that the within-duplicate lack-of-fit was unlikely to imply serious bias in abundance estimates.

Given the progress made and results presented and discussed in Annex G, it was agreed that there was no need to consider further the process of averaging estimates from the two models proposed last year (IWC, 2012). It was reassuring that two completely independent implementations of the Norwegian Product (NP) model appear to be giving consistent results and showed little sensitivity to the input values for mean dive-time in the neighbourhood of the best independent estimates of dive time from SC/64/IA12.

The starting point for determining the best available consensus estimate, was the authors' 'preferred

estimates' in SC/64/IA2 using the best estimates of mean dive-time from SC/64/IA12, and then applying the appropriate adjustment factors agreed last year (IWC, 2012e) with some minor changes. All the adjustments are estimates, but are modest enough that their impact on CV can reasonably be neglected. A CPII spatial adjustment of 15% is the largest adjustment, and reflects some imbalance of coverage within survey strata in CPII, something that was much reduced in CPIII. All other adjustments are minor.

The resulting estimates are shown in Table 9. Because the northern extent of the surveyed regions differs between CPII and CPIII, two sets of estimates are given, 'survey-once' and 'CNB' (Common Northern Boundary). The survey-once estimates cover all of the surveyed regions in each CP series (using the most recent or most complete survey in cases of duplication). The CNB estimates exclude part of the surveyed regions in each series to ensure a consistent northern limit; these are the most appropriate estimates for a comparison of abundance estimates between CPII and CPIII. The CNB estimates are also the basis for the Additional Variance (AV) calculations (SC/61/Rep9) which address the non-synoptic nature of the surveys, i.e. that whales may move into and out of any given surveyed area from year to year. The 'CV internal' row reflects the uncertainty associated with the abundance estimate of whales in the surveyed region at the time of the survey, whereas the "CV with AV" row reflects the uncertainty associated with the average number of whales present in the surveyed region across the whole of that CP series, and is more useful for most subsequent analyses. CVs are approximately the same for survey-once as for CNB, so only one set is shown. Note that there are also correlations between the estimates (not shown) in different *Management Areas* within each CP (but not between CPs) since model parameters are estimated jointly for each whole CP.

The Committee **agrees** that the numbers in Table 9 represent the best available abundance estimates of Antarctic minke whales in the surveyed areas during the years of CPII and CPIII. The potential sources of bias have now been much more thoroughly addressed than in the existing "standard method" estimates (Branch, 2006), and the results are consistent with recent external datasets (e.g. the post-2004 SOWER cruise experiments on school size estimation, video dive time and BT-mode). The explanation for the large difference between the estimates from original OK (e.g. Okamura and Kitakado, 2011) and original SPLINTR (e.g. Bravington and Hedley, 2009) methods has been identified as the interaction between diving behaviour and timing errors and the difference has been reduced to plausible levels by imposing direct estimates of mean dive-time in the NP models. The Committee agrees that it is unlikely that any remaining bias is substantial.

Table 9

Best estimates of Antarctic minke whale abundance by *Management Area* adjusted by the factors agreed in Table 1. See text for explanation.

CP		IWC Management Area						TOTAL
		I	II	III	IV	V	VI	
II	Survey once	85,688	130,083	93,215	55,237	300,214	55,617	720,054
	CNB	84,978	120,025	86,804	51,241	285,559	49,885	678,493
	CV internal	0.16	0.14	0.20	0.17	0.13	0.22	0.08
	CV with AV	0.34	0.40	0.44	0.39	0.31	0.39	0.18
III	Survey once	38,930	57,206	94,219	59,677	183,915	80,835	514,783
	CNB	34,369	58,382	68,975	55,899	180,183	72,059	469,866
	CV internal	0.20	0.19	0.15	0.34	0.11	0.14	0.09
	CV with AV	0.39	0.38	0.35	0.49	0.36	0.37	0.18
CPIII:CPII		0.40	0.49	0.79	1.09	0.63	1.44	0.69

The new **agreed** estimates for the survey-once case are 720,000 for CPII (1985/86-1990/91) with 95% CI [512,000, 1012,000], and 515,000 for CPIII (1992/93-2003/04) with 95% CI [361,000, 733,000]. The estimates are subject to some degree of negative bias because some minke whales would have been outside the northern and southern (surveyable, ice edge) boundaries. The improved analyses have resulted in many estimates differing appreciably from the 'Standard Method' estimates (Branch and Butterworth, 2001; IWC, 2006b, p.21). For CPII, the new best estimate of total abundance is slightly lower (720,000 compared to 769,000 standard estimate) whereas for CPIII the new best estimate is substantially higher (515,000 compared to 362,000). There are two primary reasons for the differences: (1) the spatial adjustment required for CPIII is much less than for CPII; and (2) the mean school size is appreciably smaller in CPIII than CPII which affects the net adjustment for $g(0)$. The ratio of total abundance in CPIII to CPII, formerly 0.47 with the standard method, is now estimated to be 0.69 with 95% CI [0.43, 1.13] for the 'CNB' estimates.

Annex G Item 5.3.2 identified some future work, partly to check and deal with any small remaining bias issues, and also for the benefit of other abundance estimation in general. A valuable aspect of SOWER/IDCR is the consistency of its protocols and its large sample size, unparalleled amongst cetacean sightings datasets, which allow the development of realistic tests and sophisticated estimation methods applicable to many cetacean abundance estimation cases beyond Antarctic minke whales.

The Committee **expresses** its thanks to the Abundance Estimation Working Group for their tremendous collaborative efforts in obtaining agreed estimates after several years of intensive and innovative work. The developers (Bravington, Hedley, Kitakado and Okamura) are to be particularly commended as is the recent input and enthusiasm of Butterworth, Skaug and Walløe. The Committee now has confidence in these open-water estimates and a more comprehensive understanding of the modelling requirements for

IDCR/SOWER data. The Committee also places on record its considerable appreciation to all those involved in the IDCR/SOWER cruises (1978/79 - 2009/10) – the Japanese Government (and in the early years the government of the then USSR), the IWC, the originators of the programme, the scientists and crews of the participating vessels, the planners of the cruises and the analysts, whose dedication and hard work over many years have led to this agreed result.

10.1.3 Reasons for differences between estimates from CPII and CPIII

The confidence interval for the ratio of the total estimated abundance from CPII and CPIII included 1.0 and thus a null hypothesis of no change in overall abundance between the two periods would not be rejected. Nevertheless, the Committee considered that a change was quite likely, and discussed possible reasons for a decline in the estimated abundance of whales in the surveyed areas.

Between CPII and CPIII, the point estimates of Antarctic minke whale abundance show a large decline in three Management Areas (I, II, and V) and an increase in Areas IV and VI (Table 9). Overall, the circumpolar estimates are some 30% lower between CPII and CPIII. Since the Committee is now satisfied that the remaining biases in the agreed estimates are unlikely to vary greatly over the duration of the CPII and CPIII cruises. Therefore the differences seen in Table 9 probably do reflect real changes in abundance in the open-water areas surveyed.

The Committee is exploring possible reasons for this. Noting that the IDCR/SOWER cruises were neither synoptic nor did they cover the entire range of potential minke whale habitat, one hypothesis is that the decline in estimated abundance was due to more whales being in unsurveyed regions during CPIII than in CPII. This suggests the following (not mutually exclusive) possibilities:

- (1) a much higher proportion of whales in the pack ice or in open-water areas (polynyas) within the pack ice in CPIII, as compared to CPII

- (2) extensive longitudinal (east-west) whale movements from year to year, and surveys conducted as part of CPII happened to encounter higher densities in certain areas, as compared to those during CPIII,
- (3) a much higher proportion of the total population was north of 60°S during CPIII,
- (4) intra-year movements in open water within the surveyed areas that were not adequately covered by the trackline design in space and time, with respect to environmental variables, and
- (5) a genuine decrease in abundance of Antarctic minke whales.

In order to examine (1) above, a sea ice intersessional group was established last year to: (i) consider technical aspects of sea ice data which will be used to bound or estimate the abundance of Antarctic minke whales in the south of the ice edge, and (ii) consider appropriate analysis methods to bound or estimate the abundance of whales south of the ice edge.

SC/64/IA3 reviews some technical aspects of the sea ice data obtained by IDCR/SOWER, ASPeCt (Antarctic Sea Ice Processes and Climate), satellite sensors and NIC (National Ice Center). The definitions of the sea ice edge vary between the different data sources because their objectives and applied techniques are different. The IDCR/SOWER definition of the sea ice edge is somewhat operational compared to that for other data sources. However, its definition is believed to be consistent for the period 1978 to 2003, and the authors believe it is the most appropriate boundary for abundance estimation in years and areas where IDCR/SOWER surveys were undertaken. They also conclude that the sea ice concentrations derived from passive microwave (PM) remote sensing are probably the best sea ice data to be used for the purpose of estimating abundance of Antarctic minke whales to the south of sea ice edge in areas where IDCR/SOWER observations are not available (the PM records date back to 1979).

SC/64/IA10 is an appraisal of methods and data to estimate abundance of Antarctic minke whales within sea ice covered areas of the Southern Ocean. With new estimates of densities of Antarctic minke whales (from aerial surveys) in certain areas of sea ice (i.e., Weddell Sea and east Antarctica), and model-based abundance methods which allow extrapolation, there is an opportunity to compare bounds and magnitudes of abundances, both inside and outside of the sea ice region, to assess how likely the 'moved-into-sea ice' hypothesis is. In the first instance, the authors recommended that comparisons of inside/outside abundances be made for areas and years where the aerial surveys were conducted. If these analyses are inconclusive from the perspective of the 'moved-into-sea ice' hypothesis, there is a recommendation to

extend the analysis to estimating circumpolar densities, and extrapolating back over the period of CPII and CPIII. The recommended analysis will give full consideration to how variable minke whale densities can be over space and time. Furthermore it should be recognised that such analyses will involve a great deal of work and may not yield helpful results.

Since Antarctic minke whales congregate along the ice edge, potential problems in estimating abundance inside/outside of an ice region using satellite data were discussed in Annex G Item 5.3.3. The Committee **recommends** that sensitivity analyses as to the position of the sea ice boundary on Antarctic minke whale abundances derived from aerial survey data be assessed before any in-depth calibrations and analyses of operational sea ice boundaries be attempted.

It is not possible to obtain reliable absolute abundance estimates of Antarctic minke whales in sea ice regions corresponding in space and time with IDCR/SOWER surveys. The Committee thus **recommends** that relatively simple analyses be conducted to generate abundances using aerial survey data. These abundances, with a range of potential availability biases, will help in producing an overall magnitude or upper bound on the numbers of Antarctic minke whales in sea ice regions during CPII and CPIII.

At present, the Committee is unable to exclude the possibility of a real decline in minke whale abundance between CPII and CPIII. Population dynamics analyses of catch-at-age data from Area IIIE to VIW (e.g. as in SC/64/IA1) can potentially account for the changes in overall abundance in terms of variations over time in mortality and recruitment. Such explanations are descriptive but they do not attempt to explain why, for example, recruitment might have dropped commencing in the 1970s. There is a second class of more mechanistic explanations concerned with, for example, why pregnancy rates might fall; this is where ecosystem effects, competition, climate, etc. would need to be considered.

As noted in Annex G Item 5.3.3, Murase and Kitakado suggested that the difference in abundance estimates between CPII and CPIII can (to a large extent) be attributed to process error (i.e., additional variance), reflecting a large inter-annual variation in distribution of the Antarctic minke whales (Kitakado and Okamura, 2009). However, they also suggested that systematic environmental changes observed in some areas do not alone account for the process error. Others suggested that the that JARPA and JARPA II data can assist the interpretation of the CPII and CPIII differences given the long time series data in Areas IIIE, IV, V and VIW (e.g see Matsuoka *et al.*, 2011). Hakamada will present information on some diagnostics from analyses to estimate minke whale abundance from JARPA next year.

In conclusion, the Committee noted that after many years work it had now been able to **agree** on estimates of minke whale abundance within the areas surveyed in CPII and CPIII. As yet, though, there was no conclusion on whether (and if so to what extent) these numbers indicate a real decline in abundance of Antarctic minke whales between the periods of the two surveys. Time constraints meant that it was possible to have only preliminary discussions of this question this year; discussions will continue at next year's meeting.

10.1.4 Continue development of the catch-at-age models

Population dynamics modelling provides a way to explore possible changes in abundance and carrying capacity within Areas III-E-VW, where appropriate data are available. The inputs are catch, length, age, and sex data from the commercial harvests and both JARPA programs, as well as abundance estimates from IDCR/SOWER. Early attempts used the ADAPT-VPA approach of Butterworth and Punt (1999); Butterworth *et al.* (2002); and Butterworth *et al.* (1996). A number of issues and concerns were raised with respect to that particular modelling framework for Antarctic minke whales, and it was concluded that an integrated statistical catch-at-age (SCAA) model was the most appropriate modelling framework (IWC, 2003c). Punt and Polacheck (2005; 2006) developed such a model, and it has been refined over the last few years. The SCAA approach allows for errors in catch-at-age data, more than a single stock, time-varying growth, multiple areas, environmental covariates, fleet-specific vulnerabilities, and changes over time in vulnerability. The technical problems and inconsistencies identified in previous years have largely been resolved (JCRM 2012, p180).

SC/64/IA1 provides a summary of the specifications of the current SCAA. The approach allows for multiple

breeding stocks, which can be allowed to mix across several spatial strata on the summer feeding grounds where catches are taken. It also allows carrying capacity and the annual deviations in juvenile survival to vary over time. The model is fitted to length and conditional age-at-length data collected from the Japanese commercial and scientific permit catches, as well as indices of abundance from the IDCR/SOWER and JARPA/JARPA II cruises. The results provided in the paper are illustrative primarily because the IDCR/SOWER abundance estimates used had not been finalised, and the age-at-length data for recent years from JARPA II are not yet available.

As noted in Annex G Item 5.2, a number of suggestions for further work were made in this regard. Until now, application of the SCAA has been held up by the lack of agreed IDCR/SOWER abundance estimates, but that obstacle has now been removed, and the application of the SCAA in testing hypotheses concerning changes between CPII and CPIII abundance estimates has become a high-priority task. The time series of earplug age data, which is an important input that would improve the resolving power of the SCAA, has not been updated since 2004 or 2005 although samples are available through to 2011/12, because of difficulties in finding and validating age-readers. Preliminary age readings have been made from the 2006-2008 samples, but have not yet been validated. Last year, the Committee had recommended that these preliminary data be made available and included in the SCAA on a provisional basis pending validation (IWC, 2012l, p.180). This year, the Committee **reiterates** this recommendation; the recent age data should be incorporated into the SCAA model as soon as possible. The Committee recommends the SCAA modelers request the new data via the Data Availability Group and the data owners provide it as soon as possible.

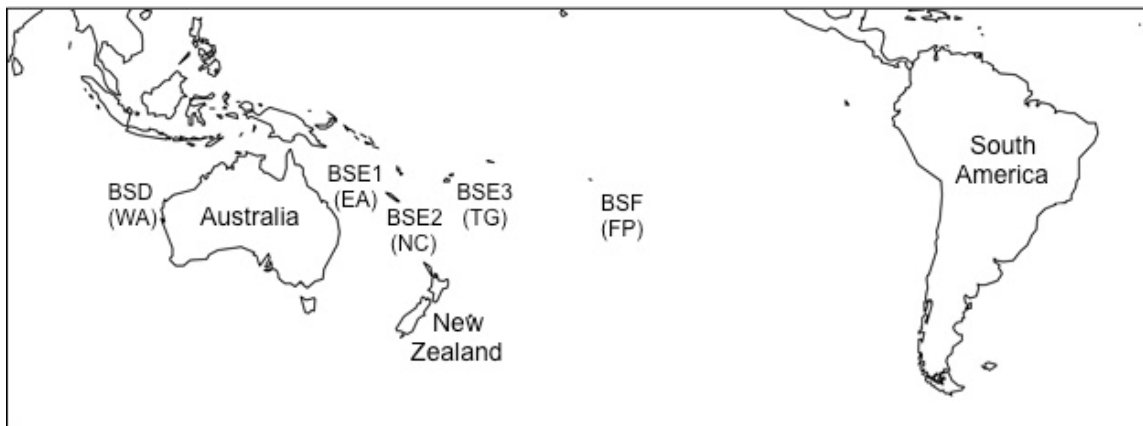

Fig 1. Distribution of Southern Hemisphere humpback whales breeding stocks grounds for BSD, BSE1, BSE2, BSE3 and BSF2 (WA = Western Australia, EA = Eastern Australia, NC = New Caledonia, TG = Tonga and FP = French Polynesia).

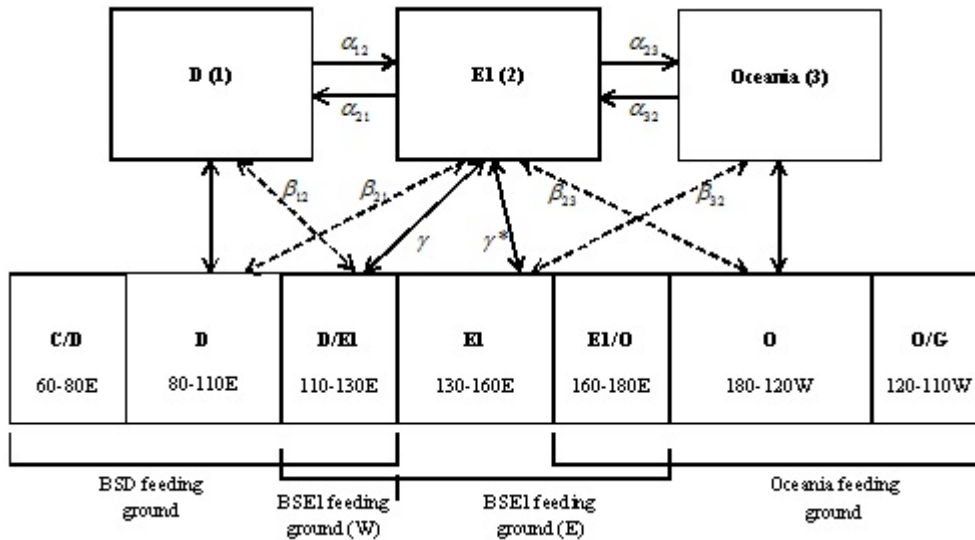

Fig. 2. Proposed model structure for breeding stocks D, E1 and Oceania. Arrows indicate possible interchange between stocks. These interchange rates will be estimated in the model, informed by data given in Table 1 of Annex H. Solid lines indicate movement of a breeding population to its own feeding ground, while dashed arrows indicate whales moving to a neighbouring feeding ground. Note that in order to avoid three breeding stocks mixing in the E1 feeding ground, an artificial boundary for catch allocation has been imposed. No catches taken east of this boundary will be allocated to BSD, while no catches taken west of the boundary will be allocated to Oceania. The longitude 130°E was chosen based on the longitudinal range of documented connections between BSD, Oceania and the Antarctic (J. Jackson, *pers. comm.*)

10.2. Southern Hemisphere humpback whales

The IWC Scientific Committee currently recognises seven humpback whale breeding stocks (BS) in the Southern Hemisphere (labelled A to G; IWC, 2011k), which are connected to feeding grounds in the Antarctic. An additional population that does not migrate to high latitudes is found in the Arabian Sea. Assessments of BSA (western South Atlantic), BSD (eastern Indian Ocean) and BSG (eastern South Pacific) were completed in 2006 (IWC, 2007d) although it was concluded that BSD might need to be re-assessed with BSE and BSF in light of mixing on the feeding grounds. An assessment for BSC (western Indian Ocean) was completed in 2009 (IWC, 2010) and for BSB in 2011 (IWC, 2012).

10.2.1 Begin assessment of breeding stocks D, E and F

Last year, the sub-committee on Southern Hemisphere whales initiated the re-assessment of BSD, and the assessment of BSE and BSF (IWC, 2012m). These stocks correspond, respectively, to humpback whales wintering off Western Australia (stock D), Eastern Australia (sub-stock E1) and the western Pacific Islands in Oceania including New Caledonia (sub-stock E2), Tonga (sub-stock E3) and French Polynesia (sub-stock F2) (Fig 1). For simplicity the combination of BSE2, BSE3 and BSF2 will be referred to as Oceania.

10.2.1.1 ABUNDANCE, TRENDS AND POPULATION STRUCTURE

SC/64/SH6 presented a POPAN open model abundance estimate of 562 whales (CV=0.19, CI 351-772) from

the New Caledonia humpback whale breeding ground (BSE2) using fluke photo-identification data collected over 16 years (1996-2011). Beginning in 2006 through to the current estimate, all population models examined show a trend of increasing abundance with a large ‘pulse’ after 2008. Whether these whales represent part of the New Caledonia sub-stock or permanent or temporary immigration from different regions is currently unclear.

In discussion, it was noted that a phenomenon similar to that observed in New Caledonia in the late 2000s had also been recorded off Eastern Australia in the late 1980s (Chaloupka *et al.*, 1999). To attempt to examine this apparent increase, the Committee noted that a possible movement of Eastern Australia whales to New Caledonia was consistent with an observed decrease in the rate of population growth of whales migrating off the Australian coast (Noad *et al.*, 2011) and levels of F_{st} differentiation between E1 and E2 (0.01, Olavarria *et al.*, 2006) were the lowest among any pair of populations in Oceania. However, at this time the available data are not sufficient to explain the observed patterns.

Salgado Kent *et al.* (2012) provided new estimates of abundance and trends for Western Australian humpback whales. A number of statistical issues were raised in discussion as can be seen in Annex H. The Committee **encourages** further analyses and intersessional contact with the authors and that, if

necessary they are invited to SC65 for further discussion of their work.

SC/64/SH28 reported on the outcome of a workshop held in November, 2011 to discuss future surveys and analyses of Breeding stock D humpback whales at two locations off Western Australia - North West Cape and Shark Bay. The workshop proposed a pilot survey to trial both cue-counting and racetrack aerial abundance survey methods, in conjunction with land-based work at both locations, to determine the most appropriate survey method for a full-scale absolute abundance survey in the near future. Prior to the survey, simulation work will be conducted to determine the operational protocols for the racetrack abundance estimation method as applied to humpback whales. The Committee **concurs** that a pilot study is the appropriate next step in method development for the provision of an absolute abundance for the Western Australian stock of humpback whales.

Four documents were available for discussion of stock structure issues, SC/64/SH5, SC/64/SH15, SC/64/SH22, and Pastene *et al.* (2011). These documents were reviewed by the Working Group on Stock Definition and their conclusions are reported in Annex I, Item 3.1.1.

10.2.1.2 ASSESSMENT MODELS

In order to facilitate discussions and identification of further model runs, SC/64/SH29 provided initial results of population model fits to the Southern Hemisphere humpback whale breeding grounds D (West Australia; BSD), E1 (East Australia; BSE1) and Oceania (BSE2, BSE3, and BSF2). As anticipated, this led to considerable discussion and the details can be found in Annex H. As a result, the Committee **agrees** on a series of recommendations (details are in Annex H) regarding future work to facilitate the assessment:

- (1) authors of some of the abundance estimates should be contacted to learn more about the estimates and how they might be incorporated into the assessment;
- (2) a multinomial likelihood should be incorporated into the Bayesian population dynamics model;
- (3) the new movement model structure (Fig. 2) should be incorporated to take into account the documented connectivity between breeding grounds in Western (D) and Eastern Australia (E1) and Oceania (E2+E3+F2) and between the breeding and feeding grounds;
- (4) a two stock model for Eastern Australia and Oceania should be explored;
- (5) catches should be allocated to the feeding areas associated with each of the three breeding stocks according to Hypothesis 1 of (IWC, 2010e);

- (6) 'Discovery' mark data from the whaling period which contains information on movements between breeding grounds, between feeding grounds, and between breeding and feeding grounds, should be explored in the context of the assessments.

- (7) the Pastene *et al.* (2011) analysis on relative proportions of mixing in the feeding grounds should be expanded to include samples from Eastern Australia (E1).

The Committee also **endorses** the input data for the population dynamics model given in Table 1 in Annex H and **agrees** that any additional datasets must be provided by 31 December 2012, after which time no more new data will be used for this assessment. The results of the analyses using the agreed model will be presented for discussion at the 2013 Annual Meeting. To ensure this work is completed, a work plan has been developed which identifies who will do each task (Table 2 in Annex H) and an intersessional working group has been appointed convened by Muller (Annex Q). The Committee anticipates that the assessment of these stocks should be completed in 2014.

Reconciliation of the large photo-identification catalogue (6,500 + IDs from 1984-2011) held by Pacific Whale Foundation with existing catalogues from Western Australia, Oceania and the Antarctic humpback whale catalogue is also encouraged to inform estimates of interchange for future assessments.

10.2.2 Review new information on other breeding stocks

10.2.2.1 BREEDING STOCK A

SC/64/SH17 reported 58 stranded humpback whales that were recorded between 1981 and 2011 off the coast of Rio de Janeiro, southeastern Brazil (annual mean 2.6, maximum 13 records in 2010). Reported strandings have increased over the past 20 years, which is consistent with the population increase observed for this stock. Three cases of entanglement were found (two were calves). Bacteriological agents in three live stranded whales assessed indicated evidence of animal impairment that resulted in or were associated with the cause of death.

The Committee **welcomes** this information but expressed concern that information is available from only a small part of the total Brazilian population. It **encourages** the provision of information from the full range of animals passing along the coast.

10.2.2.2 BREEDING STOCK B

SC/64/SH4 described a newly-discovered humpback whale wintering ground off northwest Africa with a seasonal signature consistent with a South Atlantic stock; the presence of adult/calf pairs, suggests it may be a nursery ground. Since the observations were six

months out of phase with the nearest (and only) known breeding ground in the northeast Atlantic – the Cape Verde Islands, these sightings possibly comprise the most northwestern component of the Southern Hemisphere BSB.

During a joint cruise organised by the South African Department of Environmental Affairs and the University of Pretoria in November 2011, a total of 107 biopsies were collected and numerous images obtained from humpback whales on the west coast of South Africa.

In discussion, numerous sightings of humpbacks have been made alone on the Atlantic African coast. The Committee **recommends** that the location and timing of all the existing Atlantic African records of distribution, seasonality, and timing of sightings should be synthesised in a single map/database to show the extent of range and movements for humpback whales within a calendar year.

10.2.2.3 BREEDING STOCK C

SC/64/SH3 provided the first description of humpback whale movements between breeding grounds in the Comoros Islands and coastal western Madagascar. During 11-14 October 2011, five satellite transmitters were deployed on humpbacks off Moheli Island (12° 24'S, 43° 45'E) in the Comoros Archipelago. Three individuals were tracked successfully: mean tracking duration was 18 days (range 8-28 days); mean distance travelled was 467 km (146-749 km) and mean travelling speed 26.7 ± 22.3 km/day. This is the first record of whales visiting different islands of the Comoros and western Madagascar in the same season.

Ersts *et al.* (2011) reported that between 1996 and 2006, nine whales (six males and three females) were identified using two breeding areas in separate years: the northern Mozambique Channel, currently the breeding region for sub-stock C2; and eastern Madagascar, currently a breeding region for sub-stock C3. This led the authors to believe that sub-stocks C2 and C3 were probably the same breeding sub-stock.

10.2.2.4 BREEDING STOCK D

Information was presented on examinations of eight neonatal humpback whales stranded on the Western Australian coast in 2011, all at least 1000 km south of the currently known major breeding grounds off the Western Australian northwest coast (see Annex H, item 2.3.4). Examinations indicated that all but one of the eight neonates was severely malnourished, and were believed to be non-viable from birth due to a lack of energy reserves and a compromised ability to thermoregulate and control buoyancy. Similar examinations are expected to be conducted on strandings on the Western Australian coast in 2012 and, hopefully, in future years.

10.2.2.5 BREEDING STOCK G

SC/64/SH16 provided information collected from whale-watching boats on distribution and behaviour of humpback whales from the south Pacific coast of Costa Rica, as discussed in Annex H, item 2.3.5.

In discussion, attention was drawn to the unusually high number of cow/calf pods reported together: nine groups with three or more adults with calves. The Committee **encourages** structured surveys to more completely document the distribution of these animals and **recommends** comparisons with catalogues from other areas, including breeding grounds, in the Southern Hemisphere.

SC/64/SH23 presented information on 1,580 individually photographed humpback whales off Ecuador that were compared with 611 animals identified in the southeast Pacific in four different catalogues. This confirmed Antarctica as the main feeding ground for humpback whales found off Ecuador and suggested that feeding areas for whales identified off Ecuador may extend as far east within Area II as the South Orkney Islands. The Committee was also informed that individual animals may migrate either to the Magellan Strait or the Antarctic Peninsula, but not to both. Comparison with the catalogue of animals found off Chiloe Island, Chile, had yet to be undertaken, and the Committee **recommends** that this comparison be undertaken and looks forward to receiving further information.

Information on 15 long-term resightings of humpback whales off Ecuador was reported in SC/64/SH24. One animal was resighted over a 26 year time span. The paper also provided the earliest connection from Ecuador to Antarctica and further supports the findings that waters around the Antarctic Peninsula are the main feeding area of humpback whales migrating to Ecuadorian waters. The Committee **endorses** plans to extend comparison of the Ecuadorian catalogue with animals from around South Georgia and Area II and looks forward to receiving a report at next year's meeting.

SC/64/O15 discussed observations from small boats during 2006-2012, within the Golfo Duce, Costa Rica and the surrounding area of Osa Peninsula. It was shown the area is an important wintering ground, where the whales' distribution was determined by bathymetry, water temperature and possibly currents. For example, whales seem actively to avoid areas with eddies. The area seems to be used mainly by singing adults and there were competitive groups present in depths less than 60m, suggesting that mating occurs there.

The Committee **endorses** the view that spatial distribution information obtained from this study should be taken into account in establishing guidelines for appropriate management of this important Costa Rican marine coastal habitat.

10.2.2.6 FEEDING GROUNDS

SC/64/SH21 presented new information about abundance, population structure, demographic, and reproductive trends of humpback whales from the Strait of Magellan feeding area using long-term data on sightings, photo-identification and molecular analysis. The waters of Chilean Patagonian fjords and the Strait of Magellan remain today as the only recorded Southern Hemisphere feeding area for humpback whales of breeding stock G outside Antarctic waters.

The Committee thanked the authors for bringing this new information forward. It noted that it could not fully evaluate the abundance estimates with the information provided in the document and looked forward to seeing additional documentation next year. The Committee **expresses concern** regarding the potential for ship strikes and habitat displacement if the coal mining development results in a substantial increase of ship traffic in the region. It **recommends** that potential impacts are carefully assessed and that effective mitigation measures are adopted where necessary.

10.2.2.7 ANTARCTIC HUMPBACK WHALE CATALOGUE

SC/63/SH1 provided an update on the Antarctic Humpback Whale Catalogue (AHCW). The recent submissions bring the total number of catalogued whales identified by fluke, right dorsal fin/flank and left dorsal fin/flank photographs to 4635, 414 and 409, respectively. Opportunistic data represent a significant portion of the AHCW. Progress continues in efforts to stimulate submission of opportunistic data from eco-tourism cruise ships in the Southern Ocean and from research organizations and expeditions working throughout this region and the Southern Hemisphere.

The Committee thanked the authors for their hard work and **recommends** that the AHCW continue. This item has financial implications as discussed under Item 23.

10.2.3 Work plan

The work plan for the assessment of Southern Hemisphere humpback whales is described in Table 2 in Annex H and will be furthered by an intersessional working group (Annex Q). The Committee's discussions of the workplan are discussed under Item 21 and financial implications under Item 23.

10.3. Southern Hemisphere blue whales

10.3.1 Review new information

10.3.1.1 PHOTO-IDENTIFICATION CATALOGUES

SC/64/SH8 provided an update on the Antarctic Blue Whale Photo-Identification Catalogue, which includes photographs collected during 20 years of IWC IDCR/SOWER cruises (1987-88 to 2009-10). In 2011 and 2012 the photographs of eight new whales and one re-sighted whale (2007-2010) were added. Currently the catalogue contains a total of 227 identified whales. Seven whales were re-sighted in multiple years. Mark-recapture analysis of Area III in the 3-year time period

2004/2005-2006/2007 yielded estimates of abundance ranging from 818 to 1097 whales.

The Committee welcomed this update and recognised that the data have also been submitted to the Southern Hemisphere Blue Whale Catalogue. Photographs of blue whales from the JARPA programme has not yet been included in the ABWPIC but have been submitted to the IWC Secretariat. The Committee **reiterates** that the photographs should be added to the catalogue and reconciled and a proposal to achieve this has been developed. This is discussed further under Item 23.

SC/64/SH20 presented an update on the Southern Hemisphere Blue Whale Catalogue that holds photo-identification catalogues of research projects from major areas off Antarctica, Eastern South Pacific and the Eastern Tropical Pacific (ETP). A total of 822 and 826 individual blue whales photographed from left and right sides respectively are held in this Catalogue. Left-side comparisons have been completed and right-side comparisons are underway for ETP and the other areas. There are re-sightings both within Chile and in the Southern Ocean. However, none of the 84 whales photographed off ETP have been re-sighted within or outside of the ETP.

The Committee **encourages** contributions of regional catalogues not yet in the Southern Hemisphere Blue Whale Catalogue (e.g. eastern and western Australia) to facilitate full reconciliation of the catalogue for the Southern Hemisphere blue whales and a proposal to achieve this has been developed. This is discussed under Item 23.

10.3.1.2 ANTARCTIC BLUE WHALES

SC/64/SH14 reported methodological developments for estimating relative abundance from historic Antarctic whaling records using catch per unit effort data (CPUE). Once the work has been completed and accepted by the Scientific Committee, the Committee welcomed the commitment of the authors to submit the datasets and script to the IWC Secretariat.

SC/64/SH11 summarised two voyages conducted by the Australian Antarctic Division off southeastern Australia to refine acoustic tracking methodologies to address the aims of the Southern Ocean Research Partnership's Antarctic Blue Whale Project (see Item 19 and Annex H, item 3.1.2.1). The primary aim of this project is to estimate the circumpolar abundance of Antarctic blue whales using mark-recapture methods. The passive acoustic tracking system, using DIFAR sonobuoys, operated continuously during the voyages recording nearly 500 hours of audio, while acousticians processed over 7,000 blue whale calls in 'real-time'. The two voyages yielded 52 sightings (104 animals) of blue or like-blue whales; 48 animals were identified photographically (one on both voyages). Some blue whales that had been seen were not heard.

SC/64/SH12 summarised the methodological development of the use of DIFAR sonobuoys for real-time tracking of blue whales. The results indicate that acoustic surveys may offer increased effective range over purely visual surveys of blue whales.

SC/64/SH26 presented an exploration into what encounter rates are plausible using acoustic-assisted tracking of whales, as opposed to a traditional visual-only survey (such as IDCR/SOWER). Given the lack of data, and the number of assumptions, abstractions, and approximations required in this simulation exercise, the authors stressed that the estimates in the paper should not be considered accurate or precise.

SC/64/SH10 presented a great advancement on the feasibility study of methods to obtain a new estimate of circumpolar abundance of Antarctic blue whales. Using the seasonality and location of sightings and acoustic detections from IWC-SOWER surveys, and historical catch data, it was concluded mark-recapture surveys should target putative hotspots and make use of passive acoustic tracking to increase encounter rates. With a reasonable level of effort a viable estimate of circumpolar abundance could be obtained for Antarctic blue whales within a ten-year period (and see Item 19).

The Committee recognises that the longer-term timeline to estimate abundance of Antarctic blue whales is more appropriate and logistically more feasible than the shorter periods considered earlier in the project's development. It **welcomes** the suite of papers linked to the Antarctic Blue Whale Project and the considerable advancement in the project's development. Further mark-recapture simulations studies may be valuable to investigate the effects of variability in effort between years within the suggested ten year timeframe and also to investigate the interaction between spatial variability in effort and possible population structure. This simulation could assess the consequences of only targeting 'hotspots' and the potential heterogeneity in capture probability potentially generated through this approach.

Further the Committee **encourages** ships contributing to the ABWP to, whenever possible, also collect environmental data for habitat modelling and data on other whale species sighted. In some circumstances environmental data can be collected through remote sensing but this is often problematic around Antarctica due to extensive cloud cover. Gliders and floats may provide another opportunity to collect high resolution water column data.

10.3.1.3 PLANNING OF FUTURE RESEARCH

The Committee was pleased to receive a number of papers on future blue whale research (see Annex H, item 3.1.2.2 for full discussion of these).

SC/64/SH13 presented a preliminary plan for an Australian funded voyage to contribute to the SORP

Antarctic Blue Whale Project. The aim of the Antarctic Blue Whale Project is to develop technologies and collect data that will ultimately deliver a new circumpolar abundance estimate for Antarctic blue whales. The voyage will focus on blue whales in waters west of the Ross Sea (i.e., 135-175°E), an area that has been associated with higher densities of blue whales. The plan will be further developed and reviewed once the project management structure for the Antarctic Blue Whale Project is established which includes the formation of technical committees on passive acoustics, individual identification, and survey design.

The Committee **emphasises** the importance of collecting opportunistic data on other whales (sightings, faecal collection, biopsies) and environmental data, while recognising the value of clear priorities, particularly when the number of days 'on-site' in good weather can be few, even for longer Antarctic voyages.

SC/64/O16 presented the South African Blue Whale Project which is intended to initiate a long-term monitoring programme of blue whales in the Antarctic sector east of the Greenwich meridian, coupled with investigations of their seasonal pattern of abundance at lower latitudes. Acoustic technology will be combined with traditional line transect sighting survey and mark-recapture methodology to study the distribution, abundance and movements of blue whales in the southeast Atlantic. This joint study is conducted by the University of Pretoria and the University of Washington, and has received funding for 3 years from the South African National Antarctic Programme, starting in 2012/13. One team member will receive training in AAR deployment during a cruise off Greenland this summer (SC/64/O17) under the SORP programme. Although data valuable to the SORP Antarctic Blue Whale Project will be collected on this voyage (photo-ID and biopsy samples), the project is more closely linked with another SORP project 'Acoustic trends in abundance distribution and seasonal presence of Antarctic blue whales and fin whales in the Southern Ocean (see SC/64/O13).

SC/64/SH25 proposed a project on the genetics of Antarctic blue whales in part using IWC samples. The contemporary Antarctic blue whale has been described by a relatively high mitochondrial DNA (mtDNA) haplotype diversity, and may have escaped a greater loss of genetic diversity due to its long life span, overlapping generations and the brief period of the bottleneck. The impact of 20th century commercial whaling on genetic diversity can be explored through a comparison of historic and contemporary genetic diversity. The Committee **recommends** that access to the samples continues for this work and encourages further sampling in South Georgia.

The Committee **endorses** these research projects and looks forward to reviewing the results.

10.3.1.4 PYGMY BLUE WHALES

SC/64/SH27 presented a study on the identity of blue whales that are regularly sighted in the Geographe bay region of Western Australia. Preliminary results based on measures of genetic structure indicate that the whales were all of the pygmy subspecies. Further samples from Geographe Bay are required to clarify whether these blue whales have fine scale genetic differentiation.

The Committee **welcomes** this paper which is discussed fully in Annex H, item 3.1.3, noting the contribution made by IDCR/SOWER samples to the study.

10.3.1.5 CHILEAN BLUE WHALES

The Committee was pleased to receive three papers on blue whales in Chilean waters and a full discussion can be found in Annex H, item 3.1.4.

Galletti Vernazzani et al. (in press) described the results of a collaborative research programme (the Alfaguara Project) conducted by Centro de Conservacion Cetacea on Chilean blue whales. From 2004 to 2010, eight aerial and 85 marine surveys were conducted off Isla de Chiloe, southern Chile, where a total of 363 individual blue whales were photo-identified. Recapture data support the hypothesis that the feeding ground off southern Chile is extensive and dynamic. Blue whale distribution off southern Chile was assessed and relative abundance, using sighting per unit effort and kernel density estimators was obtained.

SC/64/SH18 provided an update on the 2012 blue whale field season that reported the occurrence of a shift in blue whale distribution during 2012 from the southern Chile feeding area (Isla de Chiloe), as reported in previous years, to an additional feeding aggregation of blue whales in northern Chile (Isla de Chanaral).

The Committee recognized the value of such long-term datasets for understanding blue whale populations and **recommends** that they continue.

SC/64/SH19 presented an abundance estimate of Chilean blue whales by mark-recapture and line-transect techniques.

The Committee recognised that the area covered by the line-transect survey does not include the entire range of the population and so will underestimate the total population size. There are also issues related to possible structure among feeding groups and sampling that require further consideration with respect to mark-recapture estimation. The Committee **encourages** further work on this and looks forward to receiving additional analyses.

10.4 Western North Pacific gray whales

10.4.1 New scientific information

Results regarding mixing of western (WNP) and eastern (ENP) North Pacific gray whales illustrate the great conservation and management importance of a

more comprehensive examination of gray whale movement patterns and population structure in the North Pacific. At last year's meeting the Committee noted that for such an effort to be successful it must be international and collaborative (Weller *et al.*, 2012). To facilitate this, and noting the existing safeguards for collaborators provided under the Committee's Data Availability Agreement, it recommended that a collaborative Pacific-wide study be developed under the auspices of the IWC, recognising that *inter alia* this will contribute to the Committee-endorsed Conservation Plan for Western North Pacific Gray Whales and incorporate previous recommendations made by the Committee. Appendix 7 of Annex F provides an update on progress made to date.

The Committee **commends** the highly collaborative, international research effort for the progress made to date and look forward to future updates. The Committee also received several papers on stock structure and movements of north Pacific gray whales that resulted from this or other related programmes. Details can be found in Annex F, Item 4.1.

10.4.1.1 SATELLITE TAGGING

Mate summarized results regarding the recent collaborative efforts between Russian and US scientists to satellite track western gray whales under a programme undertaken with guidance from the IWC Scientific Committee and the IUCN GWAP (Western Gray Whale Advisory Panel). The main goal of the project was to determine migration routes and breeding areas of tagged gray whales from the western North Pacific in order to develop improved conservation measures for this very small population. A total of seven whales were tagged in 2010 and 2011. The three longest tracked whales moved east across the Bering Sea and into the northeast Pacific where they overlapped with the range of eastern gray whales. Each animal followed a different route. The transmitter for a whale tagged in 2011 has lasted almost a year and continues to transmit. It travelled to near the southern tip of Baja California, Mexico during the winter and returned to near Sakhalin Island, Russia this spring. The autumn and spring migratory routes differed. These results, along with those from photo-identification matches from the eastern and western Pacific have caused the Committee to examine overall stock structure of gray whales in the North Pacific and to initiate the ocean wide research programme referred to above.

Mate also presented information on a plan for the A.N. Severtsov Institute of Ecology and Evolution of the Russian Academy of Science (IPEE) and Marine Mammal Institute of the Oregon State University to continue tagging western gray whales following the guidelines already developed by the IWC (IWC, 2012k). It is intended to tag up to 20 animals off Kamchatka (there is some interchange between animals

off Kamchatka and Sakhalin) beginning in early July. The objective is to provide additional information on stock structure and to assist in developing conservation measures. The programme will also involve photo identification and biopsy work. Photos will be made available to all catalogues and genetic samples will again be submitted to the IWC archive.

There was some discussion about whether tagging in Kamchatka was as beneficial as further tagging off Sakhalin as detailed in Annex F. The Committee **agrees** on the value of future telemetry work off Kamchatka and Sakhalin and **reiterates** its previous guidelines for such work (IWC, 2012k). Advice from the IWC/IUCN steering group chaired by Donovan on the full proposal will be provided to the research team in sufficient time to assist preparations for the field programme. The Committee also **recommends** that an evaluation of healing of the wounds caused by the satellite tags be undertaken and provided at next year's meeting.

The Committee also received information on plans for telemetry work on eastern gray whales. Quakenbush and her colleagues plan to tag up to 10 gray whales near Barrow and Saint Lawrence Island in 2012. The main goal is to document the distribution, movements, and feeding areas of gray whales relative to oil and gas activities in the Chukchi Sea. The project will include the collection of photographs and biopsies. Data will be shared with other gray whale research groups. Mate plans to tag some additional PCFG gray whales in 2012 in Oregon and northern California. The objective is to investigate if the variable migratory timing, routes, and Baja California destinations are similar to those found in 2009 and 2010.

10.4.1.2 PHOTO-IDENTIFICATION

SC/64/BRG13 provided results from a photographic comparison of gray whales off Sakhalin Island, Russia with animals in lagoons of Baja California, Mexico. Additional information about another match was reported subsequent to the submission of SC/64/BRG13. In total, photographs of 217 identified gray whales were obtained from the Sakhalin Island feeding grounds and compared with 6,546 photo-identified individuals from the Baja California breeding lagoons. The research team found a total of 14 matches from the 217 Sakhalin whales, including six males, six females and two animals of unknown sex. Thirteen whales had sightings in Russia prior to and after their respective sighting in Mexico. Five females with calves were sighted in the winter in Mexican waters and in the next summer off Sakhalin, three of them without calves suggesting that these females had either separated from their calves or that their calves did not survive. The matches made between whales sighted off Sakhalin and the Mexican Pacific are the first results of the multinational collaboration.

The Committee **thanks** the authors and their colleagues for reconciling the Mexican photo catalogue. This will be a useful tool to address many questions, such as the relationship between Sakhalin and Mexico gray whales. The Committee also **acknowledges** the collaboration among the international group of gray whale researchers as a great example of how scientists can work together to address questions of great importance.

Another example of the multinational collaboration involves the photo comparisons being conducted among three: the Russia-US Sakhalin catalogue, the Institute of Marine Biology (IBM) Sakhalin catalogue, and the IBM Kamchatka catalogue (Appendix 9 of Annex F presents preliminary results from this study).

Updated information on research and conservation in Japan was presented in SC/64/O8. In March 2012, a gray whale was sighted on the Pacific coast of Aichi Prefecture, in the middle of Japan and some photos of the animal were taken. No stranding or entanglement of this animal occurred. The Committee was also informed that there are some photographs (and genetic samples) in Japan that might contribute to a better understanding of stock structure of north Pacific gray whales. Japan expressed interest in joining the international collaboration and named Kato as the contact person. The Committee welcomes this news and **encourages** sharing of photographs and genetic samples with existing catalogues and genetic databases.

The Committee **commends** the above highly collaborative, international research effort for the progress made to date and **encourages** enhanced collaboration, if at all possible. The Committee **strongly recommends** the continuation of the IWC collaborative programme as outlined in Annex F, especially the plans to collect additional biopsy samples for genetic comparisons and photographs for catalogue comparisons. It was suggested that analyses be conducted to assess whether any patterns in the genetic data could be identified when Sakhalin whales known to have overwintered in the Eastern North Pacific are compared to the other sampled animals off Sakhalin as well as to those sampled in the Eastern North Pacific. The Committee also **recommends** that existing data be used to attempt to estimate the proportion of animals that regularly feed off Sakhalin and also migrate to the eastern North Pacific in the winter.

10.4.1.3 OTHER

SC/64/BRG10 provided a summary of past and current records of gray whales off the coasts of Japan, China and Korea. There are only 13 known sighting or stranding records in Japanese waters between 1990 and 2007 (Nambu *et al.*, 2003). Observations of gray whales in China are also exceptionally rare. Gray whales were once common and hunted off the coast of the Korean Peninsula but the last reported commercial catches were in 1966 and the last known sighting off

Korea was in 1977. This suggests that they have abandoned the migration corridor along the Korean Peninsula or that a subpopulation using the Korean Peninsula is now extinct. The evidence that some Sakhalin animals migrate to the west coast of North America during the winter/spring, along with observations off Japan, Korea and China during the winter/spring, in combination with significant genetic differences between the eastern and western populations (Lang *et al.*, 2011) suggest that the number of whales in the western North Pacific population is potentially smaller than the currently estimated ~150 whales that use the Sakhalin summer feeding area.

This paper stimulated considerable discussion as can be seen in Annex F. The Committee emphasises the importance of the collaborative oceanwide programme and the need to review stock structure of gray whales throughout the North Pacific. It was noted that photographs (albeit low quality) of a gray whale that died in fishing gear in China in November 2011 have been compared with several catalogues (i.e., the Russia-US, IBM Sakhalin, and IBM Kamchatka) but no matches have been made.

In conclusion, the Committee **welcomes** all of the information on this critically endangered population and the broader question of stock structure. It **encourages** further work and as in previous years, **re-emphasises** the importance of continued long-term monitoring. Recognising some difficulties of interpretation given the new information on movements, the Committee also encourages Cooke to complete and publish his assessment of the gray whales feeding off Sakhalin using the combined photo-identification datasets. This rich dataset can provide valuable information for assessing possible anthropogenic impacts on animals feeding in the area.

10.4.2 Conservation advice

As in previous years, the Committee **acknowledges** the important work of the IUCN Western Gray Whales Advisory Panel. This year's update on the panel's activities is given in Appendix 10 of Annex F. The Committee **re-emphasises** its view of the importance of the Panel's work and reiterates its support. Furthermore, the Committee **recommends** that appropriate monitoring and mitigation plans be implemented for all oil and gas activities that occur in the range of western gray whales, especially if another platform is to be built or installed off Sakhalin.

The Committee again **recognises** that the problem of net entrapment of western gray whales is a range-wide issue. It **welcomes** Japan's administrative actions related to conservation of gray whales (SC/64/O8) and the efforts of other range states to reduce mortality, such as net entrapments that occur in other range states, including Canada, US and Mexico on the eastern side of the Pacific. Continued international collaboration to

elucidate population identity and stock structure, as emphasised above, will provide valuable information for future management advice.

10.5 Southern Hemisphere right whales

10.5.1 Review report from intersessional workshop

Bannister introduced the report of workshop, held in Buenos Aires, Argentina, from 13-16 September 2011 (see SC/64/Rep 5). He noted that although substantial progress had been made on much of the agenda, additional work was needed on some sections, especially the completion of analyses related to abundance and assessment. It was also noted that subsequent revisions of some analyses meant that sections of the report required clarification or amendment. As a consequence, two groups (an assessment group and a drafting group) were established to complete this work.

The Committee recognises the substantial work undertaken at the workshop and **welcomes** the report, thanking particularly the Chair, rapporteurs and the host. It noted the large number of recommendations the report contained and prepared the following consolidated version incorporating additional comments and recommendations from the Committee as appropriate.

10.5.1.1 LONG-TERM POPULATION MONITORING

The Committee has long recognised the value of long time-series in informing, prioritising and evaluating conservation and management actions for whales, including monitoring the effectiveness of mitigation measures and Conservation Management Plans. In particular, it stresses the value of maintaining annual data sets, especially those that include information on the calving intervals of individual females, for their potential importance in analysing the influences of climate and environmental variables on southern right whale reproduction. The Committee therefore **strongly recommends** that all existing southern right whale data sets of this nature (e.g. in Argentina, Australia and South Africa) be continued on an annual basis, and that similar programmes be established wherever possible for other areas.

In this connection, the Committee received a proposal requesting interim relief funding for the 2012 aerial survey off South Africa (Annex F, Appendix 2) and **recommends** its support (see item 23).

In addition, the Committee **recommends** that the annual CENPAT programme of aerial surveys around Peninsula Valdés, which is independent of the long-term aerial photo-identification programme and substantially increases the areal and temporal survey coverage, should be continued on an annual basis.

10.5.1.2 POPULATION STRUCTURE AND LINKAGES

The population structure and stock identity of southern right whales remain incompletely described. A

particular challenge is to distinguish adjacent stocks with different demographic histories and apparent rates of recovery. To address this, the Committee **recommends** that a circumpolar collaboration proceed to assemble standard genetic information from all available samples (see SC/64/Rep5, Table 5), that could *inter alia* update the previous analysis by (Paternaude *et al.*, 2007) of the genetic structure of southern right whales on their calving/nursery grounds.

A number of standard genetic protocols are **recommended**, including standardisation of mtDNA preparation and nomenclature, standardisation of microsatellite loci, and the exchange of samples between laboratories to establish allelic standards and provide quality control (see SC/64/Rep5). Further tissue sampling is also **strongly recommended** in a number of areas including Australia, Chile/Peru, Southern Africa and Brazil (see Annex F and SC/64/Rep5 for more details). In addition, to investigate relationships with other southern populations, further analysis of existing genetic samples from South Africa ($n = \sim 600$) is **recommended**.

Recognising the importance of being able to allocate offshore ('pelagic') catches in the Southern Ocean and in low-latitude areas to the appropriate calving/nursery/breeding grounds, the Committee **recommends** that genetic (biopsy), photo-identification and satellite tagging data are applied to identify linkages. Further investigation is **recommended** of: (a) connections between whales in the New Zealand sub-Antarctic and those in mainland New Zealand and (b) philopatry to mainland New Zealand (for details see Annex F and SC/64/Rep3). It is also **recommended** that biopsy samples, satellite tagging data and photo-identification data be linked, where possible.

While recognising the value of genetic analyses in solving the problems of population structure and linkages, the Committee also **recommends** other approaches such as inter-catalogue comparisons. Similarly, the value of strategically deployed satellite tags in depicting movements has already been demonstrated for southern right whales, and the Committee **recommends** that such studies continue.

10.5.1.3 MODELLING

The Committee **recommends** further investigation of the conversion factor used to estimate total population size from the estimated adult female component. Such investigation needs to consider that there has been only a relatively short period of recovery and that therefore the age distribution is unlikely to be steady and the estimated survival rate is likely to be biased upwards from the average that would apply in a steady situation.

10.5.1.4 JOINT ARGENTINA/BRAZIL ASSESSMENT

Noting the preliminary nature of Cooke's analyses, the Workshop had decided not to append the results to their

report. It had recommended that progress towards the 'joint assessment', using data from both Argentina and Brazil, be made as quickly as possible and that an update also be presented on this work at the 2012 Scientific Committee meeting. Cooke provided an assessment of the 2010 Argentine population including a rate of increase from 2000-2010 to the meeting (Annex F, Appendix 3). The Committee **welcomes** this and **agrees** to include the results in the Workshop's assessment of the status of the southern right whale population in 2009, appreciating that until a joint Argentine/Brazilian assessment had been completed these results must be considered preliminary in nature. The Committee **recommends** that the joint Argentine/Brazilian assessment be completed as soon as possible, and the results presented to the 2013 Annual Meeting.

10.5.1.5 ASSESSMENT OF THE CHILE/PERU POPULATION

In order to obtain information on the distribution and abundance of this Critically Endangered population, to clarify its status and identify any threats and possible mitigation actions, the Committee **recommends** that surveys, photo-identification and genetic studies should be conducted as a priority. Specifically, the following steps should be taken:

- (1) determine geographical/temporal areas where quantitative studies can best be conducted, through analysis of existing historical whaling and sighting data and appropriate temporal/geographical spatial modelling;
- (2) design a systematic survey programme (aerial surveys may be the most efficient) to cover potential calving or nursery areas, bearing in mind logistical and practical limitations; and
- (3) further consider stock structure issues by examining existing genetic samples (including museum specimens where possible) and collect new samples in southern Chile/Argentina.

10.5.1.6 IDENTIFICATION OF CONCERNS AND THEIR MONITORING

Given that there was evidence of continuing direct removals via entanglements in fishing gear and ship strikes, the Committee **recommends** all countries to include reports of ship strikes and entanglement events in their annual progress reports to the IWC through the new online portal (see item 3.2).

The Committee **strongly reiterates** the research and management recommendations made at the Workshop on the Southern Right Whale Die-off (IWC, 2011h). In addition, in view of the severe impacts of gull attacks documented at Península Valdés and the risk that this learned behaviour on the part of gulls could proliferate, the Committee **recommends** that Brazilian authorities consider taking immediate action if and when similar gull behaviour is observed. Some members felt that this

action should specifically include the removal of attacking gulls, following similar steps being undertaken by Argentina in the Peninsula Valdes area.

The Committee noted that some concerns have been raised about the potential effects of fishing and climate change on krill and hence on krill predators. The Committee also noted that the CCAMLR Scientific Committee was investigating these matters and encourages further collaboration between IWC and CCAMLR on the development of relevant ecosystem models.

10.5.1.7 DEVELOPMENT OF CONSERVATION MANAGEMENT PLANS (CMPS)

The Committee **recommends** that any draft CMPs take into account the recommendations made at the Buenos Aires workshop and the workshop on the die-off of southern right whales and use these as the basis of action development (IWC, 2011h). The Committee was pleased to note that this was the case for the two draft CMPs it received (see below).

10.5.1.8 CONCLUSION

The Committee noted that the Workshop Report (SC/64/Rep5) had reached conclusions on the current status of the overall Southern Hemisphere right whale population based on a modelling exercise undertaken during the workshop using the best available parameter values. However, the Workshop had recognised that the calculations were very dependent on (1) the results of the as yet incomplete analysis of the Argentinian/Brazilian population to be provided by Cooke, and (2) on different conversion factors from mature female to total population size derived from the Argentine and South African populations.

Cooke advised that the parameter values for Argentina he had provided during this meeting (Annex F, Appendix 3) still required some updating. However, he agreed that he would forward them by 1 July 2012 to Butterworth and his colleagues so that a revised circumpolar analysis using the same approach as in Buenos Aires could be completed. It was agreed that the updated analysis would be incorporated into the Buenos Aires workshop report with an appropriate editorial note. This full report would then be circulated to workshop participants for any final comments and included in the published version in JCRM.

Cooke reported that it was impossible to undertake the recommended joint Argentina/Brazilian assessment until matching between photo-identification catalogues had been completed. However, he confirmed that excluding Brazil from the overall assessment was unlikely to have a major effect on the resultant circumpolar estimate because of its relatively small size (some other small populations for which no estimates exist are also excluded from the assessment). It was also noted that updated calculations using the Argentina and South African data had resulted in a convergence

of conversion factors (Annex F, Appendix 3) so that these are no longer a major issue in estimating total population size for use in the assessment.

10.5.2 Review new information

10.5.2.1 SOUTHWEST ATLANTIC

The Committee received three papers on this population. They are briefly summarised below but a full discussion can be found in Annex F, Item 3.3.2.

SC/64/BRG12 presented updated information on the southern right whale die-offs at Península Valdés, Argentina for the 2010-2011 seasons. Systematic efforts to study the strandings have continued since 2003. A total of 482 dead whales were recorded at Península Valdés between 2003 and 2011. At least 55 whales died in 2010 and 61 died in 2011. As in previous years, the vast majority of strandings were calves of the season.

SC/64/BRG7 reported an analysis of metal levels in the skin of living southern right whales at Península Valdés, Argentina, as part of efforts to investigate the recent die-offs. The levels of nonessential and essential metals in the skin of 10 animals were on the low end of the spectrum of measured concentrations when compared to other studies. The authors cautioned that these low levels should not necessarily be interpreted as being safe since the effects of metals in marine mammals are largely unknown.

There was lengthy discussion on the possible reasons for changes in the observed calving interval. In conclusion, the Committee **reiterates** the recommendations of the southern right whale die-off workshop (IWC, 2011h) and **encourages** the continuation of the studies presented in SC/64/BRG7 and SC/64/BRG12 to better understand the mechanism(s) behind the observed mortality.

SC/64/BRG20 presented an abundance estimate of southern right whales by aerial line-transect surveys for a bay area of Bahía San Antonio, Argentina, from late summer to fall in 2009-2011. A corrected abundance estimate using $g(0)$ is 207 (CI=99-315) in 2010, which is the maximum among the three years. These aerial surveys resulted in the first specific estimates of southern right whale abundance in this north Patagonian bay although more consistent aerial surveys should be conducted.

10.5.2.2 SOUTHERN AFRICA

SC/64/BRG24rev applied the three-mature-stages (receptive, calving and resting) model of Cooke *et al.* (2003) to photo-identification data available from 1979 to 2010 for southern right whales in South African waters. The 2010 mature female population is estimated to be 1,309, the total population is 4,725, and the annual population growth rate 6.8%. Information from re-sightings of grey blazed calves as adults with calves allows estimation of first year survival rate of

0.914 and an age at 50% maturity of 6.4 years. In contrast, the relative proportions of grey blazed animals amongst calves and amongst calving adults suggest rather a value of 10% (SE 8%). If the proportion losing markings is in fact 10%, first year survival rates estimate drops to [0.859] and the population growth rate to [6.6%] per year.

Best presented an analysis in which he had assembled data from foetuses, biopsied calves and stranded calves to test the assumption that the neonatal sex-ratio in southern right whales was 50:50. The most appropriate data set suggested a ratio closer to 46 male: 54 female (Annex F, Appendix 4). The base case model of SC/64/BRG24 with this alternative sex ratio of 54:46 resulted in the total population 4,359 (Annex F, Appendix 5). The main differences in the parameter estimates were a lower first year survival rate with a corresponding higher value of the estimate for the probability that a grey blazed calf maintains its markings until becoming an adult.

10.5.2.3 SOUTHWEST PACIFIC AND NEW ZEALAND

Carroll et al. (*in press*) provided results on paternity assignment and ‘gametic recapture’ to examine the reproductive autonomy of southern right whales on their New Zealand calving grounds. The ‘gametic mark-recapture’ estimate of male abundance 1,001 was directly comparable with the ‘census estimate’ of male abundance, $N=1,085$, for the stock, based on standard genotype mark-recapture modelling. Simulations indicated the assumption of equal reproductive success amongst males was not violated. Power analyses suggested that these findings would be highly unlikely if the population was open to gene flow from other, larger populations in the Indo-Pacific region. The authors concluded that these findings are consistent with the hypothesis that southern right whales returning to the New Zealand calving ground are reproductively autonomous on a generational timescale, as well as isolated by maternal fidelity on an evolutionary timescale.

10.5.2.4 AUSTRALIA

SC/64/ProgrepAustralia provides information on southern right whales obtained on survey flights off the southern Australian coast between Cape Leeuwin and Ceduna in August 2011. The most recent updated increase rate for this Australian ‘southwest stock’ for 1993-2011 is 6.82% for all animals (CI 4.24-9.47), and 7.21% for cow/calf pairs (CI 3.70-10.85) with current population size *ca* 2,900; including the much smaller ‘south east’ Australian stock, the Australian population as a whole is likely to number *ca* 3,500.

10.5.2.5 SOUTH EAST PACIFIC RIGHT WHALES

Off northwestern Isla de Chiloe, four sightings of the critically endangered Chile/Peru “sub-population” between September and November 2011 were documented, including the first incidence of

reproductive behaviour and the first resighting of a known individual in Chile. In addition, some 30km north, the southernmost record of a mother-calf pair was recorded. These observations suggest that northwestern Isla de Chiloe is part of a breeding area with undetermined boundaries. This highlights the importance of these coastal waters and the need to continue long-term studies, both dedicated and opportunistic, to monitor this critically endangered population.

10.5.2.6 GENETIC RESEARCH

SC/64/BRG15 reported on progress with the investigation of the worldwide genomic diversity and divergence of right whales. Through collaborative agreements, the investigators have obtained representative samples from all three oceanic species. The investigators have used next-generation sequencing technology to develop genomic profiles by sequencing the complete mitochondrial genomes and multiple nuclear genes for each individual. To date, the results provide greatly increased resolution of the divergence between the three recognised species, and the diversity within each oceanic population.

The Committee noted that the project was generally methodologically sound and the objectives of the study were likely to be achieved. Although some concerns were expressed about limited number of samples and a possible need for more emphasis on the nuclear aspect of the survey, the Committee **recommends** funding the final stage of the project (see Item 23).

Review of “Draft Conservation Management Plans for Southern right whales”

The Commission has agreed that Southern right whales of South America should be candidates for IWC Conservation Management Plans (IWC, 2012b). As discussed in Annex F, two draft plans were available, one for Southwest Atlantic southern right whales (IWC/64/CC7Rev1) and one for southeastern Pacific southern right whales (IWC/64/CC9).

The Committee examined these draft CMPs for their scientific content and related actions and found them to be in accord with the results and recommendations from the IWC workshops on the Status of Southern Right Whales (SC/64/Rep3) and the Southern Right Whale Die-off (IWC, 2011h).

10.6 Other stocks of right whales and small stock of bowhead whales

An update was provided on North Atlantic right whales for the period November 2010 - October 2011, reflecting the work of North Atlantic Right Whale Consortium, 2011. A collaborative photographic catalogue suggested that there were 490 North Atlantic right whales in 2010. Five right whale deaths were documented during the report period. Additionally, there were 11 new entanglement cases documented.

The Committee **thanks** the authors for this update and looks forward to receiving further information next year.

SC64/ProgRepJapan reported that in February 2011, a right whale was found dead in a set net in Oita prefecture. A skin sample was sent to the Institute of Cetacean Research (ICR), where DNA was extracted and it was confirmed as a right whale. However, the ICR branch in the Tohoku region was hit by the tsunami on 11 March 2011 and the sample was lost.

SC/64/O6 reported sighting information for North Pacific right whales from sighting surveys conducted in May 2011 in the western North Pacific. A total of 13 schools (20 individuals) was sighted, from which 19 individuals were photographed and 14 biopsied successfully.

The Committee **welcomes** new information on North Pacific right whales, noting that such sightings were rare. It looks forward to receiving a fuller report of the sighting survey at the next meeting.

No update was available for the small stock of bowhead whales in the Sea of Okhotsk.

Moore *et al.* (2012) provided results of a year-long acoustic study of the Spitzbergen stock of bowhead whales from September 2008 to September 2009 in western Fram Strait (79°N, 5°W). The rate of bowhead whale call detection was high from September 2008 through May 2009, including calls detected on every day of the month from November through February when sea ice was 90-100% surface cover.

The Committee continues to **reiterate** its grave concern over these small stocks and **encourages** continued or expanded research on these small populations.

10.6.2 Work

The Committee's views on the workplan for these stocks are given under item 21.

10.7 Arabian Sea humpback whales

10.7.1 Review intersession progress

The Scientific Committee has in the past (most recently in IWC, 2012m), recommended further research to help address the serious conservation status of the Arabian Sea humpback whale which is recognized as an isolated resident sub-population of humpbacks with an estimated population size of 82 (95% CI 60-111; Cerchio *et al.*, 2008; Minton *et al.*, 2011).

SC/64/SH30 provided details of surveys, shore-based observations, and passive acoustic monitoring conducted in Oman during October 2011-March 2012. A total of 36 humpback whales was encountered, 33 of which were photographed and 16 were newly identified individuals. No feeding was observed in the southern survey site and there were nearly three times fewer whales encountered this year. Differences in relative density and feeding may be due to annual fluctuations

in food availability as a result of variable oceanographic conditions. Three mother-calf pairs were recorded in Oman during 2011 - 2012, one of which entered the newly operational multi-purpose Port of Duqm. These are the first documented records of humpback whale calves in Oman since 2000. Two mortalities were recorded in January and April 2012. An adult female floating at sea was photographed by local fishermen and a juvenile that stranded live on a remote stretch of shoreline and was subsequently buried by the local municipal authority before scientific investigation could be conducted.

Observations of severe entanglement scarring, as well as coastal road development, operation of a large new port at Duqm, and the planned inauguration of several fast ferry routes through known humpback whale habitat are cause for concern. Efforts are underway to highlight the population's conservation needs with local, national and regional governments as well as the general public, and progress is being made toward the formation of a network of researchers and managers responsible for the design and implementation of a Conservation Management Plan, as recommended last year (IWC, 2012f, p.25).

The Committee expresses **concern** over the relatively large number of strandings from this small population (9 over a 12-year period). Given its endangered status under the IUCN red list and the potential for growth of unregulated whale watching in the region, the Committee **recommends** that whalewatching vessel operator training workshops should be conducted with a view to promoting best practice for whalewatching and to support the need for development of whalewatching guidelines (see Item 23).

The Committee further noted plans to produce an updated mark-recapture estimate of population size. It **reiterates** its earlier recommendation (see International Whaling Commission, 2011), regular abundance surveys to be repeated on a regular basis, with assistance in planning and analysis from relevant experts.

10.7.2 The development of a CMP

The Committee has previously noted that this population is a likely candidate for an IWC Conservation Management Plan (CMP). An intersessional working group was formed at last year's IWC meeting to facilitate this process in accordance with the guidelines adopted last year by the Commission (IWC, 2012b). A key component of any plan is that it is supported by a broad range of stakeholders including range state governments. The Committee welcomes the progress that has been made in assembling the documentation required to submit a proposal to the IWC for a candidate CMP. It strongly **recommends** that discussions between scientists and

relevant range state governments continue to further progress the CMP process.

10.7.3 Work plan

The Committee's views on the workplan for BRG are given under Item 21.

10.8 Cruises

10.8.1 The IWC-POWER programme

10.8.1.1 PLANNING THE IWC-POWER¹⁴ PROGRAMME

The Scientific Committee has been discussing the objectives and priorities of the IWC POWER programme since 2009 (e.g. IWC, 2012t) and this culminated in the discussions given in IWC (2012l).

The Committee and the Commission agreed the long-term objectives for the programme in IWC (2012l).

'The programme will provide information to allow determination of the status of populations (and thus stock structure is inherently important) of large whales that are found in North Pacific waters and provide the necessary scientific background for appropriate conservation and management actions. The programme will primarily contribute information on abundance and trends in abundance of populations of large whales and try to identify the causes of any trends should these occur. The programme will learn from both the successes and weaknesses of past national and international programmes and cruises, including the IDCR/SOWER programme.'

(IWC, 2012t) provided an extensive review of current knowledge in the region, and a list of medium-term priorities by species for the programme was developed.

SC/64/Rep1 presents the report of a meeting of the Technical Advisory Group (TAG) established last year. The report builds upon the extensive work already undertaken to provide an overall strategy and detailed 5-year plan for the IWC POWER programme, including statistical power calculations. The TAGshop initially focused on methodological issues to investigate distribution, abundance and trends. It made a number of practical recommendations for visual methods (SC/64/Rep1, Item 3.1) regarding survey mode, track design, and angle and distance experiments. Initial power analyses suggest the need for increased future effort (at present only one vessel is available) to be able to detect trends. The results of the short-term programme (see below) will allow improved power analyses and a better determination of required effort for the medium-long-term. Other techniques examined included mark recapture and acoustic methods and recommendations for further investigative and collaborative work were made. It also examined past data to investigate the amount of effort required to obtain photo-IDs and biopsy samples; this information is valuable for both short- and medium-term planning.

After reviewing the available information, an integrated short-term strategy (for the years up to 2015) was developed in light of the medium-long-term objectives (SC/64/Rep1, item 7.1). The objective is to complete an initial survey of the remaining poorly covered areas (SC/64/Rep1, fig 1) to facilitate choice of appropriate survey blocks and strata for a long-term monitoring plan along with the essential undertaking of a more specific power analysis of the effort required to detect trends in abundance should they occur.

The TAG also made recommendations on the need for improved data collection systems, archiving of all kinds of data collected during the programme and a mechanism to ensure prompt collaborative analyses of the data collected (SC/64/Rep1, item 6). A detailed proposal for how to address these issues will be made at the 2013 Annual Meeting.

The Committee welcomes this report and **endorses** its recommendations. Noting the valuable contributions already made by Japan, Korea, the USA and Australia, it **strongly encourages** range states and others to consider more active participation in the IWC-POWER programme.

10.8.1.2 REPORT ON THE 2011 IWC-POWER CRUISE

The 2nd annual IWC-POWER survey was successfully conducted from 11 July to 8 September 2011 in the eastern North Pacific (north of 40°N, south of the Alaskan Peninsula, between 170°W and 150°W) using the Japanese Research Vessel, the *Yushin-Maru No.3*. The cruise had five main objectives:

- (a) to provide information for the proposed future in-depth assessment of sei whales in terms of both abundance and stock structure;
- (b) to provide information relevant to *Implementation Reviews* of whales (e.g. common minke whales) in terms of both abundance and stock structure;
- (c) to provide baseline information on distribution and abundance for a poorly known area for several large whale species/populations, including those that were known to have been depleted in the past, but whose status is unclear;
- (d) to provide biopsy samples and photo-identification photos to contribute to discussions of stock structure for several large whale species/populations, including those that were known to have been depleted in the past but whose status is unclear; and
- (e) to provide essential information for the intersessional workshop to plan for a medium-long term international programme in the North Pacific.

¹⁴ North Pacific Ocean Whale and Ecosystem Research programme

Plans for the cruise were endorsed by the Committee (IWC, 2011) and the Committee agrees that it was duly conducted following the guidelines of the Committee.

On behalf of the Committee, Kato thanked the Cruise Leader, researchers, captain and crew for completing the second cruise of the POWER programme. The Government of the USA had granted permission for the vessel to survey in its waters, greatly contributing to the success of the cruise. The Government of Japan generously provided the vessel and crew for the survey.

Recognising the tremendous effort and expense in conducting the IWC-POWER survey, the Committee was yet again disappointed that potentially valuable data on stock structure was not able to have been collected as it had not been possible to resolve CITES permit issues regarding collection of biopsy samples collected outside of Japanese waters. The Committee **strongly recommends** that these issues are resolved. In planning for the 2013 survey, Hiruma reported that some initial progress on this front was made, and would continue. He hoped to be able to report a positive outcome to ongoing talks between the governments of Japan and USA in the near future. Brownell explained that the Japanese research vessel with biopsy samples collected on the high seas can enter and exit the US EEZ without a CITES permit, but biopsy samples cannot yet be collected in the USA.

10.8.1.3 THE 2012 IWC-POWER CRUISE

SC/64/Rep 7 presented the report of the detailed planning meeting for the 2012 IWC-POWER cruise that had been endorsed last year (IWC, 2012l). The cruise will take place north of 40°N to the North American coast between 140°W and 135°W. The vessel kindly supplied by Japan will depart on 13 July 2012. The Committee **endorses** the report and looks forward to receiving the report of this cruise next year.

10.8.1.4 PLANS FOR THE 2013 IWC-POWER CRUISE

SC/64/O7 presented the research plan for the fourth survey in the IWC-POWER programme. The research area will be from the area from 160°-135°W, between 30°- 40 °N latitude. The plan was drawn up following guidelines agreed at the 2010 and 2011 Tokyo Planning Meetings (SC/63/Rep5 and SC/64/Rep1) and in light of the objectives developed in SC/64/Rep1. The cruise will collect line transect data, to estimate abundance, and biopsy/photo-id data. Biopsy sampling will be undertaken on priority species (sei, fin, right, blue and humpback whales) and on other species on an opportunistic basis. Some dedicated research time will also be allocated to photo-identification and/or video-taping of fin, right, blue and humpback whales. Final planning will take place at a planning workshop to be held in Tokyo in October 2012.

The Committee thanks the Government of Japan for its generous offer of providing a vessel for this survey.

10.8.2 Other North Pacific cruises (and see Item 6)

10.8.2.1 REPORT OF JAPANESE CETACEAN SIGHTING SURVEYS IN THE NORTH PACIFIC IN 2011

Three systematic dedicated cetacean sighting surveys were conducted in 2011 by Japan (ICR) as a part of JARPNII to examine the distribution and abundance of large whales in the Western North Pacific. The total searching distance was 4,060.3 n.miles. The sei whale was the main species sighted. The plans for these surveys were endorsed in the last year (IWC, 2012f) and the surveys were conducted as planned (SC/64/O6).

10.8.2.2 PLANS FOR JAPANESE CETACEAN SIGHTING SURVEYS IN THE NORTH PACIFIC IN 2012

SC/64/IA6 reports on plans for three systematic dedicated sighting surveys by Japan (ICR) as a part of JARPNII in the North Pacific in 2012, the first of which is currently underway. The main objective is to examine the distribution and estimate the abundance of common minke and Bryde's whales for the management and conservation purposes. Distance and angle estimation experiments will be conducted on all cruises. Biopsy skin samples of blue, fin, humpback and right whales will be collected on an opportunistic basis. Photo-identification experiments on blue, right and humpback whales will be also conducted opportunistically. Reports of the three sighting surveys will be submitted to the 2013 Annual Meeting.

10.8.3 Cruises in the Antarctic Ocean

10.8.3.1 PROGRESS ON IDCR-SOWER CRUISES PUBLICATIONS

An intersessional email correspondence group (IWC, 2012s, Annex R) worked by correspondence and also met at this meeting. Its terms of reference were to consider:

- (a) updating the IWC website; and
- (b) creating a special volume of the Journal of Cetacean Research and Management.

Plans are already underway with respect to (a) including inclusion of photographs, video, acoustic recordings and links to key publications and reports. Pertaining to (b), the Group prepared a proposed outline for the volume, with suggested authors/lead persons for each topic identified (see Annex G).

The Committee endorses the approach proposed. It agrees to the appointment of Bannister to lead the creation of the commemorative volume. An Editorial Board was nominated and tasked with responsibility for the volume's preparation.

The Committee **agrees** that the work contributing to the volume would be greatly facilitated by the preparation of some standard sighting datasets (for species other

03/07/2012

than Antarctic minke whales). The Secretariat kindly agreed to prepare such datasets from DESS in collaboration with knowledgeable scientists.

10.8.3.2 REPORT OF THE 2011/12 CETACEAN SIGHTING SURVEY IN THE ANTARCTIC

Plans for a dedicated sighting survey in the Antarctic in the 2011/12 austral summer season were presented last year and subsequently endorsed by the Committee (IWC, 2012f). The research vessels *Yushin-Maru No 2* and *Yushin-Maru No 3* were to survey in Area III, Area IV and western part of Area V. The survey methods were to be the same as in IWC-SOWER surveys, and trackline design was improved to provide approximately uniform coverage probability. Furthermore, the planned sighting procedure was in accordance with the guidelines agreed by the Scientific Committee (IWC, 2012v). Unfortunately no research activity could be conducted due to external violent interference by an anti-whaling group (SC/64/IA8).

The Committee **expresses regret** that these actions had prevented the sighting survey from being conducted as reportedly planned. Following the cessation of the IDCR/SOWER programme in 2009, these surveys now provide the only dedicated cetacean sighting data in this region of the Southern Ocean that might be used for abundance estimation, and as such are extremely valuable to the work of the Scientific Committee.

10.8.3.3 PLANS FOR CETACEAN SIGHTING SURVEYS IN THE ANTARCTIC IN THE 2012/13 SEASON

A systematic two-vessel sighting survey for abundance estimation is planned in the Antarctic in the 2012/2013 season (SC/64/IA7) as part of JARPA II. The research area is south of 60°S in the Antarctic, in the eastern part of Area III, throughout Area IV and in the western part of Area V, between 35°E and 175°E from December 2012 to March 2013. Details of the cruise, which also incorporates biopsy sampling and photo-identification work are incorporated in Annex G, Item 6.5. The cruise report will be prepared by researchers and submitted to next year's annual meeting.

The Committee reviewed and endorses the plans for the proposed sightings survey. Noting the insight gained in SC/64/Rep4 on internally-estimated cue rates, it suggests that efforts be taken to ensure accurate times of sightings in IO mode, so that delayed and simultaneous duplicates could be more readily distinguished. The Committee **agrees** that this will be useful for estimating abundance from these data, and also invited any further suggestions for improved survey protocols from the developers of the methods described in SC/64/IA2 and SC/64/IA13, based on lessons learned in completing their analyses.

10.9 Progress towards an in-depth assessment of North Pacific sei whales

SC/64/IA11 presented an abundance estimate of North Pacific sei whales using data from the 2011 IWC-

POWER cruise. Standard line transect methodology was applied to estimate abundance, assuming $g(0)=1$. In order to examine the robustness of the abundance estimate to alternative stratification options and detection functions, a sensitivity analysis was conducted. The abundance estimate for the surveyed area in the eastern North Pacific (north of 40°N, south of Alaskan Peninsula, between 170°W and 150°W), was 6,587 (CV=0.420). When data from recent cruises become available, a revised abundance estimate for North Pacific sei whales will be presented using the IWC-POWER sighting data from the period 2010-2012.

The Committee also received the report of the inter-session working group that had been appointed last year to prepare for the assessment. The group saw no impediment to conducting the In-Depth Assessment (IDA) as planned in 2013. It is anticipated that analyses of sei whale sightings from the POWER surveys through 2012 will be available for the assessment. The IDA will not address the question of suitability of data for use in the RMP.

Work on the historical catch series has proceeded. Allison has received new data on Canadian historic catches that is being entered into the IWC database. The findings of a new analysis of Soviet North Pacific catch records are also being incorporated. Sei whale catches in the IWC database are higher than the true catches because protected species like fin and humpbacks were reported as sei whales.

The Committee was informed that Mizroch and Ohsumi have recently analysed a sample of Japanese coastal whaling log books, and found that the catches of sei and Bryde's whales are differentiated in the log books, while this is not the case in the IWC individual catch data base, although the total numbers agree. The Committee **recommends** that this work be extended, in collaboration with Allison, to cover the years for which the IWC and Japanese figures differ. The Committee also **recommends** that the Secretariat be requested to consolidate other historical catch series for this species, and together with the Working group, being collating all available information in order to complete this assessment.

The Committee **recommends** that the sei whale IDA proceed as planned at the 2013 Annual Meeting. An intersessional steering group was appointed to oversee preparations (Annex Q).

11. STOCK DEFINITION

This agenda item was established in 2000, when a Working Group was established (IWC, 2001c). This year, updated Terms of Reference were adopted by the Working Group to reflect the evolving needs of the Committee (Appendix 2, Annex I). Continuing its

original purpose, the Working Group will develop a reference glossary of stock related terms, to aid consistent definition of ‘stocks’ in a management context for the Committee (see 11.4). The Working Group will also continue to develop guidelines for preparation and analysis of genetic data within an IWC context (see 11.1), and software that evaluates the management utility of various population genetic analyses (see 11.3). A major change stems from the Committee’s request for the Working Group to discuss high-priority Committee papers related to population structure. The Working Group will now provide the Committee with feedback and recommendations concerning stock structure related methods and analyses used in those papers (see 11.2). The Report of the Working Group is given as Annex I.

11.1 Guidelines for DNA data quality and genetic analyses

Two sets of reference guidelines have been developed and endorsed by the Committee (IWC, 2009e) and form ‘living documents’ that can be updated as necessary. The first set addresses DNA validation and systematic quality control in genetic studies (SC/64/SD2). The second set provides guidelines for some of the more common types of statistical analyses of genetic data used in IWC contexts, and contains examples of management problems that are regularly faced by the Committee. Substantial progress on these latter guidelines was made during a small workshop in April, and this document will now be completed intersessionally (see Item 11.5). Both guidelines will also be published in the peer-reviewed literature.

11.2 Statistical and genetic issues related to stock definition

A number of stock related papers were discussed by the sub-group at the request of the following sub-committees and Working Groups: Revised Management Procedure (Annex D), Aboriginal Whaling Management Procedure (Annex E), Pre-Implementation Review of Western North Pacific Common Minke Whales (Annex D1), and Other Southern Hemisphere Whale Stocks (Annex H). Technical comments on these papers are given in Annex I.

Some general comments were made which are relevant to many papers submitted to the Scientific Committee. Firstly the Committee noted that uncertainty around point estimates is not always considered and urged that, where available, confidence intervals should always be reported in order that precision of estimates can be evaluated. Secondly, failure to reject a hypothesis, e.g. panmixia, is not equivalent to support for that hypothesis; strong statements of support should not be given to any null hypothesis that has not been rejected. Thirdly, there is often inconsistent treatment and interpretation of the genetic differentiation metric

‘FST’ amongst papers. Simplistic interpretations of this statistic should be avoided, such as conversion into migration rates, as these can misinform management scenarios.

The Committee **agrees** to compile results from past RMP trials of various species intersessionally, in order to try to identify where there were ‘tipping points’ in inter-population migration rates which made significant differences to trial outcomes, i.e. at what level does migration make a difference for each species? Such information may help to better define the parameter space over which inter-population migration rates are informative to management. This work will be presented at the 2013 Annual Meeting (see 11.5) and can be carried out in conjunction with projects being undertaken by the sub-committee on the RMP and the SWG on the AWMP (see Annexes D and E respectively).

11.3 Progress on the Testing of Spatial Structure Models (TOSSM)

The aim of TOSSM (IWC, 2007a) is to facilitate comparative performance testing of population structure methods intended for use in conservation planning. From an IWC perspective, the TOSSM software package allows evaluation of methods for detection of genetic structure, in terms of how well the methods can be used to set spatial boundaries for management. It is available for all to use and simulated datasets exist for three of the five stock-structure Archetypes previously proposed by the Committee (IWC, 2010c, p.51).

TOSSM is also a flexible simulation tool for investigating how certain observed genetic phenomena might arise among animals such as whales whose life histories are not well described by classical genetic theory. A practical example of this is provided by the Pacific Coast Feeding Group (PCFG) of eastern gray whales (see Annex E), which appears to be genetically different from the northern Aleutian feeding ground, yet also receives immigrants from it (which would be expected to influence observed genetic differentiation). Simulation testing of various immigration scenarios in the TOSSM framework was carried out in SC/64/AWMP4 (Annex E). The Committee welcomes this paper and noted its value in exploring the range of scenarios compatible with the observed differentiation, as it investigates a range of factors, including the degree and timing of isolation and effective population size of the PCFG. The results have informed the current *Implementation Review* of gray whales (Annex E, Item 2.2.2). Some longer term work items were suggested for this study: (1) to incorporate a minimum female calving interval into the most realistic (9-stage) life history model; (2) to report results using summary statistics that are as independent as possible (and therefore provide multiple checks on the similarity

between the simulations and the observed data); and (3) to identify research needs for future field surveys in order to improve current parameterisation of the models.

11.4 Terminology and unit-to-conserve

Defining and standardising the terminology used to discuss 'stock issues' remains a long standing objective of the Working Group, in order to help the Committee report on these issues according to a common reference of terms. A suite of definitions for Committee terms such as 'population', 'subpopulation', 'stock', 'sub-stock' and 'management unit' was provided in SC/64/SD3 as a first effort to build a 'living' glossary of stock related terms, with reference to past discussions within the Working Group and to terminology applied in other management contexts. This glossary will be developed intersessionally by members of the Committee, who will also try to come up with a series of agreed criteria for classifying population units by these terms, with reference to their usage in other management and conservation contexts (see Item 11.5).

11.5 Workplan

The Committee's view of the workplan for SD is given under Item 21.

12. ENVIRONMENTAL CONCERNS (E)

The Commission and the Scientific Committee have increasingly taken an interest in the possible environmental threats to cetaceans. In 1993, the Commission adopted resolutions on research on the environment and whale stocks and on the preservation of the marine environment (IWC, 1994a; 1994b). A number of resolutions on this topic have been passed subsequently (e.g. IWC, 1996; 1997a; 1998; 1999a; 1999b; 2001b). As a result, the Scientific Committee formalised its work on environmental threats in 1997 by establishing a standing working group that has met every year since then. Its report this year is given as Annex K.

12.1 State of the cetacean environment report (SOCER)

SOCER provides an annual update, requested by the Commission, on: (a) environmental matters that potentially affect cetaceans and (b) developments in cetacean populations/species that reflect environmental issues. It is tailored for a non-scientific audience. The 2012 SOCER (SC/64/E2) was restricted to the Indian Ocean as the regional focus, due in part to reduced funding. A primary source of information was the International Indian Ocean Cetacean Symposium, held in 2009 on the Maldives¹⁵. Overall, the awareness of environment-related threats to cetaceans is high in the region, but implementation and control measures are poor. However, this provides an opportunity to

introduce best practices, state-of-the-art procedures for critical issues such as fisheries interactions, ship strikes, whalewatching, and new, well-thought-out Marine Protected Areas.

During discussion, it was noted that marine research in the Indian Ocean region is focused in a few locations, despite having expanded over the past five years. Cetacean, or indeed environmental, research is scant or absent in many areas and there are few peer-reviewed reports from the region. The Committee was pleased to learn that the next issue of JCRM (published this month) contains 15 peer-reviewed papers from the Indian Ocean.

Highlighting specific issues in the region, there are clearly 'hotspots' in terms of pollution, fisheries by-catch and environmental degradation (e.g. Arabian Gulf). Reports of mass mortality events (152 small cetaceans in Iran in Sept 2007, spinner dolphins and striped dolphins in two events, and 200-250 pantropical spotted dolphins in Pakistan in March 2009) on the northern coast of the Indian Ocean are particularly concerning because these three species do not usually mass strand in these numbers and the latter event occurred the day after the commencement of a multinational naval exercise (AMAN 09) in Pakistan waters.

Next year the focus of the SOCER will be the Atlantic Ocean region and the SOCER editors request Committee members provide input, preferably in the form of pdf files, of papers published between 2011 and 2013.

12.2 Pollution

POLLUTION 2000+ is a long standing programme of the Committee. Three goals were identified at the IWC Intersessional POLLUTION 2000+ Phase II Workshop (IWC, 2011):

- (1) develop integrated modelling approaches and risk assessment framework for evaluating the cause and effect relationship between pollutant exposures and cetacean populations;
- (2) identify data needs and available datasets or case studies that would be appropriate for the models that are exposure driven, source driven or effects driven; and
- (3) develop a prioritisation framework to evaluate the broad number of environmental pollutants.

12.2.1 Update on POLLUTION 2000+ Phase II progress

At the intersessional POLLUTION 2000+ Phase II workshop held in 2010(IWC, 2011d), four objectives for the cetacean pollutant exposure and risk assessment modelling component were agreed: (1) improve the existing concentration-response function for PCB-related reproductive effects in cetaceans (completed in

¹⁵ www.mrc.gov.mv

2011); (2) derive additional concentration-response functions to address other endpoints (e.g., survival, fecundity) in relation to PCB exposure; (3) integrate improved concentration response components into a population risk model (individually-based model) for two case study species: bottlenose dolphin and humpback whale (completed in 2011); and (4) implement a concentration-response component for at least one additional contaminant of concern. The authors of SC/64/E5, funded by the IWC, investigated how contaminant-induced effects on immune function could be incorporated into the existing individual-based population framework constructed to assess the impact of polychlorinated biphenyls (PCBs) on cetacean populations (Objective 2).

By determining how the blubber PCB annual accumulation rates relate to concentrations in breeding females, comparisons with empirical data can be made and predictions about effects on various populations formulated. For example, based on the current blubber PCB concentrations determined in breeding females from two bottlenose dolphin populations in Sarasota Bay and St Joseph Bay, Florida, the model predicts that these populations would remain stable or increase slightly over the 50 –100 year timescales projected. Conversely, the bottlenose dolphin population in Brunswick, Georgia, where PCB levels in breeding females are 10 times higher, is predicted to decline over the same period without external population inputs through immigration.

In the future, impacts on other populations and species, such as humpback whales from the Gulf of Maine will be investigated (e.g., Hall *et al.*, 2011), as additional contaminant data for females become available. In addition, future developments of this model will include a sensitivity analysis; incorporation of a bioaccumulation model to estimate blubber concentrations for populations or species in which only levels in prey are known; and making the model available online with a user-friendly interface.

During discussion (Annex K), it was noted that body condition of cetaceans may have a significant effect on susceptibility to impacts from contaminant exposure. For example, body condition could affect immune function independently so when food is limited and animals are in poor condition this will further affect their ability to fight off pathogens. Furthermore, if PCBs are released from the blubber during periods of increased energy demand then more may be bioavailable. Although the current model does not account for body condition, the final phase of the project will incorporate a toxicokinetic model that will include body condition parameters, similar to an approach taken by Hickie *et al.* (1999).

The Committee **recognises** that cetaceans are exposed to a mixture of environmental contaminants. It **suggests**

that, if possible, mixtures of contaminants should be added to the model. Due to the extremely high levels of PCBs measured the bottlenose dolphins in Brunswick, Georgia, USA, the Committee **strongly recommends** the continued monitoring of this population. The Committee **commends** the authors for the most recent results from the IWC's POLLUTION 2000+ programme and **strongly supports** their continued work to develop the necessary tools for analyses of pollutant exposure risk to cetaceans.

12.2.2 Oil Spill Impacts

12.2.2.1 UPDATE ON RESPONSE TO DEEPWATER HORIZON OIL SPILL IN THE GULF OF MEXICO

An update on the 2010 Deepwater Horizon (DWH) oil spill in the Gulf of Mexico was provided, where the injury assessment for cetaceans continues. The Natural Resource Damage Assessment (NRDA), a formal process in the USA to assess damages to natural resources, has included photo-identification, remote biopsy, live capture health assessments, and evaluation of stranding data for common bottlenose dolphins in nearshore waters. Analyses of tissue, blood, and urine samples from cetaceans in the Gulf of Mexico for PAHs and PAH metabolites have also continued, as outlined in the NRDA plans.¹⁶

In addition to the NRDA, an Unusual Mortality Event (UME) is ongoing in the northern Gulf of Mexico principally involving bottlenose dolphins¹⁷. The UME involved 745 cetacean strandings in the Northern Gulf of Mexico from 1 February 2010–10 June 2012, which started before the DWH oil spill. The historical average (2002–2009) for this area is 74 dolphins per year. The vast majority (95%) of stranded dolphins have been found dead; however, 35 stranded alive and seven were taken to facilities for rehabilitation. The UME is still ongoing, however stranding rates in the Northern Gulf in April and May 2012 were near-average.

Although it is typical to see strandings of dolphins less than 115cm (perinates) in the spring, there was a marked increase in strandings of this age class in spring 2011. Of these perinatal dolphin strandings, most were found to have died *in utero*. Twelve of 51 cases targeted for testing were positive for *Brucella*, and 8 cases were confirmed to have died of brucellosis. Compared to 2011, the number of stranded perinatal dolphins was lower during the spring of 2012. Three additional cetacean studies related to the DWH spill are underway in the Gulf of Mexico, including two passive acoustic surveys and one tagging study of sperm whales.

¹⁶ <http://www.gulfspillrestoration.noaa.gov> .

¹⁷ http://www.nmfs.noaa.gov/pr/health/mmume/cetacean_gulfofmexico2010.htm

The Committee **commends** this research related to the DWH oil spill and **strongly recommends** continued investigations into the impacts of the DWH oil spill on cetaceans, including exposure to oil spill related contaminants, biomarker investigations and health assessments. Furthermore, it **encourages** the early and full reporting of the findings of DWH studies into the public domain.

12.2.2.2 CAPACITY BUILDING REGARDING OIL SPILL IMPACTS ON CETACEANS

In 2011, the Committee agreed that there was significant need and interest in cross-training between the oil spill and marine mammal communities and it has established an intersessional e-mail group to evaluate the possibilities for such training (IWC, 2012o). As part of an effort to better understand and be prepared for oil spills and their impacts on marine mammals particularly cetaceans, workshops and planning exercises are underway or have taken place including: (1) an oil spill response workshop held at the International Conference on Marine Mammal Protected Areas (ICMMPA)¹⁸ and (2) dissemination of information and data on marine mammals at international meetings on oil spill response or with oil spill responders.

The ICMMPA workshop included presentations from the Regional Marine Pollution Emergency Information and Training Centre (REMPEITC) in the Wider Caribbean Region and the Oiled Wildlife Care Network, industry, oil spill responders, and marine mammal scientists and managers. A number of recommendations developed at the workshop were reviewed and found similar in nature to those discussed last year (IWC, 2012o), in particular the desirability of companies, agencies, stakeholders and international organisations to work in cooperation with marine mammal specialists on oil spill response plans.

In discussion, the Committee noted that some response plans that are currently under development, especially those related to the Arctic, focus on identifying sensitive areas for marine mammals. However, in most areas, important baseline data are lacking and the Committee **recommends** that these data gaps be filled. It also **recommends** that oil spill response efforts throughout the world should include pelagic as well as coastal areas; further information on current capacities and mechanisms of oil spill recovery will be valuable. Last year, the Committee noted that a review of the capacity for oil spill response in the Arctic was an urgent priority in the aftermath of the DWH oil spill (IWC, 2012o). The Committee **agrees** that the recommendations from the 2011 MMPA workshop in Martinique will provide guidance on oil spill prevention and response in the Arctic at the upcoming

intersessional Arctic Anthropogenic Impacts Workshop (see Item 12.5.3).

12.2.3 Other pollution related issues

Fossi provided information on Mediterranean odontocetes exposed to environmental stressors, in particular to persistent organic pollutants, emerging contaminants, polycyclic aromatic hydrocarbons and trace elements. In Panti et al. (2011), the response of 'gene expression biomarkers' was evaluated in Mediterranean striped dolphin in three sampling areas: the Pelagos Sanctuary (Ligurian Sea), the Ionian Sea, and the Strait of Gibraltar. The mRNA levels of five putative biomarker genes were measured for the first time by quantitative real-time PCR in cetacean skin biopsies. Striped dolphins from the Pelagos Sanctuary are more exposed to ecotoxicological hazard than those inhabiting the Ionian Sea and the Strait of Gibraltar. This evidence focuses attention on the potential risk to cetaceans inhabiting the largest pelagic MPA in Europe and the Committee **stresses** the importance of effective and long-term management of MPAs in order to preserve species in their habitats.

The sources of these contaminants in the study areas are unknown. The Committee **recommends** that the sources be identified, particularly for animals within the Pelagos Sanctuary, to enable the development and implementation of mitigation measures.

In 2005, the Conservation Committee agreed that a research program to address the issue of inedible 'stinky' gray whales caught by the Chukotkan aboriginal subsistence hunters should be established (IWC, 2006a). This year, the Committee examined IWC/64/CC10, which presented information on the various chemical compounds measured in tissues of malodorous ('stinky') and clean gray whales collected from 2005 through 2011. These included polycyclic aromatic hydrocarbons (PAHs), persistent organochlorines, benzene derivatives and chlorinated PAHs. The authors commented that the odorous carbonyl compounds measured in tissues of 'stinky' whales may be a result of slow metabolism of petroleum hydrocarbons that occur in the Pacific Ocean. They also noted concentrations of persistent organochlorines in the gray whale tissues were low or not detected (DDT).

It was noted (Annex F) that the finding of non-detectable DDTs is in contrast to the finding of measurable DDT levels in gray whale calves and mothers sampled in the lagoons in the Baja California region reported in SC/64/E4. Differences in DDT levels among these gray whales are most likely due to differences in contaminant levels on their feeding grounds although levels are generally low. The Committee **emphasises** that a clearer indication of which samples were 'stinky' and which samples were controls would make the information provided easier to

¹⁸ <http://second.icmmpa.org>

interpret. Due to the lack of clarity in this regard (SC/64/CC10), no new conclusions could be drawn regarding 'stinky' gray whales. The Committee **reiterates** its previous **recommendations** (e.g. IWC, 2006c; 2007e; 2008f; IWC, 2009f) that further efforts be made to determine the cause of the 'stinky whale' condition.

12.3 CERD (Cetacean Emerging and Resurging Disease)

In 2007, the Committee recognised the need for increased research and standardised reporting in a wide range of disciplines dealing with cetacean health (IWC, 2008f), which led to the creation of the Cetacean Resurging and Emerging Disease (CERD) Working Group.

12.3.1 Update from CERD Working Group

An update to the CERD Work Plan agreed last year (IWC, 2012p) was presented. This workplan included: (i) identification of regional and national experts/points of contact via Steering Committee membership; (ii) creation of a listserve and a website; (iii) creation of a Framework Document; and (iv) identification of and contact with organizations synergistic with the goals of CERD. The CERD working group (WG) made significant progress on all tasks, except on the Framework Document, where work is now underway to better define the long-term vision and goals for the CERD working group.

12.3.2 Progress on CERD Website

The CERD website is being developed in two phases. The first phase focuses on large cetacean species and relies on a 'consultation and sharing' approach. The second phase is intended to include all cetacean species and incorporate a potential 'reporting' role. This website will have 'public' and 'registered user' levels. The public level will provide basic information on diseases in cetaceans, as well as access to selected discussion forum content. Registered users will have full access to the site, including in-depth information on cetacean disease, as well as to discussion forums and posting ability. On the main page, a 'map it' feature will allow registered users to record geographic locations of disease incidents, while a 'current events' header will alert website visitors to recent events in cetacean disease and facilitate international communication. Links will be provided for quick access to discussion boards that can be shared with groups focused on other topics such as pollution, ship strikes and marine debris.

It was noted that researchers examining photographs on the website may be able to distinguish between wounds from entanglements, ship strikes or marine debris and this discussion underlined the overlap among these areas. The Committee **agrees** that it will be useful to incorporate standardised tissue collection protocols on the CERD website. The Committee thanked the CERD

WG and the Secretariat for their efforts on developing the website and **encourages** continued development of this tool.

12.3.3 Other disease related issues

SC/64/E1 presented the results of a study of six *Morbillivirus*-infected cetaceans stranded along the Italian coastline between 2009 and 2011. The authors concluded that: (1) *Morbillivirus* infection continues to represent a major threat to cetacean health and conservation in the Mediterranean Sea with an increasingly expanding 'host range' of the virus; and (2) the cases of morbilliviral infection characterized by an apparently exclusive involvement of the animal's brain tissues are a matter of concern, both from the conservation and from the comparative pathology standpoints, thereby underscoring the role of cetaceans as models for the study of their human neurological disease counterparts.

Discussion (Annex K) focused on the types of tests and assays performed on these animals and the need for increased surveillance for neurologic diseases in cetaceans. The Committee welcomed this study and **encourages** further studies on these pathogens in cetaceans.

The Committee also noted that there was worldwide press coverage over the recent (February - May) unusual mortality event (UME) of about 900 dead long-beaked common dolphins, *Delphinus capensis*, in Peru, but based on these press reports there remains considerable uncertainty about the cause of this UME. However, no scientific reports were available on this UME for the SC to review, but the SC looks forward to receiving reports on the UME next year.

In SC/64/E4 preliminary results were presented on contaminant levels (Organochlorine Compounds - OCs,) and biomarkers from biopsies in the San Ignacio Lagoon (Mexico). These preliminary data reveal an accumulation of OCs in gray whale calves resulting from the lactational transfer of these compounds from their mothers. Exposure to OCs (such as DDTs) at early life stages may have toxic impacts on their developing endocrine, immune and neural systems. The paper was discussed fully in Annex K.

The Committee welcomed this paper, noting its relevance to the IWC's POLLUTION 2000+ programme and **encourages** continued studies.

SC/64/E8 provided a review of diseases and microorganisms, as well as the public health and conservation impacts from cetaceans that stranded in Costa Rica during 2004-2011. Humans and cetaceans affected by marine *Brucella* can develop severe disease such as neurobrucellosis and osteomyelitis, and the authors concluded that conservation policies should support research that investigates incidence,

prevalence, geographic distribution and host range of *Brucella* infection in cetaceans. The paper is discussed fully in Annex K.

The Committee **welcomes** this paper, noting that data obtained from studies such as this are part of 'The One Health' concept - a worldwide strategy for expanding interdisciplinary collaborations and communications in all aspects of health care for humans, animals and the environment¹⁹. The Committee recognised *Brucella* as an important zoonotic pathogen and **encourages** additional research on this disease agent.

12.4 Anthropogenic sound

In 2010, the Committee reviewed evidence of masking of cetacean calls from anthropogenic sound, with an emphasis on low-frequency sounds (< 1 kHz) from commercial shipping and airguns used during seismic surveys (IWC, 2011g). It had recommended that: (i) the masking potential of anthropogenic sources be quantified and acoustic measurements be standardised; and (ii) IWC member governments work to develop a quantitative approach for assessing cumulative impacts of anthropogenic sound on cetaceans.

12.4.1 Mitigation of effects of anthropogenic sound on cetaceans

US federal regulations require scientists and representatives of offshore industries to acquire incidental harassment authorizations for activities that may disturb marine mammals, but the potential impacts of sound are often considered on a project-by-project basis in isolation from one another. This precludes meaningful analysis of cumulative impacts from multiple sources. In response to consideration of offshore industrial activities in the Alaskan Arctic, Moore *et al.* (2012) proposed a three-step assessment framework based development of *acoustic habitats*, which constitute the aggregate sound field from multiple sources compiled at spatial and temporal scales consistent with the ecology of Arctic marine mammals. Assessment framework steps include: (i) the development of acoustic habitat maps depicting anticipated sound fields from multiple sources; (ii) an overlay of acoustic-habitat maps with marine mammal seasonal distribution and density maps to identify areas or periods of concern and data gaps; (iii) development of precautionary measures to protect marine mammals from potential impact and a prioritisation of data gaps and research needed to address those gaps.

In the US, the Cetaceans and Sound (CetSound) project is now working toward mapping products envisioned in the first two steps of this framework²⁰. The CetSound project consists of two working groups convened to develop mapping tools: the Underwater Sound-field Mapping (SoundMap) and the Cetacean Density and

Distribution Mapping (CetMap). The overarching objective of the SoundMap group is to create maps depicting the temporal, spatial, and spectral characteristics of both chronic (e.g., shipping) and episodic (e.g., seismic survey) underwater noise. The overarching objective of the CetMap group is to create regional cetacean density and distribution maps that are time- and species-specific, using survey data and models that estimate density using predictive environmental factors. To augment the more quantitative density mapping and provide additional context for impact analyses, the CetMap group is also identifying known areas of specific importance for cetaceans, such as reproductive areas, feeding areas, migratory corridors, and areas in which small or resident populations are concentrated. The Committee **commends** the initial development of these powerful mapping tools, **endorses** this work and **strongly recommends** support for further development and improvement of these tools.

The Committee also **welcomes** the information on work being undertaken regarding noise by IUCN's Western Gray Whale Advisory Group and especially its Noise Task Force²¹ (see Annex F, Appendix X).

12.4.2 Other anthropogenic sound related issues

Underwater noise from commercial shipping is chronic (IWC, 2011g). The IMO has established a correspondence group (CG) to develop non-mandatory guidelines to address noise from commercial ships; the IWC Secretariat participates in this group (IWC/64/4G). The IMO CG will finish the first draft of their report by the end of 2012 and it will be presented to the IMO in early 2013. The Committee **commends** the continued discussions between the IMO and IWC regarding efforts to reduce noise of newly built vessels. Further, it noted the importance of identifying ship acoustic signatures and **encourages** the collection of these data, as well as the coupling of this information with the appropriate automatic identification system data.

At past meetings, the Committee has received updates on the development of a modelling effort to determine the population consequences of acoustic disturbance (PCAD) on marine mammals initially proposed by the US National Research Council in 2005. In 2009, the US Office of Naval Research supported a Working Group whose objectives included building a formal mathematical structure for the framework, which led to key adaptations to the original framework, including the incorporation of other sources of disturbance, physiological change and the use of health as the primary metric through which changes in individuals can potentially impact the population. Combined, this led to the framework being renamed the population consequences of disturbance (PCoD). The SWG noted

¹⁹ <http://www.onehealthinitiative.com/index.php> and <http://www.oie.int/en/>

²⁰ <http://cetsound.noaa.gov/index.html>

²¹ http://www.iucn.org/wgwap/wgwap/task_forces/

that PCoD is a significant improvement on the PCAD model. Although the current model focuses on single stressors, accumulative effects, behavioural responses and other factors (e.g., acoustic masking) that could potentially affect health could also be added to the model. The SWG **strongly encourages** further work on this model and looks forward to progress updates.

12.5 Climate Change

12.5.1 Progress on recommendations from the 2nd Climate Change Workshop

At the 2nd Climate Change workshop (IWC, 2010i), three themes were recommended with regard to the study of cetaceans in the Arctic: (i) single species-regional contrast; (ii) trophic comparison; and (iii) distribution shift. With regard to the first theme, results of passive acoustic sampling in 2008-09 provided a means to compare seasonal patterns in call detection from bowhead whales in the B-C-B and Spitzbergen stocks, providing a contrast in seasonal occurrence for this species between the Atlantic and Pacific sectors of the High Arctic (Moore et al. 2012b). Details of this work are discussed in Annex K.

As also discussed in Annex K, an overview of a new programme was received which was called the Synthesis Of Arctic Research (SOAR). It is a US-based activity, which aims to bring together a multidisciplinary group of Arctic scientists and Alaskan coastal community representatives to explore and integrate information from completed and ongoing marine research in the Pacific Arctic sector²². While SOAR is not focussed specifically on cetaceans, eight projects under its auspices will focus on aspects of beluga and bowhead whale ecology, which are related to the three study themes of the 2nd Climate Change Workshop.

The Committee **welcomes** these updates on cetacean-related science in Arctic waters, **endorses** the work undertaken thus far and requests future updates.

12.5.2 Small cetacean restricted habitats Working Group

Building upon the work of an intersessional working group to further recommendations made at the IWC Climate Change Workshop on Small Cetaceans in 2010 (IWC, 2012u), the Committee **agrees** to the following definition:

The spatial extent of the range occupied by these populations may vary by orders of magnitude, but one or more of the following conditions apply: (i) the species/population has narrow habitat requirements; (ii) the habitat is bounded by physiographic or oceanographic barriers; and (iii) other suitable habitat which the population might be able to access is unavailable because it is occupied by competitors. The first two conditions might apply to fixed populations,

such as the vaquita - the third condition in particular requires further consideration and development. These conditions may also apply to populations of large whales (e.g. fin whales in the Mediterranean Sea and the Gulf of California) and it was agreed that large whales would be considered in future discussions on this topic.

The Committee **welcomes** this effort to further advance our understanding of the potential impacts of climate change in cetaceans. However, it also **urges** caution with regard to which populations and species should be focused upon with respect to climate change, so as not to detract from efforts to address more imminent threats and stressors such as bycatch. Creating a list of species or populations to which this definition might apply was suggested as one way to further develop the topic. The Committee also noted the importance of integrating and considering the findings of climate change-related analyses that have been conducted for other marine mammal species (e.g. polar bears and ice seals) when considering the issue for cetaceans.

12.5.3 Planning for intersessional Arctic Anthropogenic Impacts Workshop

In 2010, the Commission asked the Committee to develop an agenda for a workshop on Arctic Anthropogenic Impacts on Cetaceans (IWC, 2011a). Last year, a draft agenda was completed and a steering group formed (IWC, 2012q) to further develop a plan for the workshop. A revised agenda that focused on anthropogenic activities related to oil and gas exploration, commercial shipping and tourism was developed intersessionally. The Committee noted that the workshop agenda should be expanded to include consideration of other anthropogenic activities such as commercial fishing and scientific research. Given rapid environmental changes and increasing human activities in the Arctic, the Committee **encourages** the continued development of an Arctic Anthropogenic Impacts workshop focused on climate change, but **strongly recommends** that it:

- (1) carefully define the geographical area to be addressed;
- (2) focus only on Arctic cetacean species (i.e., bowhead whales, white whales, and narwhals);
- (3) consider a broad suite of anthropogenic activities; e.g., oil and gas development, commercial fishing, commercial shipping, tourism, continental shelf mapping and scientific studies;
- (4) specifically include possible impacts from underwater sounds, spilled oil, dispersants, invasive species and discharges (including dumping of ballast water) related to exploratory drilling and shipping;
- (5) include a discussion about assessing the cumulative and synergistic impacts of anthropogenic activities.

²² <http://www.arctic.noaa.gov/soar/>

The topic of anthropogenic impacts to cetaceans in the Arctic is broad and complex and the Committee **recommends** that the process should involve an initial scientific workshop followed by a more inclusive Commission meeting that addresses management and policy aspects of Arctic Anthropogenic Impacts on Cetaceans. It is anticipated that final specification for the scope, agenda and schedule for the workshop will be undertaken jointly by the workshop steering group and representatives of the IWC and Secretariat.

12.5.4 Other climate change related issues

The IMO is working to develop a mandatory Polar Code to manage the increases in ship traffic in Arctic and Antarctic waters anticipated with the reduction of sea ice associated with climate change (IWC/64/4). The Polar Code work is coordinated by the sub-committee on Ship Design and Equipment, as is the work regarding ship quieting (see item 9.2). The IWC's endorsement of noise reduction goals (i.e., 3dB in 10 years; 10 dB in 30 years) advanced at an international workshop on shipping noise and marine mammals (Wright and Okeanos Foundation for the Sea, 2008) were re-iterated in a document entitled *Status on Implementation of the Arctic Marine Shipping Assessment 2009 Report Recommendations*, available on the Arctic Council website²³. The Committee **welcomes** this information, **reiterates its endorsement** of noise reduction goals and looks forward to continued collaborations between the IWC and the IMO on this topic.

12.6 Interactions between MREDs and cetaceans

Given information and a review provided last year, the Committee had endorsed a proposal for a workshop on interactions between marine renewable developments (MREDs) and cetaceans.

That workshop was held immediately prior to the present Annual Meeting and its report, 'Marine Renewable Developments and Cetaceans Worldwide' is given as SC/64/Rep6.

Simmonds presented the report and noted that a variety of MREDs are now being deployed worldwide, with the highest concentrations in the Northern Hemisphere, especially in northern Europe. The three main forms of MREDs at this time are: (i) wind farms; (ii) tidal-stream driven devices; and (iii) wave energy converters. Each of these, as well as their supporting infrastructure, has the potential for interaction with cetaceans during the construction, operation and decommissioning phases (Simmonds *et al.*, 2010).

The workshop received detailed reports on the current state of development and management of marine renewable energy in waters of Germany, the United Kingdom, Belgium and the USA, including trans-

boundary issues now arising in the busy waters of Europe (SC/64/Rep 6, fig. 1). The workshop focused on the three main types of MREDs; and considered potential impact to cetaceans on aspects of 'supporting infrastructure' for MREDs. A number of papers and websites informed discussions throughout the workshop (Rep 7 Appendix 2); of particular use was a special synthesis of the work on MREDs conducted by ICES (Murphy *et al.*, 2012).

The Committee noted that MREDs may well play a major role in the mitigation of climate change, which may profoundly affect cetacean populations as discussed at prior climate change workshops (IWC, 1997b; 2010i). The Committee thanked Simmonds for the successful Workshop. In particular it **endorses** the Workshop's conclusions and recommendations (see especially SC/64/Rep6, item 5). These are briefly summarised below.

1. Strategy to minimise risk

Risks from both lethal and sub-lethal effects can be minimised via a series of actions: the collection, collation and analysis of appropriate baseline cetacean data and appropriate industrial data will allow the identification and quantification of threats and their potential implications for conservation objectives. All stakeholders need to be involved from the outset such that impacts from all factors are considered, ensuring that appropriate mitigation measures and associated monitoring programmes are developed. Suitable scientific evaluation and compliance mechanisms are needed to ensure that mitigation and monitoring are adequate.

2. Broad management

Governments, managers and other stakeholders need to co-operate in strategic planning for MREDs taking into account the trans-boundary nature of cetaceans. Uncertainties over the level of impacts require a staged approach to developments taking into account lessons learned from other developments and other human activities that affect cetaceans, in order to be adequately precautionary. IWC member governments can assist in encouraging the development of international collaboration in this regard, and in particular, they can assist in emphasising the importance of incorporating consideration of cetaceans from an early stage and the value of following the broad strategy and principles outlined in the Workshop report and summarised in Fig. 3.

3. 'Fundamental' research

International collaboration will be required to determine population structure, status, distribution and procedures for assessing impacts. The Committee can assist with design and evaluation of population and impact assessments. While there are established methods for assessing lethal takes, data on the effects of (sub-lethal) stressors on cetaceans are also needed.

²³ <http://arcticcouncil.gov/pame/amsa/>

4. Evaluation of threats

All lethal and non-lethal impacts of human activities should be considered in an integrated manner, e.g.

using modelling approaches that take into account the cumulative impacts from all threats when evaluating whether conservation objectives are likely to be met.

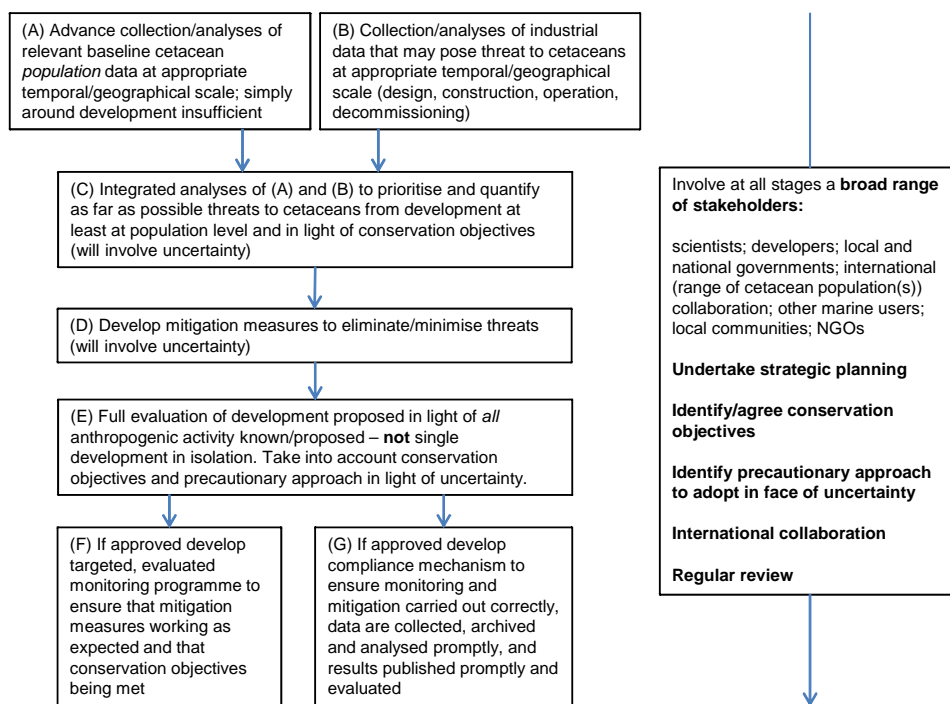

Fig. 3. Simplified schematic summary of a general strategy and principles to minimise environmental threats posed by MREDs. Some stages will occur in parallel and will involve feedback. See report for details

The Committee has considerable expertise in developing management frameworks and testing their performance against specified objectives.

5. Monitoring

Monitoring should be designed carefully, to assess impacts against pre-determined conservation objectives and to measure the efficacy of any mitigation measures that are implemented.

6. Data sharing and the future role of the IWC Scientific Committee in the consideration of MREDs

Improved information and data-sharing were identified as key and the Workshop encouraged the Committee to continue to act as a forum to review the development of MREDs and their implications for cetaceans, including promoting the sharing of data. Countries were encouraged to help in this by providing appropriate information.

In addition to the workshop report, the Committee received information from two papers on the topic of interactions between cetaceans and MREDs focused on waters offshore Scotland (SC/64/E3) and a preliminary assessment of the effectiveness of small Marine Protected Areas (MPAs) to protect dolphins offshore

Wales (SC/64/E6). It also received an update on Chilean renewable energy projects (SC/64/E12) and noted that consideration should be given on the impacts of coastal wind farms, particularly in regions that support critical habitats for cetaceans. The Committee strongly **recommends** urgent development of environmental impact studies in this area of Chile and urges that a precautionary approach should be used with regard to critical cetacean habitats.

The Committee also **agrees** that there is an urgent need to develop or improve effective noise mitigation measures or quieter foundation installation methods, as noted in past reviews of anthropogenic sound (e.g. IWC, 2010f; IWC, 2012o).

12.7 Other habitat related issues

Primary papers submitted on topics related to other habitat related issues, included potential impacts of marine debris, cumulative impacts and results of a large-scale aerial survey programme in the French tropical EEZ.

12.7.1 *Cetaceans and marine debris*

In addition to receiving five papers on the topic of marine debris (SC/64/E7, E10, E13, E15, FI 10), the SWG received the results from an intersessional working group (Debris WG) that had considered the issue of both ingestion and entanglement of cetaceans in marine debris. The intersessional group offered the following conclusions and recommendations:

- (1) Marine debris is a growing concern for marine wildlife in general, but its interactions with cetaceans are poorly understood.
- (2) To better evaluate the potential impacts of marine debris on cetaceans and to provide a forum where relevant data can be submitted, a workshop on marine debris and cetaceans should be convened.
- (3) The primary aim of this workshop would be to determine how to best investigate quantitatively the ways in which marine debris is affecting cetaceans and how best to monitor and mitigate for these effects. The workshop could also consider how best to develop a centralised database to collate cases of debris interactions, including the development of standardised criteria for data to allow more certain identification of the types of debris and the interactions involved.

Two key issues fundamental to assessing impact of marine debris on cetaceans were identified: (1) how to distinguish cetaceans that have died in active fishing gear versus those entangled in debris (including abandoned, lost, discarded - or 'ghost' -fishing gear) and the need to identify the 'worst culprit' types of fishing gear causing entanglement; and (2) how to investigate the potential accumulation of debris in the deep sea feeding areas of beaked and sperm whales. In addition, more effort is needed to investigate the impacts of microplastics on cetaceans, including baleen whales, which potentially ingest micro-litter by filtrating feeding (see Fossi *et al.*, 2012).

The Committee **recommends** that a workshop on marine debris and cetaceans be held (Annex K, Appendix 3) noting also its relevance to the Working Group on Bycatch with regard to entanglement issues (see Item 7.8). A number of potential data sources for data on marine debris were identified including those of international bodies such as CCAMLR and well as national and local bodies in several countries. SC/64/Rep1 noted the work being undertaken in by the USA, Korea and Japan and the Steering Group for the IWC-POWER cruises who are investigating how those cruises can contribute to international efforts to gather information on marine debris (see also Annex G).

12.7.2 *Issues related to the March 2011 tsunami in the NW Pacific*

Concerns have been raised with regard to increased marine debris transport to the eastern Pacific Ocean, as well as radioactive contamination of marine debris a

result of the 2011 tsunami in Japan. Modelling efforts estimate that the bulk of the debris related to this event is probably dispersed north of the Main Hawaiian Islands and east of Midway Atoll.²⁴ Furthermore, as predicted by these modelling efforts, some buoyant debris reached the east Pacific coast from Oregon to Alaska during winter 2011-2012 and continues to occur in the region. It is highly unlikely that debris transported from Japan to the eastern North Pacific poses a radioactive risk. However, transport of non-native, invasive species or pathogenic microorganisms on tsunami-released debris could occur and pose a threat to eastern Pacific coastal ecosystems. Details of potential impacts of the tsunami released marine debris on marine mammals and the potential increase in either ingested marine debris or risk of entanglement are summarised in Annex K. Discussion of some Japanese work related to the effects of the tsunami on the marine ecosystem also occurs under Item 17.

12.7.3 *Cumulative impacts of anthropogenic activities*

SC/64/E11 reported on cumulative impacts of several anthropogenic activities on cetaceans. While there are a number of quantitative processes for assessing the combined impacts of multiple stressors being developed, some are active and used in management. For example, five actions to mitigate cumulative impacts were developed during the permit cycle of the Greenland Bureau of Minerals and Petroleum for the mitigation of cetacean exposures to disturbance from seismic surveys, as given in Annex K.

The Committee **welcomes** information on efforts to develop effective tools to address concerns regarding cumulative impacts of anthropogenic activities on cetaceans. It was noted that the effects of climate change on marine ecosystems may compound the cumulative impacts of anthropogenic stressors, such as chemical pollutants and noise.

12.7.4 *REMMOA aerial surveys in the French EEZ*

The Committee received an update of the REMMOA project (Mannocci *et al.*, ; SC64/E14), aimed at providing maps of hot spots for pelagic megafauna in the French tropical EEZ and some EEZ of neighbouring countries. The long-term objective of the REMMOA surveys are to establish a baseline of information on cetaceans and other pelagic megafauna diversity and relative abundance and to build up a monitoring strategy to be implemented in the future. Mannocci *et al.* () present analyses of the Caribbean-Guiana survey where the aim of the study was to document top predator communities in terms of encounter rates, composition, abundance and spatial distribution and to compare them between these two contrasting ecosystems. SC/64/E14 presented the analysis of the southwest Indian Ocean survey with a focus on comparing cetacean and other pelagic

²⁴ <http://marinedebris.noaa.gov/info/japanfaqs.html>

megafauna communities in areas characterized by contrasted oceanographic conditions. The Committee **welcomes** these updates and **encourages** the results of their work to be presented next year.

12.8 Work plan

The Committee expressed its great appreciation to Moore for her superb guidance and chairing of the SWG over the 5-year period of her service as Chair.

The Committee discussions of the Workplan developed in Annex K is given under Item 23.

13. ECOSYSTEM MODELLING

The Ecosystem Modelling Working Group was first convened in 2007 (IWC, 2008e). It is tasked with informing the Committee on relevant aspects of the nature and extent of the ecological relationships between whales and the ecosystems in which they live. This advice is important to a number of other responsibilities of the Committee and the Commission has stated their interest in such work in a number of resolutions (IWC, 1999a; 2001b; 2002).

The Working Group's topics to address at this year's meeting were:

- (1) review of ecosystem modelling efforts undertaken outside the IWC;
- (2) explore how ecosystem models contribute to developing scenarios for simulation testing of the RMP; and
- (3) review of other issues relevant to ecosystem modeling within the Committee

The report of the Working Group on Ecosystem Modelling is given as Annex K1.

13.1 Review of ecosystem modelling efforts undertaken outside the IWC

13.1.1 Ecosystem modelling in the context of ecosystem-based fisheries management

SC/64/EM1 outlined several ecological questions relevant to whale populations that can be addressed by ecosystem models. These included: What species and fisheries can potentially compete with whale feeding? How would one evaluate the potential magnitude of such competition? What are the potential, indirect food web effects on whales? What are the ecosystem tradeoffs that most warrant evaluation? What are the best scenarios (to model) to mitigate any of these concerns? How well do such (simulated) scenarios perform? The author also provided a review of the major classes of ecosystem model being employed globally in an ecosystem-based management context, provided a map of ecosystem models as they relate to these and similar questions, and described how global best practices are being adopted in the use of these ecosystem models. A key message was that the choice of model depends strongly on the questions being

addressed. It is probably better to start with the simple multi-species models (with few components) or extended single-species models. The more complex multi-species models, food-web models or whole-system models are more suited to addressing broader questions.

SC/64/EM2 reported on efforts to place initial quantitative bounds on consumption estimates for a suite of marine mammals in the Northeast US Large Marine Ecosystem, including baleen whales, odontocetes and seals. Daily individual consumption rates were compiled from the literature and explored with sensitivity analyses to derive feasible ranges for each species which then could be raised to annual population-level consumption based on existing population abundance estimates. The results indicated that marine mammal consumption in this region might be similar in magnitude to commercial fishery landings for small pelagic and groundfish prey groups, although previous studies have indicated that targeted sizes may differ. Marine mammals probably consume as much prey as finfish predators, thus meriting continued evaluation despite the inherently wide confidence intervals of their consumption estimates.

The Committee **welcomes** this information, noting that with the move toward ecosystem-based management, consumption by marine mammals warrants inclusion as a source of natural mortality in assessments of mammal prey stocks. It also noted that reference points for marine mammal management, such as Optimum Sustainable Production, had yet to be suitably defined in a multi-species context.

13.1.2 Ecosystem models of the effect on predators of fishing forage fish

Recent studies (Cury *et al.*, 2008; Fulton *et al.*, 2011; Pikitch *et al.*, 2012) have addressed the effects of exploitation of forage fish on their predators in several ecosystems, indicating that fishing of forage fish down to their MSY level can have major impacts on predators, including birds and marine mammals. In view of the importance of this issue to cetaceans, the Committee **agrees** that this should be a priority topic for next year.

13.1.3 Status update on NAMMCO ecosystem modelling

At last year's meeting, the Committee received an update on NAMMCO's initiative to implement a series of ecosystem modelling exercises in the Barents Sea and the waters around Iceland. This year, the Committee was informed that the efforts have been delayed due to a lack of funding. However, the Committee remains interested in receiving information on these exercises as it becomes available.

13.2 Explore how ecosystem models contribute to developing scenarios for simulation testing of the RMP

Recent discussions in the sub-committee on the RMP (e.g. IWC, 2011e) on variation of r and K values in the face of environmental variability has shown that it can be useful to try to model the effects of food availability more explicitly, because this can have implications for the effects of prey abundance on whale population dynamics. The Committee **emphasises** the value of implementing this in small steps rather than going immediately to complex models and **agrees** that consideration of simple models of whales and prey should be a priority issue for next year.

13.3 Review of other issues relevant to ecosystem modelling within the committee

13.3.1 Update on Antarctic minke whale body condition analyses

Last year, the Committee discussed issues regarding the statistical significance of a decline (of about 0.2mm per year) in mean blubber thickness of Antarctic minke whales over the 18-year JARPA period reported by Konishi *et al.* (2008). The issues had been raised by De La Mare (2011), who found that the methods used by (Konishi *et al.*, 2008) could result in spurious apparent significance of trends because the nature of the sampling process and the associated components of the variance structure of the data were not taken into account. A reanalysis of the data at last year's meeting by Skaug (2012) using mixed-effect regression models to account for some of the additional variance structure resulted in a much higher variance of the estimated trend, but the point estimate changed little, and the estimated trend was still significant. Given the relevance of body condition indices to its work, the Committee agreed that further analysis of the data was warranted to determine: (i) whether the models fitted so far captured all the main features of the data; and (ii) whether the estimate of trend (whose confidence limits using the best fitting model ranged from near zero to values that could be of appreciable biological significance) could be made more precise. The Committee requested, *inter alia*, results from analysing the two sexes separately and the inclusion of slopes by latitudinal band as a random effect. It also suggested that the authors of De La Mare (2011) and of Konishi *et al.* (2008), apply for access to the data under Procedure B of the Data Availability Agreement, so that further analyses of these data could be reviewed by the Committee this year.

This year, de la Mare reported that he had applied for access to data through the Data Access Group but that a mutually satisfactory agreement was not reached. The generic data access questions raised in this case is discussed under Item 24. Pastene noted that Japan had offered to make available all data that had been requested by the Committee last year under the

conditions of Procedure B (see Attachment B of SC/64/SCP1). De la Mare responded that conditions attached to the offer were in his opinion not in accordance with Data Access Agreement Protocol B and so was unacceptable.

In SC/64/EM3, he also presented an analysis of sex ratio and female length at 50% maturity using the JARPA data available in the IWC's catch database that showed unlikely trends and much higher levels of variability than would be expected in these parameters from a biological population. He noted that this indicated the presence of 'lurking variables' that had important effects on the dependent variable but that were not included in the predictor variables under consideration. Similar adverse effects could be present in the analyses of body condition described above, with possible sources of unaccounted variance including inter-annual variability in the locations and dates on which whales were taken, the spatial distributions of one or more biological populations and the co-effects of seasonality by sex and reproductive state. Using a statistical simulation of catches along random transects, SC/64/EM3 further showed that standard errors calculated using individual animals as the sample size underestimates the true variability because of spatial/temporal pseudo-replication, and that transects are the basic sampling units, not the individual catches.

There was considerable discussion of SC/64/EM3 and the implications for inferences on biological parameters derived from JARPA data. Some members emphasised that failing to estimate the variance associated with random transect placement means that the variances in the analyses of biological parameters will be underestimated such that hypothesis tests will be invalid. They further noted that the reported catch locations in the IWC database show that clearly identifiable transects that can be treated as replicates have not been realised and where transects are identifiable they have not been traversed in random time order. Consequently these members considered that the conditions for the appropriate analysis of the data have not been met.

Other members considered that non-independence can be accounted for by using jack-knife methods, as was done during last year's meeting with the blubber thickness data, using one year as the jack-knifing unit (IWC, 2012n). This approach showed that while the estimated SE increased from 0.0225 to 0.0836 on the regression slope (-0.213 mm/year), the slope estimate itself did not change and thus was still significantly different from zero at the 5% level. This jack-knife result should, according to these members, take care of concerns about dependence between observations. In addition, as mentioned above, mixed-effects models were also applied during last year's meeting to account for some of the additional variance structure resulting in a best model (based on the AIC criterion) with a

slope of -0.19 mm/year and SE = 0.07; (Skaug, 2012 pp. 259-62). In discussion, these members understood de la Mare to have claimed that these results did not take care of all possibilities for statistical dependence between whales (e.g. whales sampled on the same track line), but they considered it highly unlikely that such dependence could be so large as to destroy the findings of negative trends in blubber thickness, fat weight, girth or weight of stomach contents.

The Committee noted that valid conclusions can often be drawn from non-random samples as long as this is accounted for in the analysis. It further **recommends** that the authors of Konishi *et al.* (2008) investigate independence issues by using mixed-effects models with track line as a random effect to address the concerns raised above. These authors will consider carrying out such analyses before next year's meeting.

13.3.2 Other issues

A decline in energy storage in Antarctic minke whales over almost two decades (Konishi *et al.*, 2008) suggests that food availability may have been declining recently. To test this hypothesis, at this year's meeting Konishi presented a paper (Konishi *et al.*, in review) that examined whether there was any annual trend in the stomach contents of the whales using catch data from 20 seasons in JARPA and JARPA II (1990/91-2009/10). Results from linear mixed-effects analyses showed a 39% (95% CI 3.2-47.3%) decrease in the weight of stomach contents over the 20 years. A similar pattern was found in both males and females, except in the case of females sampled at higher latitude (particularly in the Ross Sea), suggesting a decrease in the availability of Antarctic krill for Antarctic minke whales in the lower latitudinal range of the JARPA/JARPA II research area. However, prey availability has not changed in the Ross Sea, where both Antarctic krill (*Euphausia superba*) and ice krill (*E. crystallorophias*) are available. The decrease in Antarctic krill availability could be due to environmental changes or to an increase in the abundance of other krill-feeding predators. The latter appears more likely, given the rapid recovery of the humpback whale in the area and the fact that humpback whales are not found in the Ross Sea, where no change in prey availability was observed for minke whales.

There was considerable discussion of this paper, focusing on two main areas:

- (1) statistical issues, similar in nature to those discussed above with respect to the blubber thickness analysis, in particular as to whether the analysis takes account of all components of variance and whether the statistical significance of the apparent trends is reliable; and
- (2) the biological issues associated with the relationship between stomach fullness and

food intake and between stomach fullness and prey availability.

With respect to the statistical issues, members repeated many of the points summarised above with respect to the blubber thickness analysis and made a number of suggestions regarding additional statistical treatment of the data (see Annex K1). The Committee **recommends** that these analyses be conducted if possible.

With respect to the biological issues, some members noted the importance of considering the stomach evacuation rate and its relationship to the timing of feeding. The strong decline in mean stomach contents over the day, as shown in the results, is indicative that most feeding is occurring at night. It is possible to envisage a situation where high food abundance would lead to whales being satiated relatively early in the night, such that by the next day the stomachs are not very full. Conversely, during periods of lower food abundance, feeding may be spread over a longer period, such that more food tends to be found in the stomach during the day. Thus, the direction of the relationship between food availability or intake and observed stomach content weight is not obvious *a priori*. In response, other members draw attention to information such as the negative trend in blubber thickness, which supported the lower food availability hypothesis. Data collected during JARPA on the freshness of food in the forestomach may provide further information on the timing of feeding, and the Committee **recommends** that these data be analysed.

The Committee **agrees** that for an understanding of the possible relationships between food intake and stomach fullness, analyses of the consequences of the diurnal patterns of food intake should be reported. Furthermore, alternative models for stomach evacuation (such as linear and exponential models) should be examined. The Committee **agrees** to keep the issue on the agenda for next year and encouraged submissions on this issue.

13.4 Review new information on ecosystem model skill assessment

No new information was available for discussion on this topic.

14. SMALL CETACEANS (SM)

The Committee has been discussing issues related to small cetaceans since the mid-1970s (IWC, 1976). Despite the differences of views over competency (IWC, 1993), the Commission has agreed that the Committee should continue to consider this item (IWC, 1995c).

14.1. Review status of ziphiids whales in the North Pacific and northern Indian Ocean

The last worldwide assessment on the status of ziphiids was in 1988 (IWC, 1989). Last year the Committee reviewed the status of ziphiids in the North Atlantic and adjacent waters (IWC, 2012, Annex L). At this meeting, the priority is to review the status of the ten beaked whale species in the North Pacific and Northern Indian Ocean (Table 1). Considerable information was submitted for the review and details can be found Annex L (see Table 1 for agenda items). Only a general overview is given here.

Table 1

Ziphiids in the the North Pacific and Northern Indian Ocean

Name	Distribution	Item in Annex L
Cuvier's (<i>Ziphius cavirostris</i>)	worldwide except polar waters	3.1
Blainville's (<i>Mesoplodon densirostris</i>)	tropical and warm-temperate waters worldwide	3.5
Baird's (<i>Berardius bairdii</i>)	cold-temperate waters of the North Pacific	3.2
Hubbs' (<i>Mesoplodon carlhubbsi</i>)	cold-temperate waters of the North Pacific	3.4
Stejneger's (<i>Mesoplodon stejnegeri</i>)	cold-temperate waters of the North Pacific	3.9
pygmy (<i>Mesoplodon peruvianus</i>)	mainly in the Eastern Tropical Pacific (ETP)	3.8
Perrin's (<i>Mesoplodon perrini</i>)	Poorly known – few California specimens	3.7
Ginkgo-toothed (<i>Mesoplodon ginkgodens</i>)	Poorly known - tropical and warm-temperate Indian and Pacific	3.6
Longman's (<i>Indopacetus pacificus</i>)	Poorly known - tropical and warm-temperate Indian and Pacific	3.3
Deraniyagala's (unidentified <i>Mesoplodon</i> taxon)	Poorly known - tropical and warm-temperate Indian and Pacific	3.10

SC/64/SM 21 analysed passive archival acoustic data from across the North Pacific. Species-specific frequency modulated (FM) echolocation pulses made by Baird's, Blainville's, Cuvier's, Longman's and Deraniyagala's beaked whales at Palmyra Atoll, have been recorded and described, with visual confirmation of species identity. The species-specific features appear to be consistent within all sequences labelled to signal type level, making possible the discrimination of species. It was agreed that Cross Seamount was a good site to identify ginkgo-toothed beaked whale call signatures.

The Committee **welcomes** the report on the spatio-temporal distribution of species-specific acoustic echolocation signals of beaked whales in the North Pacific. Future research using visual sightings with biopsies in conjunction with acoustic recordings will be necessary to link several species and signal types.

SC/64/SM11 provided estimates of abundance and trends for Baird's beaked whale, Cuvier's beaked whale and *Mesoplodon* spp. in the California Current from 1991-2008 using a Bayesian hierarchical modelling approach. The analysis indicated declining abundance for Cuvier's (2.9% per year) and *Mesoplodon* spp. (7.0% per year) in the study area but no evidence of a trend for Baird's beaked whales.

The Committee **agrees** that these results should be interpreted cautiously given the variability in ocean conditions in the region since the early 1990s. In the 1990s, both *M. stejnegeri* and *M. carlhubbsi* occurred as far south as San Diego, but since the late 1990s, previously rare warm-water ziphiids appear to have moved into the area which is thought to be near the northern end of their range. An analysis of the pattern of strandings of *Ziphius* along the US west coast might be informative for evaluating the apparent decline suggested in SC/64/SM11.

SC/64/SM13 summarised records of five documented ziphiid species in the EEZ of Costa Rica. There are only a few scattered records of all species except Cuvier's beaked whale, which is sighted relatively frequently, and *Mesoplodon* sp. A (almost certainly *M. peruvianus*), which could mean Costa Rican waters are a significant part of the range of this poorly known mesoplodont.

14.1.1. Cuvier's beaked whale (*Ziphius cavirostris*)

SC/64/SM34 reviewed current knowledge of Cuvier's beaked whale in the North Pacific and northern Indian Ocean. It occurs in deep waters worldwide and ranges from equatorial tropical to cold-temperate waters in the North Pacific, north to the Gulf of Alaska, along the Aleutian and Commander Islands in the Bering and Okhotsk Seas. It is commonly found where the steep continental slope occurs close to shore, such as around the Hawaiian Islands, San Clemente Island (California), Isla de Guadalupe (Mexico – see SC/64/SM18) and the Aleutian Islands.

Few estimates of density or abundance are available, primarily due to the rarity and difficulty of detecting and identifying beaked whales. In addition large-scale cetacean abundance surveys are often focused in areas such as continental shelf waters where beaked whales usually do not occur.

14.1.1.1. CONCLUSIONS AND OTHER CONSIDERATIONS OF STATUS

Cuvier's beaked whale is classified in the IUCN Red List as of Least Concern. Abundance estimates are available only for the Eastern Tropical Pacific, the Hawaii EEZ and the west coast of the USA (to 300 n.miles offshore). Numbers in the California Current appear to have declined in recent years. Some anthropogenic mortality is known from fisheries in waters off California and Japan and probably occurs elsewhere (e.g. in driftnet fisheries off Mexico). This

species is vulnerable to noise produced by naval sonar and seismic research. Research priority should be given to understanding population trends off California and studying population structure. The Committee **agrees** that there is no basis for revising the status of Cuvier's beaked whale at the species or population level at this time.

14.1.2. *Baird's beaked whale* (*Berardius bairdii*)

Reviews of published (and some unpublished) information on Baird's beaked whales in the North Pacific were provided in SC/64/SM 8 and by Brownell and Allen. Additional information on distribution and abundance was provided in SC/64/SM5, SM11 and SM21 and by Wade.

Baird's beaked whale is endemic to the cold temperate waters of the North Pacific. It appears to be more abundant in the western than the eastern part of the basin despite the long history of exploitation in the west and relatively little exploitation in the east.

SC/64/SM5 reported on a study of Baird's beaked whales at the Commander Islands in the western Bering Sea. Baird's beaked whales were found within about 12 km of the coast, and mostly on the continental slope at depths of 100-1000m (maximum depth at sighting about 3000m). A total of 78 individuals was identified. Photo-identification confirmed associations over several years and the authors suggested that Baird's beaked whales live in a fission-fusion society. Evidence of killer whale predation was provided. More than half of the whales had marks the authors attributed to fishing gear and 3/75 had scars of possible anthropogenic origin, one apparently from harpooning.

Wade provided information on Baird's beaked whale sightings ($n=25$) made during nine killer whale surveys in nearshore waters of the Aleutian Islands, between 2001 and 2010. Baird's beaked whales were seen on every survey, generally close to the continental shelf edge break, in deeper waters on the continental slope. The extent of predation by killer whales on beaked whales might be considerable and ongoing stable fatty acid analyses may elucidate the importance of beaked whales in their diet.

14.1.2.1. LIFE HISTORY PARAMETERS

There are considerable data on life history parameters obtained from carcasses of whales taken on the Chiba ground and processed at the Wadoura station in the 1975 and 1985-1987 summer seasons (Kasuya *et al.*, 1997). This information has been interpreted assuming annual deposition of tooth growth layers (Kasuya, 1977). Full details are given in Annex L, section 3.2.4.

14.1.2.2. ABUNDANCE AND TRENDS

Abundance estimates for Baird's beaked whales are given in Table 2 and section 3.2.5. of Annex L.

14.1.2.3. TAKES INCLUDING BYCATCH

Baird's beaked whales have been hunted by hand harpoon in Japan since around 1600 and by Norwegian type whaling since 1907. Kasuya (2011) reviewed published information on the Baird's beaked whale fishery in the Chiba Prefecture.

Recent catch statistics by Japanese small-type whaling are summarised in Annex L, Table 3. Official statistics since 1932, except 1943-1946, are given in Annex L Appendix 2. The reported statistics for the 1950s may be unreliable because of the likely inclusion of illegally caught and misreported sperm whales at Wadoura, Chiba between 1959 and 1974 (Kasuya, 2011). Similarly, illegal catches of sperm whales by small-type whalers in Ayukawa on the Pacific coast of northern Honshu (Kondo and Kasuya, 2002) may have been reported as Baird's beaked whales, thus contributing to the surprisingly high numbers of the latter reported in the catch statistics in the 1950s and 1960s. The reported annual take of Baird's beaked whales in Japan (mostly along the Pacific coast) ranged between 107 and 322 during the period 1950-1969 (3,896 animals in 20 years).

The number of catcher boats operating for Baird's beaked whales off Chiba has been regulated by the prefectural government since 1920. The government introduced a licensing system to the small-type whale fishery in 1947 to limit the total number of boats operating. A voluntary quota system was introduced for Baird's beaked whales in 1983. The initial quota of 40 has since been increased to 66 (Annex L, Table 3). In 1985, the Committee noted (IWC, 1986) that such a catch level represents about 1% of the estimated population size but was unable to determine whether this was sustainable. To investigate this question further it was agreed that studies on school structure would be desirable (IWC, 1986) - see above regarding the study in the Commander Islands. The Government of Japan has increased the quota several times and whaling operations have expanded since the late 1990s into the Sea of Japan (Appendix 1 and Tables 3 in Annex L).

In the eastern Pacific, small numbers of Baird's beaked whales were taken by whaling stations in California (15) and British Columbia (29) between 1956 and 1970 (Rice, 1974).

Five cases of stranded Baird's beaked whales in Japan were categorised as incidental fishery takes (Table 4 in Annex L).

14.1.2.4. OTHER ACTUAL AND POTENTIAL THREATS

High concentrations of mercury, HDBPs and/or PCBs have been found in this species (Endo *et al.*, 2003, 2005; Haraguchi *et al.*, 2006; also see SC/64/SM3). Concern has been raised since the accidents at Fukushima No1 nuclear power plant but there is no

evidence yet for exposure of Baird's beaked whales. Their range is mainly to the north of Fukushima.

14.1.2.5. CONCLUSIONS AND OTHER CONSIDERATIONS OF STATUS

The species is classified in the IUCN Red List as Data Deficient. Abundance estimates for the US west coast reported in SC/64/SM11 showed no trend for the period 1991-2008. The three populations off Japan have been assessed as Rare by the Japan Fisheries Agency and Mammalogical Society of Japan. The Committee **agrees** that there is no basis for revising the status of the Baird's beaked whale at the species or population level at this time.

The Committee **recommends** the following:

- (1) it is especially important to clarify population structure and geographical boundaries of the stocks off Japan, particularly as long as hunting continues there.
- (2) improved and updated abundance estimates are needed for each population, and trends in abundance should be assessed. These needs particularly apply to exploited stocks.
- (3) better understanding is needed of the movements of animals from the respective stocks into and out of the three sea areas of Japan (Sea of Japan, Sea of Okhotsk, Pacific coast).
- (4) the study in the Commander Islands (SC/64/SM5) should be expanded to include biopsy sampling for determination of sex and paternity and maternity in order to support studies of social and population structure, as well as satellite tagging to learn about movements and stock relations;
- (5) the limited information suggests a peculiar life history and social structure-it is uncertain whether the characteristics of Baird's beaked whales are common, rare or even unique among the Ziphiidae, but further studies such as those recently initiated in the Commander and Aleutian Islands are encouraged to continue.

14.1.3. Longman's beaked whale (*Indopacetus pacificus*)

Published information on this species was reviewed in SC/64/SM26. It is probably endemic to tropical waters of the Indian and Pacific Oceans. The west- and southernmost record is Natal, South Africa, the northernmost is Hakodate, Hokkaido, Japan, and the easternmost is Maui, Hawaii.

Two stranded specimens in northeastern Taiwan on 22 July 2005, provided the first genetic and external morphological descriptions in the western Pacific (SC/64/SM32).

14.1.3.1. CONCLUSIONS AND OTHER CONSIDERATIONS OF STATUS

Longman's beaked whale is classified in the IUCN Red List as Data Deficient. The Committee **agrees** that there is no basis for revising the status of Longman's beaked whale at either the species or population level as no abundance estimates are available, except around the Hawaiian Islands, and there is no information on trends. The species is best known from the western North Pacific. Some anthropogenic mortality is known to have occurred in fisheries around Sri Lanka and strandings in Taiwan may have been associated with naval activities. Ingestion of plastic debris and exposure to morbillivirus are also of concern.

No high-priority research needs were identified but efforts are needed to better document the species' overall range, especially in the Indian Ocean. Continued efforts are encouraged to investigate and sample stranded animals at every opportunity following standardised protocols for beaked whale necropsy. Necropsy results should be made available in the literature and in relevant publicly accessible databases as quickly as possible.

14.1.4. Hubbs' beaked whale (*Mesoplodon carlhubbsi*)

SC/64/SM 27 reviewed published information on Hubbs' beaked whale from the seas around Japan and from North America (<60 records). It is endemic to the North Pacific and found in cold temperate currents off Japan and along the west coast of the United States and southern British Columbia, Canada. It has rarely been reported at sea.

14.1.4.1. CONCLUSIONS AND OTHER CONSIDERATIONS OF STATUS

Hubbs' beaked whale is classified in the IUCN Red List as Data Deficient. The Committee **agrees** that there is no basis for revising the status of Hubbs' beaked whale at either the species or population level. Some concern was expressed at the apparent decline of mesoplodonts off the U.S. west coast (SC/64/SM11) as this probably includes Hubbs' beaked whales. No species-specific abundance estimates are available. Some anthropogenic mortality is known to occur in fisheries off both Japan and the USA and these whales may be vulnerable to anthropogenic noise from naval sonar and seismic research.

The Committee **agrees** that priority should be given to studies of possible population differences between Japan and the USA (genetics primarily but also external and internal parasites and cookie-cutter sharks scars). Acoustic studies (e.g. SC/64/SM21) may help to better determine the range of Hubbs' beaked whale, if a species-specific signal is found.

14.1.5. Blainville's beaked whale (*Mesoplodon densirostris*)

Published information on this species (primarily from strandings) was reviewed in SC/64/SM33. This has the most extensive distribution of any *Mesoplodon*. Its acoustic signal type (the same as in the North Atlantic) was the predominant signal type in the Pacific Islands region (SC/64/SM21). It is found in tropical and warm temperate waters of all oceans, including deep offshore waters, tropical oceanic archipelagos and continental or insular coasts bordered by warm waters. There are no records from polar or other high latitude regions. It is reported infrequently at sea, and positive field identification can be difficult unless key diagnostic characters of the head are observed.

14.1.5.1. CONCLUSIONS AND OTHER CONSIDERATIONS OF STATUS

Blainville's beaked whale is classified in the IUCN Red List as Data Deficient. The Committee **agrees** that there is no basis for revising the status of Blainville's beaked whale at either the species or population level. Some anthropogenic mortality is known to occur in fisheries off both Japan and the USA and this species may also be vulnerable to anthropogenic noise from naval sonar and seismic research.

In addition to the general recommendations under item 3.12, the Committee **recommends** expanded photo-identification and tagging efforts in Hawaii to monitor movement patterns (seasonal as well as ranges) to determine whether there is site fidelity to specific types of habitat.

14.1.6. Ginkgo-toothed beaked whale (*Mesoplodon ginkgodens*)

There is only limited information on this species which is found in warm temperate and tropical waters of the Pacific and westward into the Indian Ocean. It is classified in the IUCN Red List as Data Deficient. The Committee **agrees** that there is no basis for revising the status of ginkgo-toothed beaked at either the species or population level. No abundance estimates exist. Some anthropogenic mortality is known from fisheries in at least Japan, Sri Lanka, Taiwan and Micronesia, and from anthropogenic noise from naval sonar (Wang and Yang, 2006 JCRM). It is important to confirm the species identifications of all available specimens because a number have been misidentified in the past. Its status and abundance in its apparent 'hotspot' around southern Japan and Taiwan should be investigated.

14.1.7. Perrin's beaked whale (*Mesoplodon perrini*)

IWC/64/SM30 reviewed the existing information on Perrin's beaked whale. Very little is known about this species that was described in 2002 by Dalebout *et al.* (2002) based on five stranded specimens from south and central California – it remains known only from strandings in California and may have the most

restricted range of any species of *Mesoplodon*. Many or most of the unidentified mesoplodonts observed in ship surveys off California (SC/64/SM11) may be Perrin's beaked whales.

The species is classified in the IUCN Red List as Data Deficient. The Committee **agrees** that there is no basis for revising the status of Perrin's beaked at either the species or population level. As with all of the beaked whales, Perrin's beaked whales are probably at risk from anthropogenic noise produced by military sonar and seismic surveys as well as to fishery bycatch in areas of overlap. There is a need to determine distribution and abundance in the eastern North Pacific including opportunistic biopsy sampling and correlated acoustic sampling.

14.1.8. Pygmy beaked whale (*Mesoplodon peruvianus*)

IWC/64/SM30 reviewed the existing information on pygmy beaked whales, which appear to be endemic to the eastern tropical Pacific. Most sightings are from the 'Eastern Pacific Warm Pool', an area with sea surface temperatures >27.5°C (Fiedler and Talley, 2006). It may be particularly abundant in the southern Gulf of California, Mexico (e.g. Ferguson *et al.*, 2006). There are a few records from Mexico (Urban-R, 2010) and it may be relatively common off Costa Rica (SC/64/SM13). The northernmost record is Moss Landing, California, the southernmost record in the eastern Pacific is from northern Chile (Sanino *et al.*, 2007) and the only record outside the eastern Pacific was from South Island, New Zealand (Baker and van Helden, 1999). Whether this latter specimen is indicative of a wider distribution for this species, or just an errant individual, is uncertain.

14.1.8.1. CONCLUSIONS AND OTHER CONSIDERATIONS OF STATUS

This species seems to be fairly common within its range (Ferguson and Barlow, 2001). It is classified in the IUCN Red List as Data Deficient. The Committee **agrees** that there is no basis for revising the status of pygmy beaked whale at either the species or population level given the sparseness of information. Confirmation is needed that *Mesoplodon* sp. A is *M. peruvianus*; while biopsy samples (male) seem unlikely, a colour-pattern description of a freshly stranded adult male *M. peruvianus* would suffice. The southern Gulf of California seems to be a promising region for either of these events.

14.1.9. Stejneger's beaked whale (*Mesoplodon stejnegeri*)

IWC/64/SM25 reviewed information on this species, mainly from waters around Japan but including data from North America. It is endemic to the cold temperate North Pacific and has not been reported from any of the central Pacific islands. Four mass strandings occurred in Kuluk Bay, Alaska between 1975 and 1989

(Walker and Hanson, 1999). It is the most commonly stranded ziphiid in Japan although rare on the Pacific coast of Japan (Brownell *et al.*, 2004). Park (1999) reported five strandings and two incidental catches along the east coast of South Korea (35° to 38°N).

The presence of cookie-cutter shark bites present on animals around the Aleutian Islands but not the Sea of Japan, suggest some population structure in the central and western North Pacific. Brownell *et al.* (2004) suggest that the northern Sea of Japan should be considered as a provisional management unit.

14.1.9.1. CONCLUSIONS AND OTHER CONSIDERATIONS OF STATUS

Stejneger's beaked whale is classified in the IUCN Red List as Data Deficient. The Committee **agrees** that there is no basis for revising the status of Stejneger's beaked whale at either the species or population level. No species-specific abundance estimates are available. Some anthropogenic mortality is known to occur in fisheries off both Japan and the USA and at least one case of a ship strike has been confirmed. The mass strandings in the Aleutian Islands were suspected of being related to naval sonar.

In addition to the general recommendations under Item 14.1.11, the Committee **recommends** regular and extensive sample collection from stranded or bycaught specimens (especially off Japan) in order to better understand the species' ecology, life history and vulnerability to threats. Genetic research is needed to determine whether western and eastern populations can be differentiated. Better understanding of its biology and abundance in the apparent 'hot spot' in the Sea of Japan off Honshu could be accomplished by (i) strengthening the stranding programme in order to collect specimens in fresher condition, (ii) acoustic monitoring and (iii) small-scale surveys to assess abundance.

14.1.10. *Deraniyagala's beaked whale*

SC/64/SM3 presented new genetic and morphological data supporting the recognition of a previously described but unnamed Mesoplodon in the tropical Indo-Pacific. Genetic identification has related new specimens, including those initially described by Baker *et al.* (2007), to a type specimen in Colombo, Sri Lanka described as *M. hotaula*, in 1963. Known from at least seven specimens it is genetically distinct but closely related to (and possibly conspecific with) *M. ginkgodens*. Its distribution seems to be tropical in both the Indian and Pacific Oceans. SC/64/SM3 argued that available evidence was sufficient to accept the revised taxon as a new subspecies of *M. ginkgodens* and that further characterisation could result in the resurrection of *M. hotaula* Deraniyagala, 1963 as a full species. The Committee suggested the provisional common name

'Deraniyagala's beaked whale' for this taxon, in recognition of the original description.

Further genetic investigation, including biopsy sampling of live animals, is required to clarify the systematics and taxonomy. Visual and acoustic reports from around Palmyra Atoll have been attributed to this new taxon (see SC/64/SM21) and this area clearly provides the opportunity to collect fresh tissue samples for genome-level analyses.

SC/64/SM4 reported on the species identity and local use of Deraniyagala's beaked whales (and Blainville's and Cuvier's beaked whales) in the Gilbert Islands, Republic of Kiribati. This investigation, conducted with the help of government agencies, visited several of the outer Gilbert Islands in June-July 2009 and collected bones and artefacts.

It is important to obtain new specimen material from oceanic islands and atolls in the central tropical Pacific and to confirming the identities and provenances of existing museum specimens attributed to *M. ginkgodens*. Consideration should be given to the possibility that there are island-associated nearshore populations that are geographically and demographically isolated or semi-isolated from offshore populations of both Deraniyagala's beaked whales and ginkgo-toothed beaked whales, as is the case with Blainville's beaked whales.

Almost nothing is known about overall distribution, population structure, life history, abundance or takes of Deraniyagala's beaked whales, with the exception of those in Kiribati (SC/64/SM4). The five beaked whales strandings from Palmyra Atoll and Kingman Reef between 2002 and 2007 is high for such a small area and high compared to the number of beaked whale strandings reported on other Pacific Islands.

14.1.10.1. CONCLUSIONS AND OTHER CONSIDERATIONS OF STATUS

No IUCN Red List has been made for Deraniyagala's beaked whale at either the species or population level. The Committee **agrees** that there was insufficient data to assess this status at either the species or population level. The Committee expressed concern about the apparently high numbers of strandings around Palmyra Atoll in recent years. Deraniyagala's beaked whales are probably vulnerable to sound from naval sonar and seismic research, similar to other beaked whales. Assuming that the beaked whale recorded both acoustically and visually around Palmyra Atoll is Deraniyagala's beaked whale, the first priority is to make this determination genetically.

14.1.11. *Common issues and threats*

14.1.11.1 MILITARY SONAR AND OTHER NOISE SOURCES

Evidence of gas bubble lesions (gas embolism) and fat embolism have been reported at necropsy in beaked whales from atypical mass stranding events (MSEs),

which were coincidental with nearby use of mid-frequency sonar (Fernandez *et al.*, 2004). Exposure to sonar may alter the behaviour and/or physiology of beaked whales, potentially resulting in decompression sickness (DCS) in some circumstances.

Bernaldo de Quirós and Fernandez Rodriguez (2011) studied gas presence and composition in order to compare decompression vs. decomposition gases present at necropsy. Bubbles alone cannot be used to determine cause of death and it is important to differentiate between gas embolism and putrefaction gases. They recommended scoring gas bubble presence and sampling bubbles for gas composition analysis within 24 hours, but preferably within 12 hours, to minimise the masking effects of putrefaction gases.

The Committee **recommends** that groups working on mass strandings make all reasonable efforts to examine dead animals within 12 hours (or at most 24 hours) after death. Response teams should, if at all possible, include a veterinarian, a veterinary pathologist or a responder with experience in necropsy and sample collection. Routine necropsy protocols should include examination of bubbles present in tissues, scoring relative prevalence and sampling for gas composition analysis, particularly to detect and describe intravascular and peri-renal subcapsular emphysema bubbles.

The Committee took note of the latest investigations of MSEs in the Canary Islands, Spain associated with the use of naval sonar (Fernandez *et al.*, 2004). No further atypical MSEs have occurred since international naval exercises ended in 2004 following a recommendation of the parliament of the European Union and a Spanish government resolution banning the use of military sonar around the Canary Islands. This supports the inference that the atypical MSEs before the ban were caused by mid-frequency sonar.

Noting the ample evidence about the vulnerability of beaked whales to military sonar and seismic surveys and the potential for impacts at the population level (including not only animals that strand and are detected but also the potentially large number that die at sea and do not strand), the Committee strongly recommends that military exercises and seismic surveys should avoid areas of important habitat for beaked whales; that further effort should be made to mitigate their impacts; and that further efforts should be made to identify such areas (MacLeod and Mitchell, 2006; Cañadas, IWC/63/SM10).

The Committee also reiterates two previous recommendations.

- (1) The continuation and expansion of studies of how anthropogenic noise, especially from naval sonar and seismic survey airguns, affects ziphiids. These should include efforts to

determine if and how vulnerability differs between species, habitat types, animal activities (e.g. travelling, foraging) etc.

- (2) Collaborative arrangements with military and industry authorities should be made to ensure researchers have advance notice of sonar exercises, seismic surveys and other activities so that the possibility of beaked whale stranding events can be anticipated with enhanced beach surveillance etc.

14.1.11.2. MARINE DEBRIS

Available data from the North Pacific and northern Indian Ocean (IWC/64/E10; Simmonds in press) indicates that beaked whales may be especially vulnerable to the ingestion of plastics and other marine debris; this can cause pathology and mortality. The population-level and long-term implications of the ingestion of plastic debris are unknown. The Committee **recommends** that this issue is further investigated via the collection, collation and analyses of relevant data from around the world concerning ingestion rates, debris types and associated pathology. It also **recommends** that standardised protocols are developed for pathology investigations. Consideration should also be given to investigating marine debris accumulation and associated processes in areas of important habitat for small cetaceans.

14.1.11.3 GENERAL RECOMMENDATIONS

The Committee **recommends** that for all North Pacific and northern Indian Ocean ziphiid species, further efforts are made to define population structure, delineate population boundaries, obtain estimates of abundance and identify and rank threats. Attention should be given to populations known or suspected to be small and/or exploited. The available evidence suggests that most ziphiid species occupy relatively narrow ecological niches and occur as local, largely isolated groups, which should be regarded as putative subpopulations (in the IUCN Red List sense).

The Committee **recommends** that more effort be made to investigate and validate methods of estimating population size for ziphiids, including those that incorporate passive acoustics for application in areas where the local species are acoustically distinguishable. Further data are needed to adjust density estimates from line transect surveys to account for visibility bias (given that these deep-diving whales spend relatively little time at the surface and species are difficult to distinguish) and for responsive movement. Consideration should also be given to interrupting line transect surveys (closing mode) in order to obtain photographs and biopsies as a way of reducing the 'unidentified ziphiid' component of abundance estimates.

Initial efforts have been made to map high-use areas for ziphiids on a global scale (MacLeod and Mitchell,

2006) to provide guidance for mitigation measures to reduce the risks from naval sonar and seismic survey operations. However, a more detailed examination is needed of these 'hotspots', including fine-scaled habitat characterisation and predictive habitat modelling. The Committee **recommends** that collaborative efforts similar to those described last year in SC/63/SM10 be made by the relevant scientists and research groups in the North Pacific and Northern Indian Ocean where anthropogenic sound is considered a problem.

Ziphiids are at risk of entangling in nets, especially pelagic driftnets, which tend to be deployed in or near their habitat. They are also known to get hooked or entangled in longline gear. The Committee **recommends** that methods be developed and applied to estimate fishery-related mortality, giving special attention to areas where there is direct evidence of incidental mortality as well as to areas where driftnetting and longlining operations overlap known concentrations of ziphiids.

Evidence of beaked whale population decline along the North American coast (SC/64/SM11) raised concern that beaked whales, and particularly resident populations, may be negatively affected by large-scale environmental change. The Committee **recommends** efforts be devoted to understanding impacts of changes in habitat on the distribution and abundance of beaked whales. This could involve pursuing an improved understanding of beaked whale feeding ecology and deep-water oceanographic processes as well as prey-community dynamics.

The Committee further **recommends** broad-scale collaborations to generate integrated results from analyses of genetic material, photograph collections and survey data. Particularly for *Mesoplodon* species, biopsies should be obtained from live animals to verify species identification. This is especially important for females and young males. Efforts are also needed to validate acoustic signatures of *Mesoplodon* species by collecting biopsies (and good photographs) along with acoustic recordings at sea.

14.2. Report on the voluntary fund for small cetacean conservation research

14.2.1. Status of the voluntary fund for small cetacean conservation research

In 2009, Australia made a generous donation toward the IWC Small Cetacean Conservation Research Fund of about £250,000 which enabled eight grant awards to research and conservation projects on small cetaceans (IWC, 2012r). At the Commission meeting in 2011 and during the interessional period, France, Italy, the United Kingdom and a number of NGOs provided extra funding of £73,000 which allowed: (i) the full funding of the two remaining projects recommended by the Committee in 2011; (ii) support for invited

participants in 2011 and 2012; and (iii) a chance to start rebuilding the Fund. The Committee **thanks** the above governments and the NGOs for their generous contributions to the fund and hopes that the next Conservation Committee and Commission meetings will generate new funding that will allow another call for projects by the end of 2012.

14.2.2. Review on Progress on Funded Projects

The Committee reviewed brief project reports on five of the nine projects selected in 2011 (Annex 2) and received more extensive reports on three of them, which are presented in Annex L (Solomon Islands, in this section; franciscana, Item 14.3.3; Atlantic humpback dolphin, Item 14.3.5).

SC/64/SM23 presented preliminary results of an assessment of dolphins in the Solomon Islands where there is a long history of exploiting dolphins through traditional drive-hunts. More recently, the Indo-Pacific bottlenose dolphin (*Tursiops aduncus*), has been live-captured for export, with a current annual export quota of 50. This Committee as well as several intergovernmental bodies (CITES, CMS, IUCN, SPREP) have expressed concern in the past about the potential conservation implications of these removals.

The Committee expresses its appreciation for this work and acknowledges the constructive involvement of the Solomon Islands Fisheries and Environment ministries in collaborating and providing support. The preliminary results reinforce previously expressed concerns regarding the sustainability of past and ongoing live-capture removals of *T. aduncus* from what appear to be small island-associated populations. The Committee **encourages** the authorities responsible for conservation management (e.g. under CITES) to carefully consider the information from this study. It recommends that efforts to integrate the current and historical photo-identification catalogues be pursued as a priority.

14.3. Progress on previous recommendations

14.3.1. Vaquita

The Committee has expressed its grave concern over the status of this species and its continuing decline over many years. Last year, the Committee was informed about the pilot phase of implementation of an acoustic monitoring programme to track future changes in vaquita abundance in the Upper Gulf of California (IWC, 2012w). SC/64/SM19 provided further information on the implementation of the scheme in the first full sampling season. An overall loss rate of 44% of the detectors resulted in data being available for 38 sampling sites within the refuge. Deployment of buoys is the only way to obtain year-round information so an alternative method of deployment that reduces loss must be found. An analysis of the acoustic encounter rates in 2008 (0.74 encounters/day, CV 0.44) compared to those from the current study in 2011 (0.58 encounters/day, CV 0.05) is indicative of further

decline of the population since 2008, i.e. when strategies to reduce fishing effort by the Federal Government were already being implemented.

Jaramillo-Legorreta noted that redeployment of the array in late spring of 2012 was delayed because the presence of 87 boats fishing illegally within the refuge at that time presented too great a risk of loss of equipment; deployment was underway at the time of the Committee meeting.

The subcommittee considered the report²⁵ of the fourth Meeting of the International Committee for the Recovery of Vaquita (CIRVA) held in Ensenada, Mexico from 20-23 February 2012. The role of CIRVA has been recognised by the Government of Mexico in the agreement for the creation of the Vaquita Protection Refuge and in the current federal Action Program for the Conservation of Vaquita (PACE-Vaquita). Hence, the recommendations of CIRVA are important in terms of driving recovery actions. The report notes that the population has continued to decline, with an estimated reduction of nearly 60% between 1997 and 2008 and possibly as few as 220 porpoises remaining in 2008 (CIRVA, 2012). The report is discussed in detail in Annex L.

CIRVA's assessment of progress is that switch-out programmes (conversion to vaquita-safe gear) has been poor with only a very small proportion of the total fleet using such gear. Fishermen using such alternative trawl gear would have great difficulty operating safely in the middle of the large gillnet fleet. A working group has been engaged in a public process to amend the Mexican Official Standard 002-PESCA that regulates shrimp fishing. A three-year process beginning in 2013-14 to ban shrimp gillnets and exchange them for the new small artisanal trawl net design has been approved but not yet published in the Federal Register.

Details on CIRVA recommendations are given in Annex L and the Committee **strongly endorses** the CIRVA recommendations.

At last year's meeting the Committee concluded, as it has in several previous meetings, that the only reliable solution for vaquita conservation is to eliminate vaquita by-catch by replacing gillnets with alternative fishing gear. In a detailed recommendation, the Committee strongly supported robust gear trials to assess alternative gear effectiveness and economic viability (IWC, 2012r).

The Committee again **reiterates its extreme concern** for the status of this species and, as stated in 2011 (IWC, 2012r), **reaffirms** that the only reliable approach for saving the species is to eliminate vaquita bycatch by removing entangling gear from areas where the animals occur. It **strongly recommends** that, if extinction is to

be avoided, all gillnets should be removed from the upper Gulf of California immediately. This is in accord with the Committee's strong recommendation made in 2009 (IWC, 2012f, p.66) regarding the extinction of the vaquita.

In light of reports on the successful development of an alternative shrimp trawl and the CIRVA recommendations summarised in Annex L, the Committee also **recommends** that vaquita conservation efforts focus on:

- (1) expedited approval and adoption of the small shrimp trawls as an alternative to gillnets and prohibition of shrimp fishing with gillnets throughout the entire range of the vaquita;
- (2) continued research on technologies to replace gillnetting for finfish or otherwise to remove all gillnets from the vaquita's entire range.

In this regard the Committee **notes** the ongoing project funded under the Voluntary Fund for Small Cetacean Conservation Research "Supporting the assessment of alternative fishing gears for replacing gillnets that cause bycatch of vaquita (*Phocoena sinus*) in the Upper Gulf of California, Mexico" and **looks forward** to a progress report at next year's meeting.

14.3.2. Harbour porpoise

In 2001, the Committee acknowledged the efforts by ASCOBANS to address serious harbour porpoise bycatch problems in the Baltic, Kattegat/Belt and North Sea areas and encouraged further efforts in that regard (IWC, 2010g). Since then, the ASCOBANS Jastarnia Group has met and considered new analyses of survey and bycatch data, which have had the effect of reinforcing and increasing concern about sustainability of bycatch as well as other factors potentially affecting the porpoise populations in the region, including declines in availability of prey, ship traffic, construction work, seabed exploitation, contaminants, and diseases.

The Committee remains concerned about the status of harbour porpoises in the western Baltic, the Belt Seas and the Kattegat ('Gap' area, also known as Belt Sea stock according to the ASCOBANS Jastarnia Group). Although the abundance estimates for harbour porpoises from SCANS and SCANS II were almost identical for the wider North Sea area, there was a southward shift in density distribution of porpoises between SCANS and SCANS II. However, there are indications of a possible decline in abundance in the Gap area. Bycatch is the major source of anthropogenic mortality and should be monitored and mitigated. EC Regulation 812/2004 does not adequately protect harbour porpoises from bycatches in this area because it requires bycatch monitoring only on boats > 15m and pinger use only on boats >12m.

In the current state of scientific uncertainty, the Committee looks forward to receiving the results of a

²⁵ <http://www.iucn-csg.org/index.php/downloads/>

planned dedicated shipboard survey to be conducted in the Gap area in the summer of 2012 with the intention of obtaining a new abundance estimate.

The Committee recommends with regard to the Gap area to:

- (1) assess porpoise bycatch levels;
- (2) monitor porpoise abundance on a regular basis;
- (3) introduce measures to mitigate bycatch and other anthropogenic mortality;
- (4) monitor the health status of the porpoises;
- (5) ensure all bycaught and stranded animals are reported and delivered to qualified institutions for necropsy and sampling;
- (6) implement the recovery plan for harbour porpoises which is currently being developed by ASCOBANS for the Gap area.

The Committee also repeats its longstanding concern regarding the critically endangered harbour porpoise population in the inner Baltic ('Baltic proper') and encourages all possible efforts to eliminate the bycatch there and address other factors that may be preventing this very small population's recovery. The current process of developing management plans for Special Areas of Conservation under the European Habitats Directive, offers a concrete chance to implement monitoring and mitigation as foreseen by the Jastarnia Plan. The Committee urges that effective monitoring and mitigation measures focusing on harbour porpoises be included in such national management plans.

14.3.3. *Franciscana*

SC/64/SM17 describes results of a project conducted with funding from the IWC Small Cetacean Conservation Fund. The main goal of the study was to assess distribution and obtain an abundance estimate of franciscanas inhabiting the region known as Franciscana Management Area I (FMA I), as recommended in IWC (2004). In December 2011 and January 2012, design-based aerial surveys were conducted to assess distribution and to estimate abundance of franciscanas in FMA I. The fully corrected abundance estimate was 1,998 (CV=0.48, 95% CI: 796-5,013). The most recent (2001-2002) estimate of incidental mortality in FMA I (Di Benedetto, 2003) corresponds to 5.5% of the estimated population size presented here. This indicates high and unsustainable bycatch if current mortality is similar to that in the early 2000s.

The Instituto Chico Mendes para a Conservacao da Biodiversidade (ICMBio) is the government agency responsible for establishing management and conservation strategies for endangered species in Brazil. In 2010, ICMBio published the 'National Action Plan for the Conservation of the Franciscana' (Di Benedetto et al., 2010) and made a series of general recommendations for research and monitoring

(summarised in Annex L) which the Committee endorsed.

The Committee further recommends the following with respect to FMA I

- (1) Additional aerial surveys with increased sampling effort in order to:
 - a) produce more robust (lower CVs, estimates for the northern range of FMA I) population estimates;
 - b) further assess distribution (e.g. offshore limits, discontinuity);
 - c) evaluate potential habitats that could be protected (e.g. by one or more no-take zones, marine protected areas) to improve conservation.
- (1) Resume systematic and long-term by-catch monitoring in northern Rio de Janeiro and Espírito Santo, in order to produce more up-to-date mortality estimates.
- (2) Studies be conducted to assess areas within the range of the species where other human activities could pose a threat to the long-term viability of franciscanas in FMA I.

Melcon *et al.* (2012) illustrated the potential for the use of autonomous acoustic detectors or towed arrays designed specifically for the identification of porpoise-like signals (e.g. C-PODs or A-tags) in franciscana research.

14.3.4. *Narwhal and white whale*

Bjørge reported on progress towards organising and convening a proposed global review of the monodontids (IWC, 2012 p. 279). The NAMMCO Secretariat has indicated interest in organising and convening such a review jointly with the IWC Scientific Committee and the inter-sessional correspondence group has identified a list of scientists interested in attending from four of the five range states (Norway, United States, Canada, Russia). Broader involvement of other scientific groups and individual scientists for a range-wide workshop or symposium on monodontid science may be appropriate. The involvement of groups as disparate as oceanaria and environmental NGOs as co-conveners might bring greater organisational motivation and financial resources to support such a workshop or symposium. The Committee recommends that a steering committee (Bjørge, Reeves, Suydam, a scientist from Canada, Donovan and Mario Aquarone from NAMMCO Secretariat) be established to meet intersessionally to discuss these issues and report back at next year's meeting.

14.3.5. *Atlantic humpback dolphin*

SC/64/SM22 presents a brief update on the project funded by the IWC Small Cetacean Conservation Research Fund for Atlantic humpback dolphins in

Gabon and Congo. There have been some challenges and shifts in focus and priorities over the last year, given boat failures and the discovery of a significant bycatch problem in Congo. As the project is ongoing, more complete reporting will be provided next year. The Committee thanks the authors for this preliminary report and expressed its appreciation for their perseverance in the face of the difficult challenges faced to date in this research.

14.3.6. River dolphins

IWC (2001) recommended that ‘scientists with appropriate theoretical and/or analytical skills should be directly involved in river cetacean studies, so that surveys result in statistically robust estimates of abundance’. In 2002, two biologists and two statisticians led a pilot survey (line and strip transect data and some photo-ID data) of boto (*Inia geoffrensis*) and tucuxi (*Sotalia fluviatilis*) in portions of the Amazon in Colombia and Peru (IWC 2003). SC/64/SM24 revisited this dataset and reported on preliminary analyses. Participants drew attention to the existence of both older and more recent abundance estimates for the study area and suggested that a three-way comparison of abundance estimates would be of great value. The Committee expresses its appreciation to the Government of Brazil for supporting a proposed PhD studentship to work on this issue.

14.3.6.1. BOTO AND TUCUXI

Two largely sympatric endemic cetaceans, the tucuxi and the boto, inhabit the Amazon basin and both are increasingly killed for use as bait in the piracatinga (*Calophysus macropterus*) fishery (see IWC, 2007; 2008; 2009; 2012). Catches in this fishery, primarily for export to Colombian markets but also for sale in domestic markets, have increased in Brazil in recent years. Alves et al. (in press) reported on an interview study with fishermen and traders, to elucidate interactions between fishermen and river dolphins, including the occurrence of illegal, indiscriminate killing and growing trade in dolphin carcasses. In the view of fishermen, botos damage gear, steal (and also probably damage) catches. Botos are negatively portrayed in numerous traditional Amazonian folk myths and superstitions. These factors make them extremely unwanted or even hated and they are considered as pests. Now they have also become an economic resource as bait in the increasing piracatinga fishery. Additional information suggests that the true extent of the area of the piracatinga fishery and the area of direct takes is unclear, although the reported expansion of the piracatinga market and fishing effort add to concerns regarding the impacts on dolphins.

As previously noted (IWC, 2001), the population status of botos and tucuxis has been assessed in only relatively small portions of their Amazonian range. The Committee reiterates its serious concerns with the potential population implications of the intentional

killing of botos and tucuxis for use as bait in the piracatinga fishery. It welcomes the information provided at this year’s meeting but notes that the true extent of this exploitation throughout Amazonia is poorly understood. It also emphasises that this relatively new and rapidly growing problem is in addition to other historical and ongoing threats to these dolphins, e.g. from incidental mortality in fisheries, vessel traffic, construction of hydroelectric dams, mining and other development.

In view of these concerns and the information gaps, the Committee recommends the organisation of an international scientific workshop involving scientists and managers from the range states, with the goals of addressing research and conservation priorities, standardising methodologies and planning long-term strategies. The following specific topics could be discussed at the workshop:

- (1) geographic and temporal extent of the piracatinga fisheries and associated dolphin use;
- (2) methods to assess abundance and mortality (rapid assessment as well as longer-term approaches);
- (3) improved understanding of dolphin movements and habitat use (including population structure);
- (4) ways to reduce (or preferably eliminate) the pressure on dolphin populations from exploitation as bait for the piracatinga fishery.

The Committee agrees that the status of the boto and tucuxi should be added as a recurrent item on its agenda.

14.3.6.2. INDUS RIVER DOLPHIN

WWF-Pakistan hosted the Indus River Dolphin Conservation Strategy Planning Workshop in Lahore (Pakistan) last April. The objective was to lay the groundwork for development of a ten-year strategic action plan for conservation of endangered Indus River dolphins (*Platanista gangetica minor*), which are restricted to the Indus River system in Pakistan. Details can be found in Annex L, section 5.6.2.

14.3.6.3. MEKONG RIVER POPULATION OF IRRAWADDY DOLPHINS

A Mekong Irrawaddy Dolphin Conservation Workshop was held in Kratie, (Cambodia) last January. The workshop was jointly hosted by the Commission for Dolphin Conservation and Development of Mekong River Dolphin Ecotourism, the Fisheries Administration of the Ministry of Agriculture, Forestry and Fisheries, and the World Wide Fund for Nature – Cambodia. Participants reviewed the available evidence on possible causes of mortality of Irrawaddy dolphins in the Mekong in particular, the high and as-yet-unexplained level of calf mortality. Details can be found in Annex L, section 5.6.3.

All freshwater populations of Irrawaddy dolphins (*Orcaella brevirostris*) are listed on the IUCN Red List as Critically Endangered. The Mekong River population is estimated at 85 individuals (95% CI 78-91), excluding young calves (Ryan et al. 2011) with recruitment close to zero. Although births occur, few animals survive to adulthood. The available information, suggests a slow decline (2.2%/year during the study period). If confirmed, the current population composition has serious implications for the long-term viability of the Mekong River population.

Last year, the Committee expressed grave concern about the rapid and at least partially unexplained decline of this riverine population. Unfortunately, the high mortality of young calves has continued as has the occasional mortality of adults from entanglement. The Committee **recognises** and **commends** Cambodian government agencies and WWF-Cambodia for making serious, concerted efforts since the last meeting to diagnose the cause(s) of calf mortality and further reduce the risk of entanglement. The Kratie Declaration²⁶ is a major step forward and the Committee recommended that it be fully implemented as quickly and as effectively as possible.

14.3.7. Killer whales

The Committee was pleased to receive information on the first photo-ID catalogue of killer whales in Adélie Land, East Antarctica (SC64/SM6) as discussed in Annex L. This catalogue will be augmented in coming years and made available for regional matching and for a global Antarctic killer whale catalogue.

14.3.8. Clymene dolphin

The Committee was pleased to receive information a study underway on the first molecular characterisation of the Clymene dolphin (*Stenella clymene*) a recently rediscovered dolphin species. It has been suggested that the species could have had a hybrid origin, with *S. coeruleoalba* and *S. longirostris* acting as parental species (see Annex L).

14.4. Takes of Small Cetaceans

Annex L (Appendix 3) presents information on catches and associated quotas for small cetaceans from 1997-2010 obtained by Funahashi from the Japanese National Research Institute of Far Seas Fisheries website. The Secretariat developed the summary of catches of small cetaceans in 2009-2011 from this year's national Progress Reports.

The importance of these reports was noted, but concern was expressed that the Committee was not doing enough to take advantage of the significant information therein. The Committee **agrees** to explore intersessionally more specific terms of reference for

evaluating direct take data, including the idea of developing case studies (e.g. assessing sustainability of bycatch in Europe) or other analyses from this information.

The Committee **thanks** Funahashi and the Secretariat for their work in compiling this information for the Scientific Committee each year and reiterated the importance of having complete and accurate catch and bycatch information and encourages all countries to submit data, appropriately qualified and annotated.

The Committee **expresses** its continuing concern about the lack of assessment of the exploited stock or stocks of killer whales in Greenland where reported catches were 14 in 2009 and 15 in 2010.

14.5. Local studies

SC/64/SM20 reported on the presence of long-beaked common dolphins in coastal waters of northern Colombia for the first time. These sightings extend the known range in the Caribbean, previously known primarily from the eastern Caribbean, some 700-800km.

Bolaños-Jiménez reported on: (1) work to gather records and sightings of killer whales in the Caribbean Sea and adjacent waters in collaboration with other North Atlantic killer whale studies and databases; (2) preliminary abundance estimates of Atlantic spotted and common bottlenose dolphins in the State of Aragua, central Venezuela, on the basis of mark-recapture models and photo-ID techniques as part of efforts to provide a stronger foundation for proper management and monitoring of dolphin-watching activities; and (3) new records of common dolphins in central-western Venezuela-common dolphins have recently been recorded on the Colombian side of the Guajira Peninsula (SC/64/SM20).

SC/64/BC2 reported on unusual strandings of two species of oceanic dolphins on the Pacific coast of Costa Rica. The first was a mass stranding of 38 rough-toothed dolphins in 2002, 34 of which were returned to the sea. The second was of an adult female Fraser's dolphin in 2006. Both strandings are the only ones known for each of these species in Costa Rica.

SC/64/SM10 reported on studies to identify critical habitats for coastal pantropical spotted dolphins in Golfo Dulce, Costa Rica, as the foundation of the design and implementation of Marine Spatial Planning and Marine Protected Areas. The current study investigates the underlying behavioural mechanisms that govern patterns of niche differentiation and the resulting conservation implications.

The Committee expresses its gratitude to the presenters of local research papers and noted that such work to establish baselines, distribution records, and habitat requirements is essential to addressing the concerns of the Committee.

²⁶ <http://www.iucn-csg.org/wp-content/uploads/2010/03/Kratie-Declaration-signed-with-appendices-1.pdf>

14.6 Hector's dolphins

Slooten reported on a number of recent findings and processes in New Zealand concerning Hector's dolphins. Bycatch in gillnet and trawl fisheries is the most serious threat to this endangered species. A substantial increase in survival rates (5.4%/yr) has been detected in one of the protected areas created to reduce the overlap between dolphins and these fishing methods (Gormley et al., 2012). The Banks Peninsula population was declining at approximately 6%/yr before 2008 and is now declining at about 1%/yr (Gormley et al., 2012; Slooten and Dawson, 2010). The population was predicted to recover if the boundaries of the protected areas were extended to the 100m depth contour. Slooten explained that the survival rate increase demonstrates that protected areas can work if (i) they are large enough and in the right place; (ii) key threats are managed by removing rather than displacing them; (iii) no new threats are added (e.g. in this example marine mining, tidal energy generation); and (iv) effective monitoring and enforcement is in place.

Bycatch in 'exemption' areas without protection measures, and in areas with incomplete protection, is causing continued population declines and population fragmentation (DOC and Mfish, 2007; (Davies *et al.*, 2008) Slooten and Dawson, 2010; SC/64/ProgRepNewZealand). Weak protection on the west coast of South Island, a lack of protection on the north coast of South Island and 'exemption' areas in other regions are slowing or preventing species recovery ((Davies *et al.*, 2008) Slooten and Dawson, 2010). There is also continued bycatch from illegal setnetting inside protected areas.

Full details are given in section 7.2 of Annex L.

The Committee expresses particular **concern** about the low abundance of Maui's dolphins (North Island subspecies of Hector's dolphin). The latest abundance estimate of 55 individuals over one year old (CV 0.15) was calculated from a genetic mark-recapture analysis (Hamner *et al.*, 2012).

The Committee **recommends** the immediate implementation of the proposal by the New Zealand Ministry for Primary Industries to extend the North Island protected area to approximately 80km south of the latest dolphin bycatch site (Maunganui Bluff to Hawera), offshore to the 100m depth contour, including the harbours, for gillnet and trawl fisheries. This would protect part of an area with high gillnet and trawl fishing effort between the North and South Islands. Further population fragmentation could be avoided by also protecting the north coast of the South Island, providing safe 'corridors' between North and South Island populations (Hamner *et al.*, 2012).

Adequate observer coverage across all inshore trawl and gillnet fisheries is important in order to obtain

robust scientific data on continuing bycatch as a means of assessing the effectiveness of protection measures.

14.7. Workplan

The Committee's views on the workplan for the sub-committee on small cetaceans is given under Item 21.

The sub-committee reviewed its schedule of priority topics which currently includes:

- (1) status of ziphiids in the Southern Hemisphere;
- (2) systematics and population structure of *Tursiops*.

There is a need for extensive preparatory work for the proposed *Tursiops* review. Therefore the Committee agrees that the review of the systematics and population structure of *Tursiops* should be conducted in 2014 and an *ad hoc* group (Brownell, Perrin, Fortuna) was established to prepare for this. The Committee will need to carefully manage other agenda items to allow sufficient focus on the priority topics.

The Committee agrees that ziphiids of the Southern Hemisphere will be the priority topic at the 2013 Annual Meeting.

The Committee on small cetaceans intersessional group evaluating the feasibility of having the so-called 'marine bushmeat' issue as a future priority topic agreed on a number of attributes important for defining and delineating the issue (see Annex L). The Committee agrees to proceed with planning for a workshop characterised along the lines of 'poorly documented hunts of small cetaceans for food, bait or cash' although this may change somewhat at the discretion of the Convenor. It was emphasised that terminology and definitions as well as the scope and purpose of any workshop should be clarified to in advance. A steering group was established under Ritter (Annex Q).

15. WHALEWATCHING

The report of the sub-committee on whalewatching is given as Annex M. Scientific aspects of whalewatching have been discussed formally within the Committee since a Commission Resolution in 1994 (IWC, 1995b). The Commission also has a standard working group on whalewatching (IWC/64/CC6) that reports to the Conservation Committee (see Item 15.4.1).

15.1 Assess the impacts of whalewatching on cetaceans

SC/64/WW1 reviewed recent advances in whalewatching research. Steckenreuter *et al.* (2012a) investigated the impact of vessel interactions on the behaviour of a genetically distinct population of Indo-Pacific bottlenose dolphins; Steckenreuter *et al.* (2012b) examined the effectiveness of two Speed Restriction Zones (SRZs) in a dolphin-watching area;

03/07/2012

and Harris *et al.* (2012) documented interactions between cruise ships and humpback whales at Glacier Bay National Park (GBNP) in Alaska. Summaries are presented in Annex M, item 5.

SC/64/WW2 reported on a resident population of bottlenose dolphins in Bocas del Toro, Panama, of 100-150 animals. Their predictability and site fidelity has encouraged the development of several dolphin-watching operations. Resolution ADM/ARAP No. 01 (2007) regulates whalewatching activities but few operators are well-informed about the regulations and their importance. This preliminary study found that group size and group presence decrease with increasing number of dolphin-watching boats, although this trend was not statistically significant and that overall, dolphins interacting with boats showed more avoidance behaviour. Future studies in the region will increase survey effort and include new data collection parameters to better characterise effects of dolphin-watching boats on these animals. Discussion and concerns expressed by some members of the sub-committee regarding SC/64/WW2 are detailed in Annex M, item 5.

The discussion further noted that one factor influencing the high volume of operators watching dolphins at the same time is that all operators have similar tour schedules. This results in competition among boat captains, little compliance with the regulations, and an increased risk of boat strikes (three dolphins were killed by dolphin watching boat strikes in 2011). The Committee **draws attention** to the need for developing strategies that minimise the impact of dolphin watching on the dolphin population, including staggering departure times to even out boat presence at any one time of day.

The Committee thanks the author for her presentation regarding a relevant situation in the host country and expressed concern regarding the intense and uncontrolled dolphin watching in Bocas Del Toro. The Committee **strongly recommends** that Panamanian authorities enforce the relevant whalewatching regulation (ADM/ARAP No. 01) and in particular promote adherence to requirements regarding boat number and approach speed and distances. It also **welcomes** the continuation of the Cooperative Agreement between Argentina and Panama to develop and conduct operator training workshops. The Committee **recommends** continued research to monitor this dolphin population and the impacts of tourism on it.

SC/64/WW7 presented a controlled study on the swim-with-whale operations targeting humpback whales in Tonga. Up to five swimmers approached the whales while behaving in one of three ways: quietly slipping into the water and approaching at the surface making minimal noise; approaching whales at the surface

making loud vigorous splashes; or, approaching whales with surface swimming and subsurface diving. The control treatment involved the boat approaching whales with no swimmers entering the water. The measure of disturbance was the time until the whales moved from their original location. Preliminary analyses suggest there was no significant difference between the quiet approach and the control, whereas there was a significantly shorter time to departure when the swimmers were loud and splashing, suggesting the management of swimmer behaviour could reduce the disturbance. Discussion is detailed in Annex M, item 5.

SC/64/WW3 presented a modelling approach to examine the potential effects of dolphin watching. Health was used to link individual behavioural changes to vital rates, since health can moderate survival and reproduction. Behaviours had a cost-benefit relationship with dolphin motivations (e.g. foraging reduces hunger), and health was linked to hunger to avoid biologically unrealistic variation. Trade-offs between motivations (e.g., hunger versus fear) then determines behaviour. Application to a bottlenose dolphin population in New Zealand found increased time foraging and decreased time resting leading to a negative shift in the population's health. A theoretical, larger population was then considered, looking at the potential loss of foraging time due to whalewatching vessels. Population-level impacts were dependent on population size and the intensity of whalewatching activities: larger populations required greater disturbance intensity to realise a population-level effect. These results highlight the need to consider whalewatching impacts and management at the population level. Short-term changes in behaviour can be significant, but do not automatically indicate a threat to the population's long-term health. Discussion and concerns over some aspects of SC/64/WW3 are detailed in Annex M, item 5.

The Committee **welcomes** the use of modelling to address the effects of whalewatching on cetaceans. It was suggested that Bocas del Toro, Panama, might be a location where this model could be tested.

15.2 Review whalewatching off Central America

SC/64/SH16 reported on whalewatching operations used as platforms of opportunity in Costa Rica, mainly offering trips to Marino Ballena National Park and Isla del Caño Biological Reserve, areas used by humpback whales during the winter. It was noted that this is a location where, without action, whalewatching could expand without sufficient oversight or control. It was suggested that this could be an important location for future focussed work to assess the development and evaluation of regulations, monitoring efficacy and compliance. The Committee **expresses** concern that whalewatching operators appear to target mothers and calves, especially as the season progresses.

A survey investigating whalewatching tourists' attitudes toward cetacean conservation issues was undertaken in Blackbird Caye, Turneffe Atoll, Belize in 2007 and 2008 (Patterson, 2011), an area that provides year-round habitat to approximately 200 coastal bottlenose dolphins. Two main types of whalewatching were identified: dedicated cetacean research and incidental cetacean watching. Information relevant to the Committee is detailed in Annex M, item 6.

Annex M, Appendix 2 presents information summarising the known whalewatching operators, areas and targeted species in Central America. All Central American countries have whalewatching activities, primarily concentrated in the Pacific, but only Costa Rica and Panama have organised their industries with tour operator associations. In the south Pacific coast of Costa Rica, workshops to train and certify operators in best practices are being held twice a year. In Panama, operator training started in 2006 and will continue this year. In Guatemala and Nicaragua, whalewatching operators are becoming organised. Belize, Honduras, and El Salvador do not yet have organised whalewatching operators or associations or whalewatching regulations.

The Committee **welcomes** the information provided in Annex M, Appendix 2. It was noted that more whalewatching may be occurring in the region, but it is likely to be incidental or opportunistic.

15.3 Reports from intersessional working groups

15.3.1 Large-scale whalewatching experiment (LaWE) steering group

The convenor for this intersessional correspondence group was unable to attend this year's meeting. A detailed progress report of this group's intersessional work is provided in the appendix of SC/64/WW6.

SC/64/WW6 introduced a meta-analysis to test for significant changes in speed, activity budget, inter-breath intervals and cetaceans' paths during whalewatching events. These changes could lead to increased energy expenditure and reduced foraging. In a call for participants, 10 ultimately provided data, after accounting for quality assurance and control procedures. A random effects model allowed for incorporation of heterogeneity due to moderators, such as study quality and body size. Only presence versus absence of vessels was modelled due to data limitations. Whalewatching activities had an impact in all studies, although the magnitude of the response varied. The only consistent response across species was path linearity and changes in resting behaviour. The only significant moderator was the effect of body size: smaller species and populations were less likely to rest in whalewatching vessels' presence. Researchers were receptive to suggested protocols meant to improve the quality of data collected.

15.3.2 LaWE budget development group

This intersessional group was unable to make progress. The convenor sought information on budget requirements from the LaWE principals, but did not receive sufficient information to develop a budgetary framework. The Committee **strongly recommends** that the principal researchers on the LaWE steering group provide concrete information on budget requirements to the convenor of the budget development intersessional group well before the next annual meeting, to allow this group's work to progress.

15.3.3 Online database for worldwide tracking of commercial whalewatching and associated data collection

Work continued intersessionally to develop a database to keep track of the details of whalewatching operations worldwide. The database developer is working towards putting the current version on the Commission's server for evaluation by the Committee.

15.3.4 Swim-with-whale operations

The questionnaire for operators (Rose *et al.*, 2007) was field-tested on three companies in the Dominican Republic in early 2012. Their responses indicated that the questionnaire was appropriate and sufficient to present more widely to operators. Further work will be undertaken intersessionally to distribute the questionnaire to more operators and report results at IWC 66. The Committee thanks Rachel Ford, who conducted the field test of the questionnaire and the Pacific Whale Foundation which funded Ford's trip to the Dominican Republic.

15.3.5 In-water interactions

The Committee discussed the issue of human-cetacean in-water interactions in the wild in 2011 and an intersessional correspondence group was established (see IWC 2012). In order to examine potential risks to both cetaceans *and* humans, key points will be to identify for whom these in-water interactions are dangerous and what is considered dangerous. Definitions are elaborated in Annex M, item 7. In its workplan, the group proposes to work on a comprehensive list of human cetacean in-water interactions, based on Scheer (2010), and to elaborate a list of areas and operations where in-water-interactions take place.

In discussion, the Committee noted that the Commission's Five Year Strategic Plan for Whalewatching (see Item 15.4.1) may not adequately account for swim-with-whale and in-water interactions as forms of whalewatching. The Committee **recommends** that the Commission address issues that arise uniquely from operations that allow customers to swim with or feed cetaceans. It was suggested that the Commission refer to the Committee's definitions of types of whalewatching, as reported in Parsons *et al.*

(2006), as well as the General Guidelines²⁷ as it progresses its work on whalewatching.

15.4. Other issues

15.4.1 Review scientific aspects of the Commission's Five Year Strategic Plan for Whalewatching

The Committee **agrees** that the goal of its review was to offer the Commission advice that will lead to results that benefit both the work of the Conservation Committee's SWG on whalewatching as well as the Scientific Committee's work. It was clarified that while the Committee focused its input on Objectives 1 (Research) and 2 (Assessment), all five objectives of the Strategic Plan could benefit from further cooperation between the two Committees, particularly in regards to elements such as regulatory frameworks, where this Committee could contribute expertise, data, and other work. The Committee again recognises the ambitious scale of the science-related work programme found in the Strategic Plan and noted that the Commission should consider which actions would require additional time to address (see Annex M, Appendix 3). A working group was convened to formulate the Committee's comments back to the Commission. The Committee **endorses** the results of their consultation, which can be found in Annex M, Appendix 3.

An intersessional correspondence group (Annex Q) was established to discuss and develop guiding principles per Action 1.1 in the Strategic Plan. Action 1.2 should be completed intersessionally, with results reported to the next meeting.

15.4.2 Consider information from platforms of opportunity of potential value to the Scientific Committee

The United Nations Environment Programme-Caribbean Environment Programme (UNEP-CEP), through the Specially Protected Areas and Wildlife Protocol and with the support of the National Environmental Authority of the Government of the Republic of Panama, convened a regional Workshop on marine mammal watching on 19-22 October 2011 in Panama City, Panama (Anon. 2011), bringing together marine mammal tour operators and government regulators from across the wider Caribbean region (WCR). The participants concluded that the data collected during marine mammal watching operations have the potential to answer questions about marine mammal populations in the WCR. Furthermore, these data should involve a network of collectors that cover larger field areas and archived so that they can be accessed and facilitate collaborations. Acknowledging the importance of standardised data, a template data form was developed. A copy of the proposed data form

for the WCR may be found in Appendix V of the workshop report.

The Committee **welcomes** this report on UNEP-CEP's activities and encouraged the submission of work related to this initiative to future meetings (and see Item 15.4.3)

Sollfrank and Ritter () presented results from a study conducted on La Gomera (Canary Islands). Boat-based studies have been on-going for years, but little effort has been made to observe cetaceans systematically from land. This study demonstrated that it is possible to direct whalewatching boats to cetaceans spotted from land, allowing comprehensive and simultaneous data collection from land-based stations and boat-based platforms of opportunity. Land-based observations are the best way to monitor compliance with whalewatching regulations and to measure impacts from whalewatching vessels, as the presence of a research vessel does not influence operators or confound impact results.

M.E.E.R. (2012) laid out a model for a marine protected area for sustainable whalewatching in the Canary Islands. Almost 15 years of cetacean data collected exclusively on whalewatching vessels (platforms of opportunity) were used to elaborate a marine protected area (MPA) model. With anthropogenic threats increasing, the MPA model is especially designed for long-term development of whalewatching and other uses in a sustainable way. It is hoped that this report will contribute to the process of designating effectively managed marine protected areas within the European Union and elsewhere.

The Committee **welcomes** this presentation, as it represents the type of data most relevant to this agenda item and the work of the Committee as it can be applied toward science-based management decisions and actions.

SC/64/O12 reported on the situation in Samaná Bay, Dominican Republic, part of a national marine mammal sanctuary (along with the Navidad and Silver Banks). The Samaná Bay Boat Owners Association provides space aboard whalewatching vessels as platforms of opportunity. Data obtained over a period of 12 years were analysed to determine the spatial and temporal distribution of humpback whales in Samaná Bay. This information has played a vital role in the marine spatial planning of Samaná Bay and the creation of a conservation zone with restricted fisheries and tourism activities during the whale calving season. Details on the results of the study and discussion are found in Annex M, item 8.2

In particular given the expanding development of tourism in Samaná Bay, the Committee **recommends** that monitoring and research continue, especially in

²⁷ <http://iwcoffice.org/conservation/wwguidelines.htm>

light of the increasing number of cruise ships entering the bay during the calving season.

SC/64/SH16 reported that along the South Pacific coast of Costa Rica, whalewatching boats have been used as platforms of opportunity to collect data on distribution and behaviour of humpback whales from breeding stock G from 2009-2011. The results indicated a high number of mother-calf pairs and the use of coastal waters as a breeding ground. It was suggested that this location might be a good place to study the efficacy of a MPA by conducting research on the behaviour of animals inside and outside the MPA.

15.4.3 Review whalewatching guidelines and regulations

Carlson noted that the compendium of regulations and guidelines²⁸ on the Commission website was open, as always, to additions and updates. The Committee thanks Carlson for her committed work in this regard and **agrees** that the compendium is a valuable tool and should be continued. SC/64/WW5 analysed the compendium. The analyses, like the compendium, are intended as a reference, in this case to demonstrate both the diversity and similarities in existing rules. The Committee **agrees** that this analysis would also be a useful reference for the Commission and **recommends** that it also be posted on the Commission website.

The Committee reviewed the General Principles²⁹ and considers them robust. However, it **recommends** that they be renamed 'General Guidelines' (to avoid confusion with the term 'guiding principles'). It **agrees** to revisit them on a more regular basis to ensure they remain representative of 'best practices' and to address them under the standing agenda item on reviewing whalewatching guidelines and regulations.

SC/64/WW1 reviewed several studies that addressed whalewatching guidelines and regulations: Howes et al. (in press) investigated the effectiveness of the Ticonderoga Bay Sanctuary Zone to mitigate pressures of dolphin-swim operations on a small population of bottlenose dolphins; Alves et al. (2011) report on tourists swimming with and feeding Amazon river dolphins in Brazil; Ponnampalam (2011) collected baseline data on the nature of whalewatching in the Sultanate of Oman; and Pacheco *et al.* (2011) describe the success rate of sighting humpback whales from a marine wildlife-watching vessel operating in the coastal waters off northern Peru. Summaries are found in Annex M, item 8.3.

A product of the regional Workshop on marine mammal watching held in Panama (Anon., 2011) was the development of overarching principles and best practice guidelines for marine mammal watching in the WCR (UNEP-CEP, 2011a; 2011b). These principles

and guidelines take into consideration pre-existing codes of conduct and regulations from countries within, and outside, the WCR and closely follow the steps and language used in the document *Pacific Islands Regional Guidelines for Whale and Dolphin Watching* (IFAW, 2008). All of the principles and guidelines developed for the WCR were agreed upon by the tour operators and regulators present at the workshop and may serve as the basis upon which each country's own codes of conduct and regulations may be developed.

Galletti reported that the Chilean Government enacted whalewatching regulations in 2012. Many of the recommendations made by the Scientific Committee in 2007 were included, such as a maximum 300m approach distance for blue whales and allowing only land-based whalewatching for critically endangered southern right whales. Regulations will be translated into English and submitted for the compendium. The Committee **welcomes** this news.

15.4.4 Review of collision risks to cetaceans from whalewatching vessels

No new information was presented under this item.

15.4.5 Swim-with-whales operations

SC/64/WW1 presented information on swim-with programs: Mangott et al. 2011a, reported on swim-with dwarf minke whales on the Great Barrier Reef. The summary is found in Annex M, item 8.5. The Committee **reiterates its recommendation** from item 15.3.5.

15.4.6 Emerging whale watching industry in Oman

Oman's whalewatching industry has experienced gradual growth over the last 10 years, reflecting a steady increase in tourism and a growing awareness of cetacean fauna. The Arabian Sea humpback whale has recently become a target of opportunistic and unregulated whalewatching in southern Oman. The Committee has previously expressed concern over the status of this population which is discussed further under Item 10.7; unregulated whalewatching represents an additional potential threat to this population.

Existing, unofficial whalewatching guidelines in Oman are now over 10 years old. Progress has been made on updating these guidelines as well as gathering data on whalewatching operations, but further technical support is required to finalise the new guidelines as well as to assist with the training of operators.

The Committee **strongly recommends** that operator training workshops should be conducted with a view to promoting best practice for whalewatching and to aid the interpretation and implementation of revised whalewatching guidelines (and see Item 21).

15.5 Work plan

This is discussed under Item 21.

²⁸ www.iwcoffice.org/conservation/whalewatching.htm#regulations

²⁹ <http://www.iwcoffice.org/conservation/wwguidelines.htm>

15.6 Other matters

It was noted that the development of general data requirements on the effects of whalewatching would be valuable in situations where a country is considering whether it would be sustainable to increase the level of whalewatching (e.g., a proposed increase in whalewatching permits for Kaikoura, New Zealand). The concept of assessing 'whalewatching carrying capacity' is of interest in the management and scientific communities and the Committee **encourages** presentation of a paper outlining the situation in New Zealand at the next meeting of the Committee to facilitate its discussions of the broader issue.

16. DNA TESTING

The report of the Working Group on DNA is given as Annex N. This particular agenda item has been considered since 2000 in response to a Commission Resolution (IWC, 2000).

16.1 Review genetic methods for species, stock and individual identification

No documents were presented this year. The Committee encourages the preparation of technical documents on methods for species, stock and identification for discussion at the next year meeting (see also Item 16.5).

16.2 Review results of the amendments of sequences deposited in GenBank

During the first round of sequence assessment (IWC, 2009 pp. 347) some inconsistencies were found that appeared to be due to a lag in the taxonomy recognized by GenBank or uncertainty in taxonomic distinctions currently under investigation: 23 labelled as *Balaenoptera acutorostrata* in GenBank were identified as *B. bonaerensis*; 9 labeled as *B. edeni*; and 10 labeled as *Eubalaena glacialis* were identified as *E. australis* and *E. japonica*. The Committee had recommended notifying the original submitter about the inconsistency and encouraging an amendment to be made to the entry.

Following 2010/11 intersessional work, amendments were made for four cases of Bryde's whale and one case of minke whale, respectively (IWC, 2012 p 52). In view of the limited responses, the Committee had requested that an official letter be sent from the Secretariat requesting the submitters to make the amendments in Gen Bank. This was done for three scientists for which addresses were available, involving nine cases of right whale (one scientist), one case of right whale (one scientist) and one case of Bryde's whale (one scientist). Unfortunately no responses have yet been received and thus no amendments have been made in GenBank during the intersessional period.

In view of this, for the next period, the Committee **reiterates** its previous suggestion on the addition of a field in GenBank where comments on taxonomy updates of the entries can be made (IWC, 2012 p 52). The Committee **agrees** that Cipriano should make a request to GenBank and that he should inform the IWC Secretariat and the Convenor of the DNA Testing Group if a more formal request is required.

16.3 Collection and archiving of tissue samples from catches and by-catches

Last year, the Committee endorsed a new format for the updates of national DNA registers to assist with the review of such updates (IWC, 2012 p 53). The updates of the DNA registers by Japan, Norway and Iceland this year were based on this new format.

The collection of tissue samples in Japan is from special permit whaling in the North Pacific (JARPN-JARPN II) and Antarctic (JARPA-JARPA II), and from bycatches. It includes coverage for 1994-2011 (JARPN-JARPN II), 1987/88-2011/12 (JARPA-JARPA II). In the case of bycatches it includes coverage for 2001-2011 (see Appendix 2 of Annex N).

The collection of tissue samples in Norway is from the commercial catches of North Atlantic common minke whales. It includes coverage for the period 1994 to 2011 (see Appendix 3 of Annex N).

The collection of tissue samples in Iceland is from scientific whaling and from commercial catches. It includes coverage for 2003-2007 (permit whaling) and 2006-2011 (commercial whaling) (see Appendix 4 of Annex N).

16.4 Reference databases and standards for diagnostic registries

In the Japanese register, almost all common minke whale sampled by JARPN-JARPN II in 1994-2011 were screened for mtDNA and microsatellites. Almost all of minke whales bycaught in 2001-2010 were screened for mtDNA and microsatellites. For animals bycaught in 2011, the percentage for microsatellite is lower (77.8%). This lower percentage is a result of the loss of 26 samples after the 2011 tsunami in Japan (see Appendix 2 of Annex N).

Almost all Bryde's whales sampled by JARPN II in 2000-2011 were screened for mtDNA and microsatellites. Genetic work for mtDNA and microsatellite was completed for four whales bycaught in 2001-2010. Almost all sei whales sampled by JARPN II in 2002-2011 were screened for mtDNA and microsatellites (see Appendix 2 of Annex N).

Almost all sperm whales sampled by JARPN II in 2000-2010 were screened for mtDNA and microsatellites. The single animal sampled in 2011 was screened for mtDNA. Microsatellite work has not been completed yet. All sperm whales bycaught in 2001-

2010 were screened for mtDNA and microsatellites (see Appendix 2 of Annex N).

In the case of Antarctic minke whales, 16.5% and 92.3% of the whales sampled by JARPA in 1987/88-2004/05 were screened for mtDNA and microsatellites, respectively. Work for mtDNA is ongoing. Many of the samples of JARPA II (2005/06-2010/11) were lost after the 2011 tsunami in Japan. DNA work is ongoing on the recovered samples. For animals sampled in 2011/12, the mtDNA and microsatellite work has not yet been completed. For Antarctic fin whales, the 17 samples collected by JARPA II in 2005/06-2010/11 were screened for mtDNA and microsatellites. The DNA work on the single animal sampled in 2011/12 is ongoing (see Appendix 2 of Annex N).

All North Pacific humpback whales bycaught in 2001-2011 were screened for mtDNA and microsatellites. Two North Pacific right whales and three North Pacific fin whales bycaught from 2001-2010 were screened for both mtDNA and microsatellites (see Appendix 2 of Annex N).

Almost all samples in the Japanese DNA registry have been sexed (see Appendix 2 of Annex N).

A suggestion was made that the genetic data of bycaught humpback whales could be of utility for testing hypotheses on stock structure of this species in the western North Pacific.

In the Norwegian register, after discounting for duplicates, missing samples and laboratory problems, 100% of the North Atlantic common minke whale caught in 1997-2011 were screened for mtDNA and microsatellite (see Appendix 3 of Annex N). The Committee **commends** the analyses on quality control carried out on the Norwegian DNA register (Glover *et al.*, 2011).

In the Icelandic registry, all common minke whales sampled under scientific permit whaling in 2003-2007 were screened for mtDNA and microsatellites. The percentage for both markers is 6.1% for whales taken by commercial whaling in 2007-2010. The percentage is 3.5% for whales taken by commercial whaling in 2011. All fin whales caught by commercial whaling in 2006-2010 were screened for both mtDNA and microsatellites (see Appendix 4 of Annex N). A question was raised on the low percentage for the commercial samples of common minke whale. In response, Víkingsson noted that while not required by IWC rules or regulations, tissue samples had been collected for the DNA register from all animals caught in the Icelandic commercial hunt. The delay in the laboratory analyses of samples collected since 2007 is due to funding restrictions but these will be completed before the *Implementation Review* of North Atlantic common minke whales scheduled for 2014.

The Committee appreciates the efforts of Japan, Norway and Iceland in compiling and providing detailed information on their registries in the new format. The Committee **agrees** that the information provided in the new format facilitated greatly the annual review.

16.5 Work plan

The Committee **encourages** the submission of papers in response to requirements placed on the Committee by the IWC Resolution 1999-8 (IWC, 2000). Relevant information in documents submitted to other groups and sub-committees of the Committee will be reviewed next year. Results of the ‘amendments’ work on sequences deposited in GenBank will be reported next year.

17. SCIENTIFIC PERMITS

This Agenda Item was discussed by the Working Group on Special Permits in two late afternoon sessions to enable all Committee members who wished so to attend. Bjørge was elected Chair of the Working Group. Weller acted as Rapporteur, and the Working Group report has been directly incorporated here.

17.1 Review of results from existing permits

As in previous years, the Committee received short cruise reports on activities undertaken but spent relatively little time on discussion of the details. For long-term programmes the Committee has agreed that regular periodic detailed reviews (following ‘Annex P’) were more appropriate.

17.1.1 JARPN II

17.1.1.1 AUTHORS’ SUMMARIES

SC/64/O3 presented the results of the 2011 Japanese Whale Research Program under Special Permit in the Western North Pacific-Second Phase (JARPN II) offshore component survey in sub-areas 7, 8 and 9 of the western North Pacific. There were three main research components: the whale sampling survey; the dedicated sighting survey; and the whale prey species survey. Two sighting/sampling vessels (SSVs), 1 research base vessel (NM whale sampling survey component), 1 whale prey survey vessel equipped with scientific echo sounder (PSV and 3 dedicated sighting vessels (SVs) were used. The whale sampling survey took place from 11 June to 5 September 2011. A total of 5,156 n. miles was surveyed in 76 days (by the SSVs and NM) sightings included, 53 common minke, 476 sei, 149 Bryde’s, 295 sperm, 66 fin and 8 blue whales. A total of 49 common minke, 95 sei, 50 Bryde’s and one sperm whale were sampled by the SSVs. Sampled whales were examined on board the research base vessel. In July, common minke whales fed mainly on Japanese anchovy near Syriya, and they fed mainly on walleye pollock around east of Hokkaido. There were geographical changes of prey species of minke whales

in sub area 7. Sei whales fed mainly on copepods and Japanese anchovy from June to August in sub areas 8 and 9. Bryde's whales fed mainly on krill in sub area 7 in July. Dominant prey species in the stomach of the sperm whale included mid- and deep-water squid. The dedicated sighting surveys took place from 28 April to 6 June 2011 in sub areas 8 and 9. During 4,060 n. miles surveyed 3 common minke, 51 sei, 6 Bryde's, 116 sperm, 31 fin and 4 blue whales were sighted. The prey species survey was carried out from 13 to 28 June in 2011. In parts of sub areas 8 and 9 by the PSV. Its objective was to estimate sei whale habitat and prey preference in relation to oceanographic and prey environments as well as productivity in early summer. Data obtained in this research will be used to elucidate the role of whales in the marine ecosystem through the study of whale feeding ecology in the western North Pacific.

SC/64/O4 presented the results of the 2011 JARPN II - coastal component- survey in spring. Usually the coastal spring survey is carried out in the locality of Ayukawa. On March 11 2011 the Ayukawa town, including all research facilities of JARPN II there, was destroyed by a large earthquake and tsunami. For this reason, the 2011 spring coastal survey was conducted in Kushiro, from 25 April to 10 June, using three vessels. Sampling occurred within 50 n. miles from Kushiro port, and animals were landed at the JARPN II research station. A total of 3,867.4 n. miles was surveyed and 36 schools (43 individuals) of common minke whales were seen and 17 common minke whales were sampled. Average body length was 6.70 m (SD=0.84, $n=9$) for males and 6.29 m (SD=1.02, $n=8$) for females. Dominant forestomach prey species were walleye pollock (*Theragra chalcogramma*) throughout all of the survey period, and krill (*Euphausia pacifica*) that was observed less frequently. Walleye pollock is one of the most important food items for common minke whales in Kushiro in both spring and autumn seasons. Distribution of common minke whales appeared to differ between spring and autumn surveys in Kushiro, at least for some years.

SC/64/O5 outlined the results of the autumn survey of the JARPN II coastal component off Kushiro, northeast Japan (the sub-area 7CN) in 2011. The survey was conducted from 9 September to 30 October 2011, using four vessels. During 5,367.8 n. miles searched, 144 schools and 150 individual common minke whales were sighted and 60 whales were sampled. Average body length was 6.24 m (SD=1.06, $n=35$) for males and 6.05 m (SD=1.08, $n=25$) for females. Overall, 19 of the 35 males (54.3%) and 3 of the 25 females (12.0%) were sexually mature. The dominant forestomach prey species was Japanese anchovy (*Engraulis japonicas*) (61.7%), followed by walleye pollock (26.7%), and krill (8.3%). Pacific saury (*Cololabis saira*) and Japanese common squid (*Todarodes pacificus*) were

not observed. The frequent sightings of whales in combination with the slightly higher ratio of mature and larger whales in the 2011 survey, as compared to the 2010 survey, as well as more whales consuming Japanese anchovy suggested that the abundance and distribution of this prey item may have attracted whales to the coastal waters off Kushiro in autumn 2011. During the survey, no apparent impact due to the earthquake in March 2011 was detected in the distribution, density or catch composition of common minke whales. This implied that effect of the earthquake on the migration of common minke whales in the coastal waters off Kushiro might be negligible.

17.1.1.2 DISCUSSION

Following the cruise report presentations, there was some discussion of how the cruise tracks for the coastal survey off Kushiro were designed and if the intent was to obtain a representative sample or rather to increase the probability of encountering whales. The authors of SC/64/O5 explained that survey vessels used during the coastal component of the programme departed port each day following a number of predetermined lines with 15° radials that were selected on a daily basis after review of weather, oceanographic conditions and the distribution of whales. Survey tracks were concentrated relative to whale distribution and differed from standard line transect methods in that the first 30 n. miles were dedicated to survey search mode followed then by the vessels moving freely within the study area. In further discussion, the Working Group was reminded that at last years meeting it was suggested that whales taken during coastal operations be examined for radionuclides, especially caesium-137, for use in stock elucidation (IWC, 2012). The authors of SC/64/O4 stated that one of the three objectives of the JARPN II programme was to monitor environmental pollutants in cetaceans and the marine ecosystem. Data collection for radionuclide assessment is being undertaken and data are available on the website of the Fisheries Agency of Japan.

17.1.2 JARPA II

17.1.2.1 AUTHORS' SUMMARY

SC/64/O2 presented the results of the 2011/12 survey of the Second Phase of the Japanese Whale Research Program under the Special Permit in the Antarctic (JARPA II). Two dedicated sighting vessels (SV), one sighting and sampling vessel (SSV) and one research base vessel engaged in the research for 66 days, from 1 January to 6 March 2012 in Areas V (130°E - 170°W) and VI West (VIW: 170°W - 145°W). Unfortunately, the research activities were interrupted several times by the violent sabotage activities of an anti-whaling group. The planned dedicated sighting survey had to be cancelled so that the vessels could undertake security tasks. The research activity of the SSV was also interrupted several times. The total search distance by the SSV of 3,040.5 n. miles, was approximately one-

03/07/2012

third of the search distance in 'normal' years. Eight species including six baleen whales (blue, fin, sei, Antarctic minke, humpback and southern right whale) and two toothed whales (sperm and southern bottlenose whales) were seen. The most common species seen (284 schools, 684 individuals) was the Antarctic minke whale followed by the humpback (112 schools, 208 individuals) and fin whales (11 schools, 31 individuals). A total of 266 Antarctic minke whales (99 males and 167 females) and one fin whale (female) were sampled examined on the research base vessel. A total of five blue, six humpback and four southern right whales were photo-identified. Two biopsy samples were collected from humpback whales and four from southern right whales. In March, satellite tags were deployed on two southern right whales. Oceanographic surveys to investigate vertical sea temperature profiles were also implemented using XCTD. In summary (1) whale composition in the research area was stable compared to previous JARPA and JARPA II surveys in the same area; (2) the ice-free extent in Area VIW was substantially larger than in previous seasons; (3) high density areas of Antarctic minke whales were observed near the ice edge; (4) mature female Antarctic minke whales were dominant in the southern part of Area VIW (66.8%); and (5) Antarctic minke whales in the 'transition area between 130°E and 165°E' (area of stocks mixing), were successfully sampled.

17.1.2.2 DISCUSSION

Following the presentation of the 2011/12 JARPA II cruise report, it was noted that the lack of discussion did not imply there is agreement on the issue of scientific whaling under special permits. Differing views on this activity remain and the Working Group was referred to the statements made in Annex P1 and Annex P2.

17.1.3 *Planning for a final review of results from Iceland - North Atlantic common minke whale*

The results from the Icelandic programme on common minke whales will be subject to final review during the coming intersessional period. 'Annex P' (IWC, 2009) documents the review process. The only time this procedure has been used was to review the JARPN II Special Permit in 2009 (IWC, 2010a). While the process worked well in general (IWC, 2010b), improvements on some aspects of the implementation of the process have been agreed and are detailed in Annex P4 of last year's report (IWC, 2012 pp. 310-311). One change in implementing the 'Annex P' procedure (IWC, 2009) will be the presence of observers. The general outline of the workshop includes an initial session where a restricted number of scientists associated with the proposal will present results of their research and answer questions. Then the main part of the review workshop will be closed sessions where the expert panel evaluates the results. At the end of the workshop there will be a short open session where the expert panel can ask scientists

associated with the proposal questions for clarification. Observers will be allowed to the open sessions. In light of these modifications, the timetable to be used for the Iceland and JARPA II reviews is presented in Table 3 of Annex P4 (IWC, 2012 pp. 310-311).

Vikingsson stated the Working Group that Iceland will meet the requirements of the time schedule of Annex P4 (IWC, 2012 pp. 310-311) for a review in 2013. The Working Group **agrees** that the review of results from Iceland will occur February/March 2013.

SC/64/SCP1 addressed the data availability under Procedure B of the Data Availability Agreement. A small group was set up to consider this document. The Committee agrees the clarifications to 'Annex P' (IWC 2009) included as Annex P3.

17.1.4 *Planning for a periodic review of results from JARPA II*

The Working Group **agrees** that the review of results from JARPA II will occur February/March 2014.

17.2 Review of new or continuing proposals

17.2.1 JARPA II

Japan reported that there was no plan to change the JARPA II programme.

17.2.2 JARPN II

Japan reported that there was no plan to change the JARPN II programme.

18. WHALE SANCTUARIES

The Committee received no new proposals for sanctuaries this year. The report of an international workshop on Marine Protected Areas (SC/61/O20) was discussed under Annexes K and M.

19. SORP

The Southern Ocean Research Partnership (SORP) was proposed by the Australian Government to the IWC in 2008 (IWC/60/16) with the aim of developing a multi-lateral, non-lethal scientific research programme to improve the coordinated and cooperative delivery of relevant scientific information to the IWC. The Partnership now includes ten countries: Argentina, Australia, Brazil, Chile, France, Germany, New Zealand, Norway, South Africa and the USA. A framework and set of objectives for SORP have been endorsed by the Committee (IWC, 2011) and six SORP research projects were endorsed last year (IWC, 2012). Progress of these research projects was reviewed this year. The IWC has a budget specifically related to the work of SORP established with a contribution from Australia in 2008 and supplemented by additional voluntary contributions from Australia and the USA in 2011. This budget is administered by the IWC Secretariat.

SORP was originally discussed in an open session, chaired by Gales and rapporteured by Bell. The report of that session is incorporated directly into the plenary report here.

The Committee noted that in April 2012, Bell was appointed the Southern Ocean Research Partnership coordinator replacing Childerhouse and Wadley was appointed the Antarctic Blue Whale Project coordinator.

19.1 Review of progress since IWC 63

SC/64/O13 summarised the progress of SORP since IWC63. Progress was made on the following major items:

- (1) *Overall support and progress of the six SORP research projects* – progress reports for the 2011/12 period are available in SC/64/O13;
- (2) *Provision of interim funding* – funding was provided for all six SORP projects to support research during 2011/12 (SC/63/SC-report);
- (3) *Further development of the SORP Antarctic Blue Whale Project (formerly known as the SORP Year of the Whale Project);*
- (4) *Planning and implementation of collaborative SORP Antarctic blue whale expeditions* – two expeditions led by Australia were undertaken in the austral summer of 2011/12 (SC/64/SH11) to develop and test methodologies that will be employed during the SORP Antarctic Blue Whale Voyage planned for early 2013 (SC/64/SH13). Further development of acoustic methods (SC/64/SH12) and survey design (SC/64/SH10, SH14, SH26) was also undertaken;
- (5) and *Completion of the core SORP project*: The Living Whales Symposium and Workshops, held in Chile in March 2012 (SC/64/O14).

These items are covered in more detail below. The Committee was **pleased** to note that SORP is being successfully implemented and **welcomes** the results.

19.1.1 SORP Antarctic Blue Whale Project

The title ‘Antarctic Blue Whale Project’ (ABWP) now replaces ‘The Year of the Whale’ (YOTW) to reflect the fact that the proposed research will require a multi-year, multi-platform, integrated and coordinated research effort. This became clear following discussions within the Committee and intersessionally, particularly given the extensive methodological development (SC/63/SH3; SC/63/SC-report Annex H; SC/64/SH10-14, SH26) reported. A single season effort is not an appropriate strategy to deliver an estimate of circumpolar abundance, given logistical constraints and the preferred sampling regime under a mark-recapture approach.

The specific objectives of this initiative are to:

- (1) provide a circumpolar abundance estimate for Antarctic blue whales;

- (2) improve understanding of Antarctic blue whale population structure;
- (3) improve understanding of connectivity between blue whale feeding and breeding grounds;
- (4) and to characterise foraging habitat of blue whales.

SC/64/O13, SH10-14 and SH26 were discussed in Annex H. The project was very well received as an investigation to determine the viability of ideas and methods. Gales welcomed the maturing ideas and methods under development and their implementation in the Southern Ocean during 2012/13. Results from the ABWP have been presented at international scientific meetings, including the International Polar Year conference in Montreal, April 2012.

The importance of SORP as a means to engender international cooperation was noted. There are encouraging signs that estimating the circumpolar abundance of blue whales will be possible.

19.1.2 Ways to expand Antarctic Blue Whale Project (ABWP) work

SC/64/O16 provided information about the South African Blue Whale Project (SABWP) and it was discussed in annex H. Despite evidence of recent increase, the population of Antarctic blue whales remains severely depleted from commercial whaling. Both the high concentrations of sightings of Antarctic blue whales in the 0-20° E sector of the Antarctic in recent years (IWC IDCR/SOWER and SOWER sighting records) and the high historic catches of some 12,000 probable Antarctic blue whales off the west coast of South Africa, Namibia and Angola prior to 1930, suggest that the southeastern Atlantic Ocean and neighbouring Southern Ocean region should provide exciting opportunities for research on Antarctic blue whales. The South African Blue Whale Project (SABWP) has been recently funded by the South African National Antarctic Programme (SANAP) and the National Research Foundation (NRF) to investigate the seasonality, distribution and relative abundance of this species in these areas with the long-term aim of determining relative abundance indices to measure the population trend. Research efforts will be concentrated in two regions; 67°S to the ice edge and 0-20°E region in summer, and off the south-western Cape coast in winter. Autonomous Acoustic Recorders (AARs) will be deployed in both the high and low latitude regions to determine distribution and seasonality patterns of this migratory species. Line-transect surveys (incorporating photo-identification, biopsy sampling and ship-based passive acoustic monitoring) will be carried out in the Antarctic region during summer to provide abundance and call-rate measurements for ‘broadbrush’ ground-truthing of Antarctic AAR data. Low-latitude AAR data will provide information on where and when to concentrate future research efforts off the south-

western Cape coast. Data from this voyage will contribute to the ABWP and other SORP projects. A proposal for one of the team to receive training in AAR deployment during a cruise off Greenland this summer (SC/64/O17) has been adopted.

Norway joined SORP two years ago. Norway may contribute to SORP in the following manner:

- (1) Financially: upon provision and favourable review of a budget and research proposal from existing or new SORP projects, Norway would be willing to fund research. Norway does not have to be involved in the research proposal.
- (2) In kind support: annually, Norway sends scientists on fishing vessels that work in the Southern Ocean, in 2012/13 primarily around the South Orkney Islands. Biannually, the Norwegian vessel R/V *G O Sars* operates in the Southern Ocean I.A. in the area around Bouvet Island. This is a dedicated research vessel that can be directed to other areas. It will next sail in 2013/14 (to be confirmed). Berths on these vessels could be made available to SORP researchers.
- (3) Personnel: the expertise of Norwegian scientists could be provided for collaboration on SORP research projects.

Particular interest was expressed in contributing to the Antarctic Blue Whale Project.

The Committee **greatly welcomes** Norway's offer of monetary, in kind and personnel support for SORP and **agrees** that it will be resolved intersessionally how it will be managed and administered.

The Committee was informed of France's intention to use the R/V *l'Astrolabe* to carry out a photo-identification and sightings surveys of blue whales in Terre Adélie. Surveys will be carried out over the next two years and it is hoped it can be continued for up to four years. A marine science voyage is also being considered in the southern Indian Ocean, south of Kerguelen on the Marion Dufresne. It is hoped that time may be allocated on this to perform blue whale research but it is a highly competitive process.

The Committee was informed of Germany's intention to perform their fifth cetacean survey from January to mid-March 2013 in the western Weddell Sea. This will be a repeat of the 2006/7 survey. The aim is to relate krill abundance to hydrography and oceanography. Helicopters will be used as the survey platform.

The Committee was also informed of plans by the International Fund for Animal Welfare for a Southern Ocean voyage that may be able to contribute to the Antarctic Blue Whale Project through combined acoustic surveys and photo-identification.

It was noted that collaboration with the wider Antarctic community is underway with SCAR, COMNAP,

IAATO and CCAMLR to pursue the objectives of the ABWP.

The Committee **encourages** international involvement in the SORP Antarctic Blue Whale Project in the form of research, ship time or personnel. The Committee also stressed the importance of standardised protocols and shared data access across a range of data types, and **encouraged** their adoption across international cetacean research programmes.

19.1.3 Killer whales in the Southern Ocean

The principal investigators once again participated as 'visiting scientists' on board the tour vessel M/V *National Geographic Explorer*, during four consecutive trips to the Antarctic Peninsula from 7 January to 15 February 2012; approximately 3000 photo-id images of over 200 individually-recognisable animals for future mark-recapture analyses were obtained; 2 skin biopsy samples were obtained (samples archived at SWFSC), and 3 individuals were satellite-tagged. Data are presented in the full project report in Annex 1 of SC/64/O13. Other tour ships operating in the Antarctic Peninsula area were also canvassed for killer whale photographs and thousands of images were obtained from over two dozen killer whale encounters. The principal investigators feel confident that within the next year or two they should have enough images to estimate population sizes for the three types of killer whales that are recognised in the Peninsula Area.

The Committee **commends** the work of the principal investigators.

The Committee was also informed of new killer whale photo-id data from the Institut Polaire Française (IPEV), CETacés Terre Adélie project that is available for 35 individuals in Terre Adélie, eastern Antarctica (SC/64/SM6).

19.1.4 Foraging ecology and predator prey interactions of baleen whales and krill

During the funding period, significant progress was made towards the overall goal of understanding the foraging ecology and predator-prey interactions between baleen whales and krill in the waters around the Western Antarctic Peninsula. Analysis was completed describing the diving behaviour of humpback whales from suction-cup tags deployed in 2009 and 2010. These results were presented at numerous scientific meetings including the Biennial Conference on the Biology of Marine Mammals (Tampa, FL, November 2011), and the recent SORP workshop on non-lethal research techniques for studying cetaceans (Puerto Varas, Chile, March 2012). A full project report is included in Annex 1 of SC/64/O13.

The main findings of the project to date are summarised below:

- (1) Humpback whales were found to feed almost exclusively during night-time hours in late autumn (May/June), spending daylight hours either resting or traveling. The initiation of feeding was often proceeded by deep exploratory dives that are hypothesised to sample the water column to determine where prey are distributed.
- (2) Humpback whales appear to achieve or conform to ecological predictions of optimal foraging theory in two significant ways: By increasing the number of feeding lunges executed per dive with increased dive depth; and by targeting higher densities of krill as feeding depth increases
- (3) While both of these findings are significant, the fact that the principal investigators have been able to quantify increases in prey density concurrent to whale feeding is novel. The information provided from this relationship will be a substantial component of the manuscripts that are currently in preparation to be submitted for peer review.
- (4) Humpback whales vary the depth of their feeding in relation to the diel vertical movement of krill in the water column.

The Committee **welcomes** these results and **encourages** further work to enhance understanding of humpback whales that overwinter in Antarctica. Gales noted that additional satellite and datalogger work on humpback and minke whales was planned.

19.1.5 Oceania humpback whale mixing

The focus of this project has been on preparing for the proposed 2013 satellite tagging work at the Kermadec Islands and American Samoa (SC/63/O13). The Oceania humpback whale population estimate has been published (Constantine *et al.*, 2012) with a sex-specific POPAN super-population model, which accounted for residents and whales migrating through the survey areas, giving an estimate of 4329 whales (3345–5313) in 2005.

In the winter of 2011, satellite tagging work was undertaken in New Caledonia (Garrigue in collaboration with Zerbini and Clapham) adding to the 2007 (Garrigue *et al.*, 2010) and 2010 tagging efforts. The general trend observed was for the majority (~75%) of whales to head in a south-southeasterly direction once they left the New Caledonia breeding grounds. Some whales stopped at seamounts or other undersea geographic features along the way for varying lengths of time.

The Raoul Island (Kermadec group) single day four hour survey conducted between 0800 and 1200 hrs was conducted on the 8th October 2011. This adds to the previous three years of October surveys using a standard set of seven land-based locations (Potier, 2008; Brown, 2009; Brown, 2010)³⁰. Previous whale-counts from these surveys have ranged from 62-153

whales and the 2011 survey counted 126 individual whales (Potier and Shanley, 2012)³⁰. The consistently high number of humpback whales observed migrating past Raoul Island, peaking in October, confirms the Kermadec Islands as the southernmost location in Oceania with regular whale sightings and the ideal site to attach satellite tags as the whales migrate south. Constantine will visit the Kermadec Islands in August 2012 to consider this research site. Research in American Samoa conducted in the 2011 field season continued preparation for the planned satellite tagging in 2013.

Future work will focus on addressing two questions.

- (1) What is the connection between the humpback whales from Area V feeding grounds and their migratory corridors and breeding grounds in Australia and Oceania?
- (2) Do whales from Area V represent a single breeding ground or are they a mix of individuals from several distinct breeding grounds?

A full project report is included in Annex 1 of SC/64/O13.

19.1.6 Fin and blue whale acoustics

Understanding baleen whale distribution and abundance in the Antarctic, particularly blue and fin whales, is complicated by the pelagic distribution of both species, the difficulty of working in the Southern Ocean (SO) and the massive decline of both due to commercial whaling. After a half-century of protection, little is known about the present-day status of each species. Blue and fin whales are congeners that are the largest mammals on earth. Both occur in all oceans of the world with similar distribution patterns. In particular, each species occurs in high latitudes in the Southern Hemisphere. In the Antarctic, blue whales are generally thought to occur closer to the ice edge than fin whales. Blue whales are designated as different subspecies, i.e. Antarctic (*B.m. intermedia*) and pygmy types (*B.m. brevicauda*), and Chilean blue whales are also considered an unnamed subspecies, or at least a separate management unit. In the case of fin whales in the Southern Hemisphere, two subspecies have been considered: *B. physalus quoyi* for the Southern Ocean form and the pygmy fin, *B. p. patachonica* found in the northern parts of the Southern Hemisphere.

Both blue and fin whales were targets of commercial whaling, particularly from the early 1900's through the 1930's, leading to heavy depletion. Blue whales were protected internationally from whaling in 1966 and fin whales in 1985. At present, both species are listed as Endangered by the IUCN and there are no reliable population estimates for either species globally. A recent examination of almost 40 years of sighting data resulted in an estimate of 2,280 (CV = 0.36) Antarctic blue whales, which is less than 1% of the original

³⁰ Unpublished field reports

population (Branch 2007). There are no equivalent estimates for SH fin whales.

From 1978 to 2010 the IWC supported the annual IDCR/SOWER Antarctic cruises that consisted of three circumpolar sets of cruises over multiple years that focused primarily on minke whale abundance but that also provided an estimate of abundance for Antarctic blue whales (Branch *et al.* 2004). Only two of the recent cruises focused on fin whales (Ensor *et al.* 2006, 2007). Given the amount of effort, ship time, high risk of poor weather and cost of sighting cruises, it is unlikely that the tremendous shipboard effort of IDCR/SOWER will be repeated. In order to continue to monitor Antarctic blue and fin whales, the use of a network of long-term passive acoustic recorders has been proposed *in lieu* of dedicated circumpolar visual surveys.

Passive acoustic monitoring is a robust means of monitoring blue and fin whales in remote areas over long time periods, including around the Antarctic. The present analysis of all the available data shows the geographic and seasonal occurrence of blue and fin whales around the Antarctic. However the lack of overlap in the years and locations monitored, the differences among instruments and analysis methods used, underlines the need for coordinated effort. To best exploit passive acoustic data long term, a pan-Antarctic monitoring system needs to be put in place and maintained. Thus far there has been a positive response from many countries regarding this project. In the near term the principal investigators need to find the finances and continue instrument development to facilitate a coordinated research effort. Further a single method either for each species or for both needs to be adopted for analysing the data. A review of existing methods for estimating relative abundance from passive acoustic sensors demonstrates that the scientific question of interest will drive the analysis methods chosen. The principal investigators suggest that the Australian Marine Mammal Centre, based at the Australian Antarctic Division, Hobart, maintain a database of the metadata and data from hydrophones and make these freely available if possible.

Acoustic data from a single hydrophone present unique challenges to density estimation: to overcome these, the principal investigators need to improve their knowledge of call rate, acoustic behavior and source level of whales; detection distance and sound propagation (environmental parameters and ambient noise level). Methodology to estimate the density of whales from acoustic data is advancing rapidly and it is anticipated that if understanding of the parameters above is improved, density estimation using passive acoustic data will become the state of the art for monitoring Antarctic blue and fin whales. A full project report is included in Annex 1 of SC/64/O13.

The Committee **commends** the work of the principal investigators and it was noted that this project addresses the research priorities identified by SORP to meet the overall objectives of the IWC.

It was highlighted that it will provide valuable data for blue whales and may provide the only practical way to obtain data about fin whale abundance, information that the scientific community currently does not have. From this data it may be possible to estimate trends in blue and fin whale populations over decadal scales.

This work is closely aligned with the objectives of the Antarctic Blue Whale Project. It was also noted that that the global economic situation is very likely to reduce the amount of ship time available to researchers in the future, therefore the development of acoustic methods such as these are essential for continued, non-lethal cetacean research.

19.1.7 Living Whales Symposium and non-lethal research techniques workshops

SC/64/O14 summarised the Southern Ocean Research Partnership Symposium and Workshops entitled 'Living whales in the Southern Ocean: advances in methods for non-lethal cetacean research'.

The Symposium and accompanying workshops were held in Puerto Varas, Chile from 27-29th March 2012, to discuss recent advances in methods for non-lethal research on whales in the Southern Ocean. The Symposium was attended by 124 registered participants from 16 countries and was also live streamed on the web, allowing an 1,553 simultaneous viewers.

The first day was an open Symposium with invited experts who showcased new non-lethal research methods for whales in the Southern Hemisphere. The Symposium talks were divided across five sessions that covered an overview of the history of whaling, evolution of non-lethal techniques and the role of whales in Southern Ocean ecosystem. These were followed by sessions on molecular techniques, biologging, remote sensing and long-term non-lethal research. A PDF of the talks are already available³¹ and the videos of each talk, in English and Spanish, will soon be available.

The Symposium was followed by two days of Workshops that covered specific research areas. The Workshops were each one day in duration and covered the following topics:

- (1) health assessment of live cetaceans;
- (2) advances in long term Satellite Tagging Techniques for Cetaceans;
- (3) population dynamics and environmental variability; and
- (4) estimation of diet and consumption rates from non-lethal methods.

³¹ www.simposioballenas.cl

The workshop health assessment of live cetaceans reviewed several techniques obtained from blow samples, biopsy samples, collection of faeces, visual health assessment, photogrammetry, blow intervals and respiration rates, among others. The workshop identified two main aspects:

- (1) health assessment data and studies should be integrated with population dynamics data, where possible; and
- (2) integration of live animal health assessment with studies on dead and stranded animals, particularly within the same geographical region, is highly informative and should be a priority. The priority areas for further consideration in health assessment include nutritive stress and body condition; feeding and fasting or starvation state; skin lesions; stress; emerging issues and exposures; and particularly, standardisation of methodologies.

The workshop on large whale population dynamics and environmental variability explored which life history parameters can be connected with environmental variability and highlighted the need for researchers to collect data on body condition, mortality and reproductive output, among others. The workshop also evaluated different analytical and simulation techniques to incorporate environmental variability into population models and recognised the need of long term data sets to detect such effects. The workshop recommended that long-term studies, photo-identification and biopsy sampling be routinely collected and promoted the use of geochemical tracers (e.g. stable isotopes) and other 'eco-markers', including DNA, since this approach can help to identify foraging locations of populations.

The workshop advances in Long-Term Satellite Tagging Techniques for Cetaceans and their Application to Address Research Questions in the Southern Ocean reviewed advances on tag development and dedicated studies to address possible physical and physiological effects of satellite tags on cetaceans. The workshop highlighted that effort could be directed to minimise the size and diameter of body-penetrating satellite tags in order to minimise trauma of implant and water ingress and promoted the use of an alternative to body-penetrating tags, such as new designs with external electronics and a long anchoring system. It was agreed that new designs for cetacean tags ought to be developed and that priority should be given to accelerometer and dive/surface interval data and to the development of algorithms that can compress data for transmission via Argos. The workshop also recognised that some devices have the potential to cause considerable tissue damage and that studies on carcasses derived from incidental mortality should be conducted, as well as monitor tagged animals. Finally, the workshop highlighted the need to create awareness on the use of these techniques within local

communities, regulatory agencies and the general public prior to tagging project.

The workshop on Estimation of Diet and Consumption Rates highlighted several techniques that might be used to achieve this difficult objective. Tagging studies could provide information about foraging effort, photogrammetric techniques about individual fitness and steroid-hormone samples (from faeces or biopsy) about reproductive status. Understanding interspecific differences in prey preference will help to predict how climate driven changes affect krill and, ultimately whales. The value of understanding how local oceanographic conditions and prey availability affect the foraging behaviour and distribution was highlighted. Also recognised was the need to improve understanding of foraging strategies, prey choices, feeding destinations, etc. and recommended the use of several dietary tracers, such as stable isotope analysis, and molecular techniques, for diet reconstruction alongside fecal sampling and fatty acid analysis.

In summary, the Symposium and Workshops were very successful. The event drew a large audience and the Symposium organisers recommend the use of live broadcast technologies alongside simultaneous translation as a means to reach a wider audience in future events. The workshops gave an excellent overview of existing and new research techniques and contributed enormously toward setting guidelines and prioritising research needs for improving our current scientific understanding and techniques.

The Symposium organisers and the SORP Scientific Steering Committee **thanked** the sponsors of the Symposium and Workshops: the Ministry of Foreign Affairs, Chile; the directorate of Maritime Territory and Merchant Marine of Chile; the Australian Government; the National Oceanic and Atmosphere Administration of the United States (NOAA); Oregon State University; the International Fund for Animal Welfare; the South Pacific Research Whale Consortium; Altavoz; and the Cetacean Conservation Center Chile. The Symposium and Workshops represent a completed Southern Ocean Research project. The full report can be found in SC/64/O14.

The Committee **thanks** the Symposium organisers, in particular Galletti, Baker and their teams for their work and congratulated them on their success. The usefulness of the Symposium and Workshops for improving current non-lethal techniques for cetacean research was stressed. It was noted that some of these will be applied to research to be conducted in the coming field season, e.g. by Argentinean researchers. It was also noted that useful recommendations came out of the Workshops with regard to research on climate change impacts on cetaceans, e.g. Southern right whales in the southwest Atlantic, in line with wider SORP objectives.

Table 10
SORP funding requests and allocations for 2012/13

Project	PI	Line item	Requested (GBP)	Allocated (GBP)
SABWP	Best	Travel	2,500	2,500
SORP 1: ABWP	Wadley	-	0	11,700
SORP 2: Killer whales	Pitman	Travel	2,235	2,235
		6 x wildlife computers on location-only tags	10,360	10,360
		6 Wildlife Computers depth and location tag	17,267	0
SORP 3: Baleen whales	Friedländer	Coordinator's salary [#]	13,430	0
SORP 4: Blue and fin whales	Stafford	Salary	7,963	7,963
		Support for coordination and development activities	15,926	15,926
		Steering Committee meeting*	4,778	0
SORP5: humpback whales	Constantine	Photo-ID and tissue sampling	9,548	9,548
		Project assistant**	6,376	6,376
		Steering Committee meeting*	3,819	0
SORP 6: Symposium	Baker/Galletti	-	0	0
Total requested 2012/13			94,202	
Total allocated 2012/12				54,908

[#] The Committee requested clarification of the use of the money requested for consideration intersessionally.

*No money was allocated to individual projects for Scientific Steering Committee meetings because of proposals to hold a SORP conference in 2013 (see workplan item 6).

** The principal investigators also requested 182,748 GBP to support research in 2013/14. It was noted that SORP cannot support such large requests for money. Therefore, the Committee **encourages** that SORP funds allocated for 2012/13 be used in part to allow the project assistant to write proposals for additional project funding.

19.2 Budget

The IWC has a budget specifically related to the work of SORP established with a contribution from Australia in 2008 and supplemented by additional voluntary contributions from Australia and the USA in 2011. This budget is administered by the IWC Secretariat.

19.2.1 Budget overview

Bell presented a summary of the SORP money spent to date and remaining funds. A total of 76,947 GBP remain unallocated and unspent. A figure of £37,730 GBP³² remains in the SORP budget allocated but unspent.

19.2.2 Request for funds from projects

Table 10 summarises the requests for SORP funds received from existing SORP projects for 2012/13.

SC/64/O17 requested 2,500 GBP for the South African Blue Whale Project (SABWP; SC/64/O17) to support travel for one investigator, Meredith Thornton, from South Africa to Greenland to participate in a week-long cruise in which five Autonomous Acoustic Recorders (AARs) will be deployed west of Disko Bay

in August 2012. The cruise will be led by the Greenland Climate Research Centre and Applied Physics Laboratory of Washington University. The intention is that the investigator gain the necessary technical experience in deployment of AARs at sea, that otherwise might entail an experienced person accompanying a long supply voyage from Cape Town to the ice and back just for a few days' work. An official response from the organisers of the cruise has still not been received.

The Committee **approved** this request for funding.

Funding requests from existing core SORP research projects for 2012/13 are outlined in Table 10 alongside the agreed allocations.

19.2.3 Reallocation of funds

A small group was formed consisting of the SORP Scientific Committee and other interested parties to discuss reallocations of remaining SORP funds to projects in 2012/13.

A figure of £37,730 GBP remains in the SORP budget allocated but unspent. The Committee **agrees** that 11,700 GBP of this be reallocated to the Antarctic Blue Whale Project and the remaining 26,030 GBP be

³² This figure has not been finalised because of possible outstanding invoices from the 2011/12 allocation to SORP Project 6:

rolled-over into the general SORP budget for reallocation in the future.

19.2.4 Allocation of funds

The Committee **agrees** to allocate SORP funds for 2012/13 as outlined in Table 10.

19.2.5 Seeking additional funding

Following the reallocations and 2012/13 allocations, £48,069 GBP will remain in the SORP budget administered by the IWC Secretariat.

The Committee **thanks** the Government of Australia and the USA for their generous contributions to the SORP and **encourages** support and voluntary contributions from other nations to ensure the continuation of this exciting initiative.

19.3 Requirements for formalising participation in SORP and development of new projects

The Committee is keen to promote continued and new involvement in SORP. Partners are **encouraged** to formalise their involvement in the form of a letter to the SORP Secretariat. If Partners require more formal protocols, such as a Memorandum of Understanding, this can be arranged by the SORP Secretariat. The Committee **encourages** the involvement of new and existing Partners in SORP scientific steering Committees, working groups and technical Committees.

19.4 Workplan

The Workplan is discussed under Item 21. The Committee **agrees** that data management and sharing was an important issue to consider. Gales reiterated the importance of workplan item 7.

20. RESEARCH AND WORKSHOP PROPOSALS AND RESULTS

20.1 Review results from previously funded research proposals

Research results from previously funded proposals are dealt with under the relevant agenda items.

20.2 Review proposals for 2012/13

No unsolicited research proposals were received this year. Proposals for the voluntary fund for small cetaceans were discussed under Item 14.3 and those relating to SORP are discussed under Item 19.

Table 11 lists the proposed intersessional meetings and workshops. Financial implications and further details are dealt with under Item 23.

21. COMMITTEE PRIORITIES AND INITIAL AGENDA FOR THE 2013 MEETING

As in recent years and with the Scientific Committee's agreement, the Convenors met after the close of the Committee meeting and finalised the following basis

Table 11

Proposed workshops for the intersessional period

Subject	Agenda Item	Venue	Dates
Review of MSYR workshop and WNP common minke whale's Second Intersessional Workshop	5.1; 6.6	To Be Determined	late Feb-Apr 2013
AWMP Greenland hunt SLA development	8.3	Copenhagen, Denmark	3 days within 12-18 Dec 2012
Planning for the 2013 IWC-POWER cruise	10.8.1.3	Toyko, Japan	25-27 Oct 2012
Workshop on Arctic anthropogenic impacts on cetaceans	12.5.3	Anchorage, Alaska	late Feb - Mar 2013
Workshop on assessing the impacts of marine debris	12.7	location of SC meeting	4 day pre-meeting; mid May - mid Jun 2013
"Marine bushmeat" workshop	14.6	location of SC meeting	2 day pre-meeting; mid May - mid Jun 2013
Icelandic Special Permit expert panel review workshop	17.1.3	Reykjavik, Iceland	Feb-Mar 2013

for an initial agenda for the 2013 meeting. The same criteria as previous years were taken into account and this was based on the recommended work plans developed by sub-committees and the general discussion of these within the Committee. The Committee **recognises** that it is the Commission who establishes the Committee's overall priorities. Thus priorities may have to be reviewed in light of decisions made by the Commission. Items of lower priority on sub-committee agendas will only be discussed if time allows. Therefore, the Committee **stresses** that papers considering anything other than priority topics will not be addressed at next year's meeting. This information will be included on the website when the information about document submission is published next year. Convenors will receive timely information on the titles of papers intended for the discussion within their gaps, and may contact authors if they believe the papers are unlikely to be discussed.

Revised management procedure (RMP)

The following issues are high priority topics:

- (1) Review new information on western North Pacific Bryde's whales
- (2) Conduct an *Implementation Review* for North Atlantic fin whales starting during a pre-meeting before SC65 and continuing during the 2013 Annual Meeting
- (3) Prepare for the 2014 *Implementation Review* for the North Atlantic minke whales

(4) Review information available for North Atlantic sei whales in the context of a *pre-implementation assessment*

Western North Pacific common minke whales

Complete *Implementation Review*(including hold intersessional workshop)

Bycatch group (BC)

The focus of the group will remain in estimating mortality due to bycatch and ship strikes. The work plan will include:

- (1) reviewing progress in including information in online National Progress Reports,
- (2) estimating risk and rates of bycatch and entanglement,
- (4) development of methods to estimate mortality from ship strikes,
- (5) continuing development and use of the international database of ship strikes,
- (6) review of information on other sources of mortality.

Special Permit

- (1) Review results of the expert workshop in the Icelandic special permit programme;
- (2) Plan for expert workshop on JARPA II;
- (3) Review new and existing proposals as appropriate

Bowhead, right and gray whales (BRG)

High priority items will include:

- (1) perform the annual review of catch information and new scientific information for BCB stock of bowhead whales and eastern gray whales;
- (2) review any new information on all stocks of right whales, especially results of assessments for southern right whales;
- (3) review North Pacific gray whale stock structure and movement
- (4) review any other new information on western and eastern North Pacific gray whales and other stocks of bowhead whales.

Environmental concerns (E)

- (1) Receive the SOCER (focus: Atlantic Ocean)
- (2) Pollution issues
- (3) Cetacean Resurging & Emerging Diseases (CERD)
- (4) Impacts of anthropogenic sound
- (5) Climate change issues

(6) Marine debris and cetaceans (including report from the Marine Debris Workshop)

(7) Other habitat-related issues

7.1. (MREDs)

7.2. Cumulative impacts

(8) Unusual mortality events incl. Peru

Ecosystem modelling (EM)

- (1) Modelling of the direct relationship between baleen whale populations and the abundance of their prey.
- (2) Coordination with CCAMLR's Ecosystem Monitoring and Management Programme will also be sought on its efforts to advance krill-predator models.

Aboriginal subsistence whaling management procedure

- (1) Highest priority will be to work towards the development of long-term SLAs for the Greenland hunts;
 - (a) Develop trial structures and operating models for the Greenland hunts of bowhead and humpback whales to be presented initially at an intersessional workshop
 - (b) Develop an AWMP/RMP-lite program to assist developers of SLAs for the Greenland hunts of fin and common minke whales;
 - (c) Review a full scientific paper on the work in Greenland related to the collection of information on conversion factors
- (2) Present *Evaluation* and *Robustness Trial* results to the SWG of an SLA variant that corresponds exactly to the management plan proposed by the Makah Tribe to the US Government;
- (3) Review a revised document on the probability of a gray whale that regularly feeds in the western North Pacific being taken in a Makah hunt;
- (4) Review a document that provides advice on the development of SLAs and their evaluation

In-depth assessment (IA)

High priority will be given to:

- (1) The development and application of the SCAA models to the agreed estimates and the most recent aging data.
- (2) Further work examining reasons for the differences between estimates from CPII and CPIII.
- (3) Further development of the IWC simulated datasets, specifically to

3.1 provide a testing framework for hazard probability models for internally-estimated cue rates from Antarctic minke whale schools

3.2 provide one realistic scenario for testing variance estimation.

Now that minke whale abundance estimates had been agreed, the main remaining issues are listed as follows:

(4) Modify the Hazard Probability model to cope better with real diving patterns,

(5) Improve remaining misfits, for example, to the way that the simultaneous/delayed duplicate fit changes with school size (linked to item 4 above).

(6) Embed refined Hazard Probability models into a spatial framework,

Lower priority items are:

(7) Data management

7.1 Further validation of IDCR/SOWER data

7.2 Curation of experimental IDCR/SOWER data

7.3 Production of standard datasets for analyses of species other than Antarctic minke whales.

(8) Review of abundance estimation data collected during CPII and CPIII; their utility for estimating abundance of Antarctic minke whales; and review of data insights.

SORP

Workplan items include:

(1) establishment of ABWP management structure and Committee;

(2) establishment of intersessional technical committees for methodological development;

(3) refinement of the ABWP survey plan for the 2013 ABW voyage(s);

(4) development of uniform sampling protocols for ABW sampling and voyage(s);

(5) continuation of five ongoing SORP research projects;

(6) planning and implementation of an intersessional SORP conference prior to the next annual meeting;

(7) intersessional development of a paper on data management and legacy.

22. DATA PROCESSING AND COMPUTING NEEDS FOR 2011/12

The Committee agrees the requests for intersessional work by the Secretariat given in Table 12.

23. FUNDING REQUIREMENTS FOR 2012/13

Table 13 summarises the complete list of recommendations for funding made by the Committee. The total required to meet its preferred budget is £327,000. The Committee recommends all of these proposed expenditures to the Commission.

However, it understands that the projected amount available for funding is about £315,000. Following some initial suggestions produced by the Convenors group, the Committee therefore carefully reviewed the proposed full list, taking into account its work plan, priorities and the possibility that some of the work requiring funding could be postponed to a future year or years. Such considerations are difficult and the Committee stresses that projects for which it has had to suggest reduced funding are still important and valuable. Should the Commission be unable to fund the full list of items in Table 13 the Committee agrees that the final column given in the table represents a budget that will allow progress to be made by its sub-groups in its priority topics. Progress will not be possible in some important areas, as outlined below and the Committee strongly request that the Commission or individual member governments provide additional funding in these areas. The Committee strongly recommends that the Commission accepts its reduced budget of £315,000.

Table 12

Computing tasks/needs for 2012/13.

RMP – PREPARATIONS FOR IMPLEMENTATION

(1) Work with the Norwegian Computing Centre to modify the Norwegian CatchLimit program so that only standard FORTRAN-95 statements are used (Annex D Item 2.4)

(2) Work to specify and run additional trials for testing amendments to the *CLA* (Annex D Item 2.2)

(3) Work related to the *Implementation Review* for North Atlantic fin whales (Annex D Item 3.2)

(4) Run a full set of trials using the Norwegian 'CatchLimit' program for North Atlantic fin whales, Western North Pacific Bryde's whales; and North Atlantic minke whales and place the results on the IWC website (carried over from last year)

NPM

Complete conditioning of the North Pacific minke whale trials and run a full set of trials (Annex D1)

AWMP

Work arising from the proposed workshop (see Annex E Item 4)

IN-DEPTH ASSESSMENT

Prepare a catch series for North Pacific sei whales including incorporation of additional information from Japanese log book records and a new analysis of Soviet North Pacific catch records (see Annex G Item 7)

Validation of the 2011 POWER cruise data (see Annex G Item 8)

Complete validation of the 1995-97 blue whale cruise data and incorporate into the DESS database

WHALE STOCKS

Documentation of the catch data available for Antarctic minke whales in preparation for the *pre-implementation assessment* (see Item 10.1, carried over from last year).

SCIENTIFIC COMMITTEE REPORT

A summary of each of the items is given below, by sub-committee or standing Working Group. Full details can

be found under relevant Agenda Items and Annexes as given in Table 13.

Table 13

Budget requests (see text). Note that in addition, the budget request for SORP is given in Table 10.

Title	Agenda Item	Full (£)	Reduced (£)
(1) Development of an operating model for West Greenland humpback and bowhead whales	8. AWMP	5,000	5,000
(2) Workshop on development of SLAs for Greenlandic hunts	8. AWMP	8,000	8,000
(3) AWMP developers funds	8. AWMP	3,000	3,000
(4) Ship strike database coordinator	7.8 Ship strikes	10,000	8,000
(5) Right whale survey off of South Africa	10.5 SH right whales	21,730	21,730
(6) Genomic diversity and phylogenetic relationships among right whales	10.6 N Pacific right whales	7,000	0
(7) Photographic matching of gray whales	9.2 E Pacific gray whales	9,000	9,000
(8) Contribution to the preparation of the State of the Cetacean Environment Report (SOCER)	12.1 SOCER	3,000	3,000
(9) Pre-meeting workshop on assessing the impacts of marine debris	12.8 Habitat related issues	20,500	20,500
(10) Develop simulation of Southern Hemisphere minke line transect data	10.1 Antarctic minke whales	9,000	5,000
(11) IWC-POWER cruise	10.8.1 IWC-POWER cruise	60,754	60,754
(12) Preparation for the application of the statistical catch-at-age assessment method for Southern hemisphere minke whales	10.1 Antarctic minke whales	4,000	4,000
(13) "Second" intersessional workshop on the Implementation Review for WNP common minke whales	6.3 N Pacific common minke whale Implementation Review	20,000	18,500
(14) Essential computing for RMP/NPM and AWMP	22. Data processing and computing needs	25,000	25,000
(15) MSYR review workshop	5.1 MSY rates review	5,000	5,000
(16) Review and guidelines for model-based and design-based line transect abundance estimates	5.7 Abundance estimates	5,000	5,000
(17) Modeling of Southern Hemisphere humpback whale populations	10.2 SH humpback whales	3,000	3,000
(18) Antarctic humpback whale catalogue	10.1 Antarctic minke whales	15,000	13,000
(19) Photo matching of Antarctic blue whales	10.3 SH blue whales	3,000	3,000
(20) Southern Hemisphere blue whale catalogue 2012/13	10.3 SH blue whales	3,000	3,000
(21) Expert workshop for final review of Iceland's Special Permit programme on common minke whales	17.1 Review of existing scientific permits	30,000	24,000
(22) Whale watching guidelines and operator training in Oman	10.7 Arabian Sea humpback whales	3,500	3,500
(23) Invited Participants (IP's) funds	All	64,000	64,000
TOTAL		337,484	314,984

(1) DEVELOPMENT OF AN OPERATING MODEL FOR WEST GREENLAND HUMPBAC AND BOWHEAD WHALES

The Committee developed interim *Strike Limit Algorithms (SLAs)* for the minke, fin, humpback and bowhead whales off West Greenland. These *SLAs* need to be reviewed and perhaps revised, ideally by the 2017

Annual Meeting. Development of *SLAs* for the hunts of minke and fin whales can be coordinated with the *Implementation Reviews* for these whales which are being conducted by the RMP sub-committee. In contrast, the situations for humpback and bowhead whales are relatively straightforward (essentially

single-stock situations), but without a fully-specified and coded operating model progress on these cases will be limited. The first step in the process of developing *SLAs* is constructing an operating model and associated trials, and this project aims to make sufficient progress that an AWMP Workshop (in late 2012) could finalize trials and initiate testing.

The key activities covered by the proposal:

- (1) Extend the single-stock gray whales trials so that trials can be conducted for humpback and bowhead whales.
- (2) Outline a set of evaluation and robustness trials which could form the basis for the evaluation of *SLAs* for these two groups of whales.
- (3) Present the trial specifications and results for (a) the interim *SLAs* and (b) an alternative *SLA* at an intersessional AWMP workshop.
- (4) Develop an AWMP/RMP-lite to assist developers of *SLAs* for the cases of fin whales and common minke whales.

(2) WORKSHOP ON DEVELOPMENT OF SLAS FOR GREENLANDIC HUNTS

The existing interim safe procedure for the Greenlandic hunts agreed in 2008 (IWC, 2009) was agreed to be valid for up to quota blocks so up to 2018. The Committee has identified completion of the development of long-term *SLAs* for these hunts as high priority work. With the completion of the BCB bowhead and gray whale *Implementations* this year, the SWG on the AWMP will give highest priority to the Greenland work, particularly for the complex cases of common minke whales and fin whales. In addition to the proposal for work by Punt (Annex E, Appendix 6), to meet the proposed timeframe an intersessional Workshop is required. The objectives of the workshop are to: (1) to review the work undertaken by Punt to develop proposed operating models and trial structures for the relatively easy cases of the bowhead and humpback whale hunts with a view to finalising these at the 2013 Annual Meeting; and (2) review the work undertaken by Punt to develop simple (AWMP/RMP-lite programs) to facilitate initial work on developing potential *SLAs* to allow the development of *SLAs* for West Greenland fin and common minke whales in light of the current operating models used in RMP *Implementations*. The Workshop will be held in winter 2013 for four days in Copenhagen, Denmark and the costs are for the IPs travel.

(3) AWMP DEVELOPERS FUNDS

The developers fund has been invaluable in the work of *SLA* development and related essential tasks of the SWG. It has been agreed as a standing fund by the Commission. The primary development tasks facing the SWG are for the Greenlandic fisheries. As noted above these tasks are of high priority to the Committee and

the Commission. The fund is essential to allow progress to be made. It now stands at £12,000 and a request of £3,000 is made to restore it to the initial target level of £15,000.

Bycatch and other human-induced mortality

(4) SHIP STRIKE DATABASE COORDINATOR

The ongoing development of the IWC ship strike database requires data gathering, communication with potential data providers and data management. The Working Group on Bycatch and Other Human Induced Mortality recommended a part-time post initially for 3 months a year to undertake the tasks described in Annex J. This includes:

- (1) Identify national contact points, organisations or groups that hold data on ship strikes that have not been contributed to the database and facilitate and encourage contributing data to IWC database;
- (2) Monitor and respond to emails addressed to the shipstrikes@iwcoffice.org email address, including reports of new incidents, giving feedback to data providers and dealing with requests for summary information from the database;
- (3) Keep IWC ship strike web site pages up to date including updating publicly available summaries from the database;
- (4) Develop and document a communication strategy;
- (5) Provide an annual update to Scientific Committee;
- (6) Data entry of new records including data presented in meeting papers and National Progress Reports at annual meetings of Scientific Committee;
- (7) Work with data review group to ensure that all new records are appropriately reviewed including identification of potential duplicate reports;
- (8) Further development of database handbook including criteria for determining whether ship strike was a cause of death. Ensure database documentation remains up to date;
- (9) Maintain data base and data entry system, making adjustments as appropriate in response to user problems and suggestions.

Bowhead, right and gray whales

(5) RIGHT WHALE SURVEY OFF OF SOUTH AFRICA

The southern right whale population visiting the South African coastline (arguably the largest in the Southern Hemisphere) has been monitored annually by aerial surveys since 1971 and since 1979 by a photo-identification survey. The results have been presented to several meetings of the SC, such as the Buenos Aires workshop in September 2011, where four papers were presented (SC/S11/RW15, 16, 18, 29). Since its inception the photo-id surveys have concentrated on adult females with calves: the catalogue (2010) stands at 1,217 adult females, of which resighting rates average 70% annually, leading to very precise

estimates of population size and growth rate, adult survival rate, age at first parturition and juvenile female survival rate. The application of an individual-based model has now allowed estimation of the probability of females calving at various intervals (SC/64/BRG24), which can be correlated in turn with the occurrence of oceanographic anomalies to determine the influence of environmental variation on reproductive success. The project has been funded domestically almost since its inception and has just completed a 3-year funding cycle. Unfortunately an application to the South African National Antarctic Programme for renewed funding was rejected as being geographically inappropriate, so interim funding is being sought to enable the 2012 survey to take place while an application is made for a new cycle commencing in 2013. The survey is scheduled to take place in mid October. All images should be matched by 1 April 2013 and results ready for the 2013 SC meeting.

(6) GENOMIC DIVERSITY AND PHYLOGENETIC RELATIONSHIPS AMONG RIGHT WHALES

The investigators request supplemental funding, as described in SC/64/BRG15, to do the following:

- (1) assess genetic diversity and estimate N_{min} within the central North Pacific right whale population, represented by 27 individuals (including 3 from Russia), using complete mitochondrial genomes and sequence from 23 nuclear loci;
- (2) compare mtDNA diversity in eastern North Pacific right whales with other oceanic populations based on complete mitochondrial genomes (16386 base pairs), rather than the limited resolution currently based on control region sequences (286 base pairs); and
- (3) confirm reciprocal monophyly and phylogenetic relationships among right whale species using sequence from complete mitochondrial genomes and 23 nuclear loci.

The primary funding for this project, provided by the Pacific Life Foundation, has support the development of the primary datasets but this funding is now exhausted. This proposal seeks supplemental support for two months for a postdoctoral fellow to complete analysis of the primary dataset and estimation of N_{min} for the central population of the North Pacific right whale.

(7) PHOTOGRAPHIC MATCHING OF GRAY WHALES

Results regarding mixing of western (WNP) and eastern (ENP) gray whales illustrate the great conservation and management importance of a more comprehensive examination of gray whale movement patterns and population structure in the North Pacific. The committee noted that for such an effort to be successful it must be international and collaborative. To facilitate this, and noting the existing safeguards for collaborators provided under the Committee's Data

Availability Agreement, it recommended that a collaborative Pacific-wide study be developed under the auspices of the IWC, recognizing that *inter alia* this will contribute to the Committee-endorsed Conservation Plan for Western North Pacific Gray Whales and incorporate previous recommendations made by the Committee. Such a study should involve collaborative analysis and sharing of existing data as well as the collection of new data (IWC, 2011). This is the second year of the project. The report of the results of the first year was presented in the document SC/64/BRG13 (Urbán et. al 2012). The funds requested for this year is to match gray whale photographs to photographs from Sakhalin and Kamchatka.

Environmental concerns

(8) CONTRIBUTION TO THE PREPARATION OF THE STATE OF THE CETACEAN ENVIRONMENT REPORT (SOCER)

SOCER is a long-standing effort to provide information to Commissioners and SC members on environmental matters that affect cetaceans in response to several Commission resolutions. The focus for 2012 will be on the Indian Ocean. Funds are for salaries, library services, and printing.

(9) PRE-MEETING WORKSHOP ON ASSESSING THE IMPACTS OF MARINE DEBRIS

In 2011, the IWC agreed to (1) endorse the Honolulu Commitment; (2) establish a standing item on marine debris on the Conservation Committee agenda and (3) request the Scientific Committee continue reviewing potential threats to cetaceans arising from marine debris. It is proposed that a workshop be held on marine debris and cetaceans where the primary aim is to develop tools that allow quantification of whether or how marine debris is affecting cetaceans and how best to monitor and mitigate for these effects.

The objectives of the workshop are to:

- (1) Better understand the effects of debris interactions at an individual and population level;
- (2) Identify and classify key types and sources of debris that contribute to entanglements, or are ingested by cetaceans and examine the mechanisms by which they arrive in the marine environment, with the goal of identifying possible mitigation measures;
- (3) Design and develop a centralised database to collate cases of debris interactions to obtain more accurate estimates of the incidence of mortality and injuries, help detect trends over time and identify hotspots; and
- (4) Contribute towards a quantitative assessment of the extent of the threats for cetaceans.

The report of the Workshop will, in addition to providing the analyses, review and recommendations

listed under Item 2 above, develop: (1) a series of research and conservation actions that will include a rationale, actions required and proposed responsible persons/groups; and (2) a two-year work plan to be considered. The report will be submitted to the IWC and made publicly available on their website. It is proposed to publish the results of the workshop in a peer-reviewed journal. Funds are to assist some of the expected 20 participants for a 4-day pre-meeting held before the 2013 Scientific Committee meeting.

In-depth assessments

(10) DEVELOP SIMULATION OF ANTARCTIC MINKE LINE TRANSECT DATA

This year an abundance estimate for Antarctic minke whales had been agreed upon. As discussed this estimate had to use externally-estimated cue rates from a small sample of Antarctic minke whales, though an internally estimated cue rate would be preferred to estimate a more accurate and perhaps precise estimate. However, additional methodological develop is needed to achieve this. To test these newly development methods, it was proposed to use simulated line transect data where the true abundance estimate is known to validate the new methods are working correctly. These funds are proposed to further develop the IWC simulated datasets to (i) provide a testing framework for hazard probability models for internally-estimated cue rates from Antarctic minke whales schools, and (ii) provide a realistic scenario to test variance estimation methods.

(11) IWC-POWER CRUISE

The Committee has strongly advocated the development of an international medium- to long-term research programme involving sighting surveys to provide information for assessment, conservation and management of cetaceans in the North Pacific, including areas that have not been surveyed for decades. The finalisation for the integrated mid-long-term program (IWC-POWER; the Pacific Ocean Whales and Ecosystem Research programme) that will provide information on stock structure, abundance and ultimately trends has been completed. The focus of the 2013 cruise is defined as the area bounded by longitudes 135W and 160W, and latitudes 30N and 40N. Line transect sightings abundance data collection, biopsy sampling, and photo-identification of cetaceans is planned. The cruise will last approximately 60 days between July and August 2013. By far the most important component of the cost of the provision of a research vessel, crew and fuel (up to US\$1m) and that is generously being provided by Japan. The IWC funding will provide for international researchers, equipment and a meeting to finalise the details of the 2013 cruise.

(12) PREPARATION FOR THE APPLICATION OF THE STATISTICAL CATCH-AT-AGE ASSESSMENT METHOD FOR ANTARCTIC MINKE WHALES

This year the Committee received a full description of the statistical catch-at-age (SCAA) developed by Polachek and Punt, along with initial suggestions for a baseline analysis and sensitivity tests (SC/64/IA1). This approach allows for errors in catch-at-age data, more than a single stock, time-varying growth, multiple areas, environmental covariates, fleet-specific vulnerabilities, and changes over time in vulnerability. The SCAA can be used to evaluate various hypotheses regarding the reason (or reasons) for the change in abundance estimates from CPII to CPIII, as well as other questions regarding the dynamics of the Antarctic minke whale, such as whether growth and carrying capacity have changed. This proposal is to obtain the latest datasets and update the outputs and reference models to conduct baseline and key sensitivities. A final report will be presented to the 2013 Annual Meeting and the final code, data sets and documentation will be lodged with the Secretariat.

North Pacific minke whales

(13) "SECOND" INTERSESSIONAL WORKSHOP ON THE IMPLEMENTATION REVIEW FOR WESTERN NORTH PACIFIC COMMON MINKE WHALES

The Implementation Review for western North Pacific minke whales is more complex than an previous Implementation. The Committee is one year behind the normal Schedule for Implementations. The Committee is not ready to undertake the tasks allocated to the 'second' intersessional workshop according to it guidelines (IWC, 2012). The priority tasks are to run and evaluate all trials in accordance with guidelines and present the results at the 2013 Annual Meeting to enable the Committee to complete its review in 2013.

Revised Management Procedure

(14) ESSENTIAL COMPUTING FOR RMP/NPM AND AWP

The approach used to evaluate RMP variants during *Implementations* as well as candidate SLAs involves two main steps: (1) specification and conditioning of trials, and (2) projecting simulated populations forward under alternative RMP variants/SLAs. The complexity of the operating models on which simulation evaluations are conducted has increased in recent years. Unfortunately, the relatively simple optimization methods include in current control programs (which was more than adequate in the past), combined with a complicated objective function, has led to problems producing conditioned trials quickly. This proposal will provide the Secretariat with the essential support required to complete this issue during the intersessional period. It will also continue the arrangement of recent years by which essential support is provide to the Secretariat, particularly in the key area of estimating stock mixing proportions in input to the trials), both

intersessionally, and during meetings. Without this support it will be impossible for the Committee to undertake its present work on RMP *Implementations* and development of SLAs.

(15) MSYR REVIEW WORKSHOP

Since 2007 the Committee has been discussing maximum sustainable yield rate (MSYR) in the context of a general review of the plausible range to be used in population models used for testing the Catch Limit Algorithm (CLA) of the RMP. The Committee has agreed that it will finish work on this topic in 2013 whether or not the review can be completed. It has developed a work plan to try to ensure completion of the review. As part of this it is essential that a three-day intersessional meeting be held, with at least five participants, ideally back-to-back with another intersessional meeting, thus reducing overall costs of this workshop.

All sub-groups using abundance estimates

(16) REVIEW AND GUIDELINES FOR MODEL-BASED AND DESIGN-BASED LINE TRANSECT ABUNDANCE ESTIMATES

The RMP's 'Requirements and Guidelines for conducting surveys' (RIWC (Suppl.) 13: 509-517) were written when the only realistic paradigm for planning and analyzing good sighting surveys was the design-based approach. However, there is now potentially a legitimate alternative to design-based estimates: model-based estimates using spatial modeling (smoothers), which unlike design-based approaches, also give some basis for limited spatial extrapolation. In addition, many surveys resemble design-based surveys but do not strictly meet the design-based criterion, and in such cases there is a question regarding the adequacy of design-based estimates. The Committee has frequently considered model-based and quasi-design-based estimates, but without explicit criteria and not necessarily in the context of the RMP. This proposal will (1) review statistical aspects of design-based estimators for surveys which do not strictly adhere to design-based principles, and (2) review past and current issues related to model-based abundance estimators, drawing on examples from experience with these types of models. Empirical and simulation-based diagnostics will be suggested, and a quantitative description of pitfalls when extrapolating estimates beyond the surveyed area will be given. The intended outcome of the project is (1) propose a basis to assess the reliability of an abundance estimate either from a design-based analysis for which the statistical criteria are not met, or from a model-based analysis; and (2) provide draft text for inclusion in the "Requirements and Guidelines for conducting surveys" document. The work will be presented to the 2013 Annual Meeting and is for salary to complete this project.

Other Southern Hemisphere whale stocks

(17) MODELING OF SOUTHERN HEMISPHERE HUMPBACK WHALE POPULATIONS

The project will focus on a combined assessment of Southern Hemisphere humpback breeding stocks D, E and Oceania using the model proposed at this year's meeting, SC64. Methods used will be based upon the Bayesian methodology as developed and presented for breeding stock C and breeding stock B comprehensive assessments recently completed. Initial results will utilize the data agreed at SC64, and results will be presented at the 2013 SC Annual Meeting. Further model developments and refinements in association with the final set of agreed data (and their sensitivities) would be presented at 2014 SC meeting should the Scientific Committee decide to so request.

(18) ANTARCTIC HUMPBACK WHALE CATALOGUE

The Antarctic Humpback Whale Catalogue collates photo-identification information from Southern Hemisphere humpback whales. Increasing awareness of the project among research organizations, tour operators and other potential contributors has widened the scope of the collection; research efforts in areas that had not previously been sampled have extended the geographic coverage. This catalogue has grown by 25% in the last two years, adding 1127 new individuals, and increasing the time required to analyse photographs. In addition to these requested IWC funds, we will seek funding from other sources to provide the remaining funds required. Additional resources are provided by College of the Atlantic, including equipment, student assistants, and time donated by principal investigators of this proposal. As a result this catalogue is in an excellent position to make a substantial contribution to SORP and other research and management initiatives.

(19) PHOTO MATCHING OF ANTARCTIC BLUE WHALES

The goal of this project is to compare the existing IWC-SOWER Antarctic blue whale catalogue (about 160 individuals) and the existing photo-id material collected from JARPA which are already digitized. This project may add new individuals to the Antarctic blue whale catalogue and provide new data on the movements of Antarctic blue whales both within and between years. The Committee has requested for several years that this work be undertaken.

(20) SOUTHERN HEMISPHERE BLUE WHALE CATALOGUE 2012/13

The Southern Hemisphere Blue Whale Catalogue is an international collaborative effort to facilitate cross-regional comparison of blue whale photo-identifications catalogues. Results of comparisons among different regions in Southern Hemisphere will improve the understanding of basic questions relating to blue whale populations in the Southern Hemisphere such as defining population boundaries, migratory

routes and model abundance estimates. In 2008, the Committee endorsed a proposal to establish a central web-based catalogue of blue whale identification photographs, known as the Southern Hemisphere Blue Whale Catalogue (IWC, 2008).

Currently this catalogue holds photo-identification catalogues of researchers from major areas off Antarctica, Australia, Eastern South Pacific and the Eastern Tropical Pacific (IWC, 2011). Comparisons among catalogues off Chile found one match over ten years (Galletti Vernazzani and Cabrera, 2011). Preliminary results of the 2011-2012 catalogue comparisons between the eastern South Pacific Ocean, Eastern Tropical Pacific Ocean (ETP) and Southern Ocean found no matches (Galletti Vernazzani and Olson, 2012).

During 2012-2013 it is expected that comparisons between Australian catalogues and with the ETP, Southeast Pacific and Antarctica will be finalized. Results of these comparisons will be presented to the 2013 Committee Annual Meeting.

Special Permits

(21) EXPERT WORKSHOP FOR FINAL REVIEW OF ICELAND'S SPECIAL PERMIT PROGRAMME ON COMMON MINKE WHALES

Activities under Article VIII of the Convention should be reported to the Committee for review. The Committee has agreed a procedure for periodic and final reviews of results from Special Permit research (Annex P, IWC 2009). This procedure outlines an intersessional review meeting by an expert panel. The report from the intersessional expert meeting will be reviewed and discussed at the 2013 Committee Annual Meeting, SC65. The Icelandic Special Permit programme on common minke whales is complete and thus is subject to a review by an expert panel during the 2012/2013 intersessional period. The experts to the review workshop will be identified by September 2012 and the expert workshop will be convened during four days in February/March 2013. The requested funds are for travel for the invited experts.

Whale watching

(22) WHALE WATCHING GUIDELINES AND OPERATOR TRAINING IN OMAN

Oman's whale watching industry has experienced gradual growth over the last 10 years reflecting a steady increase in tourism in the country and a growing awareness of the rich and accessible cetacean fauna, especially around the capital city of Muscat. Currently, dolphins are the main target of the industry, whilst sperm whales and other large whales are increasingly sighted as operators become more knowledgeable of their presence and distribution. The Arabian Sea humpback whale has recently become a target of opportunistic whale watching by a SCUBA dive operator in southern Oman. The precarious status of

this species, represented by a resident and discreet sub-population numbering fewer than 100 individuals, and the identification of escalating anthropogenic impacts and threats has led to expression of serious concern by the IWC and recommendation for the development of a Conservation Management Plan (work in progress). Unregulated whale watching represents another potential threat to Arabian Sea humpback whales.

Most operators are currently unaware of (unofficial) guidelines for whale watching in Oman. Recognizing the need to complete the drafting of new guidelines for Oman with appropriate technical assistance, and to train operators to enable interpretation and implementation of guidelines, this proposal includes a request for funding to complete the revision of whale watching guidelines in Oman and to hold a training workshop for operators on the interpretation and implementation of the guidelines to promote best practice in the industry. Travel for relevant experts to Oman has already been secured and expert and other participant time will be donated and/or covered by other on-going projects.

All groups

(23) INVITED PARTICIPANTS (IPS) FUNDS

The Committee draws attention to the essential contribution made to its work by the funded IPs. The IWC-funded IPs play an essential role in the Committee's work, including the critically important role of Chairs and rapporteurs. They represent excellent value as they receive only travel and subsistence costs and thus donate their time, which is considerable. As was the case for previous meetings, where possible, effort will be made to accommodate scientists from developing countries.

24 WORKING METHODS OF THE COMMITTEE

24.1 Reducing the costs of Committee meetings

In 2011 the Commission asked the Secretariat to continue exploring opportunities for cost savings. One source of cost savings is to reduce freight charges and increase use of electronic documents at annual meetings of the Scientific Committee and Commission. A review of expenditures in 2011 indicated the costs of maintaining a paper based infrastructure for the meetings was around 5% of the IWC core budget. Particular cost arise because of packing and air freight of the pigeonholes and pre-prepared documents which are both heavy and bulky, and also the hire of high volume copiers which are usually dramatically more expensive than low volume copiers.

The Committee discussed the advantages and disadvantages of moving to an electronic distribution of primary papers, working papers, and reports. If there was to be electronic distribution of paper, then the

memory sticks with the primary documents will need to still be available in a timely manner. Members would be encouraged to submit meeting papers as soon as possible to allow other members to make their own copies at home before the meeting. There would also need to be a number of modern desktop laser printers available to members and especially a local high bandwidth secure wi-fi network and document server that would be available to only the Committee members and so would be independent to local internet access and thus be robust to local IT issues.

After much discussion, the Committee agrees that primary documents should be distributed wholly electronically both on the IWC webpage and on the memory sticks. In contrast, the Committee agrees that draft and final reports of sub-groups and plenary should be distributed by paper to ensure these reports are properly edited. The Committee also agrees that working papers should, at least for a trial period, be distributed mostly by paper, with the option of some working papers, particularly very long ones, be distributed mostly electronically. To reduce freight costs of the pigeonholes, the Committee suggests the Secretariat consider having pigeonholes for sub-groups as a means to distribute working papers rather than having personal pigeonholes.

24.2 Clarifying information on data availability for Procedure B requests

The present description of the process for obtaining data for issues that fit under Procedure B is described in the Data Availability Agreement (DAA; IWC 2004). SC/64/SCPl described a recent incident where it became evident that the DAA process needed additional clarification. The Committee notes that the DAA process has generally worked well and especially so when the Committee has been able to properly specify the data request during the Committee meeting. Procedure B is designed for cases where the Committee itself believes that particular analyses (whether completely new analyses or revised analyses) are important in providing advice to the Commission. In such cases, it is important that the Committee takes the necessary time to complete and explicitly including the following within the report: objectives of the data request; details of the data required addressing the objectives; broad overview of the methods; and the principal investigators recommended by the Committee. With such report text, the Data Availability Group (DAG) can then complete and endorse a DAA request following the appropriate protocol in a timely manner. This would have, for example, removed the ambiguity that arose out of interpretation of the recommendation made last year on the blubber thickness analysis (IWC, 2012, Annex K1).

As the requests under Procedure B relate to Committee recommendations, it also seems appropriate that all correspondences between researchers and data holders

are channelled through the DAG until a request has been granted. It should also be emphasised that DAG involvement in data requests applies only to requests based on recommendations by the Committee. Requests by individual scientists should occur at the bilateral level without DAG involvement.

In addition, there appears to have been some uncertainty over what is meant by collaboration and offers of co-authorship under the DAA. This has also been considered under Agenda Item 17, Special Permit reviews and 'Annex P'.

The Committee has always encouraged collaboration in all research projects. In the context of Annex P this was clarified in a footnote. For a more formal clarification, the Committee recommends an additional point be added to the DAA Procedure B text as follows, where the text under Item 2 is new:

Procedure B

This applies to data required for analyses deemed important in providing advice to the Committee other than catch limits (e.g. on the status of stocks not subject to whaling). For data not subject to Procedure A, the data owners shall produce, in collaboration with the Committee, a published protocol for data access that applies to requests generated by the Committee, to ensure clarity and a mutual understanding of the process.

(1) The Committee shall specify the nature of the work and the data required during the meeting at which the recommendation is made, to the fullest extent possible in the time available at the meeting and in accordance with the published protocol. It should also name the appropriate scientists to undertake the work and designate an appropriate timeline.

(2) The Committee encourages collaboration between the data requestors and data providers, although this is not mandatory. As a minimum, data requestors and providers should discuss the data sufficiently to avoid misinterpretations over the nature of the data themselves. When the data requestors send their draft paper to the data providers in accordance with the timetable, they must provide an offer of co-authorship to them. The data providers may or may not accept this offer. If data requestors and data providers do not agree with the contents of the paper then they may present separate analyses or comments to the Committee. This then allows the Committee to review all analyses. The Committee will then get a balanced single conclusion from the analyses for advice to the Commission. This is in line with the spirit of collaboration the Committee encourages.

(3) Applications to the data owners following the published protocol referred to above, should be submitted by the Data Availability Group assisted by a nominated member of the relevant delegation or

institute. The Data Availability Group will consult with relevant members of the Committee if further explanation or clarification is required.

(4) If the above process is followed, then the data owners will normally approve the applications within a specified time period in accordance with the published protocol.

(5) Applications shall only be granted under conditions given above.

24.3 Updating the Committee's guidelines and Handbook

After discussion last year, the Committee agreed that the Chair of the Scientific Committee should develop a review document for consideration at this year's meeting that discusses whether or not there is a need to expand on the guidelines related to Convenors, in particular with respect to further details about the roles of Convenors and co-convenors, time frames of service etc., as well as the roles of Heads of Delegation and, if so, to provide proposed text. This review document provided background information that clarified some of these issues and suggested additional text to be considered by the Committee that could be added to the Scientific Committee's Handbook (SC/63/SCP2).

This year the Committee discussed this review document and recommends the basic responsibilities of Convenor's and co-Convenor's as described in the Handbook did not need changing. However, it recommends that the full Committee should receive the list of proposed projects to be funded by the Commission in a timely manner to allow everyone to fully consider the prioritised list. Following this recommendation, the guidelines on the role of convenors should include a new item 'f' and move the present 'f' to 'g', where the new item 'f' should read:

'To develop with other members of the Convenors' Group a prioritised list for funding that should be made available to the full Committee at least by 6 pm on the penultimate day of the Scientific Committee Annual Meeting.'

Co-Convenor's were created three years ago to assist some of the busier sub-groups and provide an opportunity to create a pool of experienced people that could become future Convenors. This concept has worked well, so the Committee recommends the following text on the eligibility of Convenors and co-Convenors be added to the Handbook:

'All Committee members are eligible to become Convenors or co-convenors. A co-convenor may be appointed to assist the Convenor of a sub-group, gain experience in chairing and learn Committee procedures. Requirements include appropriate scientific background and/or chairing experience, knowledge of Committee procedures and appropriate communication skills.'

The Committee discussed at length the time frame of Convenors' service. Some members suggested a general, though flexible, time frame could be added to the Committee's Guidelines, where this time frame would not a fixed length and would not be mandatory. However, other members considered the existing guidelines were sufficient and have worked effectively in the past and so did not need to be modified. Consequentially no changes to the Committee's guidelines were recommended this year. However, as noted in the existing guidelines, it was agreed that the Chair of the Committee would take carefully into account the length of service when choosing convenors. If necessary this issue can be revisited in future years.

The roles of Heads of Delegations were also discussed and the Committee agrees that the present guidelines are adequate as provided in the Handbook. The Committee also agrees that the Handbook, when updated, will also be available as a pdf file.

24.4 Assistance to new members on the working of the Committee

In order to assist new members, the Committee recommends that an introductory lecture should be given during the first or second day for new (and indeed nay) members that would cover primarily practical r issues including: methods of working, background history of the sub-groups and commonly used acronyms (the latter will also be added to the Handbook). In addition, the Committee recommends that all attendees are reminded of the website location of the Scientific Committee's Handbook when registering for the Annual Meeting.

24.5 Other

Galletti noticed that while management recommendations are widely given in some sub-committees, especially when addressing whaling issues, in other sub-committees and/or standing working groups, the attention seems to be more focused on scientific recommendations and only a few conservation recommendations arise. She believed that his was particularly true for small cetaceans, where there have been differences throughout the years. In this sense, the practice of the Scientific Committee should be reviewed and when there is concern over the status of any cetacean species or threats are identified, there should also be a focus on providing conservation recommendations.

Given the limited time available at this meeting, the Committee **agrees** that this matter should be placed on the agenda for discussion at next year's meeting.

25. ELECTION OF OFFICERS

This is the third and last year in the terms of the Committee's Chair (Palka - US) and Vice-Chair (Kitakado - Japan). Kitakado has agreed to assume at

the end of the 2012 Commission Annual Meeting the Chair of the Scientific Committee. To fill the vacant Vice-Chair position, the Heads of Delegations were happy to unanimously nominate Caterina Fortuna (Italy). Fortuna accepted the Vice-Chair position. The Committee stood in acclaim to thank Palka for her great contribution to the Committees work during the past three years and congratulated Kitakado and Fortuna on their new positions.

26. PUBLICATIONS

This had been a difficult year for the Journal with staff limited by maternity leave, reduced hours, illness and a change in staff. Despite that the department produced:

- (1) the 520pp supplement;
- (2) 3 issues of the journal (two are at the printers) with one more almost complete; and
- (3) the special issue on Southern Hemisphere humpback whales.

Illness to Donovan resulted in less progress than anticipated on the special issue devoted to the RMP but the timetable for its publication has been finalised and it should be available in early 2013. Most of the chapters written by Hammond and Donovan are nearing completion and will be ready for formal review in autumn 2012. These include: (1) an introductory guide to the RMP; (2) a history of the scientific approach to whale management within the IWC prior to the RMP development; (3) a history of the RMP development process including the development of various Requirement and Guidelines; (4) a history of the *Implementation* (and *Implementation Review*) process summarising the cases for western North Pacific common minke whales, western North Pacific Bryde's whales, North Atlantic common minke whales, and North Atlantic fin whales; (5) a concluding overview. In addition, the volume will include the papers from all of the original developers summarising their work in the format determined by Kirkwood. Allison is preparing the appropriate graphs and tables in the new format, including the results of the cross validation trials developed after the *CLA* was adopted.

The special volume commemorating the IDCR/SOWER cruises will be undertaken under an Editorial Board under Bannister as reported elsewhere.

The testing and trial process for the online submission, review and finalisation process has been recently completed and has recently become operational – thanks are due to those members of the Committee who kindly acted as 'guinea pigs' and have helped shape the site and develop the online instructions.

All of the *Journal* volumes are now available as pdf files and the *Journal* will become available in that format either directly via the new IWC website or through an existing company; we are in the process of

examining the practical and financial implications of this and will report back to the Committee next year, after consultation via a questionnaire by email. This issue has become particularly important given the difficulties with printers that have occurred over the past two years and the recent news that the Cambridge University Press printing division is likely to be taken over by another company.

The Committee thanked Donovan and his team for the excellent work on publications. It **reiterates the importance** of these to its work as well as providing outside scientists the opportunity to benefit from the Committee's work and to encourage co-operation.

27. OTHER BUSINESS

No other business was discussed.

28. ADOPTION OF REPORT

The report was adopted at 1700 on 23 June 2012. As is usual final editing was carried out by the convenors after the meeting. In closing the meeting the Chair thanked the Secretariat for carrying out its duties in its customary friendly and efficient manner, as well as once again thanked the Government of Panama and other Panamanian contributors for their hosting of the meeting and for providing snacks and lunches for us, which greatly enhanced productivity and mental health.

Annex B1

Agenda

1. Introductory items
 - 1.1 Chair's welcome and opening remarks
 - 1.2 Appointment of rapporteurs
 - 1.3 Meeting procedures and time schedule
 - 1.4 Establishment of sub-committees and working groups
 - 1.5 Computing arrangements
2. Adoption of agenda
3. Review data, documents and reports
 - 3.1 Documents submitted
 - 3.2 National Progress Reports on research
 - 3.3 Data collection, storage and manipulation
 - 3.1.1 Catch data and other statistical material
 - 3.1.2 Progress of data coding projects and computing tasks
4. Cooperation with other organisations
 - 4.1 Convention on the Conservation of Migratory Species (CMS)
 - 4.1.1 Scientific Council
 - 4.1.2 Conference of Parties
 - 4.1.3 Agreement on Small Cetaceans of the Baltic and North Seas (ASCOBANS)
 - 4.1.4 Agreement on the Conservation of Cetaceans of the Black Sea, Mediterranean Sea and Contiguous Atlantic Area (ACCOBAMS)
 - 4.1.5 Memorandum of Understanding (MoU) on the Conservation of the Manatee and Small Cetaceans of Western Africa and Macaronesia
 - 4.1.6 Memorandum of Understanding (MoU) for the Conservation of Cetaceans and Their Habitats in the Pacific Islands Region (MoU for Pacific Islands Cetaceans)
 - 4.2 International Council for the Exploration of the Sea (ICES)
 - 4.3 Inter-American Tropical Tuna Commission (IATTC)
 - 4.4 Agreement on the International Dolphin Conservation Program (AIDCP).
 - 4.5 International Commission for the Conservation of Atlantic Tunas (ICCAT)
 - 4.6 Convention for the Conservation of Antarctic Marine Living Resources (CCAMLR)
 - 4.7 Southern Ocean GLOBEC (SO-GLOBEC)
 - 4.8 North Atlantic Marine Mammal Commission (NAMMCO)
 - 4.8.1 Scientific Committee
 - 4.8.2 Council
 - 4.9 International Union for the Conservation of Nature (IUCN)
 - 4.10 Food and Agriculture Organisation (FAO) related meetings – Committee on Fisheries (COFI)
 - 4.11 Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES)
 - 4.12 North Pacific Marine Science Organisation (PICES)
 - 4.13 Eastern Caribbean Cetacean Commission (ECCO)
 - 4.14 Protocol on Specially Protected Areas and Wildlife (SPA) of the Cartagena Convention for the Wider Caribbean
 - 4.15 Indian Ocean Commission (IOC)
 - 4.16 Permanent Commission for the South Pacific (CPPS)
 - 4.17 International Maritime Organisation (IMO)
 - 4.18 Conservation in the SE Pacific under the framework for the Lima Convention
 - 4.19 International Committee on Marine Protected Areas (ICMMPA)
5. Revised Management Procedure (RMP) – general issues (see also Annex D)
 - 5.1 Complete the MSY rates review
 - 5.2 Finalise the approach for evaluating proposed amendments to the *CLA*
 - 5.3 Evaluate the Norwegian proposal for amending the *CLA*
 - 5.4 Modify the 'CatchLimit' program to allow variance-covariance matrices
 - 5.5 Update requirements and guidelines for conducting surveys and *Implementations*
 - 5.6 Evaluate the optimisation method used when conditioning trials
 - 5.7 List of abundance estimates and their recommended uses
 - 5.8 Work plan

6. RMP – Preparations for *Implementation*
 - 6.1 Western North Pacific Bryde's whales
 - 6.1.1 Prepare for 2013 *Implementation Review*
 - 6.1.2 Recommendations
 - 6.2 North Atlantic fin whales
 - 6.2.1 Recommendations
 - 6.3 North Pacific common minke whales (continue *Implementation*)
 - 6.3.1 Report of the December 2012 Intersessional Workshop
 - 6.3.2 Conditioning
 - 6.3.3 Update to standard datasets - abundance estimates
 - 6.3.5 Final consideration of plausibility
 - 6.3.5.1 Stock structure
 - 6.3.5.2 MSYR and other factors
 - 6.3.6 Specifications of operational features and management variants
 - 6.3.7 Specifications and classification of final trials
 - 6.3.8 Consideration of data/analyses to reduce hypotheses in future
 - 6.3.9 Inputs for actual application of the *CLA*
 - 6.4 North Atlantic common minke whales
 - 6.4.1 Review new information
 - 6.4.2 Prepare for 2014 *Implementation Review*
 - 6.5 North Atlantic sei whales
 - 6.6 Work plan
7. Estimation of Bycatch and other Human-Induced Mortality (BC)
 - 7.1 Collaboration with FAO on collation of relevant fisheries data
 - 7.2 Estimation of bycatch mortality of large whales
 - 7.3 Estimation of risk and rates of entanglement
 - 7.4 Review progress on including information in National Progress Reports
 - 7.5 Ship strikes
 - 7.6 Continue to develop global database of ship strike incidents
 - 7.7 Other issues
 - 7.8 Work plan
8. Aboriginal Subsistence Whaling Management Procedure (AWMP)
 - 8.1 Complete *Implementation Review* of eastern North Pacific gray whales with an emphasis on the PCFG
 - 8.1.1 Stock structure
 - 8.1.2 Abundance
 - 8.1.3 Catch data (direct and incidental)
 - 8.1.4 Mixing
 - 8.1.5 Biological parameters and MSYR
 - 8.1.6 Variants
 - 8.1.7 Final trials and conditioning
 - 8.1.8 Review results of trials
 - 8.1.9 Conclusions and selection of *SLAs*
 - 8.1.10 Other business
 - 8.2 Complete *Implementation Review* of Bering-Chukchi-Beaufort Seas bowhead whales
 - 8.2.1 Consideration of new information with a focus on whether this implies a need for new trials
 - 8.2.1.1 Stock structure
 - 8.2.1.2 Abundance and rate of increase
 - 8.2.1.3 Catch data
 - 8.2.2 Discussion of new trials
 - 8.2.3 Conclusions and recommendations
 - 8.3 Continue work on developing *SLAs* for the Greenlandic hunts (Annex E, Item 4)
 - 8.3.1 Common minke whales
 - 8.3.2 Fin whales
 - 8.3.3 Humpback whales and bowhead whales
 - 8.4 Guidelines for *Implementation Reviews*
 - 8.5 Scientific aspects of an aboriginal whaling scheme (AWS)
 - 8.6. Conversion factors for edible products for Greenland hunts

- 8.7 Workplan
- 9. Aboriginal Subsistence Whaling management advice
 - 9.1 Eastern Canada and West Greenland bowhead whales
 - 9.1.1 Review new information on Eastern Canada and West Greenland bowhead whales
 - 9.1.2 Review recent catch information
 - 9.1.3 Management advice
 - 9.2 Eastern North Pacific gray whales
 - 9.2.1 New information
 - 9.2.2 Review of recent catch information
 - 9.2.3 Management advice
 - 9.3 Bering-Chukchi-Beaufort (B-C-B) Seas stock of bowhead whales
 - 9.3.1 New information
 - 9.3.2 Management advice
 - 9.4 Common minke whales off West Greenland
 - 9.4.1 New information
 - 9.4.2 Management advice
 - 9.5 Common minke whales off East Greenland
 - 9.5.1 New information
 - 9.5.2 Management advice
 - 9.6 Fin whales off West Greenland
 - 9.6.1 New information
 - 9.6.2 Management advice
 - 9.7 Humpback whales off West Greenland
 - 9.7.1 New information
 - 9.7.2 Management advice
 - 9.8 Humpback whales off St Vincent and The Grenadines
 - 9.8.1 New information
 - 9.8.2 Management advice
- 10. Whale stocks
 - 10.1 Antarctic minke whales (Annex G)
 - 10.1.1 Stock structure
 - 10.1.2 Abundance estimation of Antarctic minke whales
 - 10.1.3 Reasons for differences between estimates from CPII and CPIII
 - 10.1.4 Continue development of the catch-at-age models
 - 10.2. Southern Hemisphere humpback whales
 - 10.2.1 Begin assessment of breeding stocks D, E and F
 - 10.2.1.1 Abundance, trends and population structure
 - 10.2.1.2 Assessment models
 - 10.2.2 Review new information on other breeding stocks
 - 10.2.2.1 Breeding stock A
 - 10.2.2.2 Breeding stock B
 - 10.2.2.3 Breeding stock C
 - 10.2.2.4 Breeding stock D
 - 10.2.2.5 Breeding stock G
 - 10.2.2.6 Feeding grounds
 - 10.2.2.7 Antarctic Humpback Whale Catalogue
 - 10.2.3 Work plan
 - 10.3. Southern Hemisphere blue whales
 - 10.3.1 Review new information
 - 10.3.1.1 Photo-identification catalogues
 - 10.3.1.2 Antarctic blue whales
 - 10.3.1.3 Planning of future research
 - 10.3.1.4 Pygmy blue whales
 - 10.3.1.5 Chilean blue whales
 - 10.4 Western North Pacific gray whales
 - 10.4.1 New scientific information
 - 10.4.1.1 Satellite Tagging
 - 10.4.1.2 photo-identification

- 10.4.1.3 Other
 - 10.4.2 Conservation advice
- 10.5 Southern Hemisphere right whales
 - 10.5.1 Review report from intersessional workshop
 - 10.5.1.1 Long-term population monitoring
 - 10.5.1.2 Population structure and linkages
 - 10.5.1.3 Modelling
 - 10.5.1.4 Joint Argentina/Brazil assessment
 - 10.5.1.5 Assessment of the Chile/Peru population
 - 10.5.1.6 Identification of concerns and their monitoring
 - 10.5.1.7 Development of Conservation Management Plans (CMPs)
 - 10.5.1.8 Conclusion
 - 10.5.2 Review new information
 - 10.5.2.1 Southwest Atlantic
 - 10.5.2.2 Southern Africa
 - 10.5.2.3 Southwest Pacific and New Zealand
 - 10.5.2.4 Australia
 - 10.5.2.5 South East Pacific right whales
 - 10.5.2.6 Genetic research
- 10.6 Other stocks of right whales and small stock of bowhead whales
 - 10.6.2 Work
- 10.7 Arabian Sea humpback whales
 - 10.7.1 Review intersession progress
 - 10.7.2 The development of a CMP
 - 10.7.3 Work plan
- 10.8 Cruises
 - 10.8.1 The IWC-POWER programme
 - 10.8.1.1 Planning the IWC-Power Programme
 - 10.8.1.2 Report on the 2011 IWC-Power Cruise
 - 10.8.1.3 The 2012 IWC-Power Cruise
 - 10.8.1.4 Plans for the 2013 IWC-Power Cruise
 - 10.8.2 Other North Pacific cruises (and see Item 6)
 - 10.8.2.1 Report of Japanese cetacean sighting surveys in the north Pacific in 2011
 - 10.8.2.2 Plans for Japanese cetacean sighting surveys in the north Pacific in 2012
 - 10.8.3 Cruises in the Antarctic Ocean
 - 10.8.3.1 Progress on IDCR-SOWER cruises publications
 - 10.8.3.2 Report of the 2011/12 cetacean sighting survey in the Antarctic
 - 10.8.3.3 Plans for cetacean sighting surveys in the Antarctic in the 2012/13 season
- 10.9 Progress towards an in-depth assessment of North Pacific sei whales

11. Stock Definition

- 11.1 Guidelines for DNA data quality and genetic analyses
- 11.2 Statistical and genetic issues related to stock definition
- 11.3 Progress on the Testing of Spatial Structure Models (TOSSM)
- 11.4 Terminology and unit-to-serve
- 11.5 Workplan

12. Environmental Concerns (E)

- 12.1 State of the cetacean environment report (SOCER)
- 12.2 Pollution
 - 12.2.1 Update on POLLUTION 2000+ Phase II progress
 - 12.2.2 Oil spill impacts
 - 12.2.2.1 Update on response to Deepwater Horizon oil spill in the Gulf of Mexico
 - 12.2.2.2 Capacity building regarding oil spill impacts on cetaceans
 - 12.2.3 Other pollution related issues
- 12.3 CERD (Cetacean Emerging and Resurging Disease)
 - 12.3.1 Update from CERD Working Group
 - 12.3.2 Progress on CERD Website
 - 12.3.3 Other disease related issues
- 12.4 Anthropogenic sound

- 12.4.1 Mitigation of effects of anthropogenic sound on cetaceans
- 12.4.2 Other anthropogenic sound related issues
- 12.5 Climate change
 - 12.5.1 Progress on recommendations from the 2nd Climate Change Workshop
 - 12.5.2 Small cetacean restricted habitats Working Group
 - 12.5.3 Planning for intersessional Arctic Anthropogenic Impacts Workshop
 - 12.5.4 Other climate change related issues
- 12.6 Interactions between MREDs and cetaceans
- 12.7 Other habitat related issues
 - 12.7.1 Cetaceans and marine debris
 - 12.7.2 Issues related to the March 2011 tsunami in the NW Pacific
 - 12.7.3 Cumulative impacts of anthropogenic activities
 - 12.7.4 REMMOA aerial surveys in the French EEA
- 12.8 Work plan
- 13. Ecosystem Modelling
 - 13.1 Review of ecosystem modelling efforts undertaken outside the IWC
 - 13.1.1 Ecosystem modelling in the context of ecosystem-based fisheries management
 - 13.1.2 Ecosystem models of the effect on predators of fishing forage fish
 - 13.1.3 Status update on NAMMCO ecosystem modelling
 - 13.2 Explore how ecosystem models contribute to developing scenarios for simulation testing of the RMP
 - 13.3 Review of other issues relevant to ecosystem modelling within the committee
 - 13.3.1 Update on Antarctic minke whale body condition analyses
 - 13.3.2 Other issues
 - 13.4 Review new information on ecosystem model skill assessment
- 14. Small Cetaceans (SM)
 - 14.1. Review status of ziphiids whales in the North Pacific and northern Indian Ocean
 - 14.1.1. Cuvier's beaked whale (*Ziphius cavirostris*)
 - 14.1.1.1. Conclusions and other considerations of status
 - 14.1.2. Baird's beaked whale (*Berardius bairdii*)
 - 14.1.2.1 Life history parameters
 - 14.1.2.2. Abundance and trends
 - 14.1.2.3. Takes including bycatch
 - 14.1.2.4. Other actual and potential threats
 - 14.1.2.5. Conclusions and other considerations of status
 - 14.1.3. Longman's beaked whale (*Indopacetus pacificus*)
 - 14.1.3.1 Conclusions and other considerations of status
 - 14.1.4. Hubbs' beaked whale (*Mesoplodon carlhubbsi*)
 - 14.1.4.1 Conclusions and other considerations of status
 - 14.1.5. Blainville's beaked whale (*Mesoplodon densirostris*)
 - 14.1.5.1 Conclusions and other considerations of status
 - 14.1.6. Ginkgo-toothed beaked whale (*Mesoplodon ginkgodens*)
 - 14.1.7. Perrin's beaked whale (*Mesoplodon perrini*)
 - 14.1.8. Pygmy beaked whale (*Mesoplodon peruvianus*)
 - 14.1.8.1 Conclusions and other considerations of status
 - 14.1.9. Stejneger's beaked whale (*Mesoplodon stejnegeri*)
 - 14.1.9.1 Conclusions and other considerations of status
 - 14.1.10. Deraniyagala's beaked whale
 - 14.1.10.1 Conclusions and other considerations of status
 - 14.1.11. Common issues and threats
 - 14.1.11.1 Military sonar and other noise sources
 - 14.1.11.2. Marine debris
 - 14.1.11.3 General recommendations
 - 14.2. Report on the voluntary fund for small cetacean conservation research
 - 14.2.1. Status of the voluntary fund for small cetacean conservation research
 - 14.2.2. Review on Progress on Funded Projects
 - 14.3. Progress on previous recommendations
 - 14.3.1. Vaquita
 - 14.3.2. Harbour porpoise

- 14.3.3. Franciscana
- 14.3.4. Narwhal and white whale
- 14.3.5. Atlantic humpback dolphin
 - 14.3.6. River dolphins
 - 14.3.6.1 Boto and tucuxi
 - 14.3.6.2 Indus river dolphin
 - 14.3.6.3 Mekong river population of irrawaddy dolphins
 - 14.3.7 Killer whales
 - 14.3.8 Clymene dolphin
- 14.4 Takes of small cetaceans
- 14.5. Local studies
- 14.6 Hector's dolphins
- 14.7. Workplan
- 15. Whalewatching
 - 15.1 Assess the impacts of whalewatching on cetaceans
 - 15.2 Review whalewatching off Central America
 - 15.3 Reports from intersessional working groups
 - 15.3.1 Large-scale whalewatching experiment (LaWE) steering group
 - 15.3.2 LaWE budget development group
 - 15.3.3 Online database for worldwide tracking of commercial whalewatching and associated data collection
 - 15.3.4 Swim-with-whale operations
 - 15.3.5 In-water interactions
 - 15.4. Other issues
 - 15.4.1 Review scientific aspects of the Commission's Five Year Strategic Plan for Whalewatching
 - 15.4.2 Consider information from platforms of opportunity of potential value to the Scientific Committee
 - 15.4.3 Review whalewatching guidelines and regulations
 - 15.4.4 Review of collision risks to cetaceans from whalewatching vessels
 - 15.4.5 Swim-with-whales operations
 - 15.4.6 Emerging whale watching industry in Oman
 - 15.5 Work plan
 - 15.6 Other matters
- 16. DNA testing
 - 16.1 Review genetic methods for species, stock and individual identification
 - 16.2 Review results of the amendments of sequences deposited in GenBank
 - 16.3 Collection and archiving of tissue samples from catches and by-catches
 - 16.4 Reference databases and standards for diagnostic registries
 - 16.5 Work plan
- 17. Scientific Permits
 - 17.1 Review of results from existing permits
 - 17.1.1 JARPN II
 - 17.1.1.1 Authors' summaries
 - 17.1.1.2 Discussion
 - 17.1.2 JARPA II
 - 17.1.2.1 Authors' summary
 - 17.1.2.2 Discussion
 - 17.1.3 Planning for a final review of results from Iceland - North Atlantic common minke whale
 - 17.1.4 Planning for a periodic review of results from JARPA II
 - 17.2 Review of new or continuing proposals
 - 17.2.1 JARPA II
 - 17.2.2 JARPN II
- 18. Whale sanctuaries
- 19. SORP
 - 19.1 Review of progress since IWC 63
 - 19.1.1 SORP Antarctic Blue Whale Project
 - 19.1.2 Ways to expand Antarctic Blue Whale Project (ABWP) work
 - 19.1.3 Killer whales in the Southern Ocean
 - 19.1.4 Foraging ecology and predator prey interactions of baleen whales and krill

SCIENTIFIC COMMITTEE REPORT

- 19.1.5 Oceania humpback whale mixing
- 19.1.6 Fin and blue whale acoustics
- 19.1.7 Living Whales Symposium and non-lethal research techniques workshops
- 19.2 Budget
 - 19.2.1 Budget overview
 - 19.2.2 Request for funds from projects
 - 19.2.3 Reallocation of funds
 - 19.2.4 Allocation of funds
 - 19.2.5 Seeking additional funding
- 19.3 Requirements for formalising participation in SORP and development of new projects
- 19.4 Workplan
- 20. Research and Workshop proposals and results
 - 20.1 Review results from previously funded research proposals
 - 20.2 Review proposals for 2012/13
- 21. Committee priorities and initial Agenda for the 2013 meeting
- 22. Data processing and computing needs for 2011/12
- 23. Funding requirements for 2012/13
- 24. Working methods of the Committee
 - 24.1 Reducing the costs of Committee meetings
 - 24.2 Clarifying information on data availability for Procedure B requests
 - 24.3 Updating the Committee's guidelines and Handbook
 - 24.4 Assistance to new members on the working of the Committee
- 25. Election of Officers
- 26. Publications
- 27. Other business
- 28. Adoption of Report

Annex B2

Relationship Between Commission and Scientific Committee Agendas

This table is intended to assist readers in finding information relative to the Commission agenda (IWC/64) in the Scientific Committee Report (SC/64) and the Chair's Report (2012) of IWC/63 (held in 2011). Commission agenda items not in this summary were not addressed at the Scientific Committee meeting.

No.	Commission Agenda (IWC/64)	Scientific Committee Agenda Item and Annex (SC/64)	Chair's Report (IWC/63: Agenda Item)
4.	SANCTUARIES		9
4.1	South Atlantic Whale Sanctuary		9.2
4.2	Other sanctuary issues raised in the Scientific and Conservation Committees		
4.2.1	Report of the Scientific Committee	18	9.1.1
4.2.2	Report of the Conservation Committee		9.1.2
5	THE IWC IN THE FUTURE		4
6.	WHALE STOCKS		5
6.1	Antarctic minke whales		5.1
6.1.1	Report of the Scientific Committee	10.1; Annex G	
6.2	Southern Hemisphere humpback whales		5.2
6.2.1	Report of the Scientific Committee	10.2; Annex H	
6.3	Southern Hemisphere blue whales		5.3
6.3.1	Report of the Scientific Committee	10.3; Annex H	
6.4	Western North Pacific gray whales		5.4
6.4.1	Report of the Scientific Committee	10.4; Annex F	
6.5	Southern Hemisphere right whales		5.5
6.5.1	Report of the Scientific Committee	10.5; Annex F	
6.6	North Pacific and North Atlantic right whales and small stocks of bowhead whales		5.6
6.6.1	Report of the Scientific Committee		
	• Right whales	10.6; Annex F	5.6.1
	• Bowhead whales	8.2, 9.1, 9.3, 10.6; Annexes E, F	
	• Gray whales	8.1, 9.2, 10.4; Annexes E, F	
6.7	North Pacific Research cruises (SOWER and North Pacific)		5.7
6.7.1	Report of the Scientific Committee	10.7; Annex G	
6.8	Other stocks		
7.	ABORIGINAL SUBSISTENCE WHALING		7; Annex F
7.1	Aboriginal Subsistence Whaling Management Procedure		7.1
7.1.1	Report of the Aboriginal Subsistence Whaling Sub-committee	8; Annex E	7.1.1
7.2	Aboriginal Whaling Scheme		7.2
7.2.1	Report of the Aboriginal Subsistence Whaling Sub-committee	8.3; Annex E	7.2.1
7.3	Aboriginal subsistence whaling catch limits		7.3
7.3.1	Report of the Aboriginal Subsistence Whaling Sub-committee	9; Annexes E, F	7.3.1.1, 7.3.2.1, 7.3.3.1, 7.3.4.1, 7.3.5.1, 7.3.6.1, 7.3.7.1, 7.4.1
8	CONSERVATION COMMITTEE		18; Annex G
8.1	Investigation of inedible 'stinky' gray whales		
8.1.1	Report of the Conservation Committee	12.2.3; Annex K	
8.2	Ship Strikes		
8.2.1	Report of the Conservation Committee	7.7, 8.8; Annex K	
8.3	Southern Right Whales of Chile-Peru		
8.3.1	Report of the Conservation Committee	10.6.1; Annex F	
8.4	National Reports on Cetacean Conservation		
8.4.1	Report of the Conservation Committee		
8.5	Marine Debris		
8.5.1	Report of the Conservation Committee	12.7.1; Annex K	
8.6	Voluntary fund for small cetacean conservation research		
8.6.1	Report of the Conservation Committee	14.2; Annex L	
9.	CONSERVATION MANAGEMENT PLANS		14; Annex G
9.1	Report of the Conservation Committee	10.4, 10.5.2, 10.7; Annexes F, H	
10.	WHALEWATCHING		15; Annex G
10.1	Report of the Conservation Committee	15; Annex M	
11.	WHALE KILLING METHODS AND ASSOCIATED WELFARE ISSUES		6

No.	Commission Agenda (IWC/64)	Scientific Committee Agenda Item and Annex (SC/64)	Chair's Report (IWC/63: Agenda Item)
11.1	Report of the Working Group on Whale Killing Methods and Associated Welfare Issues		6.1
12.	SOCIOECONOMIC IMPLICATIONS AND SMALL-TYPE WHALING		10
13.	REVISED MANAGEMENT PROCEDURE (RMP)		8.1
13.1	Report of the Scientific Committee		8.1.1
13.1.1	General issues	5; Annex D	8.1.1.1
13.1.2	Implementation process		8.1.1.2
	• Western North Pacific Bryde's whale	6.1; Annex D	8.1.1.2
	• Central North Atlantic fin whales	6.2; Annex D	8.1.1.2
	• Western North Pacific common minke whales	6.3; Annex D1	8.1.1.2
13.1.3	Bycatch	7; Annex J	8.1.1.3
14.	SCIENTIFIC PERMITS		11
14.1	Report of the Scientific Committee	17	
14.1.1	Review of results from existing permits	17.1	
14.1.2	Review of new or continuing proposals	17.2	
14.1.3	Procedures for reviewing scientific permit proposals	17.1.3	
14.1.4	Other		
15.	SAFETY ISSUES AT SEA		12
16.	CATCHES BY NON-MEMBER NATIONS		19
16.1	Report of the Scientific Committee	9.1	
17.	INFRACTIONS, 2011 SEASON		20
18.	ENVIRONMENTAL AND HEALTH ISSUES		13
18.1	State of the Cetacean Environment (SOCER)		
18.1.1	Report of the Scientific Committee	12.1; Annex K	
18.2	POLLUTION 2000+: Phase II Planning Workshop		
18.2.1	Report of the Scientific Committee	12.2; Annex K	
18.3	Cetacean diseases		
18.3.1	Report of the Scientific Committee	12.3; Annex K	
18.4	The impacts of oil and dispersants on cetaceans		
18.4.1	Report of the Scientific Committee	12.2; Annex K	
18.5	Marine renewable energy developments and cetaceans		
18.5.1	Report of the Scientific Committee	12.6; Annex K	
18.6	Anthropogenic sound		
18.6.1	Report of the Scientific Committee	12.4; Annex K	
18.7	Climate Change		
18.7.1	Report of the Scientific Committee	12.5; Annex K	
18.8	Ecosystem modelling		
18.8.1	Report of the Scientific Committee	13; Annex K1	
18.9	Proposal for a workshop on anthropogenic impacts to cetaceans in the Arctic		
18.9.1	Report of the Scientific Committee	12.5.3; Annex K	
18.10	Reports from Contracting Governments on national and regional efforts to monitor and address the impacts of environmental change on cetaceans and other marine mammals		
18.11	Health issues – Commission discussions and action arising		
18.12	Other		
19.	OTHER SCIENTIFIC COMMITTEE ACTIVITIES, ITS FUTURE WORK PLAN AND ADOPTION OF SCIENTIFIC COMMITTEE REPORT		17
19.1	Small cetaceans		17.1
19.1.1	Report of the Scientific Committee	14; Annex L	17.1
19.2	Regional non-lethal research partnerships		17.2
19.2.1	Report of the Scientific Committee	10.3;19; Annex H	17.2
19.3	Other activities		17.3
19.3.1	Report of the Scientific Committee	11, 16, 20, 22, 24-28	17.3
19.4	Scientific Committee Future Work Plan		17.4
19.4.1	Report of the Scientific Committee	21, 23	17.4
20	CO-OPERATION WITH OTHER ORGANISATIONS		16
20.1	Report of the Scientific Committee	4	
21	ADMINISTRATIVE MATTERS		21
21.1	Meeting arrangements and Procedures		21.1
21.2	The Commission's website		21.2
21.3	Operational effectiveness		
21.4	Cost saving measures		
22	FORMULAT FOR CALCULATING CONTRIBUTIONS AND RELATED MATTERS		21.5

No.	Commission Agenda (IWC/64)	Scientific Committee Agenda Item and Annex (SC/64)	Chair's Report (IWC/63: Agenda Item)
23	REPORT OF THE INTERSESSIONAL CORRESPONDENCE GROUP ON STRENGTHENING IWC FINANCING		
24	FINANCIAL STATEMENTS, BUDGETS AND OTHER MATTERS CONSIDERED BY THE BUDGETARY SUB-COMMITTEE		21.7
25	ADOPTION OF THE REPORT OF THE FINANCE AND ADMINISTRATION COMMITTEE		21.8
26	DATE AND PLACE OF FORTHCOMING MEETINGS		22
27	ADVISORY COMMITTEE		23
28	SUMMARY OF DECISIONS AND REQUIRED ACTIONS		24
29	OTHER MATTERS		25

Annex C

List of Documents

SC/64/AWMP

1. Philips, C.D., Hoffman, J.I., George, J.C., Suydam, R.S., Huebinger, R.M., Patton, J.C. and Bickham, J.W. Molecular insights to historical demography in bowhead whales. 20pp.
2. D'Intino, A.M., Darling, J.D., Urbán-Ramirez, J. and Frasier, T.R. Substructuring of mitochondrial, but not nuclear, markers in the 'southern feeding group' of eastern North Pacific gray whales. 14pp.
3. Morin, P.A., Archer, F.I., Pease, V.L., Hancock-Hanser, B., Robertson, K.M., Huebinger, R.M., Martien, K.K., Bickham, J.W., George, J.C., Postma, L.D. and Taylor, B.L. An empirical comparison of SNPs and microsatellites for population structure, assignment, and demographic analyses of bowhead whale populations. 27pp.
1. Lang, A.R. and Martien, K.K. Update on the use a simulation-based approach to evaluate plausible levels of recruitment into the Pacific Coast Feeding Group of gray whales. 34pp.
2. George, C. and Zeh, J. Population trend, 1978-2004, of Bering-Chukchi-Beaufort bowhead whales (*Balaena mysticetus*). 3pp.
3. George, C., Suydam, R., Givens, G.H., Bickham, J., Stimmelmayer, R., Moore, S. and Zeh, J. Selected research relevant to the 2012 bowhead *Implementation Review*. 17pp.
4. George, C., Herreman, J., Givens, G.H., Suydam, R., Mocklin, J., Clark, C., Tudor, B. and DeLong, R. Brief overview of the 2010 and 2011 bowhead whale abundance surveys near Point Barrow, Alaska. 9pp.

Report of the Scientific Committee

Bled, Slovenia, 12-24 May 2014

Although this report has been carefully read by many people, it contains almost 88,000 words. If any errors are found, please inform the Secretariat (jessica.peers@iwc.int).

**International Whaling Commission,
Bled, Slovenia, 2014**

Report of the Scientific Committee

Bled, 12-24 May 2014

1. INTRODUCTORY ITEMS	3
2. ADOPTION OF AGENDA	3
3. REVIEW OF AVAILABLE DATA, DOCUMENTS AND REPORTS	3
4. CO-OPERATION WITH OTHER ORGANISATIONS	5
5. REVISED MANAGEMENT PROCEDURE (RMP) – GENERAL ISSUES	10
5.1 Use of individual based energetics model	10
5.2 Relationship between $MSYR_{mat}$ and $MSYR_{1+}$	10
5.3 Finalise the approach for evaluating proposed amendments to the CLA	11
5.4 Evaluate the Norwegian proposal for amending the CLA	11
5.5 Other computing matters related to the CLA	11
5.6 Update ‘Requirements and Guidelines for conducting surveys and Implementations’	11
5.7 Imbalanced sex ratio in incidental catches	12
5.8 Workplan	12
6. RMP –IMPLEMENTATION-RELATED MATTERS	12
6.1 North Pacific common minke whales (additional work from completed Implementation Review)	12
6.2 North Atlantic fin whales (Implementation Review)	13
6.3 North Atlantic common minke whales (Implementation Review)	13
6.4 North Atlantic sei whales	13
6.5 Western North Pacific Bryde’s whales	13
6.6 Updated table of abundance	14
6.7 Workplan	14
7. Non-deliberate Human-induced Mortality of Large Whales	14
7.1 Entanglement of large whales	14
7.2 Ship strikes	15
7.3 Marine debris	17
7.4 Other issues including mortality from acoustic sources	17
7.5 Workplan	17
8. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT PROCEDURE (AWMP)	17
8.1 Progress on SLA development for the Greenland hunts	18
8.2 Follow-up work on conversion factors for the Greenland hunt	24
8.3 Aboriginal Whaling Management Scheme	24
8.4 Workplan	24
9. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT ADVICE	24
9.1 Bowhead whales off West Greenland	25
9.2 North Pacific gray whales	25
9.3 Bering-Chukchi-Beaufort (BCB) Seas stock of bowhead whale	26
9.4 Common minke whales off West Greenland	26
9.5 Common minke whales off East Greenland	27
9.6 Fin whales off West Greenland	27
9.7 Humpback whales off West Greenland	27
9.8 Humpback whales off St Vincent and The Grenadines	27
10. WHALE STOCKS	27
10.1 Antarctic minke whales	27
10.2 Southern Hemisphere humpback whales	30
10.3 Southern Hemisphere blue whales	34
10.4 Distribution of baleen and toothed whales in the Antarctic relative to spatial and environmental covariates	36
10.5 In-depth assessment of North Pacific sei whales	36
10.6 Gray whales in the western North Pacific	37
10.7 Southern Hemisphere right whales	38
10.8 North Atlantic right whales	38
10.9 North Pacific right whales	39
10.10 North Atlantic bowhead whales	39
10.11 Okhotsk Sea bowhead whales	39
10.12 Arabian Sea humpback whales	39
10.13 International cruises	40
10.14 Sperm whales	42
10.15 Overview of workplan	42
11. STOCK DEFINITION	42
11.1 Guidelines for DNA data quality and genetic analyses	43
11.2 Statistical and genetic issues related to stock definition	43
11.3 Testing of Spatial Structure Models (TOSSM)	44
11.4 Terminology and unit-to-convert	44

12. ENVIRONMENTAL CONCERNS	45
12.1 State of the Cetacean Environment Report (SOCER)	45
12.2 Pollution	45
12.3 Cetacean emerging and resurging diseases (CERD) and mortality events	46
12.4 Effects of anthropogenic sound on cetaceans and approaches to mitigate these effects	47
12.5 Impacts of climate change on cetaceans	49
12.6 Habitat-related issues	50
12.7 Other habitat-related issues	50
12.8 Conservation Management Plans	50
12.9 Workplan	50
13. ECOSYSTEM MODELLING	51
13.1 Review of ecosystem modelling efforts undertaken outside the IWC	51
13.2 Explore how ecosystem models contribute to developing scenarios for simulation testing of the RMP	52
13.3 Review of other issues relevant to ecosystem modelling within the Committee	52
13.4 Workplan and budget requests	53
14. SMALL CETACEANS	54
14.1 Review of status of small cetaceans in the eastern Mediterranean and Red seas	54
14.2 Review of status of small cetaceans in the Red Sea	55
14.3 Report on the Voluntary Fund for Small Cetacean Conservation Research	56
14.4 Progress on previous recommendations	57
14.5 Takes of small cetaceans	62
14.6 Update on proposed joint workshop on monodontids	63
14.7 Conservation and Management plans	63
14.8 Other information on small cetaceans	63
14.9 Workplan and budget requests	63
15. WHALEWATCHING	63
15.1 Assess the impact of whalewatching on cetaceans	63
15.2 Review whalewatching in the Mediterranean and Red Seas	64
15.3 Review reports from intersessional working groups	64
15.4 Consider information from Platforms of Opportunity of potential value to the Scientific Committee	65
15.5 Review whalewatching guidelines and regulations	65
15.6 Consider emerging whalewatching industries of concern	66
15.7 Other issues	66
15.8 Workplan	66
16. DNA TESTING (DNA)	66
16.1 Review genetic methods for species, stock and individual identification	66
16.2 Review results of the amendments of sequences deposited in GenBank	67
16.3 Collection and archiving of tissue samples from catches and bycatches	67
16.4 Reference databases and standards for diagnostic DNA registries	67
16.5 Workplan	68
17. SPECIAL PERMITS	68
17.1 Expert Panel Review of the results from JARPA II	68
17.2 Review results from ongoing permits	71
17.3 Review of new or continuing proposals	73
17.4 Workplan	74
18. WHALE SANCTUARIES	75
18.1 Preparation for the regular review of the Southern Ocean Sanctuary	75
18.2 South Atlantic Sanctuary proposal	75
18.3 Workplan	76
19. SOUTHERN OCEAN RESEARCH PARTNERSHIP	77
20. IWC LIST OF RECOGNISED SPECIES	77
21. CONSERVATION MANAGEMENT PLANS	77
22. UPDATED LIST OF ACCEPTED ABUNDANCE ESTIMATES	77
23. RESEARCH AND WORKSHOP PROPOSALS AND RESULTS	77
23.1 Review results from previously funded research proposals	77
23.2 Review workshop proposals for 2014/15	77
24. COMMITTEE PRIORITIES AND INITIAL AGENDA FOR THE 2015 and 2016 MEETINGS	78
25. DATA PROCESSING AND COMPUTING NEEDS FOR 2014/15	81
26. FUNDING REQUIREMENTS FOR 2014/15 AND 2015/16	82
26.1 Rationale for the reduced budget items	82
26.2 Summary information on all of the proposals received	84
26.2 Unspent and unallocated budget monies	89
27. WORKING METHODS OF THE COMMITTEE	89
27.1 Increasing the support of the Scientific Committee on conservation related issues	89
27.2 Data access under Annex P	90
27.3 Improving the Scientific Committee budget review process	91
28. ELECTION OF OFFICERS	92
29. PUBLICATIONS	92
30. OTHER BUSINESS	92
31. ADOPTION OF REPORT	92

The meeting (SC/65b) was held at the Golf Hotel, Bled, Slovenia from 12-24 May 2014 and was chaired by Toshihide Kitakado. The next meeting of the Commission (IWC/65) will take place during September 2014 and the next meeting of the Scientific Committee in 2015 will be SC/66a. The list of participants is given as Annex A.

1. INTRODUCTORY ITEMS

1.1 Chair's welcome and opening remarks

Kitakado welcomed the participants to the 2014 Annual Scientific Committee meeting. He thanked the Government of Slovenia for hosting the meeting and for providing the excellent facilities in the beautiful town of Bled.

Secretary of State at the Ministry of Agriculture and the Environment, Andreja Jerina, underlined the importance of nature preservation which, in many cases, is not an easy task. She highlighted that size, 'charisma' or unfamiliarity of a species alone should not play a role in nature conservation – what counts for conservation of any species is knowledge, perseverance and enthusiasm. She also stressed the importance of knowledge and good scientific propositions for political decisions in this field. She wished the participants a lot of success in their preparation of a decision basis for the September meeting in Portorož.

On behalf of the Commission, Brockington thanked the State Secretary for the invitation for the Scientific Committee to meet in Slovenia. He expressed his thanks for the excellent work of Andrej Bibic, the Commissioner for Slovenia, and his colleagues at the Ministry of Agriculture and Environment and the Ministry of Foreign Affairs. Their hard work, along with that of the staff at Sava Resorts and Hotels meant that making the preparations for this meeting had been extremely smooth and pleasant. He also referred to the great value of the work of the Scientific Committee and the wide range of topics it covers when providing its advice to the Commission.

1.2 Appointment of rapporteurs

Donovan was appointed rapporteur with assistance from various members of the Committee as appropriate. Chairs of sub-committees and Working Groups appointed rapporteurs for their individual meetings.

1.3 Meeting procedures and time schedule

The Committee agreed to the meeting procedures and time schedule outlined by the Chair.

1.4 Establishment of sub-committees and working groups

As agreed last year (IWC, 2013a) and included in the draft agenda, two pre-meetings took place in Bled prior to the Annual Meeting. A pre-meeting of the sub-committee on the Revised Management Procedure (RMP) met on 9-11 May 2014 to continue the *Implementation Review* for North Atlantic minke whales. Its report is given as Annex D, Appendix 5. The sub-committee on Other Southern Hemisphere Whale Stocks met 10-11 May 2014 to work towards the completion of the assessment of humpback whale Breeding Stocks D, E and F. It continued its work during the meeting and its report is subsumed into Annex H.

A number of sub-committees and working groups were established. Their reports were either made Annexes to this report (see below) or, in the case of that on Sanctuaries, was incorporated directly into the plenary report.

Annex D – Sub-Committee on the Revised Management Procedure;

Annex E – Standing Working Group on Aboriginal Subsistence Whaling Management Procedures;

Annex F – Sub-Committee on Bowhead, Right and Gray Whales;

Annex G – Sub-Committee on In-Depth Assessments;

Annex H – Sub-Committee on Other Southern Hemisphere Whale Stocks;

Annex I – Working Group on Stock Definition;

Annex J – Working Group on Non-deliberate Human-Induced Mortality of Large Whales;

Annex K – Standing Working Group on Environmental Concerns;

Annex K1 – Working Group to Address Multi-species and Ecosystem Modelling Approaches;

Annex L – Sub-Committee on Small Cetaceans;

Annex M – Sub-Committee on Whalewatching;

Annex N – Working Group on DNA;

Annex O – Working Group on Special Permits;

Annex P – Revisions to the Annex P process;

Annex Q – Ad hoc working group on progress reports;

Annex R – Terms of reference for Sanctuary reviews;

Annex S – Budget related matters;

Annex T – Intersessional working groups;

Annex U – Statements on the Agenda.

1.5 Computing arrangements

Allison outlined the computing and printing facilities available for delegate use.

2. ADOPTION OF AGENDA

The adopted agenda is given as Annex B. A number of statements on the Agenda were received on items related to small cetaceans, whalewatching and the JARPA II programme. These are given in Annex U.

3. REVIEW OF AVAILABLE DATA, DOCUMENTS AND REPORTS

3.1 Documents submitted

The documents available are listed in Annex C. As agreed at the 2012 Annual Meeting, primary papers were only available at the meeting in electronic format (IWC, 2013a, pp.78-9).

3.2 National Progress Reports on research

As agreed last year, all National Progress Reports were submitted electronically through the IWC National Progress Reports data portal. This data portal now allows multiple levels of data entry users within each country and has been improved to address the recommended changes provided at last year's meeting (Annex O, IWC 2014). The Committee again thanks Miller of the Secretariat for developing and enhancing the data portal.

Table 1

List of data and programs received by the IWC Secretariat since the 2012 meeting.

Date	From	IWC ref.	Details
Catch data from the previous season:			
17-03-14	Iceland: A. Þormar	E115 Cat2013	Individual catch records from the Icelandic commercial catch 2013
1-05-14	St. Vincent: J. Compton	E115 Cat2013	Individual records from the 2013 aboriginal hunt by St. Vincent and the Grenadines
6-05-14	Norway: N. Øien	E115 Cat2013	Individual minke records from the Norwegian 2013 commercial catch. Access restricted (specified 14-11-00)
12-05-14	Japan: N. Okazoe	E115 Cat2013	Individual data from Japan's catch in 2013 in the North Pacific (JARPN II) & 2012/3 in the Antarctic
15-05-14	USA: R. Suydam	E115 Cat2013	Individual data from the 2013 bowhead hunt in Alaska
13-02 & 23-05-14	Canada: L. Vuckovic	E115 Cat2013	Details of the Canadian bowhead harvest from the 2013 season and notification of the 2014 quota
Catch data from earlier seasons:			
16-06-13	Japan: L. Pastene	E111	Corrected data from the Japan Antarctic catches 1987-2012 following a thorough comparison by Japan of IWC data (from annual data submissions) and the scientists' data
27-08-13	Canada: B. Green	E108 Cat2012	Details of the Canadian bowhead harvest for the 2012 season
9-10-13	P. Best	E112	Sierra records 1976-78 in the North Atlantic (as described in Best, 1992)
17-10-13	Greenland: N. Levermann	E113	Individual catch data from Greenland 2007-2012.
18-04-14	Iceland: T. Gunnlaugsson	E116	Individual records of minke whales caught by Iceland 1973-85 and summaries of catches in earlier years
Sightings data:			
2-12-13	Japan: K. Matsuoka	E114	POWER cruise sightings data – 2013 including photographs and data forms (electronic and paper)
2-12-13	Japan: K. Matsuoka	CD98	Blue whale ID photographs from 2005/06-2012/13 JARPA II data; submitted under IWC data access Procedure B.
23-04-14	Japan: K. Matsuoka	E117	Data from the JARPN II 2013 dedicated sightings survey

This year, 16 countries provided National Progress Reports including data on bycatch, entanglement, ship strikes, direct and indirect takes, sampling, sightings and tracking studies. These countries were: Australia, Belgium, Brazil, Croatia, Denmark, Germany, Iceland, Ireland, Italy, Japan, Mexico, New Zealand, Republic of Korea, Spain, UK and the USA. Between 2010 and 2012, 22, 18 and 20 countries submitted national reports.

The National Progress Reports have their origin in Article VIII, Paragraph 3 of the Convention. All member nations are urged by the Commission to provide Progress Reports to the Scientific Committee following the most recent guidelines developed by the Scientific Committee and adopted by the Commission. The report is intended as a concise summary of the cetacean research undertaken in member countries as well as a summary of information on direct and incidental anthropogenic mortality.

The Committee again **recommends** that all member states submit National Progress Reports to the IWC through the IWC data portal (<http://portal.iwc.int>).

Further improvements were discussed in an *ad hoc* Working Group and the Committee **endorses** the report of that Group (see Annex Q) and its recommendations.

3.3 Data collection, storage and manipulation

3.3.1 Catch data and other statistical material

Data received by the Secretariat since the 2013 meeting are listed in Table 1, including catch data from the 2013 season.

3.3.2 Progress of data coding projects and computing tasks

Allison reported that work has continued on the entry of catch data into both the IWC individual and summary catch databases, including data received from the 2012 season. Additional information from earlier seasons has been entered, including catch records from British Columbia received from J. Ford in 2012, common minke whale catch data from Iceland for the period 1973-85 and some data from the catcher/factory *Sierra* in 1976-8 received from P. Best. An exercise to reconcile the IWC Japanese Antarctic catch data 1987-2012 with that held by Japanese scientists has been completed. A new version of the catch databases will be released shortly.

Validation of the data from the 2011 POWER sightings cruise has been completed and validation data from the 2012 cruise has commenced.

In response to a question about how a blue/fin whale hybrid identified in the Icelandic catch data should be recorded, Allison noted that at present this whale is included as a fin whale in the database, with a footnote to show that it is a hybrid.

Programming work during the past year has included the compilation of the final set of tables and plots from the Western North Pacific minke whale *Implementation Review* completed last year. Other work is described under the relevant sub-committee items.

4. CO-OPERATION WITH OTHER ORGANISATIONS

The Committee noted the great value of co-operation with other international organisations to its work. The observers' reports below briefly summarise relevant meetings of other organisations. The contributions of several collaborative efforts are dealt with in the relevant sub-committees.

4.1 Convention for the Conservation of Antarctic Marine Living Resources (CCAMLR)

The report of the IWC observer at the 32nd Meeting of the CCAMLR Scientific Committee (SC-CCAMLR), held in Hobart, Australia from 21-25 October 2013 is given as IWC/65/4(2014)A. The main items considered at the CCAMLR meeting of relevance to the IWC included: (1) fishery status and trends of Antarctic fish stocks, krill, squid and stone crabs; (2) incidental mortality of seabirds and marine mammals in fisheries in the CCAMLR Convention Area; (3) harvested species; (4) ecosystem monitoring and management; (5) management under conditions of uncertainty about stock size and sustainable yield; (6) scientific research exemption; (7) CCAMLR Scheme of International Scientific Observation; and (8) new and exploratory fisheries.

Reports of SC-CCAMLR and its Working Groups on Ecosystem Monitoring and Management (WG-EMM) and Fish Stock Assessment (WG-FSA) and their various subgroups are available through the CCAMLR secretariat and on the CCAMLR website¹.

The CCAMLR Working Group on Incidental Mortality in Fisheries (WG-IMAF) did not meet in 2013 and no new information on cetacean-fisheries interactions in the Southern Ocean became available to CCAMLR. The next meeting of the Working Group is likely to take place prior to the annual meeting of CCAMLR in 2014.

The Committee **thanks** Koch for attending on its behalf and for his service in this position for the past 24 years. The Committee **appoints** Currey to represent the Committee as an observer at the next SC-CCAMLR meeting.

4.2 Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES)²

The Conference of the Parties did not occur during the intersessional period.

4.3 Convention on the Conservation of Migratory Species (CMS)³

4.3.1 Scientific Council

There was no meeting of the Scientific Council during the intersessional period.

4.3.2 Conference of Parties (COP)

There was no Meeting of the Parties during the intersessional period.

4.3.3 Agreement on Small Cetaceans of the Baltic and North Seas (ASCOBANS)⁴

The report of the IWC observer at the 20th meeting of the Advisory Committee to ASCOBANS, held in Warsaw, Poland from 27-29 August 2013 is given as IWC/65/4E. The main discussions at the meeting are summarised below.

- (1) progress with three harbour porpoise action plans, including new abundance for the 'gap' area and ongoing analyses of the SAMBAH project for the Baltic Sea;
- (2) involvement in current developments concerning bycatch of small cetaceans;
- (3) mitigation advice regarding underwater noise;
- (4) chemical pollutions should accorded greater attention (ECS Workshop on Chemical Pollution and Marine Mammals) - it is possible that bottlenose dolphins and killer whales in parts of Europe are suffering from high levels of contamination;
- (5) a series of recommendations from the Marine Debris Working Group including collecting data on the distribution of debris and necropsies (in the future, information on entanglement and debris could be added to the ASCOBANS national reports);
- (6) ASCOBANS will ask Parties to provide details of those responsible for cetacean rescue and what laws require, allow and prohibit in each country.
- (7) SCANS III is a high priority that aims to establish the current abundance of cetaceans in the European Atlantic, assess mortality arising from human activities and to compare methods to create a best practice guide for monitoring to inform European directives;
- (8) the ASCOBANS/ACCOBAMS Population Structure Workshop included a definition for the term 'Management Unit (MU)' - MUs need to be established for all regularly occurring small cetacean species in the area of overlap of ACCOBAMS and ASCOBANS with priority to be given to those species for which there is not only evidence of sub-structuring but also which appear to be especially vulnerable to anthropogenic activities (include *inter alia* killer whale, bottlenose dolphin, Risso's dolphin, pilot whale and harbour porpoise);
- (9) the results of the joint ASCOBANS/ACCOBAMS workshop on 'The challenge of spatially managing cetaceans - a highly mobile animal group' were presented.

No Meeting of Parties to ASCOBANS occurred in the intersessional period.

The Committee **thanks** Scheidat for her report and **agrees** that she should represent the Committee as an observer at the next ASCOBANS Meeting of Parties and Advisory Committee meeting.

4.3.4 Agreement on the Conservation of Cetaceans of the Black Sea, Mediterranean Sea and Contiguous Atlantic Area (ACCOBAMS)⁵

Due to the attendance of Donovan at an IWC Workshop, Fortuna kindly attended the ninth meeting of the ACCOBAMS Scientific Committee held in Monaco from 14-18 April 2013. Her report is given as IWC/65/4(2014). The full report of the meeting can be found on the ACCOBAMS website.

The issues most relevant to the work of the IWC Scientific Committee included: (a) the ACCOBAMS-IWC joint effort on ship strikes; (b) the most recent involvement of IWC experts in research programmes (i.e. aerial surveys in the Tyrrhenian and Adriatic seas and a telemetry programme to

¹ <http://www.ccamlr.org/>.

² <http://www.cites.org>.

³ <http://www.cms.int>.

⁴ <http://www.ascobans.org>.

⁵ <http://www.accobams.org>.

investigate the movements and distribution of fin whales outside the summer season); (c) the IWC experience in drafting and helping the implementation of Conservation Plans (e.g. the case of recently adopted Conservation Management Plans).

ACCOBAMS and the IWC have recognised the problem of ship strikes and have been working together to develop a better understanding of the issue and to develop effective mitigation measures inter alia within the ACCOBAMS area for several years. A Working Group and according Steering Committee were established under the auspices of the ACCOBAMS Scientific Committee to ensure that the recommendations of the joint ACCOBAMS/IWC workshop and the resolutions from the Meeting of the Parties are acted upon. The Steering Committee and Working Group will work in close contact with the ACCOBAMS Secretariat, the IWC, the Pelagos Sanctuary and other relevant experts.

The IWC Secretariat and Italy have been co-operating on aerial surveys in the region to determine the extent and abundance of cetaceans as well as on a telemetry programme investigating the movements and distribution of fin whales outside the summer season. Results of these studies will be useful in addressing and potentially mitigating the issue of ship strikes within the Mediterranean Sea as well as informing the drafting of Conservation Plans at regional and sub-regional level (e.g. the future Adriatic Cetacean Conservation Plan).

With respect to conservation plans, information on the IWC experience in developing Conservation and Management Plans was presented, including relevant references and the information on the IWC's adopted process on how to handle the preparation of conservation plans including approved IWC guidelines were provided to the Scientific Committee.

The importance of continued co-operation between ACCOBAMS and the IWC was recognised.

The Committee **thanks** Fortuna for attending the meeting on its behalf and **agrees** that Donovan should represent the IWC at the next ACCOBAMS meeting.

4.4 Food and Agriculture Organisation of the United Nations (FAO)

No observer for the IWC attended the 2013 meeting of FAO.

4.5 Inter-American Tropical Tuna Commission (IATTC)

The reports of the IWC observer at the 85th and 86th meetings of the IATTC held in Veracruz, Mexico 10-14 June 2013 and 14-15 October 2013 respectively are given as IWC/65/4(2014)D. The Antigua Convention came into force on 27 August 2010 and under this the IATTC is expected to give greater consideration to non-target and associated species, including cetaceans, in taking management decisions. A summary was given of ongoing work describing what is known about the direct impact of the fisheries on other species in the ecosystem and the environment. This ongoing work will shape future directions of AIDCP (see Item 4.6) and IATTC measures aimed at managing fisheries and conserving dolphins.

The IATTC continues to focus much of its attention on conservation and management of target tunas and sharks and other non-target species. Discussions of tuna conservation measures have implications for dolphin conservation. Fishing

effort on dolphins may increase if, for example, future measures focus on further restricting the sector of the fishery that takes the greatest number of juveniles (vessels that set on floating objects). This could provide an incentive to fish on dolphins in order to remain active during closure periods for the floating object fishery and/or to not exceed bigeye tuna catch limits.

The Committee **thanks** Rusin for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next AITTC meeting.

4.6 Agreement on the International Dolphin Conservation Program (AIDCP)

The report of the IWC observer at the 27th and 28th Meetings of the Parties to the AIDCP held in Veracruz, Mexico on 4 June 2013 and in Del Mar, CA, USA 18 October 2013 respectively is given as IWC/65/4(2014)E. The AIDCP mandates 100% coverage by observers of fishing trips by purse seiners of carrying capacity greater than 363t in the agreement area and in 2013 all trips (750) by such vessels were sampled by independent observers.

The overall dolphin mortality limit (DML) for the international fleet in 2013 was 5,000 animals and the unreserved portion of 4,900 was allocated to 90 qualified vessels that requested DMLs. In 2013, no vessel exceeded its DML. The number of sets on dolphin associated schools of tuna made by vessels over 363t has been increasing in recent years, to 11,645 in 2010. However, since then, the number has been decreasing and was 8,025 in 2013. Reported dolphin deaths and mortality limits, presented by species and stock, can be found in IWC/65/4(2014)E.

While fewer dolphin sets were made since 2010, this remains a frequent practice and the predominant method for catching yellowfin tuna by purse-seine. There have been insufficient resources to conduct dolphin and ecosystem assessment surveys since 2006 so it is unclear when updated abundance estimates for cetaceans in the ETP will be available.

In 2013, the AIDCP focused significant discussion on consideration of reducing observer coverage and developing an 'Ecosystem Friendly' certification scheme for tuna caught in association with dolphins. Due to the increasing sentiment among some Parties that the dolphin problem has been solved and that dolphin-fishing methods are better economically and environmentally than dolphin-safe methods, in 2014 the AIDCP Parties are expected to continue consideration of these proposals and others that have the potential to increase fishing effort on dolphins and the magnitude of associated direct and indirect effects of this practice.

The Committee **thanks** Rusin for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next AIDCP meeting.

4.7 International Committee on Marine Protected Areas (ICMMPA)

The report of the observer documenting the activities ICMMPA is given as IWC/65/4(2014)K. The International Committee for Marine Mammal Protected Areas was formed as an international committee of experts in 2006 to address common issues and challenges faced by scientists and managers using spatial management tools to manage and conserve important cetacean habitats or populations. In 2008, the IWC endorsed and supported a proposal by ICMMPA to

host the first international conference on marine mammal protected areas in 2009. Since that time, the ICMMPA has undertaken several initiatives and has co-hosted, with France, a second conference in Martinique, in 2011⁶. Since that conference, the Committee has been working with the Australian Government and WDC Australia in order to hold the third International Conference on Marine Mammal Protected Areas (ICMMPA3) 9-11 November 2014 in Adelaide, Australia.

The IUCN Marine Mammal Protected Areas Task Force (IUCN-MMPA-TF) was officially announced at the third International Marine Protected Areas Congress in Marseille, France, 24 October 2013, at which time it began its first major initiative by holding a workshop to develop criteria for defining 'important marine mammal areas' (IMMAs). It was agreed that:

- (1) the Task Force should start to apply existing suites of criteria specifically to IMMAs as a means to test their utility and to refine or add any additional sub-criteria as may be useful for marine mammals;
- (2) IMMAs will be able to provide important data to support the identification of between Ecologically or Biologically Significant Areas EBSAs;
- (3) the similarity in objectives between Important Bird Areas (IBAs) and IMMAs, which both focus on wide-ranging species, and the fact that IBAs are considered to be a subset of Key Biodiversity Areas (KBAs), would suggest that IMMAs could fit adjacent to IBAs and other taxa-based sets of criteria, with KBAs as the global umbrella;
- (4) EBSA descriptions draw on all available information including KBAs, IBAs, plus other data sets, and would take IMMAs into account, if such designations were available; and
- (5) the Task Force will endeavour to work with partners including the CBD Secretariat and the IUCN to ensure IMMAs are included in the EBSA and KBA

The Committee **thanks** Ridoux for his report and **agrees** that he should represent the Committee as an observer at the next ICMMPA meeting.

4.8 International Council for the Exploration of the Sea (ICES)⁷

The report of the IWC observer documenting the 2013 activities of ICES is given as IWC/65/4(2013)B. The ICES Working Group on Marine Mammal Ecology (WGMMME) met 4-7 February 2013.

Requests for determining Good Environmental Status (GES) were reviewed and delineated for cetaceans. Boundaries were specified so that the management units can be populated with abundance and bycatch estimates. As previously agreed, these boundaries coincide with ICES Area/Division boundaries where possible. Further consideration was given to ICG-COBAM's common indicators for marine mammals.

There was discussion of monitoring efforts to determine the distribution and habitat use of marine mammals, in relation to environmental impact assessments e.g. for marine renewable energy developments. Too often, monitoring programmes in adjacent marine renewable energy developments occur

independently without broader coordination. Regulators and seabed owners need to acknowledge the need for data pooling, require it as an integral part for marine renewable consenting and develop internationally standardised comparable data formats for easy access and analysis. The Joint Cetacean Protocol (JCP) may serve as such an example.

The ICES Working Group on Bycatch of Protected Species (WGBYC) met 4-9 February 2013. WGBYC reviewed EU Member States' reports to assess the status of information on recent bycatch estimates and evaluate the extent of the implementation of bycatch mitigation measures. It was noted that estimates are still very patchy and several member states have not fulfilled their monitoring obligations. Bycatch monitoring remains less than optimally directed in many cases.

WGBYC reviewed recent bycatch mitigation trials, including trials of gillnet modifications and experiments that attempt to quantify the effect of pingers on porpoise displacement. Implementation of bycatch mitigation measures was also found to be patchy, with few EU member states able to provide unequivocal confirmation that the obligations are being met. WGBYC continued to develop a streamlined and effective database for the collation, storage and analysis of European bycatch monitoring and fishing effort data for those fishing sectors where bycatch monitoring is mandated.

The 2013 ICES Annual Science Conference was held in Reykjavik, Iceland from 23-27 August 2013. Some sessions were designed with marine mammals included as an integral part. A number of sessions were of relevance to the Committee, including those describing:

- (1) responses of living marine resources to climate change and variability;
- (2) marine spatial planning: The multidisciplinary approach; and
- (3) advances in studying spatial distribution.

The Committee **thanks** Haug for the report and **agrees** that he should represent the Committee as an observer at the next ICES meeting.

4.9 International Maritime Organisation (IMO)⁸

The report of the IWC observer to the IMO is given as IWC/65/4(2014)H. The IWC has contributed to IMO discussions on addressing ship strikes and the impacts of underwater noise from shipping. In April 2014 at the 66th meeting of its Marine Environment Protection Committee, the IMO adopted 'Guidelines for the reduction of underwater noise from commercial shipping to address adverse impacts on marine life' (MEPC.1/Circ.833). These non-mandatory, technical guidelines recognise that underwater-radiated noise from commercial ships may have both short and long-term negative consequences on marine life, especially marine mammals. The guidelines intend to provide general advice about reduction of underwater noise to designers, shipbuilders and ship operators.

The IMO also continued to develop a mandatory Polar Code. This is intended to augment existing measures to reduce the environmental impacts of shipping in polar waters, taking into account their greater environmental sensitivity. This

⁶ <http://second.icmmpa.org>

⁷ <http://www.ices.dk>.

⁸ <http://www.imo.org>.

work will continue through 2014. Chapter 12 of the draft Polar Code addresses voyage planning which will be considered in detail by the Maritime Safety Committee (MSC 93) in May 2014. This draft contains a broader mandatory requirement for ships to take into account important areas for cetaceans during voyage planning. Some concerns have been expressed about the availability of such information and this is an area where the IWC may be able to help.

In addition, the noise guidelines note that 'Speed reductions or routing decisions to avoid sensitive marine areas including well-known habitats or migratory pathways when in transit will help to reduce adverse impacts on marine life'. The IMO and shipping industry are therefore likely to welcome further information on cetacean distribution patterns.

The Committee thanked Leaper for his report and **agrees** that he or the Secretariat should represent the Committee at the next IMO meeting.

4.10 International Union for the Conservation of Nature (IUCN)⁹

Cooke, the IWC observer, reported on the considerable cooperation with IUCN that had occurred during the past year and this is given as IWC/65/4(2014)L.

Red List updates

The Yangtze finless porpoise (*Neophocaena asiaeorientalis asiaeorientalis*), the world's only freshwater porpoise, has been uplisted to Critically Endangered following an estimated decline of over 50% during 2006-12 (see also Annex L item 8.7).

The last comprehensive assessment of cetacean species for the Red List was completed in 2008, and most cetacean species are due for reassessment in 2014. Barbara Taylor, who has replaced Bill Perrin as the Red List Authority Coordinator for the Cetacean Specialist Group, will be coordinating the revision of the cetacean listings. All cetacean species and selected subpopulations will be updated and newly recognised species in the genera *Inia* and *Sousa* will be added.

Western gray whales

Two further meetings of the Noise Task Force of the IUCN Western Gray Whale Advisory Panel (WGWP) have been held in the past year, to determine mitigation measures for seismic surveys near the Sakhalin gray whale feeding ground in summer 2015. A paper was recently published on best practices for mitigation of the effects of seismic surveys on cetaceans, based on the work of the Panel's Noise Task Force (Nowacek *et al.*, 2013).

Cetacean Specialist Group

A Marine Mammal Protected Area Task Force was established in October 2013 jointly by the IUCN Species Survival Commission (SSC) and the IUCN World Commission on Protected Areas (WCPA), to develop improved practices for the designation and implementation of different types of protected areas for marine mammals. More details of this and other activities of the IUCN Cetacean Specialist Group are provided on the its website <http://www.iucn-csg.org/> and also see Item 4.7.

The Committee **thanks** Cooke for his report and **agrees** that he should continue to act as observer to IUCN for the IWC.

4.11 North Atlantic Marine Mammal Commission (NAMMCO)¹⁰

4.11.1 Scientific Committee

The report of the IWC observer at the 20th meeting of the NAMMCO Scientific Committee (NAMMCO SC) held in Reykjavik, Iceland from 13-16 November 2013 is given as IWC/65/4(2014)I.

HUMPBACK WHALES

Following the completion of the major survey effort, T-NASS 2007, NAMMCO is to conduct a formal assessment of humpback whales. The assessment for West Greenlandic waters has been completed, but assessment in other areas not yet initiated.

NARWHALS AND WHITE WHALES

A symposium focusing on narwhals and white whales is planned for 2015.

BOTTLENOSE AND KILLER WHALES

Faroese bottlenose dolphin sightings data were analysed together with CODA and SCANS II data. The preliminary designed based estimate for the Faroese block of T-NASS 2007 was 16,284. A recent increase in catches of killer whales off Tasiilaq in East Greenland (8 on average per year from 2010 to 2012) was reported and there is a possibility of a high struck and lost rate in this hunt. Higher levels of annual catches of killer whales (19 on average per year from 2010 and 2012) and low levels of bottlenose catches (20 animals) were noted for West Greenland.

PILOT WHALES

The T-NASS surveys have indicated decreasing abundance of pilot whales subsequent to the 1989 survey. An index has been developed in order to determine trends in abundance. It uses only the three largest surveys and including the data from the CODA survey for enlarging the reference area. The reference area still comprises only a small portion of the summer range of the species and changes in distribution may have influenced the results.

Estimation of pilot whale group size has a strong influence on estimated abundance and varied significantly among the surveys. Although it seems unlikely that an annual harvest of around 1,000 whales could have caused the population to decline, the apparent reduction of pilot whale abundance in the reference areas, which include the hunting area around the Faroes, should be of concern. Tagging of pilot whales in the Faroes has recently been conducted. More tracking data should be obtained from offshore areas, with a focus on the period during sightings surveys (July-August).

HARBOUR PORPOISES

An aerial survey conducted in West Greenland in August-September 2007 gave an abundance estimate of 274,883. Another estimate from Danish waters resulted in a corrected estimate of 50,461. There were large increases in catches in the past 19 years in the settlements with the largest catches, which may be due to multiple factors, including technological improvements, increased harbour porpoise population, and the new reporting system. The catches were corrected based on a survey among hunters for missing data on harbour

⁹ <http://www.iucn.org/>.

¹⁰ <http://www.nammco.no/>.

porpoise catches. A struck and lost rate of 8% was also revealed. The WG used age-structure data from the hunt and combining the two different availability corrections of the abundance estimate, with three different estimates of the historical catches, the model estimated the dynamics of harbour porpoises in West Greenland quite differently, from increase to rapid decline. Hence, to obtain a consistent assessment model that is useful for providing management advice, it is essential that the uncertainties associated with the abundance and catch history estimates are resolved. Nevertheless, the working group noted that the average annual catches since 1993 in West Greenland were 2,126 harbour porpoises and that a large abundance is needed to sustain such catches.

Bycatch by coastal monkfish and cod in Norwegian gillnet fisheries is estimated to be about 6,900 harbour porpoises per year. Although no abundance estimate is available for the coastal harbour porpoise population, the annual bycatch is likely not sustainable. Incidental sightings show that the species is commonly observed in near coastal waters, archipelagos and fjord systems along the entire Norwegian coast. Harbour porpoises have been observed in the southern Barents Sea, including the Pechora Sea, and a vessel-based survey gave uncorrected estimates of about 3,000 animals.

BOWHEAD WHALES

Aerial surveys were completed in West Greenland in 2012 and a comparison with a simultaneous genetic mark recapture study showed the genetics give higher abundance estimates. The reasons for the higher estimates are that the aerial surveys are snapshots of the situation, whereas the genetics represent a whole influx of bowhead whales.

SURVEY PLANNING

Acoustics are not included in the NAMMCO T-NASS 2015 proposal, but could be conducted during national survey activities. The specific objectives for the planned T-NASS 2015 are to obtain unbiased abundance estimates of:

- (1) pilot whales around Faroe Islands - useful for assessing the sustainability of the hunt;
- (2) common minke whales in West Greenland, around Iceland, Jan Mayen and Svalbard and the central Norwegian Sea; and
- (3) fin whales southwest of Iceland.

The Committee **thanks** Walløe for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next NAMMCO Scientific Committee meeting.

4.11.2 Council

The report of the IWC observer at the 22nd Annual Council Meeting of NAMMCO held in Oslo, Norway from 25-27 February 2014 is given as IWC/65/4(2014)C.

A number of topics were discussed including T-NASS 2015, tagging efforts and the international observer scheme. A planning group is preparing for a meeting in 2015 focusing on marine mammals in the context of food security.

NAMMCO has completed two authoritative manuals; one dealing with large baleen whaling and the use of whaling cannon and the penthrith grenade and a second dealing specifically with the use of the spinal lance and hook in the pilot whale hunt. An English language version of each is

accessible on the NAMMCO website, they will be available in native languages as required for the hunting communities in due course.

The Committee **thanks** Sakamoto for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next NAMMCO Council meeting.

4.12 North Pacific Marine Science Organisation (PICES)¹¹

The report of the IWC observer at the 22nd annual meeting of PICES held from 11-20 October 2013 in Nanaimo, Canada is given as IWC/65/(2014)F. The Marine Birds and Mammals Advisory Group (AP-MBM) requested that a seabird observer be included in the IWC-POWER cruise, however the IWC observer noted that this was difficult due to the capacity of the sighting vessel. The AP-MBM proposed the following topics for projects starting in 2015:

- (1) marine climate impacts on MBMs through food web;
- (2) marine mammals and seabirds as indicators of temporal and spatial variations of pollutants;
- (3) MBMs as a predictive indicator of forage fish; and
- (4) MBMs as consumers.

The Committee **thanks** Tamura for attending on its behalf and **agrees** that he or Kato should represent the Committee as an observer at the next PICES meeting.

4.13 Protocol on Specially Protected Areas and Wildlife of the Cartagena Convention for the Wider Caribbean (SPAW)¹²

The report of the IWC observer to SPAW is given as IWC/65/4(2014)/M. At the 5th Meeting of the Scientific and Technical Advisory (STAC), 22 October 2012, Punta Cana, Dominican Republic, the SPAW recommended that:

- (1) 'The Secretariat emphasises the activities in support of the Marine Mammal Action Plan, including follow-up to the work and recommendations emanated from implementation of the LifeWeb Project; and
- (2) The Secretariat continues to collaborate and to identify synergies, to the extent possible with relevant partners and MEAs and strengthens collaboration with IWC through the possible conclusion of a Memorandum of Cooperation.'

Two training workshops have recently been held, focusing on the forensic detection of human impacts and the response to entangled large whales. These workshops assisted participants in developing improved and safer human impact capabilities and entanglement responses. A further Joint IWC and SPAW/UNEP Workshop to address collisions between marine mammals and ships, with a focus on the wider Caribbean will take place in June 2014 in Panama.

Implementation of the Spain-UNEP LifeWeb project 'Broad-scale Marine Spatial Planning of Mammal Corridors and Protected Areas in Wider Caribbean and Southeast & Northeast Pacific' has led to regional maps and factsheets have been produced for the following issues:

- (1) distribution of the 25 marine mammals species that occur regularly in the WCR (24 cetaceans);
- (2) species richness;

¹¹ <http://www.pices.int/>

¹² <http://www.cep.unep.org/cartagena-convention>.

- (3) threats and human impacts faced by marine mammals: pollutions, interactions with fisheries, maritime traffic, etc.; and
- (4) existing policies, marine protected areas and governance for the conservation of marine mammals.

All the outputs are available from the SPAW website. Data from the project has led to identification of three priority areas of study for conflicts between marine mammal and human activities. A workshop on transboundary marine mammal management in the wider Caribbean was recently held in Puerto Rico. Proposed scenarios for the three priority areas identified were discussed along with possible mitigation measures and application of marine spatial planning for transboundary management of marine mammals. A similar workshop focusing on Northern South America was held last year.

The Committee **thanks** Carlson for attending on its behalf and **agrees** that she should represent the Committee as an observer at the next SPAW meeting.

4.14 Other organisations

4.14.1 Pacific Regional Environment Programme (SPREP)

Following the 2013 Annual Meeting, the IWC Secretariat was invited to give a presentation about areas of possible cooperation at the annual meeting of the Secretariat of the Pacific Regional Environment Programme (SPREP), in Noumea, New Caledonia, 17-19 September 2013. Since that meeting the two Secretariats have continued to communicate and are working together on two upcoming cooperative projects; (1) SPREP is actively involved in the preparation for the IWC's second workshop on marine debris, which will be held August 5-7 2014, in Honolulu, Hawaii; and (2) IWC technical adviser Mattila, is working with SPREP to co-host an IWC entanglement response training in Tonga.

The Committee **thanks** Mattila for his report and **agrees** that he continue reporting on the activities of SPREP on its behalf.

4.14.1 Regional Convention on Fisheries Cooperation among African States Bordering the Atlantic Ocean (ATLAFCO)

The main objective of ATLAFCO is to foster effective and active cooperation between Member States for conservation and sustainable development of fisheries in the region. ATLAFCO encourages Member States to exchange their experiences in scientific research and promotes coordination between their institutions and the sharing of scientific data on fish stocks. ATLAFCO began cetacean sighting surveys in maritime waters of Member States in order to obtain scientific information on cetaceans, which are top predators in the ecosystem. The first was conducted in Gabonese waters in 2011 and the second in the gulf of Guinea covering the EEZ of Côte d'Ivoire, Ghana, Togo and Benin in 2013. The results are presented as Diallo and Bamy (2013). ATLAFCO will continue cetacean sighting surveys in waters of Member States, where scientific information on cetaceans are relatively insufficient.

The Committee **thanks** Diallo for his report and **agrees** that he should continue reporting on the activities of ATLAFCO on its behalf.

5. REVISED MANAGEMENT PROCEDURE (RMP) – GENERAL ISSUES

The Committee **draws attention** to the fact that the RMP (and AWMP) approach, which was pioneered at the IWC and is now increasingly being used in fisheries management, is of broad relevance to the work of the Committee when examining status and the effects of human-related mortality. Irrespective of whether the *Catch Limit Algorithm* (or a *Strike Limit Algorithm*) itself is used, the modelling framework and approach to dealing with uncertainty are of wide application (Bunnefeld *et al.*, 2011; Dichmont *et al.*, 2013; Punt, 2006). Lessons learned during the RMP *Implementations* and *Implementation Reviews* are of value in assessments generally. The Committee **notes** that this approach is now being used for North Pacific gray whales (e.g. see SC/65b/Rep08).

5.1 Use of individual based energetics model

Last year, the Committee recommended that $MSYR_{1+}=1\%$ be adopted as a pragmatic and precautionary lower bound for use in trials, and that $MSYR_{mat}=7\%$ be changed to the roughly equivalent $MSYR_{1+}=4\%$. However, it recognised that much remains to be learnt regarding $MSYR$ for baleen whales and that the issue of the appropriate range for $MSYR$ should continue to be reviewed as new information becomes available. A workplan was developed to consider the incorporation of the individual based energetics model (IBEM) into the RMP software framework.

SC/65b/RMP03 reported on progress with this work noting that there were no technical difficulties in linking to the existing FORTRAN master program. Results from one set of 100 trials for the $MSYR \sim 4\%$ development case showed that the software produced results broadly consistent with those using the standard population models.

The Committee **welcomes** this work which allows it to conduct trials of the RMP where the operating model is spatially- and individual-based. Prior to use of this model by the Committee, the code would need to be validated by the Secretariat.

5.2 Relationship between $MSYR_{mat}$ and $MSYR_{1+}$

SC/65b/RMP04 included results requested last year (IWC, 2014d) which had used the IBEM to examine the relationship between the $MSYR_{1+}$ and $MSYR_{mat}$. The results revealed that the relationships between the $1+$ and mature MSY rates are quite different from those derived from the standard Baleen II model, and attributed the difference to the action of density dependence in the IBEM acting on a wide range of demographic parameters. The author of SC/65b/RMP04 concluded that the standard Baleen II model should not be used for inferring the relationship between $MSYR_{1+}$ and $MSYR_{mat}$.

The Committee noted that the energetics-based model is rather complex, with several functional relationships leading to different density-dependent processes. Several qualitative outcomes from the model runs were consistent with results from the stochastic model of Cooke (Cooke *et al.*, 2007) and were *a priori* plausible; at this stage it is not possible to reach conclusions on the quantitative nature of the results. The Committee considered it important to obtain a better understanding of the reasons underlying these emergent properties, including whether the conclusions regarding the

relationship between $MSYR_{mat}$ and $MSYR_{1+}$ were robust to, *inter alia*, species life history.

As discussed fully under item 2.2 of Annex D, the Committee **agrees** that it is desirable to further explore the relationship between $MSYR_{mat}$ and $MSYR_{1+}$ arising out of the IBEM results, and developed a workplan to achieve that. The work is necessary before any conclusions or the need for additional RMP/CLA-related trials are considered. This work does not imply a need to change or delay the current *Implementations* of the RMP for North Atlantic minke and fin whales. The Committee established a Steering Group under de la Mare (see Annex D, Items 2.2 and 5) to coordinate intersessional work.

Recognising that the IBEM is just one approach to this issue, the Committee also **encourages** the development/presentation at the 2015 Annual Meeting of alternative models which represent alternative plausible density-dependent processes.

5.3 Finalise the approach for evaluating proposed amendments to the CLA

The Committee agreed in 2006 that two steps needed to be completed before the evaluation of the Norwegian proposal to amend the CLA could be completed. The first was the review of MSY rates, completed in 2013, and the second was specification of additional trials for testing the CLA and amendments thereto and to the RMP. Last year, the Committee re-established a working group under Allison (see Annex D, Items 2.3 and 5) to formulate and run trials related to environmental degradation.

The trials agreed by the intersessional group in which the density-dependence function is modified so that the change in fecundity with density for stocks sizes above K are not as extreme as implied by the conventional Pella-Tomlinson model. The results (see Annex D, Appendix 3) suggest that the proposed solution does not lead to results which differ much from those when density-dependence is modelled using the standard Pella-Tomlinson approach.

The Committee thanked Punt and Allison for conducting this work but **agrees** that allowing natural mortality to be density-dependent would provide a more stringent test for the impacts of environmental change. It **recommends** that Allison and Punt include the model of density-dependence in natural mortality in Annex D, Appendix 3 into the common control rule program and provide results of such tests of the CLA to the 2015 Annual Meeting.

5.4 Evaluate the Norwegian proposal for amending the CLA

Walløe reminded the Committee that Norway had stated that it intended to develop and propose a change to the CLA of the RMP at the 2004 meeting (IWC, 2005). Norway proposed a new tuning mechanism for the CLA and that the $MSYR$ should refer to the $1+$ component of the population (with $MSYR_{1+} = 1\%$ as the minimum) instead of the mature component. The revised tuning mechanism and some simulation results were presented to the 2006 meeting, and were discussed extensively. The Committee established two working groups then, one of which led to the $MSYR$ review completed in 2013, and the other to specify trials and diagnostic plots for testing amendments to the CLA. Revised results (Aldrin and Huseby, 2007) were presented to the

Committee in 2007. However, the $MSYR$ review had not been completed so no decision had been made at that time.

The $MSYR$ review was completed last year and it concluded that the lower bound for $MSYR$ in trials would be $MSYR_{1+} = 1\%$. However, as noted in Item 5.3, some work remains to be completed in regard to trials in which $MSYR$ and K change over time.

The Committee **recommends** that Punt and Allison include the variants of the RMP considered by Aldrin and Huseby (2004) in their further analyses. This item has been outstanding for many years and the Committee **confirms** its intention that the evaluation of the Norwegian proposal would be completed at the 2015 Annual Meeting.

5.5 Other computing matters related to the CLA

Allison noted that a few minor issues related to how the code for the CLA was integrated into the control program remained outstanding. However, there had been insufficient time during the intersessional period to address these issues. They would be addressed during the current intersessional period, for report to the 2015 Annual Meeting.

5.6 Update 'Requirements and Guidelines for conducting surveys and Implementations'

SC/65b/RMP11 had been written in response to a request (and contract) from the Committee to update the Requirements and Guidelines for Conducting Surveys and Analysing Data within the Revised Management Scheme (IWC 2012, hereafter 'the Guidelines'). The specific tasks were to summarise developments in design- and (spatial) model-based abundance estimation since 2004 when the Guidelines were last revised, and to provide suggested text for updates to the Guidelines. SC/65b/RMP11 reviewed the fundamentals of design-based abundance estimation; described new approaches to variance estimation for design-based analysis; considered how the Committee might decide whether the criteria for design-based assessment might be met; suggested some ways to evaluate the adequacy of design-based estimates when the strict criteria are not met; presented a paradigm for (spatial-)model-based abundance estimation, and a checklist of decisions that need to be made when making a spatial abundance estimate; and proposed some updated text for the Guidelines. An important overall conclusion concerned the necessity, when the Committee reviews an abundance estimate for 'acceptability', for thorough descriptions of the design and analysis process, including the rationale for making particular choices.

The Committee **welcomes** this review, recognising the value of updated criteria for evaluating abundance estimates (both design- and model-based) to the full Committee rather than simply the sub-committee on the RMP, since abundance estimates are central to much of its work (see Annex D, Appendix 4). To progress the update of Guidelines (both in an RMP sense and in a wider context) to (1) assist evaluation of design-based estimates of abundance, and (2) accommodate recent (and future) developments in abundance estimation, the Committee **recommends**:

- (1) development of a simple-to-use diagnostic software that uses model-based analysis to assist in evaluating design-based estimates that can be applied when design-based criteria are not strictly met;

- (2) refinement of the material in SC/65b/RMP11, both in the explanatory background text and in the proposed Guidelines, on specific issues (see Annex D);
- (3) hold a workshop with two objectives:
 - (a) to test the proposed new Guidelines against several test cases of model-based abundance estimates made specifically for and during the workshop;
 - (b) to demonstrate and discuss the proposed diagnostic software with a wider Committee audience involved in basic line-transect abundance estimation.

Part (a), which would involve only a small number of analysts familiar with spatial modelling, could be held as a pre-meeting next year, and part (b) could follow on at the start of the Committee meeting. Updates to the Guidelines could then be considered during the full Committee meeting.

An appreciable amount of intersessional work would be required, particularly for item (1) and preparation for item (3). The Committee appointed at Steering Group under Bravington (see Annex D, items 2.6 and 5) to develop an agenda for the workshop and facilitate preparations.

5.7 Imbalanced sex ratio in incidental catches

Last year, the Committee requested further consideration of the generic issue of how to deal with imbalanced sex ratios in incidental catches under the RMP. The Committee **agrees** that the current specifications for the RMP are sufficient but it **recommends** that annotation 26(a) to the RMP be adjusted to improved clarity as follows:

‘Any subtraction of incidental catches from the catch limits output from the RMP as above would take place at the end of this process at the Small Area level, and separately at the Medium/Large Area level if Catch-capping was applied. However, as this is an RMS rather than an RMP feature, no wording to cover this is proposed here. Since imbalanced sex ratios in incidental catches have been taken into account in (iv) above, as this computation is with respect to the total catch, there is no need for further adjustment for this factor in this subtraction.’

5.8 Workplan

The Committee **notes** that the iterative nature of its work means that it is challenging to determine the exact nature of its work plan beyond a single year. Detailed work plans for before and during the 2015 meeting, and before and during the 2016 meeting, are given in Annex D, item 2.8 although there is some uncertainty about the latter. Prioritised budget requests are detailed in Annex D, item 6. The Committee

budget is discussed under item 26. An overview of the workplan is given as Table 2.

6. RMP–IMPLEMENTATION-RELATED MATTERS

6.1 North Pacific common minke whales (additional work from completed *Implementation Review*)

6.1.1 Review of intersessional work

Last year, the *Implementation* for the North Pacific common minke whales identified six RMP variants which were ‘acceptable without research’ and four RMP variants which were candidates for being ‘acceptable with research’. The latter are variants that lead to higher catches in some specific sub-areas in this instance. RMP variants which are ‘acceptable with research’ need to have a research programme that the Committee agrees has a good chance of determining within ten years whether trials on which performance was not ‘acceptable’ should have been assigned low plausibility. The Committee established an Advisory Group under Butterworth (see Annex D, items 3.1.1 and 5) to provide feedback to those developing research programmes during the intersessional period if requested. Pastene reported that Japan had not developed a research programme to date.

The Committee **re-establishes** the Advisory Group to provide advice to those developing research programmes if required.

6.1.2 Survey plans

SC/65a/RMP02 presented a research plan for a sighting survey for common minke whales in the Sea of Okhotsk, including the Russian EEZ, in summer 2014. It was revised from that presented last year owing to logistical and permit issues. The primary aim is now to obtain biopsy samples in one sub-area rather than obtaining abundance estimates for the whole of the Okhotsk Sea. A joint Russian-Japanese sighting survey in the Okhotsk Sea will occur in summer 2015 (see SC/65b/RMP02).

The Committee noted the revised research plan and **welcomes** the plan for a joint Russian-Japanese survey for common minke whales in Okhotsk Sea. It looks forward to seeing a detailed research plan for the latter survey at the 2015 Annual Meeting. The Committee appointed Miyashita to provide oversight on its behalf.

Table 2

Overview of work on RMP general matters 2015-2016

Topic	Intersessional 2014-15	SC66a 2015	Intersessional 2014-15	SC66b 2015
Evaluate energetics based model	For details see Annex D, item 2.2	Review progress	Continue work	Review results
Evaluate <i>CLA</i> performance when density-dependence acts upon natural mortality	For details see Annex D, item 2.3 and 2.4	Review results	If necessary	Complete if not done at SC66a
Other <i>CLA</i> related tasks	For details see Annex D, item 2.5		If necessary	As above
Diagnostic software to assist in evaluating design-based estimates	For details see Annex D, item 2.6	Hold pre-meeting	If necessary	As above
Evaluate Norwegian <i>CLA</i> proposal	For details see Annex D, item 2.4	Review results	If necessary	As above
Refine workplan		In light of progress		

6.1.3 Recommendations

The Committee:

- (a) again **strongly requests** that the Commission **urges** the Government of the Russian Federation to give permission for the survey to take place in its EEZ throughout sub-area 12, noting that there are often major difficulties making use of abundance estimates for only part of a sub-area; and
- (b) **recommends** that future surveys be more synoptic, as this will better facilitate their use in the RMP.

6.2 North Atlantic fin whales (*Implementation Review*)

6.2.1 Report of intersessional workshop

Donovan introduced SC/65b/Rep07, the report of the technical intersessional Workshop on the *Implementation Review* for North Atlantic fin whales, held in Copenhagen in January 2014. The Workshop was primarily technical, to finalise trial specifications and make progress towards conditioning the trials.

The Workshop reviewed the progress made since SC/65a (see Annex D, item 3.2.1) and made several additional changes to the code for the operating model. Given the complexity of the trials, it had not been possible to complete conditioning successfully by the end of the workshop.

The Workshop developed a workplan with the objective of finishing the *Implementation Review* at the 2015 Annual Meeting, and established a Steering Group under Elvarsson (see Annex D, items 3.2.1 and 5) to assist with implementing the workplan.

The Committee **thanks** Donovan for chairing the workshop and the participants for their work during the workshop and subsequently, in particular Elvarsson. In reviewing progress made since, it noted that further changes to the optimisation method had been implemented and the density-dependent dispersal model had been developed and included in the control program. Progress had been made assembling data and in updating the catch series to include incidental catches off Eastern Canada. In addition, Elvarsson had conditioned base-case trials for eight stock-structure hypotheses (Annex D, item 3.2.1).

6.2.2 Consideration of available results

Elvarsson provided an overview of progress on conditioning the set of trials identified during the workshop. Many of the trials can now be conditioned successfully, but some problems remain (see Annex D, item 3.2.2).

The Committee received two papers that may be useful when assigning plausibility ranks to the *Implementation Simulation Trials* during the 2015 Annual Meeting. SC/65b/RMP06 presented cetacean sightings and effort during winter fishery (mainly capelin) surveys conducted during 1991-1995, 2003 and 2009 around Iceland, while SC/65b/RMP08 investigated differences between the first and second or later fin whales taken per catching trip.

6.2.3 Recommendations

The Committee **recommends** that a workshop takes place in early 2015 to ensure that it is in a position to complete the *Implementation Review* at the 2016 Annual Meeting, if not earlier. A Steering Group was appointed under Donovan (see Annex D, Items 3.2.2 and 5). Holding this meeting back to back with the workshop proposed under Item 6.3 will reduce costs.

6.3 North Atlantic common minke whales (*Implementation Review*)

The *Implementation Review* for North Atlantic minke whales started with an AWMP/RMP joint workshop on stock structure in April 2014 (SC/65b/Rep04), and continued with a pre-meeting of a working group whose report is given as Annex D, Appendix 5.

The Working Group built upon the excellent progress made at the joint Workshop where a major review of data including comprehensive new genetic information led to an agreed set of stock structure hypotheses. The Working group built upon this to evaluate abundance estimates, biological and operational parameters, removals data, and trials structure. The preliminary results from the sighting surveys suggest that the abundance in the E *Medium Area* has not changed from the last six-year period, but that there has been a decrease in abundance in the C *Medium Area*. It developed a workplan with the objective of completing the *Implementation Review* at the 2015 Annual Meeting (Annex D, Appendix 5, item 7).

6.3.3 Recommendations

The Committee **endorses** the report of the Working Group and **adopts** its work plan. It **thanks** Donovan for chairing the pre-meeting and the participants for their work. It established a Steering Group under Walløe (see Annex D, item 3.3) to guide the intersessional work that will include a technical intersessional workshop.

6.4 North Atlantic sei whales

6.4.1 Pre-Implementation Assessment

The North Atlantic sei whale Steering Group (see IWC 2014, Item 6.4) proposed that the feasibility of a pre-Implementation assessment be investigated further during the intersessional period by a Correspondence Group chaired by Víkingsson (see Annex D Item 3.4.1) and with Terms of Reference to finalise the compilation of the available data and develop a draft set of possible stock structure hypotheses for consideration during the 2015 Annual Meeting. It **notes** that initiation of an *Implementation* follows only from a decision by the Commission.

As for other North Atlantic balaenopterids, genetic analyses conducted so far for sei whales indicate low levels of population genetic structure. There is value in conducting further genetic analyses to aid in the formulation of plausible stock hypotheses for North Atlantic sei whales.

6.4.2 Recommendations

To maximise the amount of genetic data from the existing set of samples, the Committee **recommends** the generation and analysis of ddRAD-based SNP genotypes from the available tissue samples. In addition, it **agrees** that information on the distribution of sei whales from catch records be summarised by the intersessional group.

6.5 Western North Pacific Bryde's whales

6.5.1 Prepare for 2016 Implementation Review

The *Implementation Review* for Western North Pacific Bryde's whales was originally scheduled for 2013. However, in 2012, the Committee postponed the *Review* until 2016 to allow additional sightings and genetics data to be available and analysed (IWC, 2013a). Miyashita, on behalf of Japan, requested that the *Implementation Review* be deferred to 2017 for reasons detailed in Annex D, item 3.5.1.

Table 3

Overview of the work plan as it relates to *Implementations*.

Species / area	Intersessional 2014-15	SC66a 2015	Intersessional 2015-16	SC66b 2016
Common minke whales (WNP)	Possible work by Advisory Group (if requested)	Review hybrid RMP variants & research proposals if submitted; agree abundance estimates for use in actual applications of the RMP		Review hybrid RMP variants & research proposals; agree abundance estimates for use in actual applications of the RMP
Common minke whales (NA)	Assemble data; finalise trial specifications; validate code and condition; hold intersessional workshop	Assign plausibility to trials; review trial results; complete <i>Implementation Review</i> ?	Run trials and hold intersessional workshop (if needed)	Complete <i>Implementation Review</i> (if needed)
Fin whales (NA)	Assemble data; validate code; Hold intersessional workshop	Review trial results; Assign plausibility; finish <i>Implementation Review</i> ?	Run trials and hold intersessional workshop (if needed)	Complete <i>Implementation Review</i> (if needed)
Sei whales (NA)	Summarise data on stock structure and develop hypotheses	Decide to initiate or not pre-implementation assessment		Pre-implementation assessment (if agreed at SC66a)
Bryde's whale (WNP)		Review new information		Review new information

In discussion, it was noted that considerable new data were likely to be available by 2017. It was also noted that since no new abundance estimates had been adopted by the Committee, application of the RMP would lead to use of the 'phase out rule'.

6.5.2 Recommendations

The Committee **agrees** that the next *Implementation Review* be deferred to 2017, and that it be a 'full review' such as those currently being undertaken for North Atlantic minke and fin whales. Since the *Implementation Reviews* for North Atlantic minke and fin whales will not both be completed before the 2016 Annual Meeting – it is infeasible for the Committee to initiate another 'full' *Implementation Review* until these two reviews are completed.

6.6 Updated table of abundance

Allison advised that the 2001 estimate of abundance for sub-areas CG+CIP for the North Atlantic minke whales of 23,592 was an error and the correct estimate is 10,740. The estimate had been used in the applications of the RMP, which took place in 2010 (IWC, 2011a).

Annex D, Appendix 6 lists updated abundance estimates for North Atlantic minke and fin whales and North Pacific minke and Bryde's whales. Allison advised that review of these estimates is continuing and Annex D, Appendix 6 will be updated with any new information.

6.7 Workplan

Detailed Work Plans, both for 2015 and 2016, are given in Annex D, Item 3.7, and prioritised Budget Requests are detailed in Annex D, item 6 and Appendix 7. An overview of the workplan is given in Table 3.

7. NON-DELIBERATE HUMAN-INDUCED MORTALITY OF LARGE WHALES

The report of the Working Group on Non-deliberate Human-induced Mortality of Large Whales is given as Annex J. This work originally arose out of the need for information on such mortality for use in the RMP but has now broadened in scope, amongst other things providing advice to the Commission working groups on such matters.

7.1 Entanglement of large whales

7.1.1 Estimation of rates of entanglement, risks of entanglement and mortality

Online tools are now available to allow data entered into National Progress Reports to be queried. In reviewing the output from such queries it was noted that only a small proportion of countries submit bycatch data and it is important to distinguish no report from no data. The Committee **recommends** that member nations fill out the relevant fields appropriately and provide information on efforts to estimate total bycatch of large whales. Some discrepancies in field codes were also noted with reports of ship strikes.

The Secretariat's technical adviser, Mattila, has provided entanglement response training for 156 individuals from 14 different countries in the past year. A result of this work is that detailed data on large whale entanglements are being brought to the Committee. The IWC's expert group on entanglement will discuss the development of a global database at its next meeting, currently planned for December 2014. The Commission has recommended that the expert group develop this database and that it is hosted by the IWC.

Entanglement injuries have been noted for decades during post-mortem examinations of harvested bowhead whales, raising concerns about potential interactions with pot fisheries for cod and blue king crab (Citta *et al.*, 2013). Young whales showed less scarring than older animals and this was attributed to a gradual accumulation in scars from entanglement as whales grow older. Although the spatial distribution of 21 satellite tagged bowhead whales partially overlapped fishery areas, there was no temporal overlap suggesting that lost gear was the most likely source of entanglement. The finding of a spatial but not temporal overlap suggested that this type of analysis might be helpful in the Committee's work on determining entanglement risk from debris versus actively fished gear.

A sperm whale calf and female pair were reported entangled in a mass of ropes, nets and plastic cans off Guadeloupe in November 2013 (SC/65b/HIM02). The material was suggestive of local artisanal Fish Aggregating Devices which

would represent the first data on large whale entanglement in this type of fishing gear.

Of the 63 baleen whale entanglement records off Western Australia from 1982-2010, humpback whales accounted for 56. Almost half of entanglements occurred in rock lobster fishing gear. There is an upward trend in entanglements reported between 1990 and 2010 in this fishery despite a reduction in fishing effort (Groom and Coughran, 2012). The numbers of entanglements have increased significantly since the fishery went from a seasonal to year-round. Fisheries and conservation agencies have responded by developing cooperative relationships and protocols to reduce entanglement risk. The Committee noted that other countries have been investigating and attempting to mitigate whale entanglements in similar pot fishery gear but currently the most certain way to avoid entanglement is to minimise the amount of entangling materials in the water column used by the whales. One solution for the Western Australian rock lobster fishery would be for the fishery to return to a seasonal one, avoiding gear in the water during whale migration. The Committee **recommends** that a careful monitoring scheme is enacted prior to any modifications of the fishery, so that the effectiveness of any changes can be determined. This might include a scar or wound monitoring programme. The Committee **recommends** that the relevant authorities in Australia contact Kristy Long (co-ordinator of the USA Take Reduction Teams) and Robbins, who is using monitoring of the annual accumulation of raw wounds on both humpback and right whales in the region affected by the USA lobster fishery.

The Committee **recommends** that Australia reports on any potential solutions that it tests as these could have beneficial global applications. In addition, recognising the global nature of the problem and the Commission's recommendation to prevent entanglement, the Committee **strongly encourages** members to bring forward papers on the effectiveness of various mitigation measures to future meetings, and that a dynamic matrix or table of various potential measures and their effectiveness be maintained.

7.1.2 Collaboration with Commission's Whale Killing Methods and Associated Animal Welfare Issues Working Group including consideration of mitigation measures and future work

The aim of the IWC Workshop on Euthanasia Protocols to Optimise Welfare Concerns for Stranded Cetaceans held in 2013 was to bring together international experts to inform guidelines on achieving the best welfare outcome when cetaceans strand (IWC/65b/Forinfo42). The Workshop recommended that where chemical euthanasia methods were used additional studies or evaluations on the persistence and relay toxicity of chemicals used should be undertaken. In particular, at a minimum the injection site should be removed and disposed of, and when barbiturates are used, the whole carcass must be removed from predation possibilities. The Workshop recognised the effectiveness of penthrate grenades and encourages the development of a darting gun delivery device that may be suitable for use by trained personnel in specific large whale stranding situations. The addition of further fields into the national progress report would allow evaluation of techniques for euthanasia and disposal of live

stranded whales. The workshop recommended euthanasia of injured cetaceans at sea and the issues related to mass strandings should be considered for future workshops. Finally, the Workshop recommended that IWC member nations refine existing or develop new incident response protocols based on the principles and guidelines in the workshop report. The Committee **endorses** these recommendations, including those to refine the data requested in National Progress Reports.

7.2 Ship strikes

7.2.1 Progress on the global database

The ongoing development of the IWC ship strike database requires data gathering, communication with potential data providers and data management. The second year of work carried out by the data coordinators resulted in a variety of outreach actions, with a large number of contacts being established, and the drafting of a series of documents, including guidance documents for sailing and cruise ships. In May 2014, the database held a total of 1,221 incidents. A downloadable summary is available on the IWC website¹³. The Committee **recommends** that the important work of the data coordinators continue, both for its value to the Commission's mitigation efforts, contribution to a better understanding of the factors that relate to risk (such as ship type and speed), as well as estimates of ship strike mortalities.

7.2.2 Estimating rates of ship strikes, risk of ship strikes and mortality

Vessel strike risk for bowhead and gray whales in the Bering Strait region has been assessed using Automatic Identification System (AIS) data combined with data on habitat use and satellite telemetry data. The recent IWC workshop on the Arctic discussed the possibility of seeking Particularly Sensitive Sea Area status for some high risk areas of bowhead distribution through the International Maritime Organisation (IMO). It was noted that the IMO was now considering known high density whale areas in relationship to voyage planning within the development of a Polar Code. Voyage planning in relation to high density areas will be further discussed at the ship strike workshop in Panama, June 2014. Other examples of mapping the co-occurrence of whales and shipping to assess risk included data from satellite tagged humpback whales in the eastern South Atlantic, and from Arabian Sea humpback whales off the coast of Oman. Preliminary findings showed all three whales off Oman passed through the main approach channels to major international shipping ports.

A simulation study was conducted to estimate the impact of ship strikes on the small Magellan Strait population of humpback whales (SC/65b/SH18). A single collision every three years randomly distributed among sexes and age classes would result in the median population growth shifting from stable to slightly decreasing. The concentrated shipping traffic through the area and the relatively small size of the population suggests potentially high vulnerability to ship strikes. Given the estimated size of the population (<100), the low estimated survival rate and the restricted nature of the Straits of Magellan, the Committee **expresses concern** over this situation and **agrees** that mitigation measures may be needed. While the Committee **agrees** that further studies of shipping and whale density are needed, the confined waters

¹³ <http://iwc.int/ship-strikes>

allow little scope for routing options and there may be a need to consider speed limits, if feasible.

AIS data has been used in cases of known ship strikes where a vessel has entered port with a carcass on the bow in an attempt to re-trace a ship's path to determine if any abrupt change in speed could indicate where the collision may have occurred. The Committee **recommends** that NOAA collaborate with the IWC to further test this application of AIS by attempting to retrace the routes and speeds of relevant ship strikes in the IWC ship strike database.

The probability of whale-vessel collisions in the Hawaiian breeding grounds for humpback whales was investigated by systematic transects recording surprise encounters and near misses as proxies for collisions with vessels. The rate of surprise encounters was found to increase with vessel speed. It was noted that there is not currently a standard definition of a 'near miss' which will depend on the size and manoeuvrability of the vessel involved. The Committee **encourages** work to develop definitions of a 'near miss' which could be considered at next year's meeting. Noting that the suggested speed of 15knots to reduce risk was greater than the 10-12knots in some other areas, the Committee **agrees** that the size and type of vessel associated with any speed recommendations needs to be explicit; otherwise speed recommendations might be used inappropriately.

Literature on ship strike records around Japan was reviewed to identify possible cases that could be included in the IWC database (SC/65b/HIM03). Twelve incidents between 1978 and 2012 were identified all of which involved jetfoil vessels. In two thirds of the incidents reviewed, pieces of meat or blubber were found suggesting potential for DNA analysis to identify species in future cases if samples are collected and appropriately preserved.

The Committee has previously noted an urgent need for long-term monitoring of the blue whale population in Sri Lankan waters and elsewhere in the northern Indian Ocean because of the potential for population impacts from ship strikes (IWC, 2014c). In 2012, two blue whales were struck and killed off Sri Lanka within a 12-day period (De Vos *et al.*, 2013) but it was noted that the observed mortality was an unknown fraction of actual mortality. Consequently, ship strikes could limit the recovery of this endangered subspecies, particularly given the projected doubling of large vessel traffic in the next 10-20 years (Southall, 2005). Surveys off the southern coast of Sri Lanka were conducted during February to April 2014 to investigate the distribution patterns of blue whales in relation to current shipping lanes and further offshore. The highest densities of blue whales were observed in the current shipping lanes, peaking at an average of 0.12 individuals km⁻² in the westbound shipping lane. These high densities of whales combined with one of the busiest shipping routes in the world suggest a severe risk of ship strikes. The results suggest that the blue whale distribution is related to bathymetry and that observed distribution patterns may be consistent over time. Hence moving the current Traffic Separation Scheme further offshore would likely substantially reduce risk of collisions with blue whales. The Committee **agrees** that further surveys of blue whale distribution in the area at different times of year would provide important data. Given that Sri Lanka is not a member of the IWC, but there has been a dialogue between IWC and

the Government of Sri Lanka on the issue, the Committee **recommends** that the IWC should begin to discuss possible mitigation measures with the relevant authorities and stakeholders in the area. The Committee **requests** that the Secretariat send a letter to the Sri Lankan Government, with an update on the information from its discussion of this topic and ways in which the Committee or the IWC Ship Strikes Working Group may assist. In addition, it **recommends** that a representative from Sri Lanka be invited to relevant IWC meetings and workshops.

Information was provided on an ongoing project between the University of California, Santa Cruz (De Vos *et al.*, 2013) and Southwest Fisheries Science Center (Redfern *et al.*, 2013) on reducing the risk of ship strikes to blue whales in Sri Lankan waters. The project will attempt to assess ship-strike risk to this population including (i) developing habitat models that can be used to predict blue whale distributions off Sri Lanka and validating predictions using available data from the region; (ii) re-examination of strandings records for baleen whales to confirm data and any evidence of ship strikes; (iii) use available shipping data to characterise traffic patterns; (iv) evaluate strategies to mitigate risk by overlaying predicted blue whale distributions with alternative shipping lanes (Redfern *et al.*, 2013); (v) expand the sightings data available for this region, especially in the context of the two monsoon periods; and (vi) work with industry and economists to determine short-term economic costs of moving shipping lanes.

A dead male blue whale stranded in Puerto Montt, southern Chile in February 2014, with its right flipper and left mandible broken and the bone exposed (SC/65b/HIM08). This evidence strongly suggests that this whale was hit by a large vessel. The Committee **agrees** that the evidence was most consistent with the authors' conclusions that one of the two recently arrived cruise ships had likely brought the carcass into the harbour on its bow. The Chilean Navy does provide information about whales and collision risk to vessels in the area but an IWC guidance document for cruise ships would be very useful support to these outreach efforts. The Committee **endorses** the suggestion that the reporting system needs to be expanded to collect additional details on vessel strikes in Chile, especially in the inland passage region, and that mitigation measures may be needed. Similar to the Straits of Magellan, the confined waters allow little scope for routing options and there may be a need to consider speed limits.

The Hellenic Trench southwest of Greece is a known area of high sperm whale density which coincides with major shipping routes. This area had been identified as potentially high risk during the IWC/ACCOBAMS workshop in 2010 (IWC, 2011a). An analysis of twelve seasons of visual and acoustic observations of sperm whales identified high risk areas where whales were exposed to very high shipping densities. The potential for small changes in shipping routes to dramatically reduce risk in these high risk areas suggest considerable scope for effective mitigation. Given the evidence for a high incidence of ship strikes from stranded sperm whales the Committee **recommends** that a dialogue should be initiated with shipping regulators and interests in the area, perhaps in conjunction with ACCOBAMS. Leaper will work with the Secretariat to establish contacts. However, given the possibility of fin whales occurring further offshore of the current shipping routes, it was suggested that there

Table 4

Overview of the work plan as it relates to non-deliberate human-induced mortality.

Species / area	SC66a 2015	SC66b 2016
Reviews of mitigation measures for ship strikes and entanglement	Review information collated intersessionally (see Annex J, item 9) and produce simple summary information and advice table	Finalise if not completed at SC66a
Entanglement (annual reviews)	Continue to examine new information on rates, risks and mortality and provide advice	Continue to examine new information
Entanglement (support Commission initiatives)	Communication of key issues; advice in relation to specific CMPs; review recommendations from December 2014 workshop, incl. database; assist in work with other organisations	Continue to support
Ship strikes (annual reviews)	Continue to examine new information on rates, risks and mortality and provide advice	Continue to examine new information
Ship strikes (database)	Work with co-ordinators and Secretariat to update and improve database, including review process and criteria	Continue
Ship strikes (support Commission initiatives)	Communication of key issues; advice in relation to specific CMPs; review recommendations from June 2014 workshop; assist in work with other organisations	Continue to support

should be further study of those deeper waters prior to recommending that shipping move offshore.

The efficacy of mandatory 10 knot speed restrictions in high risk areas for North Atlantic right whales has been evaluated by Laist *et al.* (2014). The results indicated a statistically significant reduction in right whale ship strikes in Seasonal Management Areas (SMAs) where speed limits were imposed, suggesting that these have been effective. Noting previous recommendations regarding reducing anthropogenic mortality to North Atlantic right whales (e.g. IWC, 2011a), the Committee **endorses** the recommendations in the paper for extension to the SMAs to cover a greater portion of vessel tracks across core migratory areas.

7.2.3 Collaboration with the Commission's Ship Strikes Working Group including consideration of mitigation measures and future work

Collisions between sailing vessels and cetaceans have been reported for a number of species, and this appears to be an increasing problem (Ritter, 2012). Many of these collisions have caused serious damage to the vessel or even vessel loss, as well as and serious or fatal injury to the whale. A draft guidance document was developed so as to provide information to sailors and offshore race organisers. A similar draft guidance document for reducing collisions with cruise ships was also reviewed. Both guidance documents contain information on relevant mitigation measures currently in place, as well as educational resources and existing reporting tools. It is foreseen that these documents will be discussed at the upcoming joint UNEP-CEP-SPAW-IWC workshop on ship strikes in Panama in June and then be brought to the attention of the IMO. The Committee **recommends** that similar guidance be developed for other classes of vessels where there may be specific issues to that type of vessel not covered by the general IMO guidance on reducing ship strikes.

7.3 Marine debris

Aspects of this issue are discussed under Item 12.6.1.

7.4 Other issues including mortality from acoustic sources

Aspects of this issue are discussed under Item 12.4.

7.5 Workplan

The workplan includes a planned review of mitigation measures for both ship strikes and entanglements. This should

lead to a simple summary table that would provide a useful communication tool. Such a table might be of particular value to the Secretariat in reaching out to other organisations.

The Committee **welcomes** a proposal for a workshop on preventing the entanglement of large whales in fishing gear to be held in 2016 noting that advice for preventing entanglements would be relevant to many countries and that this would best be achieved by collaboration with fishers, managers, gear manufacturers and scientists.

The Committee's budget proposal is discussed under Item 26. The detailed workplan is given in Annex J, item 9. A simple overview is given as Table 4.

8. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT PROCEDURE (AWMP)

This item continues to be discussed as a result of Resolution 1994-4 of the Commission (IWC, 1995). The report of the Standing Working Group (SWG) on the development of an aboriginal whaling management procedure (AWMP) is given as Annex E. The Committee's deliberations, as reported below, are largely a summary of that Annex, and the interested reader is referred to it for a more detailed discussion. The primary issues at this year's meeting comprised: (1) developing *SLAs* (*Strike Limit Algorithms*) and providing management advice for Greenlandic hunts, with an initial focus on bowhead and humpback whales; and (2) providing management advice for the Greenland hunts and the humpback whale fishery of St. Vincent and The Grenadines (see Item 9). Considerable progress on item (1) was made as a result of an AWMP intersessional workshop (SC/65b/Rep06), a joint AWMP/RMP intersessional workshop (SC/65b/Rep04) and the AWMP Developers' Fund.

The Committee **notes** that the approach used by the SWG (and the sub-committee on the RMP) is of broad relevance to the work of the Committee when examining status and the effects of human-related mortality. The modelling framework and approach to dealing with uncertainty is of wide application, for example when assessing the effects of bycatch in fishing gear or ship strikes. This approach is now being used for North Pacific gray whales (SC/65b/Rep08).

8.1 Progress on SLA development for the Greenland hunts

In Greenland, a multispecies hunt occurs and the expressed need for Greenland is for 670 tonnes of edible products from large whales for West Greenland; this involves catches of common minke, fin, humpback and bowhead whales. The flexibility among species is important to the hunters and satisfying subsistence need to the extent possible is an important component of management. For a number of reasons, primarily related to stock structure issues, development of SLAs for some Greenland aboriginal hunts (especially for common minke and fin whales) is more complex than previous *Implementations* for stocks subject to aboriginal subsistence whaling. The Committee endorsed an interim safe approach to setting catch limits for the Greenland hunts in 2008 (IWC, 2009a), noting that this should be considered valid for two blocks i.e. the target will be for agreed and validated SLAs, at least by species, for the 2018 Annual Meeting at the latest.

The Committee has recognised that in a multi-species fishery, hunters would like to have some flexibility across species in terms of meeting the overall need expressed in terms of edible products. It has agreed that the inclusion of such flexibility across a series of interlinked SLAs is complex (e.g. IWC, 2011b). The Committee has therefore agreed that this aspect only be considered after single species SLAs have been developed and adopted.

In accordance with the Workplan developed last year, the SWG on the AWMP made considerable intersessional progress, in particular through three intersessional workshops, one of which was a dedicated AWMP workshop with a focus on finalising the trial structure for the bowhead and humpback whale hunts of Greenland (SC/65b/Rep06); the second was a joint AWMP/RMP workshop on the stock structure of common minke whales in the North Atlantic (SC/65b/Rep04) and the third was an RMP workshop focussing on fin whales for which the operating model discussions were relevant (SC/65b/Rep07).

8.1.1 Development of an SLA for the bowhead whale hunt off West Greenland

8.1.1.1 DATASETS, TRIAL STRUCTURE AND CONDITIONING

An important component of the intersessional Workshop was the finalisation of the datasets to be used in the trials. The question of stock structure had been extensively discussed last year (IWC, 2014c). Although the Committee's current working hypothesis is a single Baffin Bay-Davis Strait stock, pending the availability of some genetic analyses, the Committee had agreed that the possibility that there are two stocks present in the overall area, (with the second being the Foxe Basin-Hudson Strait stock) could not be ruled out (e.g. see IWC, 2009b). The Committee had therefore agreed to

'proceed first on a conservative basis that assumed that the absolute abundance of bowhead whales on the West Greenland wintering area would be informed by abundance estimates from data for that region only (see below). Only if such an SLA proved unable to meet need would abundance estimate information and stock structure considerations from the wider area be taken into account.'

With respect to abundance estimates, two new abundance estimates for West Greenland were discussed (see item 3.1 of SC/65b/Rep06). The Committee **endorses** the agreement of the Workshop that:

- (1) the mark-recapture abundance estimate of 1,274 (CV=0.12) constituted the best available estimate of abundance for the number of whales visiting West Greenland;
- (2) given the present operating model, it was appropriate for this *Implementation* to continue to use (and project into the future), sighting survey estimates – determining an approach to use mark-recapture estimates should however be undertaken in the future (this is a major task);
- (3) conditioning would be based therefore on (a) the fully-corrected 2012 sighting survey abundance estimate of 744 (CV=0.34, 95% CI: 357-1,461); and (b) a comparable estimate for the 2006 survey of 1,103 (CV0.47). See Annex E of SC/65b/Rep06 to see how this comparable estimate was obtained.

With respect to removals, considerable work was undertaken to compile a complete list of direct and incidental catches and to discuss how Canadian catches should be incorporated into the trial structure (item 3.2 of SC/65b/Rep06). Greenland indicated that the need envelope that increased strikes to 15 over the 100-year period should be removed.

The Committee **endorses** the final trial structure given in Annex D of SC/65b/Rep06. This provides *inter alia* details on the population model, conditioning, trials, removals, need envelopes and abundance.

Factors considered within the trials are summarised in Table 5 and the *Evaluation Trials* are given in Table 6; the *Robustness Trials* can be found in SC/65b/Rep06 (Annex D, table 6). The conditioning of the operating models was conducted intersessionally. The SWG reviewed the conditioning by examining the diagnostic plots in the usual manner and agreed that conditioning had been achieved successfully except for one trial. The Committee **endorses** this view.

8.1.1.2 CANDIDATE SLAS

In SC/65b/AWMP/03, Brandão and Butterworth presented initial results for four potential SLAs.

- (1) the 'Interim SLA' agreed by the Committee in 2008 (IWC, 2009b) which is based on the most recent estimate of abundance;
- (2) a weighted-average 'Interim SLA' which uses all abundance estimates, but earlier abundance estimates are downweighted compared to more recent ones.
- (3) and (4) were variants of the weighted-average interim SLA that apply an adjustment to the multiplier of the abundance estimate in the interim SLA that depends on the trend of the abundance indices. This allows for additional reduction of the *Strike Limit* if abundance shows a reasonably precise downward trend. The two SLAs differ in the values for the control parameters. The SLAs can thus provide either a 'large' or 'lesser' change in depletion compared to the weighted-average SLA so that the resource is not reduced as much by strikes if MSYR is low.

The authors noted that although the weighted-average SLA performs well in terms of need satisfaction, it performs poorly for some 1% MSYR₁₊ trials in terms of conservation; improvement in terms of relative increase in population size with the variants comes at the expense of need satisfaction. This trade-off also occurs for trials with a higher MSYR₁₊.

Table 5
Summary of factors tested in the trials

Factors	Levels (Reference levels shown bold)	
	Humpback whales	Bowhead whales
MSYR ₁₊	1%, 3%, 5% , 7%	1%, 2.5% , 4%
MSYL ₁₊	0.6	0.6 , 0.8
Time dependence in <i>K</i> *		Constant, Halve linearly over 100yr
Time dependence in natural mortality, <i>M</i> *		Constant, Double linearly over 100yr
Episodic events *	None; 3 events occur between yrs 1-75 (with at least 2 in yrs 1-50) in which 20% of the animals die; Events occur every 5 years in which 5% of the animals die	
Need envelope	A: 10, 15, 20; 20 thereafter B: 10, 15, 20; 20->40 over years 17-100 C: 10, 15, 20; 20->60 over years 17-100 D: 20, 25, 30; 30->50 over years 17-100	A: 2, 3, 5; 5 thereafter B: 2, 3, 5; 5 -> 10 over years 17-100
Future Canadian catches	N/A	A: 5_constant over 100 years B: 2-> 8 over 100 years D: 2 constant over 100 years
Survey frequency	5 yr, 10 yr , 15 yr	
Historic survey bias	0.8, 1.0 , 1.2	0.5, 1.0
First year of projection, τ	1960	1940
Alternative Priors	$S_{1+} \sim U[0.9, 0.99]; f_{\max} \sim U[0.4, 0.6];$ $a_m \sim U[5, 12]$	N/A
Strategic surveys	Extra survey if a survey estimate is less than half of the previous survey estimate	
Asymmetric environmental stochasticity	$\tilde{\rho}_f = \mathbf{0.320}$	
Depletion	Depletion = 0.3 Depletion = 0.15/ 0.6	

*Effects of these factors begin in year 2013 (i.e. at start of management). The adult survival rate is adjusted so that if catches were zero, then the average population size during years 250-500 equals the carrying capacity. Note: for some biological parameters and levels of episodic events, it may not be possible to find an adult survival rate which satisfies this requirement.

Table 6

Bowhead whale *Evaluation Trials* (each conducted conditioning to the estimate of abundance for West Greenland, treating this as absolute abundance). Values given in bold type show differences from the base trial

Trial	Description	MSYR ₁₊	Need Scenario	Survey freq.	Canadian Catches	Historic Survey Bias
1A	MSYR ₁₊ = 2.5%	2.5%	A, B	10	A	1
1B	MSYR ₁₊ = 1%	1%	A, B	10	A	1
1C	MSYR ₁₊ = 4% (and MSYL ₁₊ =0.8)	4%	A, B	10	A	1
2A	5 year surveys	2.5%	A, B	5	A	1
2B	5 year surveys; MSYR ₁₊ = 1%	1%	A, B	5	A	1
3A	15 year surveys	2.5%	A, B	15	A	1
3B	15 year surveys; MSYR ₁₊ = 1%	1%	A, B	15	A	1
4A	Survey bias = 0.5	2.5%	A, B	10	A	0.5
4B	Survey bias = 0.5; MSYR ₁₊ = 1%	1%	A, B	10	A	0.5
5A	3 episodic events	2.5%	A, B	10	A	1
5B	3 episodic events; MSYR ₁₊ = 1%	1%	A, B	10	A	1
6A	Stochastic events every 5 years	2.5%	A, B	10	A	1
6B	Stochastic events every 5 years; MSYR ₁₊ = 1%	1%	A, B	10	A	1
7A	Alternative future Canadian catches	2.5%	A, B	10	B	1
7B	Alternative future Canadian catches; MSYR ₁₊ =1%	1%	A, B	10	B	1
9A	Alternative future Canadian catches	2.5%	A, B	10	D	1
9B	Alternative future Canadian catches; MSYR ₁₊ =1%	1%	A, B	10	D	1
10A	Asymmetric environmental stochasticity (depletion = 0.3)	2.5%*	A, B	10	A	1
10B	Asymmetric environ. stochasticity; MSYR ₁₊ =1% (depletion = 0.3)	1%*	A, B	10	A	1

In SC/65b/AWMP02, Witting outlined candidate *SLAs* based on adjustments to the 'Interim *SLA*'. The core calculation is an initial *Strike Limit* that is given as a percentage of a lower percentile of an abundance estimate. The percentage is determined by an *r* parameter, that is specified as a proportional take (e.g., *r*=0.03). The lower percentile is determined by a point estimate of abundance for the most recent survey estimate, a percentile parameter *p*, and the CV of the estimate (assuming a log normal distribution). The point estimate is given by a linear regression over the most

recent four survey estimates, so that noise from random fluctuations between estimates is reduced, while a possible trend over time is maintained in the calculation. The CV is a time-weighted average of the CV's of the four estimates.

The initial *Strike Limit* is modified for increased need satisfaction and increased protection. Need satisfaction is increased by a 'snap to need' function, which sets the *Strike Limit* equal to need if the initial *Strike Limit* is greater or equal

Table 7

Proportion of times that each *SLA* achieves the conservation performance benchmark for various subsets of the 36 *Evaluation Trials* for bowhead whales off West Greenland, and the mean of the 5th percentile need satisfaction (N9 over 20 and 100 years) values within each such subset of trials. For all table entries, higher numbers indicate better performance.

(a) Results by MSY rate					
	Interim	SLA1	SLA2	SLA3	SLA4
MSYR ₁₊ =2.5% trials (18 trials)					
Conservation performance	1.00	1.00	1.00	1.00	1.00

Need satisfaction 20 yrs	0.85	1.00	1.00	0.72	0.72
Need satisfaction 100 yrs	0.88	0.72	0.91	0.62	0.61

to 80% of need. If the point estimate of abundance is lower than a specified abundance, a protection function forces the *Strike Limit* to be very low. For the case of West Greenland bowhead whales, the yearly *Strike Limit* is set to 2 if the point estimate of abundance is 800, and it is then scaled linearly downwards to zero at a point estimate of 400.

After examining the influence of the variation in the CV on the performance of the *SLA*, $p=2$ was chosen for the candidate *SLAs* (equal to an approximate lower 5th percentile). The *SLA* was then tuned to $p=2$ to obtain the highest average need satisfaction. This was achieved under the conservation constraint that the lower 5th percentile of the ratio of the final 1+ population size at the end of the simulation period to that at the start was larger than 1 (for the *Evaluation Trials* with $MSYR_{1+}=0.01$). The result was a proposed 'best' candidate (denoted p2r0.9) with $r=0.009$.

8.1.1.3 TRIAL RESULTS

The Committee has previously agreed the appropriate the statistics and plots to compare candidate *SLAs* (e.g. see IWC, 2014). Initial evaluation of the candidate *SLAs* focussed primarily on the following tables and plots (the full set is available from the Secretariat):

- (1) a table with rows by trial for the interim *SLA* and each candidate *SLA*, along with scenarios in which all future catches are set to zero, in which there are only incidental

catches into the future (no aboriginal catches), and in which the strike limit equals need. The tables include the lower 5th percentile and median for the following performance statistics (see Annex D of SC/65b/Rep6 for definitions): D1 (final depletion) for the 1+ component of the population; D1for the mature female component of the population; D8 (rescaled final depletion) based on incidental catches; D8 based on no future catches, D10 (relative increase), and N9 (need satisfaction) for 20 and 100 years.

- (2) Time-trajectories of the lower 5th percentiles and medians for 1+ population size in which the area which encompasses the results for zero future catches and future strikes equal to need is shaded, and lines are shown for the scenario in which there are only incidental catches into the future as well as for the 'Interim *SLA*' and the candidate *SLAs* (see example in Annex E, fig 2a).
- (3) 'Zeh' plots which show the same results as the table, except that the N12 (mean downstep) statistic is also reported (see example in Annex E, fig 2b).

The performance of four new *SLAs* was examined in detail, along with the 'Interim *SLA*' for comparison. These were:

- (1) SLA1: (SLA3 of SC/65b/AWMP03).
- (2) SLA2: (SLA4 of SC/65b/AWMP03).

(3) SLA3: SLA p2r0.9 of SC/65b/AWMP02

(4) SLA4: SLA p2r1 of SC/65b/AWMP02

The Committee noted that the time taken to determine and condition the trials meant that developers had had relatively little time to work on their *SLAs*.

Evaluation of the *SLAs* concentrated on: (a) the conservation performance, particularly for trials with $MSYR_{1+}=1\%$, high need, and high future Canadian catches; and (b) their performance in relation to the current 'Interim *SLA*'. The four *SLAs* are tuned to somewhat different need-conservation trade-offs, which is reflected in the results of the trials.

In order to summarise inferences from the trials, attention was focussed on cases where either the lower 5th percentile of the D1 (1+) statistic exceeded 0.6 or the 5th percentile of D10 statistic was below 1 and in addition, examined the average of the lower 5th percentile of the N9 statistic.

Table 7 summarises various aspects of the trials in terms of conservation and need performance using these criteria. Overall, all of the *SLAs* performed adequately in terms of conservation performance if $MSYR_{1+}=2.5\%$ but as would be expected, performance was more variable for $MSYR_{1+}=1\%$ (Table 7a). From an examination of the tabular and graphical results, the Committee identified some general features:

- (a) *SLAs* 3 and 4 generally had better conservation performance but poorer need satisfaction;
- (b) *SLAs* 1 and 2 had better conservation and need satisfaction performance for the $MSYR_{1+}=2.5\%$ trials;
- (c) *SLAs* 3 and 4 exhibited higher levels of variability than *SLAs* 1 and 2;
- (d) as expected, performance in terms of need satisfaction was better for the trials in which the Canadian catches were lower than for the basecase trials.

The Committee **agrees** that the performance of the 'Interim *SLA*' in these trials confirms the earlier recommendation of the Scientific Committee that at least for up to two quota block it was indeed a suitable *SLA*. However, the Committee also **agrees** that for the longer 100-year period, the results showed that better performance than the 'Interim *SLA*' could be obtained for bowhead whales off West Greenland.

Performance for the *Robustness Trials* is generally as expected given the results of the *Evaluation Trials*, as discussed under Annex, item 2.5.

8.1.1.4 CONCLUSIONS AND RECOMMENDATIONS

The Committee **agrees** that developing *SLAs* for bowhead whales off West Greenland that fully meet both conservation and need objectives is particularly difficult since:

- (1) the *SLA* is only able to 'control' one source of mortality, i.e. strikes for the Greenland hunt, whereas mortality also occurs from catches by a non-member nation and from bycatches;
- (2) it is also not possible to assume that future Canadian abundance surveys will occur; and
- (3) the remaining uncertainty over stock structure (and therefore abundance) means that the scenarios that must be considered may be overly conservative.

With respect to (3) the Committee **strongly encourages** scientists from Canada and Greenland to co-operate on issues related to stock structure and abundance that may allow revision of the trial structure at a future *Implementation Review*.

Given the difficulties presented by these circumstances, the Committee **agrees** that although improved performance over the *SLAs* considered this year was possible, it was unlikely that an *SLA* could be developed that fully met the conservation objectives (the highest priority) whilst also meeting need fully for the most difficult scenarios. Given this, the SWG **requested** Witting to consult within Greenland as to whether it wished to proceed with the 'high' need envelope.

The Committee **concludes** that further work should be undertaken by the developers during the coming year. It noted that now conditioning had been completed, progress on *SLA* development could take place at a faster rate, with progress being reported at the proposed intersessional workshop discussed below. The objective would be for the Committee to be in a position to recommend an *SLA* to the Committee next year (see the Workplan).

8.1.2. Development of an *SLA* for the humpback whale hunt off West Greenland

8.1.2.1 DATASETS, TRIAL STRUCTURE AND CONDITIONING

An important component of the intersessional Workshop was the finalisation of the datasets to be used in the trials. With respect to stock structure, the Committee has agreed that the appropriate 'unit-to-conserve' is the West Greenland feeding aggregation (e.g. see IWC, 2008a; 2012b).

The abundance estimates (including indices of abundance) for use in the trials have been discussed previously by the Committee and were agreed last year (IWC, 2014c); they are summarised in Annex E, table 7 and in SC/65b/Rep06 (Annex D).

Intersessional work (SC/65b/Rep06) focussed on developing removals series that took into account the incidental captures of 'Greenland' animals elsewhere in their range based *inter alia* on photographic matches from the College of the Atlantic (SC/J14/AWMP1) and movement information from telemetry data. The full review of information confirmed that approach previously adopted to incorporate bycatches outside Greenland. The final series can be seen in Annex F of SC/65b/Rep06.

The Committee **endorses** the final trial structure given in Annex D of SC/65b/Rep06. This provides *inter alia* details on the population model, conditioning, trials, removals, need envelopes and abundance.

The factors considered in the trials are given in Table 5. The *Evaluation Trials* are shown in Table 8. The conditioning of the operating models was conducted intersessionally. The SWG reviewed the conditioning by examining the diagnostic plots in the usual manner and agreed that conditioning had been achieved successfully. The Committee **endorses** this view.

8.1.2.2 CANDIDATE *SLAs*

In SC/65b/AWMP01, Witting outlined candidate *SLAs* for humpback whales off West Greenland, that have the same

structure, parameters and ‘snap to need’ function as those applied to bowhead whales (SC/65b/AWMP02; see Item 8.1.1.2 above). The selected ‘protection level’ within the *SLA* is slightly higher than that for bowhead whales. While this may seem counterintuitive given the higher growth rates of humpback whales, the developer’s choices reflect that the bowhead whale is managed on what is known to be a sub-component of a stock, which allows for a somewhat lower protection level. ‘Snap to need’ occurs when the *Strike Limit* is 80% of need, and p is set to 2. The value of r was tuned which results in an *SLA* with $r=0.04$ that provides full need satisfaction for all of the *Evaluation Trials*, and also ensures that the $1+$ population size at the end of the 100-year simulation period is higher than that at the start of this period for all of the *Evaluation Trials*.

The *SLAs* developed for humpback whales off West Greenland by Brandão (SC/65/AWMP04) have the same structure as those developed for the bowhead whales (see Item 2.3). The control parameters of these *SLAs* were not ‘tuned’ for the humpback case; rather the same values were used as for the bowhead case, due to a lack of time.

Table 8

The *Evaluation Trials* for humpback whales. Values given in bold type show differences from the base trial

Trial Description	<i>MSYR</i> ₁₊	Need Scenarios	Survey freq.	Historic Survey Bias
1A <i>MSYR</i> ₁₊ = 5%	5%	A, B, C, D	10	1
1B <i>MSYR</i> ₁₊ = 3%	3%	A, B, C, D	10	1
1C <i>MSYR</i> ₁₊ = 7%	7%	A, B, C, D	10	1
2A 5 year surveys	5%	B, C, D	5	1
2B 5 year surveys; <i>MSYR</i> ₁₊ = 3%	3%	B, C, D	5	1
3A 15 year surveys	5%	B, C	15	1
3B 15 year surveys; <i>MSYR</i> ₁₊ = 3%	3%	B, C	15	1
4A Survey bias = 0.8	5%	B, C, D	10	0.8
4B Survey bias = 0.8; <i>MSYR</i> ₁₊ = 3%	3%	B, C, D	10	0.8
5A Survey bias = 1.2	5%	B, C, D	10	1.2
5B Survey bias = 1.2; <i>MSYR</i> ₁₊ = 3%	3%	B, C, D	10	1.2
6A 3 episodic events	5%	B, C, D	10	1
6B 3 episodic events; <i>MSYR</i> ₁₊ = 3%	3%	B, C, D	10	1
7A Stochastic events every 5 years	5%	B, C, D	10	1
7B Stochastic events every 5 years; <i>MSYR</i> ₁₊ = 3%	3%	B, C, D	10	1
8A Asymmetric environmental stochasticity (depletion = 0.3)	5%	B, C, D	10	1
8B Asymmetric environmental stochasticity (depletion = 0.3)	3%	B, C, D	10	1

8.1.1.3 TRIAL RESULTS

The Committee explored the performance of four new *SLAs* in detail as well as the interim *SLA* for comparison. These were the same as for the bowhead whale:

- (1) *SLA*1: *SLA*3 of SC/65b/AWMP03.
- (2) *SLA*2: *SLA*4 of SC/65b/AWMP03.
- (3) *SLA*3: *SLA* p2r4 of SC/65b/AWMP01
- (4) *SLA*4: *SLA* p2r3 of SC/65b/AWMP01

The Committee noted that the time taken to determine and condition the trials meant that developers had had relatively little time to work on their *SLAs*. However, it also noted that the humpback case was relatively data rich compared to the

bowhead case and that future catches from non-member nations was not an issue.

Consideration of the full set of graphical and tabular results (available from the Secretariat) followed the process agreed for the bowhead whale described under Item 8.1.1.3. There was relatively little impact of the need envelope in terms of need satisfaction performance of the *SLAs* (Table 9b). Performance in terms of conservation and need satisfaction was primarily evaluated using the same performance evaluation statistics (D1, D10 and N9) as for West Greenland bowhead whales (Table 9) as well as consideration of the graphical output. All of the *SLAs* except *SLA* 1 achieved satisfactory levels of performance when *MSYR*₁₊=5%. However, only *SLAs* 3 and 4 achieved fully satisfactory performance when *MSYR*₁₊=3%. Generally, *SLAs* 3 and 4 achieve notably better performance than the other *SLAs*, especially with respect to need satisfaction.

Table 9

Number of times that the each *SLA* does *not* achieve the benchmark levels for *SLA* performance for the 18 *Evaluation Trials* for humpback whales off West Greenland. In this table, low numbers represent better performance.

(a) Results by *MSY* rate

	Interim	<i>SLA</i> 1	<i>SLA</i> 2	<i>SLA</i> 3	<i>SLA</i> 4
<i>MSYR</i> ₁₊ =5% trials (24 trials)					
Conservation performance	0	0	0	0	0
Need satisfaction 20 yrs	0	0	0	0	0
Need satisfaction 100 yrs	0	3	0	0	0
<i>MSYR</i> ₁₊ = 3% (24 trials)					
Conservation performance	0	0	0	0	0
Need satisfaction 20 yrs	9	3	3	0	0
Need satisfaction 100 yrs	0	7	0	0	0

(b) Results by Need Level *

Need Level A (2 trials)					
Conservation performance	0	0	0	0	0
Need satisfaction 20 yrs	1	0	0	0	0
Need satisfaction 100 yrs	0	0	0	0	0
Need Level B (16 trials)					
Conservation performance	0	0	0	0	0
Need satisfaction 20 yrs	1	0	0	0	0
Need satisfaction 100 yrs	0	2	0	0	0
Need Level C (16 trials)					
Conservation performance	0	0	0	0	0
Need satisfaction 20 yrs	1	0	0	0	0
Need satisfaction 100 yrs	0	3	0	0	0
Need Level D (16 trials)					
Conservation performance	0	0	0	0	0
Need satisfaction 20 yrs	6	3	3	0	0
Need satisfaction 100 yrs	0	5	0	0	0

The Committee **agrees** that the performance of the 'Interim *SLA*' in these trials confirmed the earlier recommendation of the Scientific Committee that it was indeed a suitable *SLA*, at least for up to two block quotas. However, the Committee also **agrees** that for the longer 100-year period, the results showed that better performance than the 'Interim *SLA*' could be obtained for humpback whales off West Greenland.

In terms of *Robustness Trials*, performance was as expected for all *SLAs*.

8.1.1.4 CONCLUSIONS AND RECOMMENDATIONS

Unlike the situation for the bowhead whales, the Committee **agrees** that the performance of two of the candidate *SLAs* (*SLAs* 3 and 4) meets the Commission's objectives in terms of conservation and need. However, in terms of need satisfaction, *SLA3* performed slightly better than *SLA4*. For example, the lower 5th percentile of need satisfaction exceeded 0.99 for all except one trial for *SLA3* while *SLA4* achieved lower than 99% need satisfaction with 95% probability for 3 trials (20 year need satisfaction) and 8 trials (100-year need satisfaction). In accordance with its previous agreement (e.g. see IWC, 2014) that once an *SLA* had been developed that fully met the Commission's objectives, that time would not be spent trying to improve it even further, the Committee **recommends** that *SLA3* (hereafter the *Humpback SLA*) be used to provide long-term management advice to the Commission on the subsistence hunt of humpback whales off West Greenland, subject to final validation of the code by the Secretariat and archive running of the full set of statistics and graphical output.

The Committee was pleased to note that this component of its workplan had been completed and **thanks** the SWG on the AWMP for its hard work in this regard since focussing on this case in 2012. In particular, it wished to thank the developer of *The Humpback SLA*, Witting, and the other developers, Brandão and Butterworth, for their hard work in reaching this stage. Special thanks are also due to Brandão, Witting and Punt for their conscientious work in developing and finalising the operating model and conditioning. The Committee **stresses** that this work could not have been accomplished without assistance from the AWMP Developer's Fund established by the Commission, the funded intersessional workshops and the hard work of the intersessional Steering Group. It **agrees** that this process (i.e. maintenance of the Developer's Fund, holding of intersessional workshops and an active Steering Group) should be followed with respect to completing the development of the remaining *SLAs* for the Greenland hunts.

8.1.3 Development of an *SLA* for the common minke whale hunt off Greenland

The Committee has previously noted connection between the development of an *SLA* for the Greenland hunts and the RMP *Implementation Review* for common minke whales in North Atlantic and the need for consistency in a number of aspects of operating model development and stock structure hypotheses (see IWC, 2013b). Given this, the joint AWMP/RMP intersessional workshop was held in Copenhagen in April 2014; an important component of this successful workshop was simulation work and co-operative genetic analyses supported by the IWC. A short Chair's summary of the results of the workshop is given in Annex D, Appendix 5, Item 2.1.

The Workshop had developed stock structure hypotheses based on a thorough review of the data from a suite of sources and began the work to develop the appropriate modelling framework. This work continued intersessionally and was reviewed at the pre-meeting of the RMP (Annex D, Appendix 5). The Committee **agrees** that framework developed for the RMP *Implementation Review* (Annex D, Appendix 5, Adjunct 5) is applicable to progress work on *SLA* development.

Much of the discussion within the SWG on the AWMP focussed on developing a workplan for *SLA* development with the objective of having a recommended *SLA* ready by the 2017 Annual Meeting. The Committee thanked Punt for working hard at this meeting to ensure that the initial conditioning of the basic operating model had begun. This will allow a preliminary version of the program to be available to developers shortly after the end of the SC meeting. However, the full version of the control program will not be finalised until after the end of the proposed intersessional workshop. In view of the new approach being used to model the sex-ratio, minor amendments to the operating model may be necessary following consideration of the conditioning results, particularly given the interaction between aboriginal and commercial catch patterns.

The need envelopes for West Greenland common minke whales will be confirmed later but will include a constant level of 200 whales for West Greenland and of 12 whales for East Greenland.

The Committee **welcomes** the information that Witting, Butterworth and Brandão expect to begin work intersessionally on the development of candidate *SLAs* for Greenlandic minke whales.

8.1.4 Development of an *SLA* for the hunt of fin whales off West Greenland

The Committee has previously noted connection between the development of an *SLA* for the Greenland hunts and the RMP *Implementation Review* for fin whales in North Atlantic and the need for consistency in a number of aspects of operating model development and stock structure hypotheses (see IWC, 2013a). A technical RMP workshop was held in Copenhagen in January 2014 and this was followed up by work at the present meeting (see Annex D, item 3.2).

The Committee **confirms** that the general trial specifications developed for the *Implementation Review* for North Atlantic fin whales are suitable for testing *SLAs* in the West Greenland area. However, the operating model is complex and is not yet operational. The Committee is concerned that the complexity of the model may not allow development of an *SLA* for fin whales in time for the 2017 Scientific Committee meeting. It **agreed** that priority should be given to development of an *SLA* for minke whales, in view of the greater contribution of minke whales to the overall interspecies need satisfaction for Greenland. With respect to fin whales, the Committee **agrees** that an alternative approach to develop a single-stock operating model will be conservative (i.e. from a conservation perspective) in that it assumes that the animals found of West Greenland comprise a single stock, and should be investigated. The trials steering group (Witting, Givens, Brandão, Butterworth, Punt, Allison, and Donovan) will consider this suggestion further and report back to the Intersessional workshop.

Table 10

Two-year workplan (the second year is more tentative than the first and depends on progress)

Topic	Intersessional 2014-15	SC66a May-June 2015	Intersessional 2015-16	SC66b May-June 2016
Validate <i>Humpback SLA</i>	Complete by July 2014	Receive report formally	No	No

Development of <i>SLA</i> for fin whales	Workshop Developers' work	Review progress	Workshop Developers work	Review progress Developers' work
Annual review of catch limits	No	Complete	No	Complete
<i>Implementation Reviews</i>	No	None scheduled	No	Prepare for gray whale <i>Implementation Review</i>

8.2 Follow-up work on conversion factors for the Greenland hunt

This item relates to follow up work on conversion factors (i.e. related to converting edible whale products in to numbers of whales by species) that was undertaken by Donovan *et al.* (2010) at the request of the Commission. That report, endorsed by the Scientific Committee, provided a conversion factor for the common minke whale (for which data were abundant) and provisional factors for the other species (often by analogy with other areas as data are sparse for Greenland). They had recommended *inter alia* that data for those species be collected in Greenland such that the factors could be modified if necessary.

SC/65b/AWMP05 provided a full report on the work undertaken on conversion factors within Greenland, including explaining improved procedures for data collection and updating the new information obtained. All reliable weights obtained since 2009 are listed in table 2 of SC/65b/AWMP05 (bowhead whale $n=6$; humpback whales, $n=8$; fin whale, $n=4$). A detailed summary is given in Annex E, item 8. Greenlandic biologists will continue their close contact with hunters to improve the number of reported weights.

The Committee **thanks** the authors for this work which responded appropriately to its recommendations last year for a full report and **encourages** continuation of the study. It noted that the provisional conversion factors developed in 2009 (Donovan *et al.* 2010) appear to overestimate the amount of edible products actually obtained (although sample sizes are small), but were generally within the confidence intervals. It also noted the low numbers of lost whales in the Greenlandic hunts.

The Committee **recognises** the difficulties inherent in obtaining the weight data, including (i) persuading the hunters to modify their behaviour and obtain accurate weight measures; and (ii) enabling researchers to be present to assist in the data collection. The latter is extremely difficult given the opportunist nature of the hunt and the variety of locations (both in distance and difficulties in access) where flensing is carried out.

Recognising (1) the difficult field conditions; (2) the relatively low number of catches (and thus slow increase in sample size) of the species for which the conversion factors were deemed provisional; (3) the fact that the new data, albeit few, did not suggest that the provisional factors from the 2010

study required major modification; and (4) that the information was not required for *SLA* development, the Committee **agrees** that annual update reports are unnecessary for the work of the Scientific Committee. It **suggests** that data are submitted directly to the Commission when it meets and incorporated as necessary into need statements.

8.3 Aboriginal Whaling Management Scheme

In 2002, the Committee **strongly recommended** that the Commission adopt the Aboriginal Subsistence Whaling Scheme (IWC, 2003). This covers a number of practical issues such as survey intervals, carryover, and guidelines for surveys. The Committee has stated in the past that the AWS provisions constitute an important and necessary component of safe management under AWMP *SLAs* and it **reaffirms** this view as it has for the previous 12 years.

8.4 Workplan

The Committee noted that this year it was expected to put forward a draft workplan and budget for a two-year period. The two-year workplan for AWMP work summarised in Table 10 has to include a degree of expectation of progress that may not be realised.

9. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT ADVICE

The Committee noted that the Commission had not reached agreement on strike limits for Greenland at the 2012 Annual Meeting (IWC, 2013a). The Committee has based its management advice this year on the same need requests considered last year. In providing this advice, the Committee noted that the Commission had endorsed the interim safe approach (based on the lower 5th percentile for the most recent estimate of abundance) for providing advice for the Greenland hunts developed by the Committee in 2008 (IWC, 2009b, p.16); it was agreed that that this should be considered valid for two blocks i.e. up to the 2018 Annual Meeting. The Committee **emphasises** that the results of the simulation exercise being undertaken as part of the development process for *SLAs* for the Greenland humpback and bowhead whales **reconfirms** the Committee's original advice with respect to the interim safe approach (see Items 8.1.2 and 8.1.3).

The Committee notes that when providing management advice on subsistence whale hunts it provides advice in a specific way i.e. it comments only on whether the need request or present limits can be safely met from the perspective of the Commission's conservation objectives. If

it or they cannot be safely met then the Committee provides advice on what strike limit is acceptable from a conservation perspective.

9.1 Bowhead whales off West Greenland

9.1.1 New information (incl. catch data and agreed abundance estimates)

No bowhead whales were taken in West Greenland in 2013 while three bowhead whales were taken in North East Canada in 2012 and 2013; no struck and lost whales were reported. The catch corresponds with the quota set by the Canadian authorities. Samples were reported to have been collected from the Canadian hunt and the Committee **encourages** collaboration with Canada on genetic work (and see Item 2.6). The Committee **thanks** Canada for providing this information and **encourages** future reporting to the IWC Secretariat.

It was reported that 65 biopsy samples had been collected from West Greenland bowhead whales in 2013. The Committee **welcomes** this information and **encourages** continuation of the work and collaboration with Canadian scientists to resolve the outstanding stock structure issues.

The Committee **endorses** the following two new abundance estimates for 2012 (SC/65b/Rep06): (i) a fully-corrected sighting survey abundance estimate of 744 (CV=0.34, 95% CI: 357-1,461); and (ii) a mark-recapture estimate of 1,274 (CV=0.12). It **agrees** that the mark-recapture estimate provides the best estimate of abundance for the number of whales visiting West Greenland.

9.1.2 Management advice

Based on the agreed best 2012 estimates of abundance for bowhead whales (1,274 CV=0.12), and using the agreed interim approach, the Committee **repeats** its advice that an annual strike limit of two whales will not harm the stock.

9.2 North Pacific gray whales

9.2.1 The report of the rangewide workshop and related future work

A rangewide review of the population structure and status of North Pacific gray whales was carried out at an IWC workshop in La Jolla, California, 8-11 April 2014 (SC/65b/Rep08).

The Workshop objectives, as agreed last year (IWC, 2014c), were to: (1) review available information (especially new telemetry, genetics and photo-ID data) and reappraise the population structure and movements of North Pacific gray whales with a focus on examining status; (2) develop a modelling framework to better assess the status of gray whales and the potential impact of human activities and possible changes in regime or climate; and (3) provide information for updating the IUCN/IWC Conservation Management Plan for western gray whales.

The Workshop put considerable effort into reviewing all of the sources of data that could provide insights in to the movements and stock structure of gray whale across the North Pacific, including identifying available data that remained to be analysed. Using the stock structure hypotheses for the western North Pacific put forward last year as a starting point the data review, the Workshop developed a series of plausible stock structure hypotheses to take forward

into the modelling exercise. In order to make progress in developing operating models to further explore the potential implications of these hypotheses, the Workshop agreed that the initial focus should be on three of these hypotheses (and one sensitivity test). The full range of hypotheses are illustrated in Annex F of SC/65/Rep08.

The Workshop then went on to review and compile the extensive data sources and information on parameters that would be needed for the modelling exercise, including removals data, abundance and trends, population parameters and other human activities that might affect status.

The Workshop recognised that the process would necessarily be an iterative process. The first step of developing an age- and sex-aggregated model which includes multiple stocks would be taken primarily to understand whether sufficient data are available to justify the various stock structure hypotheses and whether parameterisation of the model based on the associated hypotheses can provide reasonable fits to the data. The Workshop developed a workplan and made a number of recommendations for future research. These can be found in SC/65b/Rep08, items 9 and 10.

The Committee **welcomes** the workshop report, **thanks** the participants and **endorses** its recommendations.

In response to part of the workplan of the Workshop, SC/65b/BRG1 provided the mathematical specifications for a sex- and age-aggregated population dynamics model which can represent the stock hypotheses developed during the workshop. The model allows for multiple stocks, each of which can have sub-stocks, multiple feeding and wintering grounds, as well as migratory corridors.

Based on this paper and the recommendations from the gray whale workshop, Committee **recommends** the detailed workplan provided in Annex G to take this work forward.

9.2.2 Other new information.

PACIFIC COAST FEEDING GROUP (PCFG) WHALES

SC/65b/BRG19 presented research on gray whales in northwest Washington with the goals to (1) increase our understanding of gray whale use of the study area, (2) document the annual and seasonal fluctuations in the numbers of whales utilising the area, and (3) to assess the fidelity of whales to the study area within and between years. The study confirms that even though Northwest Washington is an important feeding area, most PCFG gray whales do not have strong fidelity to this one region within the PCFG.

Mate described the satellite-tagging of 35 PCFG gray whales off the coasts of Oregon from September to mid-October ($n=12$) and northern California near Pt. St. George, CA ($n=23$) from late October to December during 2009, 2012 and 2013. The 33 telemetry tracks ranged from 3-383d ($\bar{x}=118$, $SD=98.1d$) with one of the 2013 tags still transmitting at 193d at the time of manuscript preparation. The area off Pt. St. George (Crescent City, CA) is a consistent late fall 'hot spot' that attracts large numbers of PCFG whales just prior to the southerly migration. One healthy mature adult male was tracked for 383 d and did not migrate, the first such documentation for a gray whale. Six of 12 whales that migrated to Baja for the reproductive season and back into the PCFG area, spent from 1-5 days in the Makah U&A¹⁴ area as

¹⁴ Usual and Accustomed Fishing Grounds

they migrated north. Three of the same 12 whales (one in each year) migrated as far as Icy Bay, Alaska (60°N), considerably farther north than the conventional definition of the PCFG area, spending up to 55 there.

The Committee **welcomes** this new paper and **encourages** more telemetry effort in the PCFG area, noting its value with respect to better understanding of stock structure and movements in the context of the work of the workshop and the modelling exercise discussed above.

9.2.2 Review of recent catch information

A total of 127 gray whales were struck off Chukotka, Russia in 2013 resulting in 125 landed. Of those, 39 were males and 86 were females. Two of the whales were inedible because of a strong medicinal smell (i.e. 'stinky whales'). The body length of whales ranged between 7.9 and 15.5m (average = 10.1m). Body weights ranged between 5.9 and 39.1 tons (average = 11.9 tons).

9.2.3 Management advice

The Committee **agrees** that the *Gray Whale SLA* remains the appropriate tool to provide management advice for Eastern North Pacific gray whales. It also **agrees** the proposed Makah whaling management plan agreed by the Committee last year remains the appropriate tool to provide management advice for hunts in Washington State, USA, recognising that it must include that the ongoing research programme that monitors the relative probability of harvesting a PCFG whale in the Makah usual and accustomed fishing grounds.

9.3 Bering-Chukchi-Beaufort (BCB) Seas stock of bowhead whale

9.3.1 New information

The Committee received three papers providing information on this stock.

SC/65b/BRG05 described new laboratory methods for measuring D/L ratios of aspartic acid (AAR) in bowhead whale lens nuclei, and reported upon age estimates for 64 BCB bowhead whales, ten of which had been also aged using baleen carbon cycling and/or corpora counting methods. The results strengthened previous evidence suggesting that some animals may live to 200 years or beyond: the oldest estimated age found in this research was 187 years (95% CI (142, 258)) for a 17.7 m male. The results also suggested that the AAR technique provided lower estimated ages than the corpora counting approach. One whale (estimated age 88, 95% CI 66-120 years) had a Yankee whaling projectile point patented in 1879 embedded in it, strengthening previous evidence that the age estimate was plausible. The Committee **welcomes** this study and **encourages** further work on aging studies.

SC/65b/BRG 20 reported on the occasional inadvertent harvest of bowhead whale calves in autumn by Alaskan Eskimos and updates George and Suydam (2006) which had been requested by the Commission.

SC/65b/BRG10 summarised the results of onshore observations of bowhead whales in coastal waters of Chukotka in 2010-2013, and compares them with earlier surveys dating to 1992. These observations provide spatial, temporal and relative abundance information for bowheads in coastal waters. Observations of the spring migration of bowhead whales were made in the northwest Bering Strait

region. The Committee **welcomes** this information and **encourages** work in this region.

Citta *et al.* (2013) reported on the analysis of spatial/temporal overlap of satellite tagged bowhead whales and Bering Sea pot fisheries to evaluate which fisheries had the greatest risk of interaction with bowhead whales. This is also discussed under Item 7.1.

9.3.2 New catch information

Harvest data from the Alaskan hunt were presented in SC/66a/BRG08. In 2013, 57 bowhead whales were struck resulting in 46 animals landed. Total landed of the hunt for 2013 was higher than the past 10 years (2003-2012: mean of landed = 40.5; *SD* = 8.7). Efficiency (# landed / # struck) in 2013 was 81%, which was slightly higher than the past 10 years (mean of efficiency=77%; *SD*=7.4%). Of the landed whales, 25 were females and 21 were males. Seven of the 25 females were assumed sexually mature (>13.4 m in length). Four of these were pregnant.

SC/65b/BRG03 reports that in 2013, one bowhead whales was taken in Chukotka, Russia. It was a 41-tonne, 13m male. No whales were struck and lost.

9.3.4 Management advice

The Commission adopted catch limits for a six-year block in 2012, i.e. 2013-2018. The total number of strikes shall not exceed 336 with a maximum of 67 in any one year (with a carryover provision). The Committee has agreed that the *Bowhead Whale SLA* is most appropriate tool to provide management advice for this stock. The Committee **agrees** that these limits will not harm the stock.

9.4 Common minke whales off West Greenland

9.4.1 New information

In the 2013 season, 166 common minke whales were landed in West Greenland and 9 were struck and lost. Of the landed whales, there were 127 females, 37 males and two of unknown sex. Genetic samples were obtained from 106 of these minke whales in 2013. The Committee **welcomes** the additional data and **encourages** the continued collection of samples. It was also pleased to learn that samples from West Greenland were included in the genetic analyses that formed part of the Joint AWMP/RMP workshop on stock structure (SC/65b/Rep4).

Over the years, the Committee has re-emphasised the importance of collecting genetic samples from these whales, and it **welcomes** the new genetic analysis on population structure of common minke whale in the North Atlantic (SC/65b/RMP09), where samples from the West Greenland hunt were compared with samples from the Icelandic and Norwegian hunts. Out of 66 samples from West Greenland analysed for kin relationships, one parent offspring relation was found with a whale caught in the Central CIC sub-area. Witting advised that more samples are soon to be included in this analysis.

9.4.2 Management advice

In 2009, the Committee was able to provide management advice for this stock for the first time. This year, using the Commission's agreed interim approach (IWC, 2009) and last year's revised estimate of abundance (16,100 CV=0.43), the Committee **advises** that an annual strike limit of 164 will not harm the stock.

9.5 Common minke whales off East Greenland

9.5.1 New information (incl. catch data and agreed abundance estimates)

Four common minke whales were landed in East Greenland in 2013, and two were struck and lost. Of the landed whales, there were three females and one male. The Committee is **pleased** to note that samples were collected from all four landed whales and that samples from the East Greenland hunt were included in the genetic analysis (SC/65b/RMP09). Out of 16 samples from East Greenland analysed for kin relationships, one parent offspring relation was found with a whale caught in the Central CIC sub-area (Annex D, Appendix 7). The Committee **welcomes** the new information and **encourages** the continued collection of samples.

9.5.2 Management advice

Catches of minke whales off East Greenland are believed to come from the large Central stock of minke whales. The most recent strike limit of 12 represents a very small proportion of the Central Stock which numbers around 40,000 – see Table 11. The Committee **repeats** its advice of last year that a strike limit of 12 will not harm the stock.

Table 11

Most recent estimates of abundance for common minke whales in the Central North Atlantic by RMP Small Area

Small Area(s)	Year(s)	Abundance and CV
CM	2005	26,739 (CV=0.39)
CIC	2007	10,680 (CV=0.29)
CG	2007	1,048 (CV=0.60)
CIP	2007	1,350 (CV=0.38)

9.6 Fin whales off West Greenland

9.6.1 New information (incl. catch data and agreed abundance estimates)

A total of nine fin whales (five females, three males and one of unknown sex) were landed, and none were struck and lost, off West Greenland during 2013. The Committee is **pleased** to note that genetic samples were obtained from all landed fin whales, and that the genetic samples of fin whales off West Greenland are now being analysed together with the genetic samples from the hunt in Iceland. It **encourages** the continued collection of samples.

9.6.2 Management advice

Based on the agreed 2007 estimate of abundance for fin whales (4,500 95%CI 1,900-10,100), and using the agreed interim approach, the Committee **repeats** its advice that an annual strike limit of 19 whales will not harm the stock.

9.7 Humpback whales off West Greenland

9.7.1 New information (incl. catch data and agreed abundance estimates)

A total of seven (four males and three females) humpback whales were landed, and one was struck and lost, in West Greenland during 2013. The Committee is **pleased** to learn that genetic samples were obtained from five of these whales and that Greenland was contributing fluke photographs to the North Atlantic catalogue, both from captured whales and other field studies. The Committee again **emphasises** the importance of collecting genetic samples and photographs of the flukes from these whales.

The Committee also **welcomes** a report that 11 biopsy samples had been collected from West Greenland humpback

whales in 2013 and **encourages** continuation of the work and collaborative studies across the North Atlantic.

9.7.2 Management advice

Based on last year's revised and agreed estimate of abundance for humpback whales (2,704 CV=0.34) and the agreed interim approach, the Committee **agrees** that an annual strike limit of 10 whales will not harm the stock.

Furthermore, the Committee **recommends** that the new *Humpback SLA* agreed above (see Item 8.1.2) should be used to provide management advice by the Committee in the future, following completion of the usual final validation/checking process. The Committee **notes** that the *Humpback SLA*, if used now, would provide the same management advice as the interim approach for within this period, i.e. that an annual strike limit of 10 whales will not harm the stock.

9.8 Humpback whales off St Vincent and The Grenadines

9.8.1 New information (incl. catch data)

A total of four humpback whales were landed (three males and one female) in St. Vincent and the Grenadines in 2013 and individual data on these whales (including lengths and sexes) have been supplied to the Secretariat. No lost whales were reported. Skin and/or blubber samples were collected from all four whales. Preliminary information is that these data are being analysed in collaboration with the USA [*to be confirmed before report published*]. The Committee **welcomes** this information from St. Vincent and the Grenadines and **strongly encourages** continued tissue sampling and collection of fluke photographs where possible. Data should be shared with the appropriate databases and catalogues for the North Atlantic.

9.8.2 Management advice

The Committee has agreed that the animals found off St. Vincent and the Grenadines are part of the large West Indies breeding population (abundance estimate 11,570 95%CI 10,290-13,390). The Commission adopted a total block catch limit of 24 for the period 2013-2018 for Bequians of St. Vincent and The Grenadines. The Committee **repeats** its advice that this block catch limit will not harm the stock.

10. WHALE STOCKS

10.1 Antarctic minke whales

The Committee is undertaking an In-Depth Assessment of the Antarctic minke whale, which is focused on whales within the Indo-Pacific waters. Details of the discussions summarised below can be found in Annex G. In addition, during February 2014 the JARPA II Special Permit program was reviewed (SC/56b/Rep02) where research recommendations were made, of which many were referred to in Annex G.

10.1.1 New methods or information

10.1.1.1 BIOLOGICAL PARAMETERS

SC/65b/IA01 described the yearly trend of age at sexual maturity in Antarctic minke whales collected during 1987/88-2004/05 JARPA and 2005/06-2010/11 JARPA II surveys. It is a revised version of SC/F14/J08 presented to the JARPA II Review Workshop taking into consideration some of their recommendations. The results confirmed that the age at sexual maturity of both stocks declined from around 10-12 years for the mid- 1940s cohorts to around 7-8 years for the early 1970s cohorts.

The Committee identified two additional potential methodological issues in SC/56b/IA01 not addressed in SC/56b/Rep02 (the JARPA II review) which could affect the reliability of the long-term trends and suggestions were made to investigate these issues (Annex G item 2.1.1). The Committee **endorses** the suggested workplan in SC/65b/IA01 to address the rest of the JARPA II review panel recommendations.

SC/56/IA02 described the proportion of pregnant animals among mature females (PPF) in Antarctic minke whale catches for two biological stocks using samples collected during 1987/88-2004/05 JARPA and 2005/06-2010/11 JARPA II surveys. The conducted analysis was a revision of SC/F14/J09 which was presented to the JARPA II Review Workshop (SC/56b/Rep02). The PPF of both stocks appeared stable at around 0.9.

In discussion, the Committee first considered how the measured pregnancy rate might be related to the actual birth rate. In response, the authors stated that they will be reporting on results from a feasibility study to examine the possibility of documenting recent lactation by observation of histological samples of the mammary gland to develop a potentially more appropriate index of reproductive success.

The Committee further discussed the possibility that, if birthrate could be inferred, then it would be possible to compare trends and absolute levels of the *per capita* surviving calf production estimates from SCAA estimates of birth and initial calf survival proportions. The difference might be indicative of trends in post-birth juvenile survival. Butterworth and Bravington offered differing views on the utility of and inferences to be drawn from this particular pregnancy dataset in the context of the In-Depth Assessment (Annex G, appendix 2).

10.1.1.2 ABUNDANCE AND DISTRIBUTION

When estimating abundance of Antarctic minke whales in CPII and CPIII, it was presumed that some proportion of the population of Antarctic minke whales was distributed within the sea ice fields, away from where vessels were able to survey. Though the Committee has agreed upon abundance estimates for the 'ice-free' surveyed area, it is still not known what proportion of Antarctic minke whales are in sea ice.

SC/65b/IA15 described Australian supported aerial surveys and subsequent abundance estimates to quantify the proportion of Antarctic minke whales that may be in summer sea ice regions of East Antarctica. Using generalised additive models, model-based estimates of uncorrected abundances and densities (uncorrected for availability bias) were produced. Using 'prorated' abundances from IDCR/SOWER, leveraged on simple estimates of encounter rate from open water north of the aerial survey region, there is some evidence that between 10 and 50% of the minke population can be found within 93-113°E inside ice during the 2009/10 summer.

SC/65b/IA16 provided an overview of the Antarctic minke whale data obtained from five helicopter surveys conducted from *RV Polarstern* between 2002 and 2013 in the Weddell Sea and around the Antarctic Peninsula in regions of varying ice concentrations. The results show high variability in predicted minke whale numbers over space and time, with a strong relationship to the 15% ice edge and a longitudinal

gradient, with more minke whales predicted in the west of the survey area than in the east, around the 0° meridian.

The Committee noted these two studies used different definitions of 'the ice edge'. The authors stated in the future they will use the 3% level which corresponds to the IDCR/SOWER 'ice edge'.

The Committee noted that without some idea of availability bias for Antarctic minke whales, across a range of different sea ice concentrations and types, the ability to judge the true numbers of animals in sea ice areas is limited. After discussion, the Committee strengthened its previous conclusions that there is no reliable basis for quantitatively extrapolating these results to other areas and to the past. Nevertheless, these studies open the possibility of looking at variability in proportions-in-ice as a function of changing ice-coverage.

The Committee noted that currently availability bias for Antarctic minke whales has not been evaluated. To do so the Committee **agrees** that two types of information needed are: (1) information on time-at-depth results across a range of ice conditions; and (2) information on the *visibility* of minke whales from the air as a function of depth and water clarity. The first data need may be met by using satellite-tag information like that in Friedlaender *et al.* (2014), discussed in Item 13. The second data need might be harder to resolve. At least in principle, though, it could be addressed as a gigantic Secchi disk experiment, using a whale-shaped target moored underwater at known depth and over-flights from a fixed-wing, helicopter, or drone aircraft, presumably somewhere close to an Antarctic land base. It might also be possible to derive an estimate of availability bias from forward sighting data. An Intersessional Correspondence group was established to explore these methods and data.

SC/65b/IA14 investigated possible responsive movement of whales to observer vessels by analysing tracks of humpback and Antarctic minke whales conducted from the *RV Polarstern* in the Antarctic.

In discussion, the Committee recalled that the possibility of responsive movement in Antarctic minke whales had been considered several times in the past. Overall, no clear effects had been found. Notwithstanding some of the interpretational difficulties with these data, the Committee **welcomes** the prospect of more data coming from an extension of this paper, accompanied by information on environmental conditions.

The Committee also discussed acoustic detections of Antarctic minke whales as another way that could potentially reveal distribution and possibly abundance information. Risch *et al.* (2014) documented the sound referred to as the 'bio-duck' sound is produced by the Antarctic minke whale. The Committee noted that, now that the bio-duck sound is unmasked, it may be possible to scrutinise past, present and future hydrophone and sonobuoy data for evidence of minke whale distribution and variability, since the frequency range of the calls appears to be detected and recorded with the listening devices.

10.1.1.3 STOCK STRUCTURE

Two papers, SC/65b/SD1 and SC/65b/IA13, contain new genetic information on stock structure in the Antarctic minke whale, where the technical aspects were discussed under Item 11. SC/65b/IA13 presented an integrated approach, by using

genetic and morphometric data, for estimating longitudinal segregation of two populations for Antarctic minke whale. The result indicates that the spatial distribution of the two populations has a soft boundary in Area IV-E and V-W, which depends on year and sex.

The Committee noted (as in previous years) that the results from the SC/56b/IA13 approach should be useful for the In-Depth Assessment, once the model has been embedded in a random-effects framework as the authors intend, assuming that a consistent signal between the two types of data can be shown, and diagnostics are considered. The Committee agreed that it would be reasonable to continue to use the two-stock hypothesis as a default for In-Depth Assessment, although further data might of course change the picture in future.

10.1.2 Consideration of factors that may drive Antarctic minke whale distribution and abundance

SC/65b/IA10 reported relative densities in a spatial context of the circumpolar distribution of baleen whales using the data from CPII and CPIII of IDCR/SOWER. Generalised additive models (GAMs) and available climatological data were used to estimate the relative density. These models suggest that the spatial extents of blue, fin, humpback and southern right whales expanded throughout the time from CPII to CPIII, while that of Antarctic minke whales shrank. The spatial distribution of sei whales was relatively constant between CPII and CPIII, but it was difficult to make any conclusion because of the small sample size.

The Committee **welcomes** this paper, particularly as it will eventually be a contribution to the SOWER Special Volume. In discussion it was noted the difficulty of trying to model relationships between environmental covariates and species distributions, specific issues to be considered were identified in Annex G.

The Committee considered that Additional Variance (AV) should be further explored when trying to explain the inter-survey differences of the Antarctic minke whale abundance based on the IDCR/SOWER CPII and CPIII surveys. Overall, the inter-survey differences are too large to be explained in terms of (i) a single common trend in abundance across the whole Antarctic, and (ii) the intrinsic CV of the estimates; this 'unexplained' variation is known as Additional Variance. The Committee considered that there are really only three plausible causes: (1) Changes in longitudinal distribution from year to year; (2) Changes in the proportion of Antarctic minke whales in the ice (and therefore unavailable to SOWER surveys), both in time and by Area; and (3) 'Area-specific changes'. Ways to address investigate these three possibilities were discussed in Annex G.

10.1.3 Application of statistical catch-at-age (SCAA) models

SC/65b/IA03 updated the Statistical Catch-at-age Analysis (SCAA) for Antarctic minke whales in response to recommendations from the JARPA II review panel. Parameters of the model (annual deviations about the stock-recruitment relationship, changes over time in carrying capacity, density-dependence parameters (productivity and carrying capacity), and parameters which determine growth by stock, age-specific natural mortality by stock, and vulnerability by area and 'fleet') are estimated by fitting the model to data on catches, catch-at-length, conditional age-at-length, and estimates of absolute and relative abundance. This

version of the SCAA provided analyses based on updated JARPA and JARPA II abundance indices, included results for three ways to model natural mortality-at-age, explored the sensitivity of time-trajectories of model outputs to assumptions regarding the age-averaged rate of natural mortality, explored the implications of not having the JARPA and JARPA II data, and provided results for a revised reference model which assumed that the updated JARPA and JARPA II indices are absolute rather than relative indices of abundance. The SCAA model is able to mimic all of the data sources adequately and indicates that Antarctic minke whales in the assessed area increased from 1930 until the mid-1970s and have declined thereafter, with the extent of the decline greater for minke whales in Antarctic Areas III-E to V-W than for those further east. The estimates of natural mortality (with asymptotic standard deviations) from the 'new reference case' assessment of SC/65b/IA3 for the I stock for ages ≤ 3 , 10-20 and ≥ 40 are 0.077yr^{-1} (0.016yr^{-1}), 0.048yr^{-1} (0.005yr^{-1}), and 0.107 (0.005yr^{-1}) respectively while the corresponding values for the P stock are 0.074yr^{-1} (0.016yr^{-1}), 0.046yr^{-1} (0.005yr^{-1}), and 0.103yr^{-1} (0.005yr^{-1}) respectively. Given that carrying capacity for minke whales is estimated to have changed over time, measures such as population size relative to the (current) carrying capacity are not immediately straightforward to interpret. However, the results of SCAA can be interpreted in the context of trends in abundance. The new reference case model implies that the total 1+ population size increased annually by 1.9% (SE 0.50) (stock I) and 2.1% (SE 0.70) (stock P) per annum between 1945 and 1968. Numbers of 1+ animals were estimated to have declined by 54% (stock I) and 35% (stock P) from 1968 to 2001. SC/65b/IA03 confirms that the ability to estimate trends in abundance and natural mortality rely on the availability of age and length data from the period of both commercial and Scientific Permit catches.

In discussion, the insensitivity of the results of the SCAA to ignoring the JARPA and JARPA II index data was highlighted, noting that previous analyses based on Virtual Population Analysis had indicated that information on trends in abundance are required to distinguish between different values for natural mortality. Reasons for the lack of sensitivity include the fact that the JARPA indices are fairly imprecise, and, when age and length data are included, then the JARPA abundance indices do not convey much extra information about trends.

Some members, noting the estimates above for natural mortality, held the view that this allowed inferences to be drawn concerning minimum values for MSYR for this species, essentially on a similar basis to that used in the MSYR rate review. They added that the results from SC/65b/IA03 would be of particular importance in conditioning *Implementation Simulation Trials* for these minke whale populations, as well as for further development of multi-species models.

Japanese scientists commented that the analyses of SC/65b/IA03 confirmed that age and length data collected during JARPA and JARPA II had allowed natural mortality for Antarctic minke whales to be estimated satisfactorily, as had been a key objective of JARPA.

Other members commented that, since the SCAA analysis concluded that the value of MSYR could not be estimated by

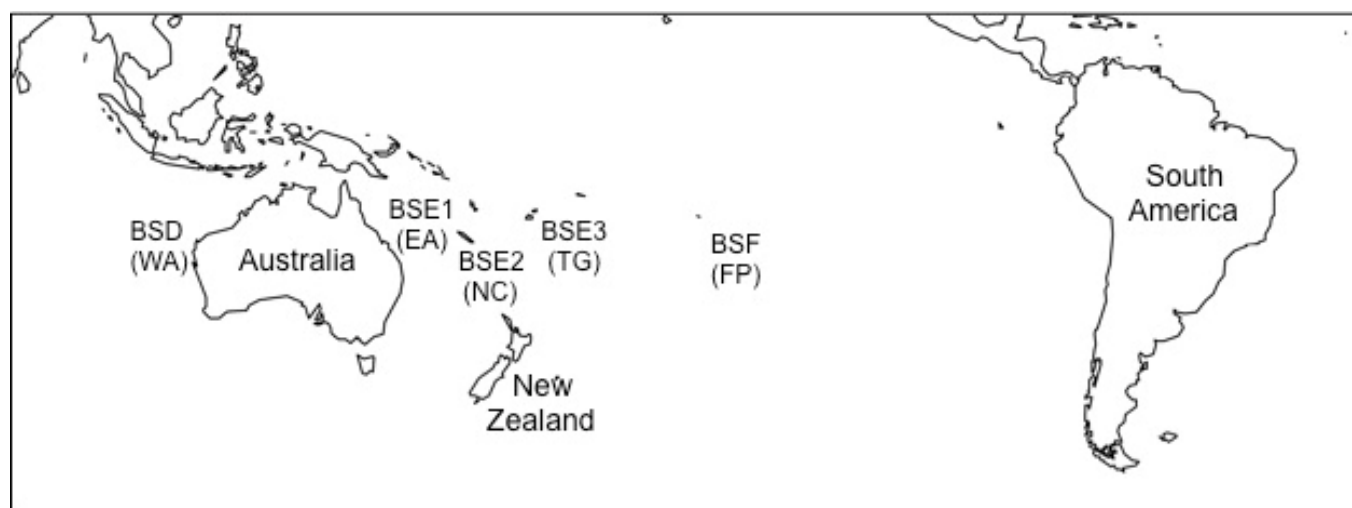

Fig. 1. Distribution of humpback whales breeding stocks grounds BSD, BSE1, and BSO (BSE2, BSE3 and BSF2). Note the following abbreviations: WA = Western Australia, EA = Eastern Australia, NC = New Caledonia, TG = Tonga and FP = French Polynesia.

the SCAA model due to lack of contrast (i.e. a wide range of MSYR values were consistent with the data under this model), it was not valid to attempt to exclude parts of the range of MSYR values from simple inspection of the model results. Therefore, it is not valid to use the SCAA results draw inferences about the level of MSYR or r_{max} .

10.1.4 Future directions for the in-depth assessment

After many years of working towards an in depth assessment of Antarctic minke whales, which has focused on the Indo-Pacific region of the Southern Ocean, the Committee can now provide conclusions and determine what outstanding issues are feasible and/or worthwhile to address in the future. The Committee noted that there were still research issues to complete, but that should not preclude the ability to provide conclusions on the assessment. Because the present In-Depth Assessment of the Indo-Pacific Antarctic minke whale has been so protracted, results are currently scattered across many different volumes of Committee reports. Thus, to complete the In-Depth Assessment of Antarctic minke whales in the Indo-Pacific region of the Antarctic next year, the Committee established an intersessional working group to summarise the state of knowledge.

The situation in the rest of the Antarctic is very different, as it has been decades since the Committee last attempted an assessment of the Antarctic minke whales in those regions. There is less data for other regions than the Indo-Pacific region, so feasibility needs to be considered before undertaking the In-Depth Assessment. It was noted that results from the Indo-Pacific might be helpful in assessing the other regions. An intersessional working group was established to summarise available data and knowledge for these other Antarctic regions.

10.2 Southern Hemisphere humpback whales

The report of the IWC Scientific Committee on the assessment of Southern Hemisphere humpback whales is given in Annex H. The Committee currently recognises

seven humpback whale breeding stocks (BS) in the Southern Hemisphere (labelled A to G IWC, 2011e), which are connected to feeding grounds in the Antarctic (Fig. 1). An additional population that does not migrate to high latitudes is found in the Arabian Sea. Assessments of BSA (western South Atlantic), BSD (eastern Indian Ocean) and BSG (eastern South Pacific) were completed in 2006 (IWC, 2007). However, it was concluded at that time that BSD might need to be re-assessed with BSE and BSF in light of mixing on the feeding grounds. An assessment for BSC (western Indian Ocean) was completed in 2009 (IWC, 2010c) and for BSB in 2011 (IWC, 2012c).

10.2.1 Assessment of breeding stocks D, E and F

In 2011, the Committee initiated the re-assessment of BSD in conjunction with assessments of BSE and BSF. As shown in Fig. 1, these correspond to the humpback whales wintering off Western Australia (BSD), Eastern Australia (BSE1) and the western Pacific Islands of Oceania, including New Caledonia (sub-stock BSE2), Tonga (sub-stock BSE3), the Cook Islands and French Polynesia (BSF2). For simplicity, the combination of BSE2, BSE3 and BSF will be referred to herein as Oceania (BSO). These are the last breeding stocks remaining in the Comprehensive Assessment of Southern Hemisphere humpback whales, and their assessments were to be completed as a matter of high priority this year.

10.2.1.1 RESULTS OF MODELS DEVELOPED INTERSESSIONALLY

The Committee had previously recommended that work be carried out intersessionally to facilitate the completion of the assessment. This included: (1) obtaining a minimum bound on the absolute abundance of BSD (see IWC, 2014c) and (2) developing a suite of assessment models.

With respect to (1), the Committee used a preliminary estimate from Hedley. For reasons discussed in Annex H, Item 3.1, the value was considered tentative and requiring future confirmation.

Fig. 2. Diagrammatic representation of the alternative three-stock model used as the base case in the final assessment of breeding stocks BSD, BSE1 and BSO. Antarctic Areas V and VI are shown for reference.

Table 12

Posterior median values of key model parameters for the base case model with 90% probability intervals in brackets.

	BSD		BSE1		BSO	
r	0.090	[0.053, 0.104]	0.105	[0.103, 0.106]	0.091	[0.071, 0.101]
K	21,686	[19016, 29383]	26,133	[21605, 29033]	14,115	[10198, 19651]
γ	-		0.068	[0.007, 0.190]	-	
N_{\min}	824	[461, 3685]	237	[203, 272]	132	[103, 250]
N_{2012}	19,264	[17,553, 24012]	16,366	[14674, 18034]	5,072	[4456, 6040]
N_{\min}/K	0.039	[0.023, 0.128]	0.009	[0.008, 0.011]	0.010	[0.007, 0.014]
N_{2012}/K	0.904	[0.739, 0.984]	0.634	[0.561, 0.729]	0.371	[0.238, 0.535]
N_{2020}/K	0.984	[0.883, 0.998]	0.915	[0.872, 0.950]	0.648	[0.409, 0.846]
N_{2040}/K	1.000	[0.991, 1.000]	1.000	[0.999, 1.000]	0.993	[0.926, 0.999]

With respect to (2), assessment models developed intersessionally included: (1) a single stock model for BSD for a range of choices of the Antarctic feeding ground catches, (2) several two stock models and (3) a three-stock model of BSD, BSE1 and Oceania (BSO). These models are summarised in detail in SC/65b/SH04rev and SC/65b/SH04Addendum.

10.2.1.2 SPECIFICATION AND EVALUATION OF ADDITIONAL MODEL RUNS

The assessment began with a pre-meeting on 10-11 May and continued. It was agreed that a three-stock model (Annex H, fig. 1) best captured the uncertainty in high latitude catch allocations across the three breeding stocks.

Key issues addressed in the pre-meeting included:

- (1) While the N_{\min} constraint for BSO tended to be problematic intersessionally, the use of 'private' haplotypes (e.g., IWC, 2011, Annex H, appendix 2) resulted in markedly better model fits.
- (2) Differences were noted (particularly for Oceania) between the high latitude catch allocations that best fitted the three-stock model and the results of a mixed-stock analysis that allocated high latitude mtDNA samples to low latitude breeding grounds (Annex H, appendix 2). The assessment proceeded by not fitting the model to the genetic data, and future work to address this question was identified.

- (3) Whilst the original three-stock model was biologically more plausible than a one or two-stock model, it required estimation of 6 mixing parameters. An alternate (simpler) three-stock model (Fig. 2) resulted in parameters that were relatively well estimated and so it was used as the base case in the final assessment of BSD, BSE1 and BSO.

With agreement reached on the base case model specifications (Annex H, table 1), sensitivity runs were carried out to evaluate the effects of: (1) shifting the Antarctic catch boundaries; (2) modifying the bounds of the BSD absolute abundance estimate; (3) alternative treatment of New Zealand catches and (4) augmenting the Noad *et al.* (2011) relative abundance data for BSE1 with Forestell *et al.* (2011) mark-recapture data in the model fit. The details of these sensitivities are presented in Annex H, item 3.1.2.3.

10.2.1.3 FINAL ASSESSMENT MODEL RESULTS

Final assessment results and sensitivity runs are provided in Annex H, Appendix 3. The results for the base-case model are shown in Table 12. Plots of the median population trajectories for the base case three-stock model are given in Fig 3.

The Committee notes that the results of the model runs did not vary substantially under the different sensitivity scenarios, except if the minimum of the prior for the BSD absolute abundance in 2008 was increased appreciably. Further discussion is provided in Annex H, Item 3.1.3.

10.2.1.4 CONCLUSION AND RECOMMENDATIONS

The posterior median estimate of population status in 2012 relative to pre-exploitation abundance suggests that BSD is approaching pre-exploitation levels (90%, 90% probability interval (PI): 74-98%). However, the results are somewhat sensitive to the lower bound on BSD absolute abundance estimates for 2008, with greater abundance resulting in a slightly greater level of recovery. Given that the available lower bound estimate was preliminary, the Committee **recommends** future work to further refine that value.

A preliminary assessment of BSD was completed in 2006 and had concluded that there had been a substantial increase since protection (IWC, 2007). However, it was agreed at that time that the assessment modelling results should be re-evaluated in the future. It was anticipated then that this would require clarification of the stock structure of Oceania and the extent of mixing at high latitudes, as catch allocation would perhaps be influenced by mixing with BSE1. The three-stock models presented in the current assessment address the concerns expressed previously by allowing for mixing of neighbouring breeding stocks in the Antarctic feeding areas. Although direct comparisons between the two assessments should be viewed with caution due to differences in model inputs and assumptions, the results of the 2006 Fringe model for BSD are very similar to the current base case assessment (Annex H, Appendix 3, Table 2).

The base-case three-stock assessment results for BSE1 and Oceania were not sensitive to the assumption of BSD absolute abundance and suggested recovery towards pre-exploitation levels to be 63% (90% PI: 56-73%) and 37% (90% PI: 24-54%), respectively.

The Committee notes that the current assessment of BSO was valuable in terms of understanding the broader aspects of population status. However, complexities in Oceania require further investigation due to inadequate stock structure definition across the broad area, a lack of population trend data for most of the region, and a lack of resolution and understanding of connectivity in eastern Oceania.

As noted above, there was an inconsistency between the high latitude catch allocations that fit the model best and the mixing proportions of breeding stocks in the Antarctic as suggested from genetic data. Further work on this question would be valuable, although unlikely to alter the outcome of this assessment. For the future, the Committee **recommends** further examination of available genetic data, assumptions and analytical approaches, as described in detail in Annex H, item 3.1.4.

In conclusion, the Committee **agrees** that its assessment of breeding stocks BSD/BSE1/BSO had been completed. It acknowledges the efforts of all those who helped to bring the assessment to a conclusion. This also concludes the Comprehensive Assessment of Southern Hemisphere humpback whales. Noting that this circumpolar assessment took eight years to complete, the Committee **recommends** that assessment results for all Southern Hemisphere breeding stocks be compiled and synthesised for discussion next year.

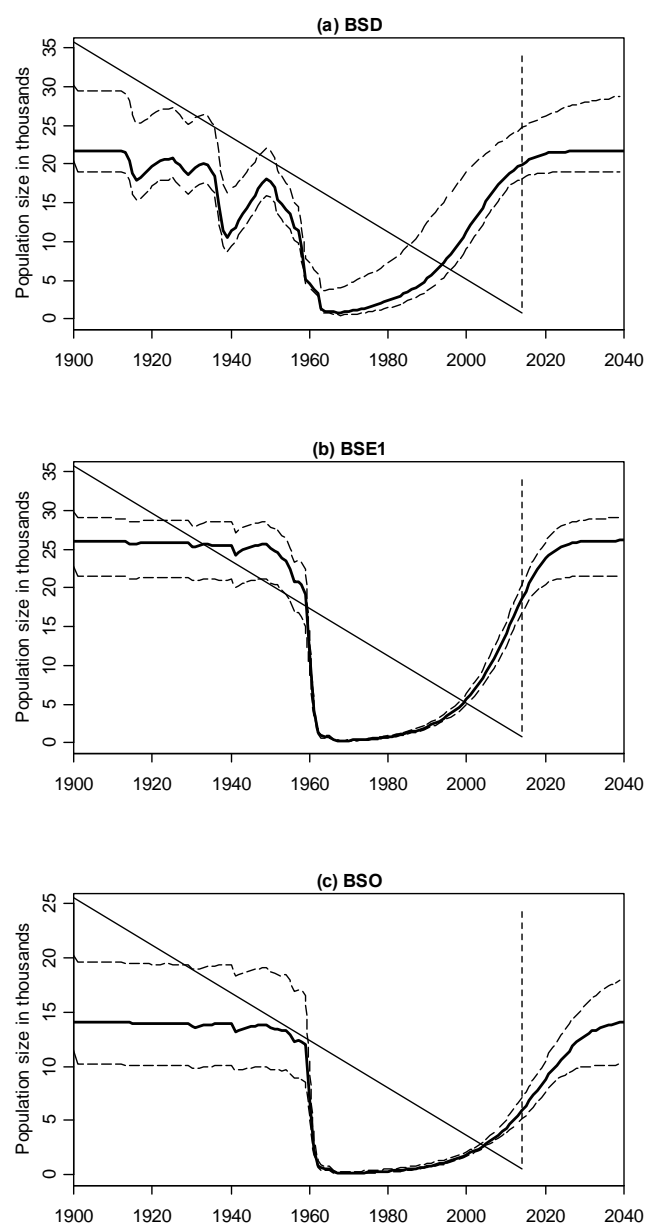

Fig 3. Median population trajectories for the base case three-stock model for breeding stocks BSD, BSE1 and BSO. 90% probability envelopes are indicated by the dashed lines.

10.2.2 Review new information on other breeding stocks

10.2.2.1 BREEDING STOCKS D, E, F

The Committee received four papers with new information on BSD, BSE and BSF, as described below. These papers, and their associated discussion, can be found below and in Annex H, Item 3.2.1. The Committee **welcomes** this new information noting that it remains consistent with the assumptions used in the assessment of breeding stocks BSD, BSE1 and BSO.

Polanowski *et al.* (2014) reported a new epigenetic technique for estimating humpback whale age from skin biopsy samples. The assay has an R^2 of 0.787 ($p = 3.04e-16$) and predicted age with a standard deviation of 2.99 years. It correctly ordered parent-offspring pairs in more than 93% of

cases. Age was estimated for 63 individuals off East Australia in 2009 and compared results to age profiles for the same population from 1952-1962. Although several caveats were noted, the authors concluded that the high apparent proportion of young animals in 2009 was interesting and warrants further study.

SC/65b/SH07 described a genetic study of humpback whales from Cook Strait, New Zealand. Samples from New Zealand (167 individuals) were compared to Oceania (1,052 individuals) and east Australia (865 individuals). DNA registers revealed six matches (and the least genetic difference) to New Caledonia. Five matches were made to east Australia, but none to any other part of Oceania. Further information is provided in Annex H and the Committee's discussion of the stock structure implications can be found in Annex I.

Orgeret *et al.* (In review) studied the population growth rate of humpback whales at New Caledonia. The results indicated a constant yearly growth rate of 1.15 (1.11; 1.20). This was higher than the maximum rate of increase for humpback whale populations (Zerbini *et al.*, 2010), but the authors hypothesised that it includes a contribution due to immigration from other areas. The Committee **welcomes** this paper and commented that analyses of this nature are important for understanding the effects of animal movement on estimates of population parameters.

SC/65b/SH10 introduced a new crowd-sourcing website, *Match My Whale*, which encourages citizen scientists to score and match humpback whale fluke photos in order to facilitate future cataloguing efforts for BSD and BSE1. The Committee notes the potential value of this project to harness increasing public interest in matching humpback whales online.

10.2.2.2 BREEDING STOCK G

SC/65b/SH15 provided an update on humpback whale research in the Gulf of Chiriqui, western Panama. This is the northernmost breeding area of any Southern Hemisphere humpback whale population, and is also used by whales migrating from feeding areas off California-Oregon-Washington in the Eastern North Pacific. The authors describe the continuation of their long-term monitoring efforts in 2013, which involved greater encounter rates, larger group sizes, and more photo-identification data collected than in prior years. The authors highlighted the importance of continued monitoring to understand population trends and underlying factors.

The Committee **agrees** that genetic studies in this area would be of particular interest given the use of this breeding ground by Northern Hemisphere animals, as well as by individuals from different Southern Hemisphere feeding aggregations.

10.2.2.3 BREEDING STOCK B

Rosenbaum *et al.* (2014) examined the movement of BSB humpback whales and their overlap with anthropogenic activities in the South Atlantic Ocean. This paper reported on the habitat use of three whale cohorts satellite tagged off Gabon and concluded that breeding areas in the eastern Atlantic were extensive and extended north of Gabon late in the breeding season. Also observed, for the first time, was direct migration between West Africa and sub-Antarctic feeding areas. Details can be found in Annex H., item 3.2.4.

10.2.2.4 FEEDING GROUNDS

Two IWC-SORP papers received by the Committee provided data on humpback whales in Antarctic and sub-Antarctic waters. SC/65b/SH05 provided an update of the CETA project which was carried on the continental shelf off Adélie Land in Area V. SC/65b/SH16rev reported on data collected from visual and acoustic observations from the Argentinean vessel *Tango* SB-15 during February 2014. Details of those cruises are provided in Annex H, item 3.2.5.

SC/65b/IA10 described an analysis of the circumpolar spatial distribution of humpback whales based on IDCR/SOWER CPII and CPIII data. A generalised additive model (GAM) was used to examine changes in the abundance of humpback whales among areas, relative to other species and environmental data. Details are provided in Annex H, item 3.2.5.

SC/65b/SH18 reported estimates of abundance and trends of humpback whales in the Magellan Strait off southern Chile. The results suggested an abundance of 88 individuals (95% CI: 81-95) in 2012 with a median population growth rate of 3.2%/year across the study, but close to zero in the past seven years. The authors concluded that this population is likely small and appears to be stable. The potential effect of ship strikes on this population was also examined. The Committee **welcomes** and **encourages** the continuation of this study. Further discussion is provided in Annexes E, H, and J.

10.2.3 Antarctic Humpback Whale Catalogue

SC/65b/SH03 presented the interim report of the IWC Research Contract 16, the Antarctic Humpback Whale Catalogue (AHWC). During the contract period, the AHWC catalogued 761 photo-id images representing 614 individual humpback whales submitted by 21 individuals and research organisations. Matches were made between BSG and the Antarctic Peninsula (18) and between BSG and the Chilean feeding area (3). Within-region re-sightings were identified in BSC3 (2), BSG (18) and the Antarctic Peninsula (7). Two individuals with 28 year sighting histories, the longest in the database, were identified during the contract period, and sixty-eight individuals had re-sightings spanning ten years or more. The fluke photographic collection has approximately doubled in size in the past five years, and now consists of 9,007 photographs of 5,923 individual whales.

The Committee has supported the valuable work of the AHWC in the past and **strongly endorses** its continuation.

10.2.4 Workplan

With the completion of the assessment of humpback whale breeding stocks BSD/BSE1/BSO, the Committee **agrees** that the Southern Hemisphere humpback whale assessment has been concluded. However, given that this circumpolar assessment had taken eight years to complete, the Committee **recommends** a thorough synthesis of assessment results and unresolved questions for discussion in SC/66a.

It further **recommends** that focus on the planning of the future direction of the Sub-committee on Other Southern Hemisphere Whale Stocks is given next year. Topics would include the feasibility of conducting assessments of other Southern Hemisphere species and consideration of future assessments of humpback whales. As foundation, a literature review is **recommended** to identify all new information

produced on Southern Hemisphere humpback whales since the Comprehensive Assessment began in 2006.

The Committee **recognises** the long-term value of photo-identification catalogues to support future assessments and **recommends** that work continue on the Antarctic Humpback Whale Catalogue. Consideration was also given to the importance of evaluating data needs to better inform future assessments. A modelling exercise is **recommended** as one means of informing this question.

Work is also **recommended** to address questions arising specifically from the assessment of BSD/BSE1/BSO. These included work to evaluate (1) the available genetic data, assumptions and analytical approaches for establishing mixing proportions of breeding stocks in the Antarctic and (2) the minimum abundance of BSD, which is only currently available as a preliminary value, but important to the interpretation of assessment results.

10.3 Southern Hemisphere blue whales

10.3.1 Review new information

10.3.1.1 ANTARCTIC BLUE WHALES

10.3.1.1.1 CRUISE REPORTS

SC/65b/SH01 reported on the South African National Antarctic Programme 2013/2014 cruise to the 000°-020°E Antarctic coastal region. Based on the relatively high numbers of blue whales sighted, the authors concluded that this region of the Queen Maud Land coast is a hotspot for Antarctic blue whales. The Committee **congratulates** the authors. Discussion held on data sharing and further cruise details can be found in Annex H, Item 3.2.5.

SC/65b/SH05 reported six sightings of Antarctic blue whales at the edge of the continental slope and in the Adélie depression. Three of the animals were individually photo-identified, one of which was re-sighted during the IWC-SORP Antarctic blue whale voyage in the Ross Sea region.

SC/65b/SH16 reported that a single blue whale was seen on one occasion on the Argentinean IWC-SORP Tango cruise in the Scotia Sea near Islas Orcadas del Sur (South Orkney Islands).

10.3.1.1.2 ANTARCTIC BLUE WHALE CATALOGUE

SC/65b/SH20 reported on catalogue comparisons of 52 individual Antarctic blue whales photographed between 2005/2006 and 2012/2013 during JARPA II from IWC Management Areas IIIIE, IV and V. Three whales matched individuals in the Antarctic Blue Whale Catalogue with elapsed time intervals of 2 years (for 1 whale) and 7 years (for 2 whales). This brings the total of photo-identified Antarctic blue whales to 354. This work provides data for capture-recapture estimates of abundance as well as information on the movement of individual blue whales within the Antarctic region.

The Committee **thanks** the authors and **recognises** the contribution of this on-going work. It also **recommends** that blue whale research be prioritised in upcoming Japanese Southern Ocean sighting cruises.

10.3.1.1.3 ACOUSTIC STUDIES

The IWC-SORP Antarctic Blue Whale Project (ABWP) reported a number of developments in the use of directional (DIFAR) sonobuoys to give bearing information to baleen whale calls. This has a number of uses including locating

animals for further study, such as photo-id, but also for applications related to estimates of abundance derived from acoustic data. DIFAR sonobuoys were used successfully during the 2013 Antarctic Blue Whale cruise to locate blue whales from distances of hundreds of kilometres and hence the steering committee of the ABWP has encouraged their use more widely within the project.

Papers were presented describing software tools to facilitate the use of DIFAR to obtain bearing information in real time (SC/65b/SH06), results of experiments to measure the accuracy and precision of a sonobuoy-based localisation system (SC/65b/SH08), and methods to estimate the drift of sonobuoys (SC/65b/SH09). Most DIFAR sonobuoys send data via VHF radio link back to an aircraft or nearby vessel. While there are some general purpose tools available for working with DIFAR signals, full analysis has required a limited number of bespoke systems, including a more user-friendly software system.

Measurements of the source levels of blue whale calls and propagation loss are important for determining the likely distances over which whale calls may be detected. SC/65b/SH11 presented preliminary estimates of source levels for the first (unit A) 25-29Hz component of Antarctic blue whale 'Z' calls. The authors concluded that with the source levels reported, and under assumed propagation conditions, these calls can be detected from thousands of kilometres away.

Miller *et al.* (2014) explored the Doppler effect as a potential explanation for the long-term linear decline in blue whale calls. Analysis suggested that this was unlikely to fully explain the observations of intra-annual pattern in the frequency of Antarctic blue whale song. Details of this study can be found in Annex H.

Taking these methodological papers as a whole, the Committee notes that the results had confirmed the potential to detect blue whales at over 1,000km in the Southern Ocean. It **recognises** the advancements that these methodologies have made towards improved abundance estimation of Antarctic blue whales and **encourages** the continuation of this important research.

Shabangu and Findlay (2014) described efforts to compile 7,500 sonobuoy acoustic data files from over 700 stations across IWC SOWER Antarctic cruises from 1996/1997 to 2008/2009 in Areas I-VI. Also included were data from three blue whale cruises off Australia, Madagascar and Chile. A total of 1547.76 hours of recordings have been reviewed and blue whale vocalisations have been detected in 55% of the 7,501 recorded files.

Van Opzeeland *et al.* (In press) reported on the SOHN initiative of the IWC-SORP Acoustic Trends Project. This is a long-term program to examine trends in blue whale and fin whale in the Southern Ocean through passive acoustic monitoring. The initiative proposes a circumpolar network of autonomous acoustic recording stations surrounding the Antarctic continent with at least one recording site in each IWC management area. Practical recommendations were also given to increase the efficiency of passive acoustic data collection in Antarctic waters.

10.3.1.4 ABUNDANCE ESTIMATION

Part of the planning process for the IWC-SORP Antarctic Blue Whale Project has been to evaluate how much effort would be required under various survey methods to obtain a precise estimate of circumpolar abundance. The Committee received four papers on such methodological considerations of abundance estimation. The Committee notes that pre-survey analyses such as these are important and are **encouraged**.

SC/65b/SH13 explored the precision of a circumpolar abundance estimate that might be expected from a line-transect survey, and how it might be predicted for varying amounts of survey effort, given population increases. The precision for 6-year research programmes was too low to be considered useful, but the predicted precision of a 12 year program was 27%. The benefits and disadvantages of a line transect approach were discussed.

SC/65b/SH14 predicted the precision and bias of estimates from a hypothetical mark-recapture survey programme. It suggested a precision of the abundance, at the mid-point of the programme, of between 0.2 and 0.3 if passive acoustic tracking were utilised to increase the encounter rate. A 12 year study would be required, but surveys would not necessarily have to occur every year. The authors highlighted that care would be required to ensure that mark-recapture assumptions were met.

SC/65b/SH17 proposed that if parent-offspring pairs could be identified genetically from biopsy samples then these 'recaptures' could be accommodated in an extended mark-recapture model and improve greatly improve precision without any additional survey effort. The model could be made robust against bias arising from un-modelled heterogeneity, without inflating the CV. Precision could be improved further using epigenetic aging techniques (Polanowski *et al.*, 2014) to tell which animal is the parent and which the offspring.

The Committee discussed the relative priority of biopsy and photo-identification sampling to achieve mark-recapture goals, as well as the availability of mark-recapture models that combine genetic identity and photo-ID information. Details can be found in Annex H.

Peel *et al.* (2014) evaluated acoustics as a tool to increase the encounter rate in mark-recapture surveys. Encounter rates were predicted using a discrete-time individual-based simulation of whales and survey vessel. The results suggested that passive acoustics should provide a 1.7–3.0 fold increase in encounter rate of Antarctic blue whales over visual-only methods.

Olsen *et al.* (In press) presents a mark-recapture analysis of Antarctic blue whale photographs taken on 15 IDCR/SOWER cruises from 1991/92 to 2008/09. Circumpolar abundance was estimated at 3,151 (95% CI: 530-24,113) from left side images and 4,286 (95% CI: 1,923-9,802) from right side images, both with large confidence intervals and based on five recaptures. For Area III, the corresponding estimates were 1,318 (95%CI: 514-3,716) from left side images and 939 (95%CI: 421-2,323) from right side images. The Committee **welcomes** this analysis, which provides the first abundance estimates of Antarctic blue whales since Branch (2007). It **agrees** that the authors be

invited to the Scientific Committee in the future to discuss this work.

10.3.1.5 PYGMY-TYPE BLUE WHALES

SC/65b/SH02 investigated evidence that blue whales have used the South Taranaki Bight in New Zealand as a foraging ground over the last 10 years. The authors concluded that photo-identification, biopsy sampling; environmental and prey data collection and behavioural observations in 2014 strongly supports this hypothesis, but that more research is needed.

The Committee recommends work to clarify the population identity of blue whales observed off New Zealand, noting that the relationship among pygmy blue whales in different areas of the Southern Hemisphere continues to be unclear and merits further investigation.

Double *et al.* (2014) reported on migratory movements of 11 pygmy blue whales between Australia and Indonesia as revealed by satellite telemetry. Individuals were tracked from between 8 and 308 days and covered an average distance of $3,009 \pm 892$ km, at a rate of 21.94 ± 0.74 km per day. The Committee notes these results on migratory movements with interest and **recommends** the continuation of this work.

10.3.1.6 CHILEAN BLUE WHALES

Galletti Vernazzani presented an update on efforts to obtain the first abundance estimates from blue whales off Chile based on photo-identification and mark-recapture techniques. The effects of different photograph quality approaches and the impact of a possible transience signal in this population are being investigated. The Committee **welcomes** this update and receiving final results next year.

10.3.2 Southern Hemisphere Blue Whale Catalogue

The Southern Hemisphere Blue Whale Catalogue is an international collaborative effort to facilitate cross-regional comparison of blue whale photo-identification catalogues. It currently includes photo-identification catalogues of researchers from major areas off Antarctica, Australia, New Zealand, Eastern South Pacific and the Eastern Tropical Pacific. These are organised into three major regions, with a regional coordinator appointed for each: (1) Australia/New Zealand/Indonesia (Salgado Kent); (2) Southern Ocean (Olson); and (3) Gulf of California/Eastern South Pacific/ETP (Galletti Vernazzani). Photos are added to the catalogue by region and the regional coordinator appoints a photo-ID expert to perform the matching. Funding is distributed between regions according to the amount of work to be done. A total of 1,101 blue whales are currently catalogued (843 from the right side, 857 from left side and 23 from flukes). The SHBWC has also identified potential improvements in procedures and matching priorities, as described in Annex H, item 5.2.1.

The Committee notes the value of the SHBWC and **recommends** its continuation. Noting that the catalogue had grown in the last few years, discussion focussed on aspects of quality control and matching processes by both the contributing institutions and the SHBWC, as detailed in Annex H. The Committee notes the importance of continued development, reinforcement and communication of SHBWC contributor protocols and terms of reference.

10.3.3 Genetic analyses

Torres-Florez *et al.* (2014) reported on genetic relationships between the whales from southeastern Pacific (SEP) areas of southern Chile, northern Chile and Eastern Tropical Pacific (ETP) and Antarctic blue whale feeding grounds. Significant differences between Antarctica and the other three areas of the SEP were found, but not between the two areas in Chile, nor the ETP. Current analyses support the hypothesis that blue whales sampled in the SEP belong to a unique population, but more data are required. Analyses now underway include eastern North Pacific blue whale samples.

The Committee discussed that, as with many areas, the population identify and structuring of blue whales in the ETP is uncertain. The intermixing of blue whales from the North Pacific, Southeastern Pacific and Antarctica provides challenges that may affect the degree of population structure that can be detected in samples from the ETP. The stock structure implications of this paper were also discussed in Annex I.

10.3.4 Work plan

The Committee **recommends** the continuation of the Southern Hemisphere Blue Whale Catalogue. It also **recommends** efforts to further develop and reinforce SHBWC protocols and to ensure clear communication of the terms of reference of the catalogue to current, pending and future contributors.

The Committee recognises that considerable new information has become available for pygmy blue whales in recent years. It **recommends** that relevant information be synthesised for SC/66a so that regions with adequate data can be identified for a potential future assessment. Further details are given in Annex H, Item 7.2.

10.4 Distribution of baleen and toothed whales in the Antarctic relative to spatial and environmental covariates

SC/65b/IA10 reported circumpolar distribution of six different species of baleen whales using the data from CPII and CPIII of IDCR/SOWER. The main purpose was not to estimate absolute abundance in the survey areas but to show relative density in a spatial context. This paper was discussed in detail under Item 10.1.2 in only the context of the Antarctic minke whale, although the analytical discussion applies to all species.

10.5 In-depth assessment of North Pacific sei whales

10.5.1 Preparations for in-depth assessment

10.5.1.1 ABUNDANCE AND DISTRIBUTION

SC/65b/IA04 provided preliminary abundance estimates for North Pacific sei whales using sighting data collected during the 2010-2012 IWC-POWER surveys. Abundance in the central and eastern North Pacific (north of 40°N, south of the Alaskan coast including both the US and Canadian EEZ between 170°E-135°W), from July to August was estimated as 34,150 (CV=0.27) for the base case scenario. In the sensitivity analysis, abundance estimates ranged from 26,926 (CV=0.205) to 32,843 (CV=0.272).

In discussion, the Committee provided some technical suggestions to improve the analysis, which are detailed in Annex G item 4.1.1. The authors indicated they will update this analysis and also provide a spatial modelling analysis of these data when the data have been validated by the IWC Secretariat.

With the completion of the first trans-Pacific series of POWER surveys north of 40°N and south of the Aleutians, the Committee concluded that there was now a sufficient basis of new abundance data for proceeding with the In-depth Assessment. The Committee **requests** that the POWER data continue to be validated by the Secretariat in the usual way.

10.5.1.2 STOCK STRUCTURE

SC/65b/IA08 reported on the uncertain stock origins of sei whales represented by 71 products purchased in Japanese market from 1997-2009. Of these products, 21 of them showed a phylogenetic affinity with available reference sequences from the Southern Hemisphere rather than the expected affinity with available reference sequences from the North Pacific. Possible explanations were explored.

In discussion, (and see Item 11), the Committee **concludes** that the possibility that the market samples reflected additional, previously undetected, genetic diversity within the North Pacific could not be ruled out at this stage and, therefore, **recommends** a direct comparison between market and JARPN II samples to (a) reconstruct phylogenetic relationships, (b) determine if there are significant difference between the market samples and the JARPN II samples and (c) investigate the levels of genetic diversity and the factors explaining possible differences. Two independent proposals were presented to address these questions and are detailed in Annex G, Appendices 3 and 4. The proponents of the two studies agreed that, for the results to be presented next year, they would focus on mitochondrial DNA sequences, because this did not require inter-lab calibration. They recognised that this would not permit individual identifications. Analysis of micro-satellites would also be performed, but not necessarily by next year.

The Committee noted that both studies depend on Data Availability requests being granted under Procedure B of the Data Availability guidelines. Because these results are needed by the Committee for the formulation of stock structure hypotheses under the In-depth Assessment to commence next year, the Committee **endorses** both proposals and **requests** their favourable consideration by the Data Availability Group and the data holders.

The Committee noted that interpretation of the market samples would be aided by knowledge of the geographical and temporal distribution of purchases and thus **requests** that date and location of purchase be included in the data set to be provided for the above studies. Several members considered that more detailed information on the origin of market samples are necessary for a better interpretation of the genetic analysis. This information should include exact location of purchase, date of purchase, labelling and proof of purchase.

The Committee also identified a need for better elucidation of the world-wide genetic structure of sei whales. Pastene reported that a collaborative study is currently underway between the ICR and the University of Groningen, (Palsbøll) to do this using samples obtained from the North Atlantic, North Pacific and Southern Hemisphere. The Committee **welcomes** this study looks forward to receiving results from this study next year.

The Committee concluded that, pending the results of the above studies, it was not yet able to formulate stock structure

hypotheses for North Pacific sei whales. This would be accomplished during the In-depth Assessment.

10.5.1.3 CATCH HISTORY

Allison reported that she had now received the remaining Canadian catches, and that these data, together with the remaining revised Soviet catches, are being entered into the IWC Catch Database. This is expected to be complete within the next 2-3 months. The catch data for North Pacific sei whales is now considered complete.

10.5.1.4 PHOTO-IDENTIFICATION

During the POWER cruises in 2011 and 2012, photo-identification data were collected for all whales that the ship approached for species confirmation and/or for biopsy sampling. Photographs were obtained with sufficient detail to catalogue 27 individual sei whales from the 2011 cruise, and 51 individuals from the 2012 cruise. There were no matches between these two years.

The Committee found these results promising but there was insufficient time to discuss them. The question of how to incorporate photo-id data into sei whale assessments was deferred and submission of a paper encouraged.

10.5.2 Work plan

Given the abundance data from POWER and JARPEN II, completed catch history, historical abundance data listed in (IWC, 2013c, p.211) and results expected from the genetic studies, the Committee **agrees** that it can proceed with the In-depth Assessment for sei whales which was expected to last two years (see Annex G item 4.2).

Since the Committee expected to specify assessment runs at the 2015 Annual Meeting, it **recommends** a proposal (Annex G Appendix 5) be funded to develop the appropriate population dynamic models and report(s) documenting the models, their structure, the data used for analysis, results and interpretation of the results to be submitted to the 2016 Annual Meeting.

10.6 Gray whales in the western North Pacific

The discussion of the rangewide workshop is given under Item 9.2.1. That workshop incorporated information from all parts of the North Pacific, including some of the information provided below.

10.6.1 New information

SC/65b/BRG12 provided a summary of sightings of western gray whales near Japan. No gray whales were seen during several cetacean sighting surveys, including JARPEN II, from spring to autumn 2013. There was a report of opportunistic sightings of gray whales in the Sea of Japan, just off the estuary of Ohkozu-Bunsuiro diversion channel, Teradomari town in Niigata prefecture in April 2014.

The Committee **welcomes** this information and **encourages** further analysis of the photographs to confirm that there were two whales and whether it was a mother-calf pair. The Committee **strongly recommends** that these photographs be compared with other photographs of gray whales from throughout the range.

SC/65b/BRG12 (also presented to the rangewide workshop) osteologically compared five specimens stranded or entangled off the Pacific coast of Japan between 1990 and 2005 (1 mature and 4 immature animals) with one whale from Ulsan, Korea and one from California, USA, which was

reported by Andrews (1914). In 2013, Nakamura and Kato examined five additional California specimens (body length, 9.3–11.7m). The Committee reiterates the view of the Workshop, **welcoming** the results of the work and **encouraging** its continuation. However, it cautions against over-interpretation of any differences between the California, Ulsan, and Japanese specimens until the sample size is increased and factors such as differences with maturity stages are addressed.

The Committee **welcomes** the annual update of the results of the collaborative Russia-US research programme on gray whales summering off Sakhalin Island, Russia (SC/65b/BRG15). The results are discussed in Annex F, item 3.2.1 2014 represents the 19th year of the study.

The Committee also **welcomes** the summary report of the annual study under the Joint Western Gray Whale Monitoring Programme off Sakhalin Island. This is also discussed under Annex F, item 3.2.1.

Although recognising some of the difficulties of sharing data, the Committee again **recommends** that the two programmes off Sakhalin should make every effort to collaborate, especially in sharing photographs and other data. Oil and gas activities are increasing near Sakhalin and the Committee **recommends** that other operators should be involved in studies and monitoring of western gray whales and follow the best mitigation practices (e.g. see Nowacek *et al.*, 2013) to ensure protection of these whales and their habitats off Sakhalin Island.

10.6.2 Other issues

There is substantial concern about interactions between gray whales and coastal fisheries in the western North Pacific. Between 2005 and 2007, four female gray whales in the western North Pacific were unintentionally entrapped and died in set nets (i.e. trap-nets) while migrating off the Pacific coast of Honshu, Japan (Kato *et al.*, 2013).

The Committee **expresses concern** about the possibility of the development of a salmon trap net fishery in the feeding areas of western gray whales off Sakhalin. Last year, the placement of these nets directly overlapped with a core portion of the feeding ground and within critical habitat for mothers with calves. An animal was seen trailing fishing gear that may have originated in this local fishery. Ilyashenko noted that his understanding is that the Russian Federation will prohibit fishing in the feeding areas of gray whales off Sakhalin Island in 2014. The Committee **recommends** that the Russian Federation and local Sakhalin authorities prohibit trap net fishing on the gray whale feeding grounds in the future.

The Committee also received information about *Exxon Neftegaz Limited's* proposed development of a temporary facility to be situated on the eastern shore of Sakhalin Island for the unloading of various modules for oil and gas activities. It **expresses serious concern** over this proposed development project and its possible immediate and cumulative impacts on gray whales, their feeding habitat and prey. The Committee **requests** additional information on the proposed project and **urges** the Government of the Russian Federation to take steps to ensure the maintenance of Piltun Lagoon.

10.6.3 Conservation advice

The Committee again **acknowledges** and **welcomes** the important work of the IUCN GWAP (Western Gray Whale Advisory Panel) as reflected in the updated report provided to this meeting and **encourages** its continuation. As previously, the Committee again **recommends** that oil and gas development activities (including seismic surveys and on- or near-shore development) in areas adjacent to or used by gray whales be undertaken only after careful planning for mitigation and monitoring. This should include a credible environmental impact assessment process prior to final decision-making. The Committee also **welcomes** the efforts of Japan with respect to the conservation and research on gray whales and **encourages** those efforts to continue.

10.7 Southern Hemisphere right whales

10.7.1 Review of new information

10.7.1.1 CIRCUMPOLAR

SC/65b/IA10 reported circumpolar spatial distribution of southern right whales using the IDCR/SOWER CPII and CPIII data. A Generalised additive model (GAM) was used to estimate the probability of occurrence. Sightings were restricted in Area II and IV both in CPII and CPIII. The abundance estimate from CPIII data in Area IV was *ca* 900.

10.7.1.2 SOUTH ATLANTIC

SC/65b/BRG06 reported on the high mortality rates at Península Valdés, Argentina in 2003, the Southern Right Whale Health Monitoring Program was established by a consortium of NGOs to monitor the health status of this population by post-mortem examinations. A total of 672 dead whales have been recorded on the Península Valdés nursery ground and surrounding areas along the Argentine coast between 2003 and 2013. At least 116 whales died in 2012, which represents the highest number of southern right whale deaths ever recorded in one calving and nursing season. The number of dead whales was 67 in 2013. As in previous years, most of the dead whales were newborn calves (97% of strandings in 2012 and 94% in 2013).

The Committee discussed the increased prevalence of kelp gull attacks at length. The authors confirmed that attacks are most common on calves and, with very few exceptions, the calves are dead before they strand. Not all stranded animals can be examined; search flights occur every 14 to 20 days so some carcasses are too decomposed before discovery. However, it is unlikely many calves are stranding outside the search area. The high variability in calf mortality between years has not been explained and is not clearly linked to environmental variation or simply variation in the number of calves born in the region. Notably 24% of the calves that died in 2012-2013 had no gull-inflicted lesions possibly because they died so quickly after birth.

The Committee **expresses concern** over the high calf mortality reported in this population and recommends that the Southern Right Whale Health Monitoring Programme continue as a high priority under the Conservation Management Plan. It also **recommends** that information on the gull control programme is reported to the IWC Workshop to be held in Puerto Madryn, Chubut in August 2014.

SC/65b/BRG7 reported on the fifteen year aerial survey monitoring programme developed by the Marine Mammal Lab. (CENPAT-CONICET). The monitoring area covers waters around Peninsula Valdes in a coastal strip of 620km.

Two difference models were used to estimate the trend of the population and in both cases the trend was positive. Also the density is increasing and the range of the whales is expanding. The Committee **welcomes** this report and **urges** that these annual surveys should be continued.

The Committee **welcomes** this study which is valuable in monitoring the recovery of this population together with changes in distribution. Even with estimates of calf mortality there would be a considerable time lag between years of high calf mortality and associated changes in the rate of population growth. High rates of very early calf mortality could explain an increase in the frequency of two-year calving intervals. This would not be anticipated in a population approaching its natural carrying capacity.

10.7.1.3 AUSTRALIA

Bannister outlined the results of a right whale aerial survey off the southern coast of Australia in late August 2013. Funded by the Australian Government through the Australian Marine Mammal Centre, Hobart, the survey, the 21st in an annual series since 1993, covered some 900 n.miles (*ca* 1700 km) close to the coastline between Cape Leeuwin, Western Australia and Ceduna, South Australia, to which the majority of Australian right whales (the 'western' subpopulation) resort in winter/spring. The 2013 cow/calf count (246 pairs) was the highest yet in the series; the calculated population growth rate, 1993-2103 was 7.39% (95% CI 4.55-10.29), and the estimated size of that part of the Australian population to be found in the survey area, based on the number of calving females recorded over the three-year period 2011-2013, is 2756. Given the likely very much smaller number in the 'eastern' Australian subpopulation, the 'Australian' right whale population probably numbers around 3000.

The Committee **welcomes** the report and **urges** that such annual survey work should continue.

10.7.1.4 SOUTH AFRICA

The Committee received a short report on the annual right whale surveys off South Africa and looks forward to a full report next year.

10.7.2 Conservation issues

The Committee received a report on progress under the Conservation Management Plans of the Southwest Atlantic and Eastern South Pacific populations of Southern right whales. The Committee congratulated the teams that have contributed to the actions of the Conservation Management Plans. It stressed the importance and effectiveness of coordinated international action under these Plans given the small number of whales in the right whale population off Chile and Peru and the high calf mortality recorded off Argentina.

10.8 North Atlantic right whales

The Committee **welcomes** SC/65b/BRG14, produced in response to last year's request for an update on the status of the North Atlantic right whale population. A review of the photo-ID recapture database indicated some 455 individually recognised whales known to be alive during 2010. There appears to be a positive and slowly accelerating trend in population size of around 2.8%. From 2007 to 2011, the minimum rate of annual human-caused mortality and serious injury averaged 4.05 per year (annual incidental fishery entanglement, 3.25; ship strike records, 0.8). To reduce ship

strikes, the 2008 US Administrative rule creating speed restriction zones was re-established in 2013 because there was evidence that the rule had been locally effective. To reduce fishery entanglements the National Marine Fisheries Service has implemented rules requiring pot gear to use sinking ground lines in areas seasonally used by right and humpbacks.

10.9 North Pacific right whales

SC/65b/BRG11 reported the sighting summary of North Pacific right whale collected by JARPEN and JARPEN II from 1994-2013. Right whales were mainly found north of 42°N in the research area (55 schools and 77 individuals; observed mean school size: 1.4); there were records of 10 mother and calf pairs.

The Committee **welcomes** this information provided in response to a request from last year. The Committee **recommends** that a photo-id catalogue be established as soon as possible to compare with existing photographs from the Okhotsk Sea, eastern Bering Sea and other western North Pacific photos held by Japanese and Russian researchers. In addition, the Committee **recommends** that Japanese scientists prepare abundance estimates for right whales in the Okhotsk Sea and off the Kamchatka Peninsula.

10.10 North Atlantic bowhead whales

Shpak reported that in recent years, bowhead whales from the critically endangered Spitsbergen population have been regularly encountered in the waters of Franz-Josef Land (FJL) Archipelago during research vessel expeditions, helicopter surveys and land-based observations conducted by the National Park 'Russian Arctic' and Russian Geographic Society.

In April 2010, 20 bowhead whales were observed in the western part of FJL, in polynyas southwest of George Island (Gavrilo and Ershov, 2010). Gavrilo and Ershov (2010) summarised other past sightings of bowhead whales in the waters of the FJL.

Since 2010, there have been continued sightings of bowhead whales in the waters of FJL. In 2013, during the two visits in the first half of April, 3 groups of at least 9 whales in total were observed in polynya west off FJL (Gavrilo, 2013a). In August, during *Pristine Seas Franz-Josef Land Expedition – 2013*, ca. 40 whales in total were observed in FJL waters (Gavrilo, 2013b). In April 2014, 3 whales were encountered in polynyas (Gavrilo, 2014). Mapping of sightings from 2010-2013 expeditions has allowed (Gavrilo, 2014) to document areas of regular bowhead encounters in the southern part of FJL.

Based on the summarised findings, Franz-Josef Land Archipelago should be considered an important habitat for Spitsbergen population of bowheads for late winter through summer.

The Committee **welcomes** this work, **encourages** its continuation and looks forward to further updates.

10.11 Okhotsk Sea bowhead whales

SC/65b/BRG17 presented new information collected in the Shantar region of the western Okhotsk Sea in 2013. Bowhead whales were encountered in Udskeya Bay in July and October; interviews with locals suggest whale presence in the bay throughout the summer. In Ulbansky Bay, in August, as

many as 56 bowhead whales were counted during a single 360-scan from the water with a limited to 2 km visibility, suggesting that the size of the stock observed is much larger.

The Committee **welcomes** this work, **encourages** its continuation and looks forward to further updates.

SC/65b/BRG17 estimated the abundance of bowhead whales in Akademii Bay in the Shantar region of the Okhotsk Sea as 328 (SE=125) whales using genetic mark-recapture population estimate methods. The endangered Okhotsk Sea population of bowhead whales face both natural and anthropogenic threats to recovery. Natural threats include killer whale predation which has been observed several times per season in the region. Anthropogenic threats include fishing activities such as salmon net entanglements (two reported cases within past two years) and industrial activities such as the planned construction of terminal for mining in Konstantina Bay (northwestern arm of Akademii Bay) and oil and gas development in the northern Okhotsk Sea. The Committee thanked the author for this update on research of the small Okhotsk Sea bowhead population. The Committee **recommends** collaboration of genetic laboratories to allow analysis of all available genetic samples for a population estimate.

10.12 Arabian Sea humpback whales

10.12.1 Review new information

SC/65b/SH19 reported on preliminary results from satellite tracking studies of male Arabian Sea humpback whales (ASHW) at Oman. Three of five tags deployed provided locations for several weeks and the movement results were consistent with a prior spatial modelling study. Further analysis is planned after additional tags are deployed in April 2015 in the Gulf of Masirah. The spatial ecology of this sub-population continues to be poorly understood and the authors proposed that tagging be part of on-going research in the region. It was further reported that the involvement of participants from other ASHW range states in the tagging programme was important to the development of cetacean research programmes in other areas of the Arabian Sea. The Committee notes the value of this work and **strongly endorses** its continuation.

10.12.2 Progress toward the development of a Conservation Management Plan and other conservation initiatives

Willson reported on progress towards a Regional Conservation Initiative. The Committee had endorsed these plans in SC/65a and during the last year, a consortium of NGOs and active researchers in the region developed an agenda to facilitate that work, including a workshop funded by the US Marine Mammal Commission and WWF. This workshop will facilitate capacity building of research personnel and prioritisation of activities toward areas considered to be hotspots. Further assessment of escalating threats will also be evaluated. Priority tasks have been identified including: genetic analysis of existing biopsy samples, field survey training, and preliminary surveys in the Gulf of Kutch on the Pakistan-India border.

The Committee **welcomes** efforts to develop regional cooperation for research and capacity and **recommends** the priority tasks listed above.

The Committee **reiterates** its serious concern about the endangered status and threats facing this distinct population.

A regionally coordinated conservation and research program is **strongly recommended** and the Committee urges the IWC and range states to consider the nomination of the Arabian Sea humpback whale for a CMP, given the benefits that a regional framework would provide. The Committee also suggests that the issue be reviewed by the Conservation Committee, with the continued support of the intersessional Arabian Sea working group.

10.12.3 Work plan

The Committee **recommends** a combination of exploratory surveys and molecular genetics for the Arabian Sea population, as well as the following planned work: (1) the continuation of satellite tagging of humpback whales off Oman; (2) an intersessional workshop in 2014 to facilitate research capacity building, prioritisation of research in potential hotspots and further assessment of escalating threats; and (3) continuation of the Arabian Sea Working Group.

10.13 International cruises

10.13.1 IWC-POWER cruises in the North Pacific

The IWC-POWER programme has been through a thorough planning process by the Committee and the Committee has developed short-, medium- and long-term goals over a number of years based upon a thorough review of data available throughout the North Pacific. The short-term part of the programme is to cover all of the poorly-covered areas of the North Pacific with sufficient coverage to allow the necessary information on distribution, density and abundance (as well as biopsy samples and photo-identification data) to enable the design of a robust medium- and long-term programme that meets the objectives of the IWC-POWER programme. Although the research programme is designed by the Committee, the Committee **acknowledges** the tremendous support of the Government of Japan who provide a vessel and crew for 60-days each year – this is tremendous in-kind support without which the programme could not take place.

This year, the Committee reviewed the results of the 2013 cruise (Item 10.13.2) and report from the Planning Meeting for the 2014 survey (Item 10.13.3) and discussed plans for the 2015 and 2016 surveys (Item 10.13.4), mid- and long-term recommendations (Item 10.13.5), and the archived photographs (Item 10.13.6).

10.13.2 Review of the 2013 IWC-POWER sighting survey

The 4th annual IWC Pacific Ocean Whale and Ecosystem Research (IWC-POWER) was successfully conducted by the Japanese from 12 July to 9 September 2013 in the eastern North Pacific (north of 30°N, south of 40°N, between 160°W and 135°W). Researchers from Japan, Korea and México participated. The cruise had five main objectives (see Annex G, item 5.1). Survey plans had been endorsed by the Committee (IWC, 2014i). The Committee **agrees** that it was duly conducted following the guidelines of the Committee (IWC, 2012f).

Further details of the cruise, including summaries of the sightings made, may be found in Annex G, item 5.1. The Committee thanks the Cruise Leader, researchers, Captain and crew, and the Steering Committee for completing this cruise. The Governments of the USA and Mexico granted permission for the vessel to survey in their respective waters, without which this survey would not have been possible. The

Government of South Korea provided one scientist, and the Government of Japan generously provided the vessel and crew. Furthermore, the IWC Secretariat was thanked for providing support. The Committee recognises the value of these data, collected in accordance with survey methods agreed by the Committee, covering many regions not surveyed in recent decades, and addressing an important information gap for several large whale species.

The Committee **welcomes** news that the photographic data had been uploaded into the IWC Secretariat's Lightroom database and **encourages** continuation of this work. Finally, it was noted that for the short-term phase of POWER, surveys will be single-platform, but that double-platform configurations will be evaluated in 2015 and 2016 for possible incorporation into the long-term survey programme if $g(0)$ appears to be less than one for the target species. Other issues concerning this survey programme will be investigated further at the POWER Technical Advisory Group (TAG) Workshop scheduled for September or October 2014 (see also Annex G, Appendix 6).

10.13.3 Planning for 2014 IWC-POWER cruise

SC/56b/Rep01 presented the report of the detailed Planning meeting for the 2014 IWC-POWER cruise, the 5th cruise in the series. The programme is designed by the Scientific Committee and would be impossible without the generous support of the Government of Japan who provide a research vessel, crew and fuel for 60-days (worth some £1m in today's market), as well as the Governments of Japan, USA and Korea who have provided scientists over the period of the programme.

The Committee drew particular attention to the satisfactory resolution of a long-standing problem involving CITES permits. It **expresses** thanks for this satisfactory outcome to the US State Department and the US Embassy in Tokyo, to Brownell, and to Sakamoto (Japanese fisheries Agency), the latter in particular for their persistence in reaching this result.

10.13.4 Recommendations for 2015 and 2016 IWC-POWER cruises

SC/56b/IA11 outlined the line transect sighting survey cruise plan for the 2015 IWC-POWER cruises. It is proposed to be 60 days long mainly in July and August 2015 and conducted in the central north Pacific between 170°E and 160°W, from 20°N to 30°N. Photo-id and biopsy experiments are also planned. It was agreed that a feasibility experiment will be implemented to determine whether $g(0)$ for Bryde's whales is likely appreciably less than one. Improvements of methods for distance and angle estimation experiment will be considered at the TAG meeting with the aim of trialling improved methods for this cruise. Information collected from the survey would contribute valuable information on blue whales, sperm whales and Bryde's whales in a poorly covered area. The data and report of this survey would be submitted to the Committee meeting soon after the cruise.

The plans for the 2016 IWC-POWER cruise are outlined in Annex G, Appendix 6. The Committee **agrees** that this survey be conducted either in a block surrounding the Hawaiian Islands or in the Bering Sea, depending on (a) the level of coverage of previous surveys that are in the block surrounding the Hawaiian Islands; and (b) permitting issues for the Russian zone of the Bering Sea. The Bering Sea was suggested because the entire Bering Sea has been poorly

covered and would also assist in discussions *inter alia* arising out of the Commission workshop on Arctic impacts. Since the short term goal is to cover all poorly-covered areas of the North Pacific, if previous abundance surveys have already sufficiently covered the Hawaiian Island block, then it is not necessary for the IWC-POWER programme to once again conduct a survey in that area. Thus, if the Planning Meeting determines the previous coverage around Hawaii is sufficient, the Bering Sea will be proposed to be covered. The Committee during the 2015 Annual Meeting will finalise this decision.

The Committee noted in discussions there may be a possibility of including the collection of passive acoustics data, with equipment such as towed-arrays. The Committee **thanks** the Government of Japan yet again for its generous offer of providing a vessel for this survey. The Steering Group for the IWC North Pacific Planning meeting that was appointed last year was re-established and will be convened by Kato. Matsuoka was assigned responsibility for IWC oversight for both the 2015 and 2016 surveys.

10.13.5 Mid- and long-term recommendations for the IWC-POWER cruises

SC/56b/Rep09 presented the report of the TAG (Technical Advisory Group) to the IWC-POWER, who met in Tokyo prior to the 2013 Planning Meeting. The TAG focussed on beginning to review the information obtained thus far in order to begin to develop the medium-term programme. The TAG addressed six issues and a number of recommendations for further analyses, improvements to procedures and information requests were made.

The Committee was asked to establish intersessional correspondence groups to examine the following issues:

(1) Collaborative efforts should be made to develop an effective and efficient onboard electronic system for the medium-term programme in the light of existing systems and the shared interest in improving such systems in other national and international cetacean survey programmes (e.g. SCANS III, T-NASS etc.).

(2) Upgrade the old IWC-DESS system to a fully functional relational database to enable efficient storage of the several kinds of data collected and to facilitate analyses of the data (including a more effective mapping option). Data include that from IWC-POWER, IDCR/SOWER, and other national programmes. These should be linked to the extensive photographic database being developed by the IWC Secretariat.

Reports related to the onboard electronic system development and the potential for the use of passive acoustics on POWER cruises will be submitted before the TAG meeting in September/October 2014. In discussions it was noted that the distribution of sei whales may be driven by environmental factors, such as gyres, and that it might be possible to design surveys to inform on these relationships. The Committee **thanks** all the members of the POWER Steering Committee and TAG for reporting back from the respective meetings. The Committee **endorses** the TAG report, and **encourages** collaboration from other countries, recognising the contributions of Japan, Korea, Australia and the USA thus far.

10.13.6 Archiving IWC-POWER photographs

Donovan reported that data continue to be added to the the Secretariat Lightroom database. All POWER photographs from 2010-2012 have been added, geo-referenced and coded as previously described in last year's paper (Taylor and Donovan, 2013) and references to associated record sheet numbers added. All of the digitised SOWER records have been incorporated and the process of digitising the negatives from the earlier cruises is underway. A user's guide to the database is complete apart from final checking. Finally, a database of biopsy records from SOWER is almost complete and will be sent to Japan and SWFSC to ensure that the record numbers for samples can be cross-referenced. POWER records are being added. The Committee **welcomes** this news and **recommends** continuation of this work.

10.13.7 Progress on IDCR/SOWER volume

Last year, the Committee noted that preparation of the volume was underway. The contents will include an introduction to SOWER and the fieldwork; distribution and movement of species encountered; their taxonomy and population structure; acoustics; species abundance; conclusions and lessons for the future.

As convenor of the Editorial Board, Bannister reported that a deadline for texts of 31 December 2013 had been set, but that progress had been slow. Only six texts of a total of 26 (excluding the introduction and conclusions) had been received so far; a further five can be expected shortly. There is still some way to go, but the Board will continue its efforts to encourage authors to produce texts as soon as possible.

The Committee also **welcomes** the news that the Secretariat Lightroom database now incorporates all of the digital photographs from the more recent cruises and that efforts are now being made to digitise all of the negatives from the earlier cruises. It **recognises** the great value of this dataset and **recommends** continuation of this work.

The Committee thanked Bannister and the Editorial Board, and looked forward to an update next year.

10.13.8 DESS database for IWC IDCR/SOWER data

The Committee had been informed during the development of the abundance estimates for Antarctic minke whales that Bravington and Hedley had found some errors in the IDCR/SOWER data. The database should of course be as accurate as possible and Secretariat has agreed to correct any errors when they are passed on. To date the Secretariat has not received the necessary information and the Secretariat has encouraged provision of this as depending on its nature, this may also require alterations to the existing validation algorithms being used which is important for future datasets as well as past ones. The Committee **recognises** the difficulties of time constraints for the researchers involved but also the need to correct errors and improve validation algorithms. It has therefore formed an intersessional working group to assist in this process.

10.13.9 IWC-SOWER sonobuoy data

The South African Blue Whale Project applied for and received the acoustic recordings from sonobuoys deployed during several IWC Antarctic and low latitude cruises (Shabangu and Findlay 2014). This resulted in some 7500 acoustic files from over 700 stations across cruises from 1996/1997 through to 2008/2009 in Areas I-VI, and the three

blue whale cruises off Australia, Madagascar and Chile. A total of 1547.76 hours of recordings had been initially reviewed and blue whale vocalisations (either Z or D calls) have been detected on 4155 (55%) of the 7501 recorded files.

The Committee **welcomes** the processing of these valuable data. Now that the 'bio duck' sound has been positively identified as an Antarctic minke whale, the Committee **recommends** this database be interrogated to identify the bio duck sound to investigate the spatial temporal distribution of the Antarctic minke whale.

10.13.10 Review of other cruises

10.13.10.1 REPORT OF JAPANESE CETACEAN SIGHTING SURVEYS IN THE NORTH PACIFIC IN 2013

SC/65b/IA06 presented a systematic vessel-based sighting survey that was conducted in 2013 by Japan to examine the distribution and abundance of large whales in the western North Pacific. A total of 3,470.1 n.miles was searched, where eight species including seven baleen whales were sighted. Photo-ID photographs and biopsy skin samples were also successfully collected.

The Committee **welcomes** this report and looks forward to receiving abundance estimates arising from these data. The Committee thanked Matsuoka for overseeing this survey on behalf of IWC.

10.13.10.2 PLANS FOR JAPANESE CETACEAN SIGHTING SURVEYS IN THE NORTH PACIFIC IN 2014

SC/65b/IA07 presented a plan for a systematic vessel-based dedicated sighting survey in the North Pacific for 2014 by Japan as a part of the Japanese Whale Research Program under Special Permit in the western North Pacific (JARPN II). The main objective is to examine the distribution and estimate the abundance of Bryde's whale for management and conservation purposes. In addition to sighting survey data, biopsy samples and photo-identifications will be collected. A report will be submitted to the 2015 Committee meeting.

The Committee **endorses** the proposal and Matsuoka was appointed to provide IWC oversight.

10.13.10.3 REPORT OF CETACEAN SIGHTING SURVEYS IN THE ANTARCTIC IN 2013/14

SC/65b/IA09 indicated that a dedicated sighting survey for abundance estimations in the Antarctic in the 2013/14 austral summer season was unable to be conducted due to external violent interferences by an anti-whaling group. This situation has now continued over three seasons, starting from the 2011/12 survey.

The Committee **expresses** its regret that the actions of an anti-whaling NGO had prevented the sighting survey. Following the cessation of the IDCR/SOWER programme in 2009 (and notwithstanding smaller-scale national projects to collect sightings data in particular regions), surveys such as this provide the only dedicated cetacean sightings that are synoptic over a wide area, and as such are extremely valuable for the work of the Committee.

10.13.10.4 PLANS FOR CETACEAN SIGHTING SURVEYS IN THE ANTARCTIC IN 2014/15

SC/65b/IA12 presented a plan for a systematic cetacean sighting survey for abundance estimation for the 2014/2015 austral summer season in the Antarctic to be operated by Japan. The research area comprises Areas IV, V and VIW between 70°E and 145°W, south of 60°S from December 2014

to March 2015, where up to four research vessels may be used using survey procedures used in the IWC/SOWER surveys. Photo-identification and biopsy studies will also be conducted. International researchers will be able to apply to participate in the cruise, but they will do so at their own cost. A cruise report will be submitted to the 2015 Committee.

The Committee **commends** the researchers for recording killer whale ecotypes as recommended in SC/65b/Rep02. The Committee **endorses** the proposal. Matsuoka was appointed to provide IWC oversight.

10.14 Sperm whales

Last year, an intersessional e-mail group was established to consider the feasibility of a future assessment of sperm whales. Its terms of reference were to evaluate data availability and work required on the following topics: (1) population structure within ocean basins; (2) population size within ocean basins and abundance in smaller areas; (3) catch history; and (4) consideration of the development of a new assessment model (IWC 2014). Brownell and Bannister met in Bled to consider four working papers on the above subjects and a number of published papers on sperm whales and had discussions with other members. For the purposes of those discussions sperm whales were divided into two broad groups: (1) North Pacific and (2) Southern Hemisphere.

It is clear a lot of preparatory work is required before undertaking a sperm whale assessment in either the North Pacific or the Southern Hemisphere. However, based on recent and ongoing research (catch histories, population size, genetic sampling, population structure, acoustics) on sperm whales in the California Current, the available data could be used for the development of a new assessment model. At the present time in the Southern Hemisphere, highest priority could be given to conducting survey[s] with acoustics to resolve the current status of the sperm whales off southern Western Australia where a 2009 aerial survey found no evidence of increase since whaling ceased in 1978.

The high priority given to the assessment of humpback whale breeding stocks BSD/BSE1/BSO left inadequate time to consider this agenda item. However, Brownell and the intersessional e-mail correspondence group will continue to develop the ideas canvassed above, perhaps with others, for report to the 2015 Annual Meeting.

10.15 Overview of workplan

The Committee's workplan for items related to whale stocks is summarised in Table 13.

11. STOCK DEFINITION

This item has been handled since 2000 by a Working Group (hereafter the SDWG). The Terms of Reference for SDWG were changed in 2012 to reflect the evolving needs of the Committee. During the present meeting, the SDWG continued to develop guidelines for preparation and analysis of genetic data within the IWC context (see Item 11.1), provided the Committee with feedback and recommendations concerning stock structure related methods and analyses presented to other sub-committees (see Item 11.2), and continued in their efforts to develop a reference glossary of stock related terms, to aid consistent definition of 'stocks' in a management context for the Committee (IWC, 2014f, pp.287-8). The Report of the SDWG is given as Annex I.

Table 13

Overview of the workplan as it relates to whale stocks

Species / area	SC66a 2015	SC66b 2016
Antarctic minke whales	Review information collated interessionally (see Annex J, item 9) to try to finalise the in-depth assessment with a focus on the Indo-Pacific region	Finalise if not completed at SC66a and [consider how to] address the remainder of the Antarctic
Southern Hemisphere humpback whales	Undertake thorough review (collated interessionally) and synthesis of the completed 8-year circumpolar assessment. Begin to evaluate data requirements and process for future assessments.	Complete evaluation and determine future workplan
Southern Hemisphere blue whales (including pygmy blue whales)	Review available existing and new information on stock structure abundance etc. and determine feasibility of conducting area-based assessments with an associated workplan	Depends on workplan developed in 2015
North Pacific sei whales	Begin in-depth assessment	Complete in-depth assessment
North Pacific gray whales	See detailed workplan provided in Annex F	Continue and possibly complete
Southern right whales	The most recent assessment was completed in 2012. The focus will thus be on reviewing new information, e.g. with respect to matters related to CMPs	Continue to review new information and develop workplan with respect to future updated assessments
North Atlantic right whales	The last assessment was completed in 2000 and since that time the Committee has reviewed new information on abundance, trends, anthropogenic mortality etc. Consideration of when to undertake a new assessment will be given and a workplan developed.	Depends on outcome of discussions in 2015.
North Pacific right whales	New information (and hopefully abundance estimates) is expected from the Sea of Japan/Kamchatka region. Consideration will be given to whether sufficient information is available to conduct an assessment and a workplan developed.	Depends on outcome of discussions in 2015.
North Atlantic bowhead whales	Continue to review new information.	Continue to review new information and develop a workplan towards and eventual assessment.
Okhotsk Sea bowhead whales	Review new information expected on abundance and stock structure.	Continue to review new information and develop a workplan towards and eventual assessment.
Arabian Sea humpback whales	Review new information expected from several research initiatives. Continue to assist in efforts to develop a CMP.	Depends on outcome of discussions in 2015.
Sperm whales	Review information and report from an interseasonal group and develop a workplan	Depends on outcome of discussions in 2015.

11.1 Guidelines for DNA data quality and genetic analyses

Two sets of reference guidelines have been developed and endorsed by the Committee (IWC, 2014e, pp.248-9) and form 'living documents' that can be updated as necessary¹⁵. The first set addresses DNA validation and systematic quality control in genetic studies. The second set provides guidelines for some of the more common types of statistical analyses of genetic data used in IWC contexts, and contains examples of management problems that are regularly faced by the Committee. One section of the data quality guidelines will be updated interessionally. During the present meeting, appendix sections of the genetic analysis guidelines were added; this document will be completed interessionally (see Item 11.5). Both guidelines will also be published in the peer-reviewed literature.

Several papers were discussed that present new methodologies of relevance for the DNA data quality and genetic data analysis guidelines. These included (1) evaluation of data quality in studies using next generation sequencing technologies, (2) development of an epigenetic assay which uses known-age humpback whales to estimate age in humpback whales of unknown age, and (3) development of a suite of computational tools that allow the

exploration and visualisation of spatial patterns in genetic diversity using data from individual-based, long-term cetacean studies.

The Committee welcomes the developments in epigenetic ageing methods. It noted that this approach can be applied to increase the power of the close-kin mark recapture by identifying the inter-generational relationships within parent-offspring pairs.

11.2 Statistical and genetic issues related to stock definition

A number of Committee stock related papers were discussed by the SDWG. These were submitted to the following sub-committees: Revised Management Procedure (Annex D), Bowhead, Right and Gray Whales (Annex F), In-Depth Assessments (Annex G), Other Southern Hemisphere Whale Stocks (Annex H), Small Cetaceans (Annex L) and Review of Special Permit Proposals (Annex O). Technical comments on these papers are given in Annex I.

The development of close-kin mark recapture methods for a number of species, including North Atlantic minke whales (Annex D item 3.3.1) and Antarctic blue whales (Annex H item 5.1.1.4) was also discussed (Annex I, item 3.1). This

¹⁵ DNA data quality guidelines are available from http://www.iwcoffice.org/sci_com/handbook.htm#ten. Genetic data

analysis guidelines are anticipated to become available before the 2015 Annual Meeting.

approach has broad utility for the work of the Committee as it can increase the stock structure-related information content available from existing sample collections. The Committee **encourages** the continuation of this developing methodology and further reporting to the 2015 Annual Meeting.

Another useful development was the concerted attempt to discover why different studies of common minke whales in the North Atlantic have led to different conclusions about stock structure. Some studies suggest substantial levels of differentiation between areas, and others identify little to no differentiation. Evaluating why these differences exist is complicated, as differences in sample size, areas sampled, years sampled, marker types, and potentially laboratory protocols exist between studies. To better understand these differences, locus-specific differentiation (F_{ST}) values were compared across five datasets, and revealed that the same markers varied substantially in F_{ST} between studies (Adjunct 3 of Annex D). It was noted that the loci in Adjunct 4 of Annex D were non-focal (i.e., heterologous; developed in one species but utilised in another species) which may contribute to the inconsistencies seen; though see Appendix 2 of Annex I. Factors thought most likely to contribute to these differences were ranked (Item 3.3.3 of Annex D), and continued analysis to identify the cause of these differences continues intersessionally (Annex D of Item 3.7). The Committee **expresses** strong appreciation for these efforts to combine allozyme and microsatellite datasets together for a locus-specific reanalysis. It is of importance to the ongoing North Atlantic common minke whale assessment to resolve what factors may be contributing to the lack of concordance among these studies as this will allow simplification of the number of hypotheses to be considered. In addition, determining the factors underscoring the different levels of differentiation between these datasets may have wider implications for other studies of interest to the Committee. In most cases, multiple datasets are not available for such direct comparisons of results, thus discordant signals such as those seen in this locus-specific F_{ST} analysis (Adjunct 3 of Annex D) could be present but unrecognised in other studies.

This year, there was extensive discussion of SC/65b/BRG02 (see author's summary in Item 3.1.2 and discussion summary in Appendix 2 of Annex I). SC65b/BRG02 reports results of a meta-analysis of microsatellite diversity and standardised F_{ST} across populations of whales, dolphins, porpoises and sharks. This analysis finds that whale and dolphin studies have been based on a significantly lower proportion of focal loci than porpoises or sharks. The authors also find significantly lower allelic diversity in whales and dolphins than in sharks and porpoises. This reduced allelic diversity is also associated with higher estimates of population differentiation (using standardised F_{ST}). The authors of SC/65b/BRG02 therefore strongly recommend that the use of non-focal microsatellites to estimate F_{ST} should be avoided in future studies since this might lead to inflated estimates of F_{ST} that are potentially statistically significant.

The potential implications of the main conclusions in SC/65b/BRG02 are far reaching, and resulted in extensive discussions (see Appendix 2 of Annex I). This particularly focuses on the author's argument that the higher measures of F_{ST} found for non-focal loci could lead to the over-diagnosing of stock structure. This inference has ramifications for the many studies based on non-focal loci in cetaceans and more

widely in the field of molecular ecology. If the authors' assertion was correct, this would call into question the conclusions of those studies and the consequent recommendations agreed by several IWC sub-committees. In discussion, many argued that the conclusion from SC/65b/BRG02 about the over-diagnosing of structure was based on a methodological misconception. The essential reasoning is as follows (see Appendix 2 of Annex I for further details). F_{ST} has two components: locus-specific effects, and population-specific effects. While highly diverse loci may not reflect a sufficient proportion of the population-specific effects to detect real population structure, it is not conversely true that markers of low variation will detect non-existent structure. Indeed, if this was the case, commonly used low diversity markers such as allozymes and SNPs would routinely, artificially detect population structure, and this is demonstrably not the case. Regardless of the specific magnitude of F_{ST} , a statistical assessment determines significance with a controlled magnitude of type I error.

In summary, the Committee **requests** that the authors provide the data used in the meta-analysis be made available to the SDWG so that it can better understand the associations identified in SC/65b/BRG02. This will allow examination of alternative explanations for the results, which is needed before drawing conclusions for the Committee.

11.3 Testing of Spatial Structure Models (TOSSM)

The aim of the TOSSM project that was developed by the Committee, is to facilitate comparative performance testing of population structure methods intended for use in conservation planning. From an IWC perspective, the TOSSM software package allows evaluation of methods for detection of genetic structure, in terms of how well the methods can be used to set spatial boundaries for management. It is available for all to use and simulated datasets exist for three of the five stock-structure Archetypes previously proposed by the Committee (see IWC, 2010b, p.51). There was no progress on Testing of Spatial Structure Models to report this year. Progress continues to be made on the work items suggested in IWC (2013b) for the Pacific Coast Feeding Group (PCFG) of gray whales and will be presented next year. The Committee **agrees** to form an intersessional email group to further advance the use of TOSSM, with the primary intent that TOSSM be used to provide general guidelines for setting sub-area boundaries for assessment processes, with particular reference to populations that pose management challenges to the Committee. It was noted that the use of particular examples, such as the ongoing work on the PCFG gray whales, was a great motivator for use of TOSSM and was helpful in making its relevance to the Committee clear.

11.4 Terminology and unit-to-serve

Defining and standardising the terminology used to discuss 'stock issues' is still a long standing objective of the SDWG, in order to help the Committee report on these issues according to a common set of terms (see Appendix 5, IWC, 2014f, pp.287-8). This year, the SDWG decided further work was needed to (1) agree the definition for 'mixtures of stocks', as well as (2) align the terms used in SDWG with terminology already in use by the sub-committee on Small Cetaceans and make additions to the developing glossary where needed. An intersessional email group was formed to complete this task.

11.5 Workplan

The Committee **agrees** to the overall workplan given in Table 14; details are given in Annex I.

Table 14

Overview of the workplan as it relates to stock definition

Topic	SC66a 2015	SC66b 2016
Terminology review and unit-to-convert	Continue to work on this issue with a focus on examining terms used for small cetaceans. Try to finalise an initial list for use by the Committee.	Finalise if not completed at SC66a.
Updates to genetic data analysis and DNA data quality guidelines (annual)	This is part of maintaining an online and evolving set of guidelines.	Review to see if updates are required
Statistical and genetic issues concerning stock definition	Continue to review technical issues regarding papers submitted to all sub-groups of the Committee.	Continue.
Testing of Spatial Structure Models (TOSSM)	Examine the future application of TOSSM datasets to new cetacean examples of interest to the Committee; advance the use of TOSSM to provide general guidelines for setting subarea boundaries for assessment, including those for the RMP and AWMP.	Continue based on discussions at 2015

12. ENVIRONMENTAL CONCERNS

The Commission and the Scientific Committee have increasingly taken an interest in the environmental threats to cetaceans. In 1993, the Commission adopted resolutions on research on the environment and whale stocks and on the preservation of the marine environment (e.g., IWC, 1996a; 1997; 1998a; 1999a; 1999b; 2001). As a result the Committee formalised its work by establishing a Standing Working Group that has met every year since.

12.1 State of the Cetacean Environment Report (SOCER)

The SOCER provides an annual update, as requested by Commission Resolutions 1997-7 (IWC, 1998a) and 1998-5 (IWC, 1999a), on: (a) environmental matters that potentially affect cetaceans and (b) developments in cetacean populations/species that reflect environmental issues. The 2014 SOCER (Annex K, Appendix 4) focused on the Atlantic Ocean, Caribbean and Gulf of Mexico. Details of this year's SOCER can be found in Annex K, item 6.

The Committee thanked the SOCER editors for compiling this year's report and **encourages** participation in the upcoming version. The focus of the SOCER at SC/66a will be on the Pacific Ocean region; at SC/66b, it will be focused on Arctic and Antarctic regions.

12.2 Pollution

12.2.1 Update on Pollution 2020+ progress

SC/65b/E13 reviewed microplastics in the marine environment and their potential impacts on cetaceans. Microplastics have a global distribution; do not biodegrade and are only partially removed by sewage treatment. The

toxicological consequences for marine life range from mechanical hazards to leaching toxic chemicals. Analysis of cetacean faeces may provide information on the assimilation and excretion of microplastics. The Committee **thinks** the authors for this comprehensive report.

The IWC Pollution 2020 Steering Group Meeting report (SC/65b/Rep05) noted that the last 4 years have seen the completion of Phases II and III of the Pollution 2000+ initiative, which has included the finalisation of an individual-based model that can be used to investigate the effects of pollution (particularly polychlorinated biphenyl or PCB) exposure on cetacean populations (Hall *et al.*, 2013). The major points identified were that: (1) the model should include the ability to change the annual accumulation over time, as this would better reflect the gradual decrease in environmental PCBs; (2) the vital rates used to parameterise both the dolphin and the humpback model may need to be updated; (3) a major source of uncertainty in the model relates to the parameters that control the offloading of PCBs from mothers to their calves; and (4) currently, there is no uncertainty incorporated into the model around the relationship between immune function and reduced survival probability. Work on prioritising current contaminants of concern for cetaceans remains important to the SWG and efforts to complete this task should be continued.

The Committee **commends** this work and recognises that the development of a practical modelling tool provides an important step in the Committee's ability to quantify the effects of chronic threats to cetaceans. The Committee **endorses** the steering committee advice and **recommends** the addition of leachate and adsorbed chemicals from microplastics to the questionnaire that will be circulated among experts for input on chemicals of concern. In addition, the Committee **recognises** that continued investigation into the effects of chemicals adsorbed to microplastics, on cetaceans, is needed.

12.2.2 Oil spill impacts

12.2.2.1 UPDATE ON DEEPWATER HORIZON OIL SPILL

An update on the 2010 Deepwater Horizon oil spill investigation on the injuries and impacts to cetaceans in the Gulf of Mexico was provided. Health assessments of bottlenose dolphins in Barataria Bay, Louisiana (an area that received heavy and prolonged oiling) and Sarasota Bay, Florida (control site) were conducted in 2011 (Schwacke *et al.*, 2014). Barataria Bay dolphins showed evidence of hypoadrenocorticism, consistent with adrenal toxicity and were five times more likely to have moderate to severe lung disease. Additional assessments and are planned for the region of concern.

An Unusual Mortality Event (UME) started in February 2010 in the northern Gulf of Mexico and was ongoing as of 14 May 2014. Most of the strandings (87%) were bottlenose dolphins. From results received to date, the cause of the UME is unlikely to have been due to *morbillivirus*, marine biotoxins, or *Brucella*. The Deepwater Horizon oil spill has not been ruled out as a possible contributing factor. Details of the discussion on these papers may be found in Annex K, item 7.2.1.

The Committee **commends** this work and **recommends** that these studies continue. It also **recommends**:

- (1) that baseline data from populations at risk be collected and knowledge about exposure and impacts following spill events maximised;
- (2) that analytical methods for oil spill-related compounds be standardised; and
- (3) that pre-planning begin for an oil spill workshop to inform the Committee on the impacts of oil, dispersants, and spill response on cetaceans and the methodological tools for the assessment of impacts to cetaceans after a spill.

12.2.2.2 OTHER OIL SPILL INFORMATION

The report 'Responding to oil spills in the US Arctic Marine Environment'¹⁶ was discussed. It noted that response actions will have to deal with the remoteness, limited infrastructure and capacity, and might have to deal with sea ice, low temperatures, and days with very little or no sun light. The report includes recommendations about all of these topics. Details can be found in Annex K, item 7.2.2.

The Committee again **stresses** the importance of baseline information on both marine mammals (and other wildlife) and their prey. It was noted that the injury assessment process is difficult to complete without this type of data available for comparisons. In addition, the Committee **recognises** the importance of subsistence species to local communities.

The 2013 *Community Oil Spill Response in Bering and Anadyr Straits* workshop report was briefly summarised (Wildlife Conservation Society, 2013). The workshop specifically focused on: (1) the role of communities in these policies and planning processes; (2) the location and role of emergency response equipment in the region; and (3) examples of how other communities in Alaska and elsewhere engage with prevention, planning, and response needs. Participants identified several key themes during this exercise including the need for oil spill response training, equipment, funding and effective local and cross-border communication plans (see Annex K; Item 7.2.2).

Further to discussions about oil spills, the Committee **agrees** that absolute priority should be given to preventing oil spills in the highly vulnerable Arctic region. However, the Committee noted that even when preventative measures are taken, oil spills may still occur. Responding to an oil spill, especially a large one in a polar area, is hindered because of limited capacity particularly due to infrastructure. In addition to abundance and distribution, baseline data should include: health assessments; contaminant levels; biomarker measurements; and habitat/prey quality. It was noted that cetaceans in other countries are also under threat of both oil and gas development and increased shipping. The Committee **recommends** that Committee members: (1) enhance the collection of baseline data related to abundance, health assessments, prey, and habitat of cetaceans for an improved capacity for injury assessment and monitoring recovery in the event of a spill; and (2) build capacity for responding to an oil spill in polar regions or other vulnerable or at risk areas. The Committee also **recommends** that the Commission seeks observer status at the Arctic Council for improved communication and coordination of Arctic issues related to

cetaceans, including issues related to shipping oil and gas activities (and see Item 10.2.1 and Item 7.2.2).

12.2.3 Other pollution information

An update on the 2011 Fukushima Nuclear Accident was provided. Monitoring efforts to determine levels of radionuclides in environmental samples have increased since the disaster. Radioactive isotopes of iodine and caesium were detected in air, water, milk and food samples collected across the entire northern hemisphere and also southern hemisphere, including New Guinea and Fiji but radiation levels were very low and did not pose a risk to the public. A report has been published on the potential impacts and monitoring efforts being conducted¹⁷.

The Committee noted that the Government of Japan has measured Fukushima-associated radionuclides in more than 45,000 seafood samples collected from various coastal waters of Japan¹⁸. Modelling efforts have projected the input of Fukushima-associated radionuclides into marine waters of eastern North Pacific and the levels in some areas could approach those reported in the 1950-1960s, i.e., a period during nuclear testing and activity in the region. The Committee **expresses** concern about this new information; the impact that radionuclides released as a result of the Fukushima accident might have on wildlife and humans remains unclear.

12.3 Cetacean emerging and resurging diseases (CERD) and mortality events

12.3.1 Update from the CERD intersessional group

The Cetacean Emerging and Resurging Disease (CERD) Group was created in 2008 in recognition of the increased need to address disease issues in cetaceans at an international level, including information on emerging diseases and the fact that for most cetacean species there is insufficient information on diseases, particularly those with potential anthropogenic drivers, to evaluate the risks to populations (IWC, 2008c).

12.3.2 CERD website and database

In 2012, the CERD working group proposed to develop a website that provides information on infectious and non-infectious diseases, as well as nutritional disorders and biotoxins (IWC, 2013a). The CERD will advertise internships to assist with data validation and input into the CERD web framework. In recent years, standardisation of the data that will be used for the CERD website has begun and the proposed format was presented to the Committee.

12.3.3 Strandings and mortality events

SC/65b/E03 provided information on an Unusual Mortality Event (UME), with increased numbers of bottlenose dolphin strandings documented from New York to Virginia beginning in July and August (> 1,200 dolphins stranded). This was determined to be a *morbillivirus* outbreak. Other stranded cetacean species testing positive by PCR (polymerase chain reaction) for cetacean *morbillivirus* included humpback, fin and pygmy sperm whales and striped dolphins. The impacts of dolphin *morbillivirus* on these species remains unknown (see Annex K, Item 8.3 for details). The Committee

¹⁶ www.nationalacademies.org

¹⁷ See: http://marinedebris.noaa.gov/sites/default/files/Japan_Tsunami_Marine_Debris_Report.pdf

¹⁸ see www.jfa.maff.go.jp/e/inspection/index.html

encourages continuation of the investigation of the *morbillivirus* outbreak, further international collaboration and looks forward to additional information as it becomes available.

SC/65b/SM03 reported the first mass stranding of seven Longman's beaked whales in New Caledonia on 16-17 November 2013. Samples were collected from 5 animals. Low concentrations of elements associated with mining activity in New Caledonia were found in the tissues, suggesting that industrial extracting activities do not represent a significant source of contaminants for this species. Cetacean *morbillivirus* was identified in one of the individuals via PCR analysis. Details can be found in Annex K, item 8.3.

On 1 April 2014, an atypical mass stranding of 6-10 Cuvier's beaked whales occurred along the coasts of south and southwest Crete, Greece, Mediterranean Sea, inside the 'area of special concern for beaked whales', discussed in Item 12.4.4. The mass stranding comprised several stranding events in three different locations/areas. At the time of the Crete atypical mass stranding event, the 'Noble Dina' naval exercise, involving Greek, US and Israeli navies, was taking place in Greek offshore waters.

In discussion, it was noted that atypical mass stranding events such as this have previously been associated with anthropogenic sound from military sonar. The Committee **recommends** that this event be investigated by marine mammal veterinarians and the findings reported next year.

12.3.4 Other health-related activities

SC/65b/E04 evaluated marine *Brucella* infections in cetaceans in the United States (see Annex K, item 8.4 for details). Manifestations of infection in cetaceans include late-term abortions and lesions in lungs, reproductive organs, bones and the brain. Collaborative work in the US over the last four years has identified more than 120 cetaceans testing positive for marine *Brucella*, many with clinical signs of brucellosis. Brucellosis due to marine *Brucella* has been found in four human cases worldwide and the wide presence of the marine *Brucella* MLST 27 in cetacean cases has raised the most concern for public health, as this was the type implicated these *Brucella* infections. Based on concerns for both cetacean populations and human health, the Committee **recommends** that the development of a reliable serological assay for the detection of marine *Brucella* antibodies be given high priority. It also **recommends** further research into virulence mechanisms, transmission pathways, pathogenesis and co-morbidity factors in cetaceans. The Committee **recognises** and **encourages** the work on *Brucella* in the Southern Hemisphere and welcomes initiatives that would allow cetacean *Brucella* types to be identified and compared. In addition the Committee **recognises** the concern about the potential risk that the marine types may pose to humans, including stranding response workers, subsistence consumers and fishermen, and **recommends** that particular attention be given to elucidating the frequency and routes of transmission of the marine *Brucellas* to humans.

SC/65b/E05 described information on a pilot project called Marine Mammal Health Map for tracking health data obtained from marine mammal strandings, mortality events, and health assessments during live capture release programs. The ultimate goal of the Marine Mammal Health Map is to share

marine mammal health and disease information on a national and international scale and evaluate potential impacts on populations. The Committee **expresses** interest in the health mapping technology and **encourages** updates on this work, as well as further development and potential application to CERC.

SC/65b/E06 summarised information on skin lesions in southern right whales from the Península Valdés area. Over the past ten years, there has been an increase of skin lesions in whales in this population. As a result of analysis of samples obtained during 2012 and 2013, the presence of poxvirus in skin lesions of southern right whales was confirmed, and several bacteria (e.g. *Erysipelothrix* spp., *Staphylococcus epidermidis*, and *Streptococcus* spp.) were isolated from wounds caused by kelp gulls.

The Committee **commends** Argentina for conducting skin lesion research on Southern right whales, especially the recent investigations of pathogens that may be expressed in the lesions and **recommends** that they continue the work on skin lesions given the prevalence and continued problems with kelp gulls. Further information on this work was discussed in Annex F, item 4.1.

Information on pathological findings of subsistence-harvested bowhead whales by Alaskan Eskimos during 2013 was presented to the Committee (see SC/65b/BRG08).

Di Guardo and Mazzariol (2013a) described some of the host and viral factors driving dolphin *morbillivirus* infection with particular emphasis on striped dolphins in the Mediterranean. An expansion of the host range has recently been observed in the Mediterranean with infection in fin whales and a captive harbour seal.

Di Guardo and Mazzariol (2014) presented a commentary on two papers recently published regarding cetacean *morbillivirus* in the Southern Hemisphere. The authors noted that data are needed on the genetic composition of the new strains and emphasis should be placed on the host and agent-related factors that drive the complex *morbillivirus* cetacean interaction dynamics.

Of note was the number of new cases of *morbillivirus* globally which may be a cause for concern. Princeton University is hosting a workshop on marine *morbilliviruses* in August 2014 and the Committee looks forward to a report at SC 66a.

Di Guardo and Mazzariol (2013b), reported that striped dolphins stranded in 2007 and 2008 showed evidence for *T. gondii* in association with brain lesions. They suggested that an 'open sea' life cycle involving this and other pelagic cetaceans should not be ruled out.

12.4 Effects of anthropogenic sound on cetaceans and approaches to mitigate these effects

12.4.1 IWC/IQOE workshop report

A two-day workshop was sponsored by the Commission, the International Quiet Ocean Experiment (IQOE) and others, to discuss regional and ocean-basin scale underwater sound field mapping techniques to provide support for decision makers seeking to characterise, monitor, and manage the potential impacts of chronic or cumulative anthropogenic noise on marine animals. Many different soundscape monitoring and modelling programs have been developed

(see Annex K, item 9.1). However, while these programmes are an excellent start, they are not standardised in their measurement or modelling parameters, making it extremely difficult to compare products across regions. In addition, they are largely focused on US and European waters, while management concerns for marine organisms are far wider ranging. The Workshop recommended identifying acoustic measurement and modelling protocols that if implemented world-wide would greatly add to the value of local and regional studies by allowing data to be combined and integrated at larger scales.

To support further development of sound modelling tools, it was proposed that the Committee should consider its management needs and designate high priority areas for the next steps in this work. Possible areas that were highlighted during workshop discussions for further evaluation by the Committee included the Arctic, Southern Ocean Sanctuary, South Atlantic, Mediterranean, North Sea, and Gulf of Mexico-Caribbean waters.

The Committee **commends** the IWC/IQOE workshop participants for their efforts, and **recommends** continuation of this effort and further work to implement the recommendations contained in the workshop report. The Committee **endorses** the recommendations from the workshop report. In order to advance this work, the Committee **recommends** conducting the two predictive sound field mapping studies in high priority areas as described in Annex K, Appendix 2. In addition, the Committee **recommends** the collection of empirical data (e.g. acoustic recordings) to assess baseline acoustic conditions in these high priority regions (particularly where rapid industrial or environmental change is occurring), and the expansion of efforts where data collection is currently limited. The Committee **recommends** continued international collaboration on the issue of underwater anthropogenic sound, and planning of additional workshops or projects with various regional management agencies, industry, and organisations.

12.4.2 New information on the effects of anthropogenic sound
Simmonds *et al.* (2014) is a history of marine noise pollution and explained how it came to emerge as a ‘significant mainstream issue,’ taking note of the role that the IWC has played in this effort and concluding that over the last two decades or so, significant progress has been made acknowledging this issue, especially in the USA. The authors call for enhanced international cooperation and the expeditious sharing of information from marine renewable energy devices (which has emerged as a new issue) and stress that temporal and spatial separation should be the primary mitigation approach.

12.4.3 Update on new tools, approaches or efficacy of mitigation of effects of anthropogenic sound on cetaceans
SC/65b/E11 describes a simulation framework to evaluate the efficiency of using Marine Mammal Observers (MMOs) for mitigation of sound-related injury. Without an adequate quantified assessment of the risk reduction, mitigation measures may often be applied inappropriately or result in regulators granting approval for activities on the basis of

measures that do little to reduce risk. The Committee **thanks** the author and encouraged publication of his findings.

SC/65b/E09 discussed the real-time mitigation measures based on the detection of animals close to airguns and other sources and, in particular, the role that MMOs play. SC/65b/E09 raised questions about the work of MMOs covering issues including: increasing distances of monitoring from sound sources required, complex multispecies requirements, the authority and independence of MMOs, their training and assessment, numbers of observer required to be effective and data availability.

The Committee noted that addressing such issues was important in ensuring that MMOs were effective and noted that an independent assessment of MMO practices does not exist. Hence, the Committee **agrees** that this issue would be a suitable focus for its consideration at a future Committee session in which MMOs and their associations would be represented.

SC/65b/E08 provided a brief overview of the various options available to reduce anthropogenic ocean noise. The overarching recommendations are: (i) governments around the world should phase in increasingly strict noise level standards for all noise-producing activities; and (ii) governments, industry and NGOs should seek ways to address and reduce the underlying demand for noise producing activities. For more specific recommendations see Annex K, item 9.3.

In SC/65b/E07, Environmental Impact Statements or Reports were examined to determine whether the focus on reducing Level A ‘takes’ under the US Marine Mammal Protection Act (i.e. a predicted level of sound that could result in physical injury or death) is sufficiently protective and effective by comparing the numbers of Level A with Level B takes (i.e. a level of sound that results in behavioural disturbance). Spatio-temporal mitigation (time-area closures) and quieting alternative technologies, such as marine vibroseis (which exposes only 1-15% of animals to higher noise levels compared with airguns), in contrast to safety zones and ramp-up, can dramatically lower both Level A and B takes. For discussion details see Annex K; item 9.3. In summary, it was considered that more animals are affected by noise, and as such the impacts to cetaceans are greater, than currently estimated.

The Committee **thanks** the author for presenting these findings, **recommends** that further consideration should be given to examining behavioural effects and possible population level effects. It looks forward to receiving additional information from studies such as this.

A German study about the development of noise mitigation measures in offshore wind farm construction was presented to the Committee.¹⁹ The aim of this study was to describe technical noise mitigation measures that can be applied during pile driving of offshore wind turbines, as well as alternative low-noise foundation concepts and to analyse their applicability. Additionally, it was noted that, in Germany, an ‘underwater noise concept’ for the North Sea has been in place since September 2013, which is applied to protect

¹⁹ http://www.bfn.de/0314_meeresnaturschutz-berichte.html.

harbour porpoises from underwater noise from pile driving activities.

The Committee welcomed the study and **stresses** the importance of sound mitigation measures. With respect to the Baltic Sea, the Committee **strongly encourages** the relevant governments in the area to apply appropriate measures to protect the highly endangered harbour porpoise subpopulation of the Baltic proper from negative effects of underwater noise through pile driving and other anthropogenic activities.

In recognising the pervasive nature of underwater sound in the marine environment and the inherent difficulties in assessing the behavioural impacts that such inputs may cause, the Committee **agrees** that increased efforts should be made to avoid, minimise and mitigate the adverse effects of anthropogenic noise on cetaceans. In particular the Committee **recommends** that Governments should promote and facilitate the adoption of noise-reducing technologies by industry including shipping noise, exploration for fossil fuels and pile-driving. The Committee also **encourages** the completion of appropriate assessments for marine activities to help ensure harm is not caused to cetaceans, including giving consideration to the development of noise exposure limits as, for example, used in Germany with respect to pile driving. The Committee **encourages** industry (and other noise producers such as the military) to release data about its noise generating activities (both completed and where possible, planned), including but not limited to activity, location, source characteristics, duration, in order that the cumulative implications for cetaceans of all activities can be assessed.

The Committee also **stresses** the importance of utilising temporal and spatial management of noise generating activities and encouraged the identification of sensitive areas in which noise would be strictly managed.

Nowacek *et al.* (2013) dealt with a responsible approach to minimising disturbance to cetaceans from seismic surveys. The authors identified a number of principles and steps that would have common application even though the final mitigation and monitoring programmes would differ (see Annex K, item 9.3) This is a feedback process with a primary objective that the monitoring and mitigation plans improve over time and the monitoring component is integral part of any programme not merely an optional extra.

The Committee thanked Donovan for presenting this paper on behalf of the authors and **recommends** the process described in this paper. It also **endorses** the approaches described in the other papers presented in this section.

12.4.4 Other anthropogenic sound issues

The Committee received a brief summary of the findings of the 2008 mass stranding of melon-headed whales in northwestern Madagascar undertaken under the auspices of the IWC and others. The full report and supplementary information can be found on the IWC website.²⁰ While seismic surveys and other factors were systematically excluded or deemed unlikely it was found that the use of a 12-kHz Multi-Beam Echosounder System to be 'the most

plausible and likely behavioural trigger for animals initially entering the lagoon system.'

The Committee noted that the investigative process described in this report could serve as a model for investigating the cause of mass stranding in other areas

The Committee drew attention to the fact that this is a new sound source to be associated with cetacean mass strandings and **recommends** that high intensity multi-beam echosounder systems be considered in addition to military sonars as possible threats to cetacean populations. The Committee **thanks** the Government of Madagascar, the US government as well as the IWC for their support in the investigation of this mass stranding event.

Di Sciara presented the work of the Scientific Committee of the Agreement on the Conservation of Cetaceans of the Black Sea, Mediterranean Sea and Contiguous Atlantic Area (ACCOBAMS), on the location of critical habitats of Cuvier's beaked whales in the Mediterranean in order to support appropriate mitigation measures. The ACCOBAMS Committee developed a map of 'areas of special concern for beaked whales' – based on a combination of modelled beaked whale habitat and locations of all known mass stranding events, surrounded by a 50 nautical mile buffer zone – showing areas that naval exercises involving sonar use should avoid.

The Committee **commends** the ACCOBAMS Scientific Committee for addressing the conservation of Cuvier's beaked whales in the Mediterranean through the identification of the species' critical habitat, and **recommends** that efforts to map Cuvier's beaked whales' habitat in the Mediterranean should be continued and improved.

12.5 Impacts of climate change on cetaceans

12.5.1 Progress on climate change

An overview of IWC work on climate change and a summary of recent relevant publications were provided in SC/65b/E12. It noted Doney *et al.* (2012) which discussed impacts of climate change on marine ecosystems structure and dynamics, and how species might adapt; Lambert *et al.* (2014) recognised limitations of current scientific understanding of cetaceans, when attempting to model future distribution under climate change scenarios; and Poloczanska *et al.* (2013) compiled a database of 1,735 marine biological climate-related changes from the literature.

In addition, the recent Intergovernmental Panel on Climate Change (IPCC) summary for policy makers (IPCC 2013) predicted continued ocean warming, higher rates of sea level rise, greater sea ice loss and ocean acidification.

During discussion, it was noted that approximately half of the members of the SWG on Environmental Concerns are currently engaged in or indirectly working on issues related to climate change. In addition, the Committee indicated that other bodies have been considering the issue of climate change and conservation (e.g. ACCOBAMS, CMS). The Committee **agrees** that an intersessional steering group should meet to develop a plan for climate change work by the Committee over the next few years.

²⁰ <http://iwc.int/2008-mass-stranding-in-madagascar>.

12.5.2 Other climate change information

Information on a recently published review of the distribution of endemic cetaceans in relation to hydrocarbon development and commercial shipping in the Arctic (Reeves *et al.*, 2014) was presented to the Committee. The results showed extensive overlap between areas inhabited by the whales and areas of increasing interest for shipping and hydrocarbon exploration and development. For details of the paper, see Annex K, item 10.2.

12.5.3 Arctic impacts workshop

A summary of the 'Workshop on Impacts of Increased Marine Activities on Cetaceans in the Arctic' (Anchorage, Alaska on 6-7 March, 2014) was presented to the SWG. It focused on shipping and oil and gas activities and involved a wide range of stakeholders who discussed number of relevant aspects of the issue, including: current and past research conducted; implementation of management measures; knowledge gaps and concerns; and information the IWC can provide to assist managers in preparing for these impacts (see Annex K, item 10.2.1 for further details and recommendations)

The Committee **commends** the workshop participants for their work and looks forward to the final report. The Committee **reiterates** that two of its recommendations are independently in accord with those arising out of the Arctic workshop: (1) that the Commission pursue stronger links with other important international organisations (e.g. the Arctic Council, IMO), range states, local authorities and industry; and (2) that IWC member nations enhance the collection of baseline data related to health assessments, prey, and habitat of cetaceans for an improved capacity to detect impacts from or recovery after oil spills or to detect changes due to other human activities.

12.6 Habitat-related issues

12.6.1 Cetaceans and marine debris

12.6.1.1. UPDATE ON PLANNING FOR THE 2ND MARINE DEBRIS WORKSHOP

The first IWC workshop on marine debris, sought to define and understand the adverse impacts of marine debris on cetaceans (IWC, 2014b, pp.521-39). A second marine debris workshop under the auspices of the Conservation Committee will be held in Hawaii in the first week of August 2014 and a report will be forthcoming in 2014 (see Annex K, item 11.1.1).

12.6.1.2 NEW INFORMATION ON MARINE DEBRIS IMPACTS ON CETACEANS

Information collated on rates of marine debris ingestion and associated mortality rates, as well as recommendations regarding reporting debris interactions to the IWC was presented in SC/65b/E02. Debris ingestion has been documented in 48 cetacean species, with rates of ingestion in necropsied stranded carcasses as high as 74% in some areas. A key recommendation of the first IWC workshop on marine debris was that information on rates of debris interactions should be reported annually by country to the IWC. SC/65b/E02 made recommendations for information that should be included in such reporting.

The Committee **thanks** the authors of SC/65b/E02 for providing the information and **notes** that there was a need to develop monitoring tools to quantify the relevance of marine debris ingestion to the incidence of strandings and mortality,

with the ultimate aim of extrapolation to cetacean mortality rates. The Committee **agrees** that information on marine debris ingestion should be included in national Progress Reports submitted to the IWC. For details on fields see Annex K, item 11.1.2.

The Committee **recommends** discussions with the *ad hoc* Progress Report group and Secretariat with the aim of adding agreed fields for inclusion of such records in the online submissions portal.

A plan for the analyses of the quantity and distribution of marine debris in German waters, collected via aerial surveys, as well as an assessment of marine debris impacts on marine mammals was described in SC/65b/E10.

Summaries of SC/65b/SP02-05 and SC/65b/J22 were presented to the Committee (see Annex K, item 3 for statement on these papers). During the 2013 JARPN II offshore survey, debris was detected in stomachs of 33 of 100 sei whales sampled and 2 of 28 Bryde's whales. Plastic was the most abundant type of (<15cm). No obvious signs of illness that may have been caused by debris ingestion were detected. Marine debris on the sea surface was recorded during the sighting surveys (1987/88-2010/11; SC/65b/J22). A total of 70 pieces of marine debris and objects other than prey were found in the stomachs of Antarctic minke whales ($n=10,041$), including feathers, stone, wood, plastic and others. The authors noted that given the low indices, the effect of marine debris on whales in the Antarctic is expected to be limited at the present time.

12.7 Other habitat-related issues

Rosenbaum *et al.* (2014) provided information on the movement of Southern Hemisphere humpback whales from Breeding Stock B and the overlap with anthropogenic activities in the South Atlantic Ocean. The extent of overlap with anthropogenic activities makes it difficult to implement effective mitigation measures over their entire range.

Rosenbaum presented information on the assessment of vessel strike risk for large cetaceans in the Bering Strait region. The conclusions were that significant overlap between whales and vessels does occur, and these interactions are likely to increase and this is an area of key concern.

SC/65b/SH19 presented preliminary information that indicated 3 satellite-tracked Arabian Sea humpback whales exhibited spatial and temporal overlap with shipping traffic, oil and gas activity and planned fast ferry routes along the coast of Oman, and all three whales passed through the main approach channels to major ports.

The Committee **thanks** the authors of the papers for presenting their findings and **encourages** the continuation of similar work.

12.8 Conservation Management Plans

This is considered under Item 21 as well as in Annex K (item 12).

12.9 Workplan

The two-year overview of the Committee's workplan for matters related to environmental concerns is given as Table 15. The workplan itself is discussed in detail under Annex K, item 13.

Table 15

Overview of the workplan as it relates to environmental concerns

Topic	SC66a 2015	SC66b 2016
POLLUTION 2020	Refine population modelling approach; finalise priority contaminants list for future studies.	Continue to refine modelling approach; in utero transfer analyses and modelling
Oil spills	Review new information	Plan for an oil spill workshop
Contaminant threat information	Focus sessions on regional trends and POPs in cetaceans	Data integration and mapping
CERD	Pre-meeting to develop workplan. Data input and website management	Improved communications on disease issues
Strandings and mortality events	Plan intersessional workshop and finalise agenda; review new information	Receive the report of the intersessional workshop; review new information
Anthropogenic sound	Continue work on soundscape mapping including next steps and priorities; plan for 'masking' focus at SC65b. Review new information	Continue work on soundscape mapping; focussed sessions on 'masking'; plan for 'stress and sound' workshop; focus session on effectiveness of marine mammal observers in mitigation
Climate change	Receive report from intersessional meeting and agree workplan	Depends on progress at SC66a

13. ECOSYSTEM MODELLING

The report of the Working Group on Ecosystem Modelling is given as Annex K1. The Ecosystem Modelling Working Group was first convened in 2007 (IWC, 2008b). It is tasked with informing the Committee on relevant aspects of the nature and extent of the ecological relationships between whales and the ecosystems in which they live.

Each year, the Working Group reviews new work on a variety of issues falling under three areas:

- (1) reviewing ecosystem modelling efforts undertaken outside the IWC;
- (2) exploring how ecosystem models can contribute to developing scenarios for simulation testing of the RMP; and
- (3) reviewing other issues relevant to ecosystem modelling within the Committee.

This year the Working Group focused on a review of competition among predator species and the work of CCAMLR on krill and its dependent predators.

13.1 Review of ecosystem modelling efforts undertaken outside the IWC

13.1.1 Competition among baleen whales: how can we measure and model it?

Friedlaender gave a presentation reviewing published and unpublished data related to baleen whale foraging ecology, energetics and competition, including Friedlaender *et al.*

²¹ Direct completion occurs when two predators are present in the same area as a prey species, and may interfere with each other's access to the prey. When the two predators occur in different parts of the area of prey distribution, indirect competition may occur because the prey's production is

(2013). This issue was first addressed by Clapham and Brownell (1996), who discussed criteria necessary to demonstrate if, in fact, direct competition²¹ among cetaceans exists. Although the potential for some direct competition may exist, the influence of any such interaction on depleted and recovering whale populations in the Antarctic is difficult to assess, given the paucity of appropriate data for analysis (Clapham and Brownell, 1996). Nonetheless, Clapham and Brownell (1996) postulate that competition is unlikely between Antarctic baleen whale species due in part to probable resource partitioning mediated by food preferences and, potentially, the biomechanics of body size.

Until recently, logistical constraints limited our ability to test many of the ecological criteria to determine direct competition between cetaceans. Work off the western Antarctic Peninsula by Friedlaender and collaborators shows that sympatric humpback and minke whales appear to partition resources vertically at broad spatial scales. Humpback whales also appear to be distributed primarily in relation to their prey, while minke whales are more strongly associated with sea ice and secondarily to prey, which may indicate lower likelihood of competition via evolved means to partition resources. Tagging studies also show that minke and humpback whales feed at very different rates, in direct relationship to the anatomical scaling of their feeding apparatuses as predicted by recent biomechanical models for rorquals. Integrated with prey data, these models can also be used to predict minimum prey density thresholds, feeding rates and energetic intake across species.

In discussion, it was noted that data obtained by these tagging studies only provided the number of lunges as a measure of feeding success, and that the amount of food consumed by the animals could not be estimated based only on data obtained by the tags. However, it was also noted that when tagging data is accompanied by simultaneous measurements of prey density, such estimates of food consumption are possible.

The Committee agrees that there is a critical need for species-specific, fine-scale data on cetacean feeding and prey to provide parameters for individual-based models of competition between baleen whales. There is also an urgent need to develop the analytical and modelling tools to scale from individual-based whale foraging scales to broad spatial scales across species and ecosystems, using information about baleen whale energetics and feeding functional forms, as well as existing satellite tag, spatial and temporal data. The development of competition models should be conducted in parallel with data collection because the models can inform data collection and experimental design, and vice versa. In light of this, the Committee recommends that further work be carried out to collect the data identified above to inform the further development of ecosystem models.

13.1.2 Update from CCAMLR's Ecosystem Monitoring and Management Programme (WG-EMM) on krill and its dependent predators

The Committee held a joint workshop with CCAMLR in 2008 (IWC and CCAMLR, 2010). Since then, the Committee has identified significant knowledge gaps in aspects such as

limited so that consumption by the one predator limits the production available for the other, and *vice versa*.

spatial variability and trends in prey species, on the relationships between predators and prey, and on the effects of environmental variability on predators. Seeking closer collaboration between IWC/SC/EM and SC-CCAMLR's WG-EMM, in 2013 the Committee established communication with SC-CCAMLR and obtained a formal invitation for an IWC Scientific Committee observer to attend the annual meeting of the SC-CCAMLR WG-EMM. At this year's meeting, the Committee nominated Watters to take on this role and asked him to bring IWC Scientific Committee priorities to CCAMLR for future joint discussion. The Committee **views** the appointment of Watters as important for the development of a continuous and long-term relationship between IWC SC/EM and SC-CCAMLR WG-EMM. In addition, the Committee noted that Currey is now SC-CCAMLR observer to IWC SC and recommended his appointment to the obverse role of IWC SC observer to SC-CCAMLR in place of Kock. The Committee **agrees** to make this collaboration its primary emphasis for 2015 and 2016, and formed an intersessional correspondence group under Currey to facilitate communications that the Committee **expects** will lead to a joint IWC-CCAMLR intersessional workshop in 2016.

Watters also gave a presentation to the Committee on the development of minimally realistic ecosystem models to evaluate management strategies for the Antarctic krill fishery, based on work by Plaganyi and Butterworth (2012) and Watters *et al.* (2013). These models are relevant to the consideration of (both direct and indirect) competition among baleen whale species, but he noted that the specific effects of competition are conditional on the various structural assumptions (e.g. the spatio-temporal overlaps of predators and prey) and parameters that are estimated or fixed (e.g. the shapes of functional responses). Watters also noted that although time series of krill biomass and predator abundance are necessary to 'condition' the models, these time series might not be sufficient to discriminate among competition hypotheses. Thus, he concluded that it seems most robust to use multiple models for making inference about the effects of competition.

The Committee **agrees** that in order to successfully model indirect competition between baleen whales there is a need to collect data on the energetic demands and foraging behaviour of individual species across a range of scales from large regional or global scale, through defined management units, to spatially confined, fine-scale situations. Moreover, an important requirement of a competition model is for it to be able to inform strategic management advice, and this requires the ability to:

- (a) Change state variables to address particular management concerns; and
- (b) Maintain open communication and feedback between modellers and management bodies to ensure reciprocal familiarity, understanding and acceptance of the priorities, scientific process and proffered advice.

13.2 Explore how ecosystem models contribute to developing scenarios for simulation testing of the RMP

At last year's meeting, De La Mare (2013) presented a modelling framework that uses spatially resolved individual based energetics models (IBEMs) to determine reproductive

success and mortality in an environment where food has a patchy spatial distribution. These models can be used to generate population dynamic scenarios for evaluation in the RMP context (IWC, 2014g, Annex K1, p.333). Among the issues that could usefully be explored using these IBEMs, the Committee accorded highest priority to the characterisation of yield curves for populations in stochastic environments, and to exploring the relationships between $MSYR_{I+}$ and $MSYR_{mat}$ and between K and $MSYR$.

SC/65b/RMP03 and SC/65b/RMP04 reported progress on using the IBEM to explore the relationships between $MSYR_{I+}$ and $MSYR_{mat}$ and to incorporate it into the RMP testing software framework. The Appendix of SC/65b/RMP03 provides the details of the model, including energetics and prey dynamics. The Committee noted that it was not immediately clear what were the main drivers of the results and that an emulator could be usefully developed to better understand the model's properties, although this would require considerable work. Further discussion of these papers is given under Items 5.1 and 5.2.

13.3 Review of other issues relevant to ecosystem modelling within the Committee

13.3.1 Update on Antarctic minke whale body condition analyses

For the last four years the Committee has discussed suggested declining trends in blubber thickness and body condition in Antarctic minke whales (Konishi *et al.*, 2008) over the 18 years (1987/88-2004/05) of the JARPA special permit programme (IWC, 2011c; 2012d; 2013d; 2014g). This item is relevant to ecosystem modelling because the findings have implications for energetics, reproductive fitness, foraging success, and the prey base itself, all of which are important as input in models. A number of concerns have been raised and addressed on the statistical methods that were used to derive these trends.

At last year's meeting (IWC, 2014g), the Committee recommended the use of mixed-effects linear models with different interaction terms as possible random effects and the inclusion of a new binary variable (near or far from the ice edge). The Review Panel at the JARPA II Review Meeting raised additional issues regarding the treatment of the time trend in body condition, the correlation among covariates, the procedure for model selection from the full model, and the diagnostics for the best model (SC/65b/Rep02). The Review Panel also recommended consideration of additional interaction terms, as well as additional variables that could potentially be included as random effects (SC/65b/Rep2).

SC/65b/EM02 presented analyses that included the recommended interaction terms for 'Date and longitude', 'Year and Latitude' and 'Year and Ice' (although these adjustments did not result in any change in model selection in terms of BIC in the cases investigated). The procedure for model selection was done with the recommended stepwise selection, and the requested correlation matrices and diagnostic plots for the best model were also included. In discussion, the Committee indicated that further clarity was required about what the full and reduced models were, including the explicit identification of a 'maximal biologically plausible model'. A small group was formed to

address this issue and the complete results are presented in Appendix 2 of Annex K1.

Konishi *et al.* (2014) reported a decreasing time trend in the weight of stomach contents from Antarctic minke whales taken during the JARPA and JARPA II programmes, and SC/65b/EM03 provided a revision of this paper following the JARPA II Review Panel recommendations (SC/65b/Rep2), but restricted to data from the JARPA period. The authors applied similar regression analyses as in SC/65b/EM02 for body condition and obtained similar results, including an indication that it was not necessary to consider year as a categorical variable. In discussion, the Committee identified similar problems to those of SC/65b/EM02, and asked that the small group tasked with addressing those issues also include SC/65b/EM03. The Committee further noted that a model with a constant time trend and with a random effect for the variation around this trend could potentially be better suited. In addition, in light of the highly skewed distribution of the residuals, they were asked to revisit model's distributional assumptions.

The results of the work of the small group are included in Appendix 2 of Annex K1. In discussion of these further analyses, the Committee **agrees** that the analyses which it had requested last year, and those requested by the Review Panel, had been satisfactorily completed. Given the results, the conclusion followed that a decline in blubber thickness and in fat weight that was statistically significant at the 5% level had occurred during the JARPA period. The Committee **agrees** that the implications of these results, together with indications of no further decline after the JARPA period, should be discussed further at next year's meeting. In particular, this will address whether a change of biological importance had occurred or not in the Southern Ocean ecosystem during the JARPA period. The Committee also **agrees** that the model presented in Appendix 2 of Annex K1 would benefit from extension to determine whether the trends identified showed any indication of change over time. It was noted that, even if not statistically significant at the 5% level, estimates of changes in trends would ultimately be important to take into account in fitting multi-species models.

Finally, the Review Panel at the JARPA II Review Meeting also recommended that a paper be presented at this meeting with details of a work plan to incorporate uncertainty in the estimates of prey consumption rate by Antarctic minke whales based on JARPA and JARPA II data (SC/65b/Rep2). SC/65b/EM01 was written as a response to these recommendations, indicating that over the next 1-2-year period the authors will implement Monte Carlo simulations for the estimation of uncertainty in the following parameters: *r* (the ratio of low/high feeding intake), the length of the feeding season and the extent of night feeding. The Committee had no further comments on this paper.

13.3.2 Case studies of the effects of long-term environmental variability on whale populations

The Committee briefly considered the types of information that should be compiled for analysing the effects of environmental change on cetaceans, for a fuller discussion next year. These analyses require decadal-length time series of cetacean demographic parameters and/or abundance together with relevant environmental variables for the same time periods and regions. An initial list of potential data sets

was identified, and an intersessional correspondence group was appointed under Cooke to continue advancing this objective.

13.3.3 Other, if new information is available

Palacios *et al.* (2013) presented an evaluation of current statistical modelling efforts applied to predict marine mammal species distributions, commonly referred to as habitat models or species distribution models. These efforts have primarily relied on correlative approaches, and the authors argued that their limited explanatory power is due fundamentally to the omission of critical environmental and behavioural processes that directly affect marine mammal distributions. Palacios *et al.* (2013) outlined field studies targeted at that the elucidation of such processes, and the subsequent incorporation of this information into habitat models, as a way forward to significantly improve our ability to predict species' distributions. Finally, the authors note a convergence between probabilistic (stochastic) and deterministic approaches as a potential solution to the incorporation of the processes of interest into species distribution models.

The Committee **welcomes** this summary and noted the paper provides a timely contribution to discussions within the Committee on methods in species distribution modelling. Given the complexity and rapid development of this field, the Committee appointed an intersessional correspondence group under Murase to develop guidance and best practices to further applications of species distribution and habitat modelling within the Committee. Appendix 3 in Annex K1 was compiled as a basis for this work.

13.4 Workplan and budget requests

The detailed workplan and Budget Requests are detailed in Annex K1. The overall two-year workplan is summarised in Table 16.

Table 16

Overview of the workplan as it relates to ecosystem modelling

Topic	SC66a 2015	SC66b 2016
Co-operation on ecosystem model development	Discuss how best to further the long-term scientific exchange between IWC SC/EM and SC-CCAMLR WG-EMM (and receive report from observer at 2014 WG-EMM meeting)	Receive results of Joint CCAMLR-IWC Workshop and continue
Processes in ecosystem model development	Receive results of IWC funded project to use tagging data to incorporate into models (especially with respect to competition, resource partitioning and total prey consumption)	Review progress and continue
Ecological change in the Southern Ocean	Review new analyses of the minke whale body condition and stomach content data to further examine temporal trends	Continue if necessary
Effects of long-term environmental change	Review work of intersessional group to determine suitable long time datasets and determine workplan	Depends on discussions at SC66a
Modelling species distribution	Build upon previous and intersessional work to develop guidelines and recommendations for modelling steps	Depends on discussions at SC66a

14. SMALL CETACEANS

14.1 Review of status of small cetaceans in the eastern Mediterranean and Red seas

This year, the priority topic given the location of the meeting, was to review the current status of small cetaceans in the eastern Mediterranean and Red Seas (fig. 1 of Annex L). The Committee noted the importance of co-operation with ACCOBAMS in this region.

Relatively little information was received on the eastern Mediterranean Sea and several areas in the region remain poorly known with respect to the status of small cetaceans. The available information was primarily for the Adriatic and Aegean seas, Libyan waters and the Levantine Basin.

14.1.1 Adriatic Sea

SC/65b/SM20 provided a general review of cetacean species in the Adriatic Sea. The common bottlenose dolphin is the only species that occurs throughout the basin and it appears to have a continuous distribution over the continental shelf area. The striped dolphins are more abundant but limited to the southern Adriatic Sea which also seems important for Cuvier's beaked whales and Risso's dolphins. The common dolphin, once abundant, is now extremely rare (Bearzi and Notarbartolo di Sciara, 1995; Genov *et al.*, 2012; Rako *et al.*, 2009). Two recent aerial surveys have covered the entire Adriatic basin and provide important new information on summer distribution and abundance²². Surveys confirmed the general distribution of cetaceans and generated preliminary abundance estimates uncorrected for availability and perception bias (Fortuna *et al.* 2011 and unpublished data). Details on available information on genetic structure of populations, interaction with fisheries and other existing threats can be found in Annex L.

The Committee **thanks** Holcer and colleagues for providing this valuable summary.

The Swiss NGO OceanCare provided an inventory²³ of the seismic offshore explorations for oil and gas in the Mediterranean since 2006, many in the Adriatic Sea. There is a concerning geographical overlap with areas thought important for cetaceans. The Committee **welcomes** this information and reiterates previous Committee concern over the difficulty of obtaining information of where and when seismic surveys are taking place (see Nowacek *et al.*, 2013). Additional discussion on beaked whales and anthropogenic noise was carried out in the joint session with the SWG on Environmental Concerns (see Annex K, items 8.3 and 9.4).

The Committee also **thanks** Genov for providing information on the bottlenose dolphins that occur year round off Slovenia and in the Gulf of Trieste (northern Adriatic Sea), that have been monitored since 2002 (Genov *et al.*, 2008). All details are provided in Annex L.

In conclusion, the Committee **recommends** that monitoring programmes in the Adriatic Sea should be coordinated among the neighbouring countries to enable regular basin-wide surveys of populations and monitoring of threats especially within the mandatory activities needed under the EU Marine

Strategy Framework Directive (*Directive 2008/56/EC*). The Committee also **recommends** that ongoing studies in the region, particularly in offshore areas of the southern Adriatic, be continued (e.g. to improve the knowledge on beaked whale).

14.1.2 Aegean Sea

Frantzis (2009) summarised the present status of knowledge on small cetaceans in Greek waters, and more recent publications (Bearzi *et al.*, 2011; Bonizzoni *et al.*, 2014) complement that information. Five species of small cetaceans are present year-round in Greek waters: striped, common bottlenose, short-beaked common and Risso's dolphins and Cuvier's beaked whales. The harbour porpoise has been recorded in the northern Aegean Sea (they are not genetically isolated from those in the Black Sea (Rosel *et al.*, 2003; Tonay *et al.*, 2012; Viaud-Martínez *et al.*, 2007) and there have been opportunistic sightings of harbour porpoises in the straits between the Aegean and Black Seas. The rough-toothed dolphin has been recorded in the central Ionian Sea. False killer whales are occasionally recorded. The common bottlenose and striped dolphins are the most common species. Cuvier's beaked whale is present along the Hellenic Trench from Corfu to Rodos Island, and over steep depressions of the Aegean plateau. Abundance estimates are very scarce and apply to limited areas (Bearzi *et al.*, 2008a; Bearzi *et al.*, 2008b; Bearzi *et al.*, 2011; Bonizzoni *et al.*, 2014). Details on threats in this area can be in Annex L.

Explosives are still used illegally to fish and the Committee **expresses concern** and **requests** the Greek authorities to stop the illegal use of explosives.

SC/65b/SM15rev provided a review of current knowledge on small cetaceans in the Mediterranean waters of Turkey, including the Aegean Sea. Information for this large area, particularly on abundance and population structure, is limited by funding and research capacity. Nine species of small cetaceans have been recorded from the area. The short-beaked common dolphin, common bottlenose dolphin, striped dolphin, Risso's dolphin and Cuvier's beaked whale are considered common based on sighting and stranding data whereas the long-finned pilot whale, the false killer whale and beaked whales are considered rare. All cetacean species are protected by national legislation. Additional information can be found in the paper.

The Committee **thanks** Öztürk and colleagues for preparing this useful overview.

SC/65b/SM04 summarised information from the summer 2013 Song of the Whale survey of the Aegean and Levantine Seas (Ryan *et al.*, 2014). Harbour porpoises were encountered for the first time in over 20 years north of Thasos Island and west of Alexandropoulos (Greece) and in Saros Bay (Turkey). Common bottlenose dolphins were most common in the Aegean Sea and striped dolphins in the Levantine Sea. Common dolphin sightings were limited to the northern Aegean Sea, primarily the Thracian Sea. Rough-toothed dolphins were observed twice in the Levantine Sea, south of Cyprus. Seven acoustic detections (no sightings) of beaked

²²Carried out by the Italian National Institute for Environmental Protection and Research (ISPRA) and Blue World Institute (Croatia) within the framework of two projects (Italian monitoring of bycatch under EU regulations and EU IPA Adriatic NETCET project).

²³ Still not exhaustive as the information about these surveys is not readily accessible.

whales were recorded, one in the Ikaria Basin, an area thought to be important for deep-diving species, and the rest along the Anaximander Seamount, south of Turkey.

The Committee **endorses** the recommendation from local scientists that Turkey develops a Conservation Action plan for small cetacean species in its waters which incorporates public awareness as well as research elements.

14.1.3 Libyan waters

SC/65b/SM16 provided a brief summary of the status of small cetaceans in Libyan waters, which occupy 40% of the southern Mediterranean coast. The cetacean fauna of Libya is little known, with seven species expected to occur. A long-term photo-identification study in Cyrenaica suggests the presence of a resident bottlenose dolphin population distributed between two areas. There is growing concern over both habitat degradation and unregulated fisheries, including the use of explosives. There are some reports of bycatch, consisting mostly of striped dolphins and common bottlenose dolphins in seasonal trammel net fisheries in the west of the country.

The Committee **encourages** relevant authorities in Libya to more strictly regulate fisheries and stop the illegal use of explosives.

14.1.4 Levantine Basin

SC/65b/SM9 presented a review of the present knowledge on small cetaceans in Mediterranean Israeli waters. Very few surveys have been conducted, but densities of all species (common bottlenose, stripes, common, Risso's and rough-toothed dolphins and Cuvier's beaked whales) appear to be relatively low. Strandings data collected between 2000 and 2010 indicate almost 30% of dead bottlenose dolphins were trapped in the safety line of bottom trawls. Entanglement in gill nets is apparently rarer (6%). The presence of large groups of short-beaked common dolphins (up to 100 individuals) off southern Israel is noteworthy. SC/65b/SM9 also contains some information on observed and potential threats, including gas and oil explorations. More details are given in section 6.1.4 of Annex L.

Discussion focused on the status of rough-toothed dolphins in the eastern Levantine basin, an area of apparent importance for the species. The species appears absent from the western Mediterranean and the Red Sea. Genetic information suggests the Levantine animals are a relict population of Atlantic origin with little if any recent exchange with other populations. Differences in behaviour and diet are suggested compared to other areas. Kerem encouraged analyses of an as yet unanalysed dataset from surveys conducted by IFAW (2013).

The Committee **thanks** Kerem and his colleagues for information on a poorly known region and **encourages** publication as soon as practicable. It also **recommends** that (1) that a preliminary analysis to define the amount of effort needed to obtain robust abundance and distribution data in Israeli waters be conducted and (2) that Israel develop Conservation Action plans for small cetacean species incorporating scientific elements and public awareness.

14.1.5 General recommendations for the eastern Mediterranean

Noting the various threats identified for small cetaceans in the eastern Mediterranean region, the Committee **recommends**

that further research be conducted to investigate their effects on the long-term viability of populations. Specifically the Committee **reiterates its previous recommendations** that:

The large-scale survey known as the 'ACCOBAMS Survey Initiative' be carried out as soon as possible in order to obtain information on cetacean distribution and abundance for the whole Mediterranean, including the eastern sub-region.

It also **recommends** that:

- (1) Systematic sub-regional surveys be implemented;
- (2) Research be undertaken to define management units, at least for the most common species (e.g. the common bottlenose dolphin and the striped dolphin), through multidisciplinary approaches (including genetics, isotopes, biomarkers and photo-identification) to evaluate the effects of anthropogenic mortality (e.g. bycatch) at population level;
- (3) The nature and extent of cetacean-fisheries interactions (including bycatch, depredation and competition/overfishing) be investigated. This could include enlarging the scope of existing fishery monitoring programmes (e.g. by collecting data on cetaceans bycatch and other interactions on a regular basis), including those for IUU (illegal, unreported and unregulated) fisheries;
- (4) Research be conducted on the extent and effects of oil- and gas-related activities;
- (5) Cooperative research with oil and gas industries be developed for sharing information on cetacean distribution and to develop models to identify areas of high density or high importance to small cetaceans;
- (6) Conduct research on the effects of boat traffic on small cetacean local populations, especially in harbours and other areas of high activity and potential overlap;
- (7) A research project be developed in the eastern Mediterranean Sea to gather data on rough-toothed dolphins in order to assess their degree of isolation and their conservation status under IUCN criteria. This assessment should make use of existing acoustic and genetic data.
- (8) Regional cooperation on science and policy for conserving/managing shared populations/species (e.g. common research/monitoring programmes, common mitigation actions) should be implemented (e.g. in the Adriatic Sea under the Marine Strategy Framework Directive);
- (9) Capacity building actions should be implemented (university, local authorities) throughout the region.

14.2 Review of status of small cetaceans in the Red Sea

SC/65b/SM13 summarised existing knowledge on cetaceans in the Red Sea based on a literature review and the authors' direct observations. Eleven species of small cetaceans are thought to occur in the Red Sea of which eight (*D. c. tropicalis*, *G. griseus*, *P. crassidens*, *S. plumbea*, *S. attenuata*, *S. longirostris*, *T. aduncus* and *T. truncatus*) are thought to occur regularly.

SC/65b/SM23 summarised the results of a dedicated survey to estimate abundance of delphinids in a portion of the southern Egyptian Red Sea (10,651 km²). Abundance estimates are provided in Annex L, item 6.2. *Stenella* species were encountered throughout the study area. Bottlenose dolphins were present at low densities, with an apparent

concentration of *T. truncatus* in offshore areas and *T. aduncus* in southern coastal areas. Within the study area *G. griseus* occurred mainly south of 23°N. Offshore reefs in the southern part of the study area appear to be used as resting areas by at least three species; this is also an area where fishing and tourist activities are concentrated. The authors stressed the need to gather more information about these zones, since similar resting areas are known to be heavily affected by tourist and fishing activities in the northern part of the study area. They also urged that there be more research effort in the southern coastal areas frequented by two coastal species (*T. aduncus* and *S. plumbea*), where unregulated fishing is conducted regularly from the main village (Shalatin) and where there are two large active Egyptian naval bases.

Despite low human densities along the region's desert coasts, observed increases in tourism and coastal development, fishing, shipping, and hydrocarbon exploration and extraction (particularly in the northern portion of the region) suggest the need for increased cetacean research efforts. Dedicated research projects and surveys should include investigations of ecology, potential threats and conservation status. Such actions could be facilitated by PERSGA, the Regional Organisation for the Conservation of the Red Sea and Gulf of Aden.

The Committee **agrees** on the importance of gathering additional detailed information on the distribution and abundance of cetaceans, particularly in the least known portions of the region (e.g., Gulf of Suez, waters of Saudi Arabia, Sudan, Eritrea and Yemen), and promoting regulation of dolphin watching in Egypt.

The Committee **encourages** the authors to publish their review in a peer-reviewed journal as soon as practicable.

14.3 Report on the Voluntary Fund for Small Cetacean Conservation Research

Fortuna presented a summary of projects funded by the Voluntary Fund for Small Cetaceans. Approximately £350,000 has been disbursed since 2010 and 16 projects have been funded (Annex L, Appendix 2). Projects were awarded through two calls for proposals (2011 and 2013). Proposals are selected through a rigorous review process by the Small Cetacean Conservation Research Fund Review Group (http://iwc.int/sm_fund). All details of funded projects were available through the Secretariat and final results will be made available on the IWC website.

The Committee **recognises** the importance of this fund and the work being accomplished and **welcomes** the most recent voluntary contributions received after the last Commission meeting in Panama (June 2012) by Italy (£12,300), the Netherlands (£19,324), the United Kingdom (£30,000), the USA (£6,320), Italian National Institute for Environmental Protection and Research (£12,132), Oceancare (£998), World Society for Protection of Animals (£3,000) and World Wildlife Fund (£1,295).

14.3.1 Update on 2011 awarded projects

SC/65b/SM21 reported progress on the 'Ecology, Status, Fisheries Interactions and Conservation of Coastal Indo-Pacific Humpback and Bottlenose Dolphins on the West Coast of Madagascar'. Interview surveys with fishers in the northwest indicated that directed hunting on coastal dolphins is not as prevalent as in the southwest, but by-catch,

particularly of *T. aduncus*, is prevalent and there is some evidence for 'directed by-catch' that may indicate a progression towards hunting. In the southwest where hunting has been documented, a model of community-based conservation has been successfully implemented; local associations for the protection of marine mammals have been established, education and outreach commenced, local traditional laws (Dina) are being developed and ratified, and alternative livelihood options (ecotourism) are being tested. Additional details on this project can be found in item 7.1 of Annex L.

In discussion, it was noted that in the southwest the overt presence of meat in markets had decreased since the project's inception (1999) and that fishers were benefiting from alternate sources of cash generated through seasonal whale watching ecotourism activities (developed in 2004). The number of local operators and clients was increasing in the Anakao area and the spatial extent of conservation work was expanding in the wider southwest region (Anakao to Andavadoaka). Continued effort was planned but requires additional funding.

The Committee **emphasises** that this project represented another good example of the important contribution made by the Small Cetaceans Conservation Research Fund.

14.3.2 Update on 2013 awarded projects

SC/65b/SM26 provided a progress review of the project entitled 'Defining the units of conservation and historic population dynamics for two small cetacean species affected by directed and incidental catches in the North Pacific' (Principal Investigator: Chen). Ten animals confiscated in PingDong Taiwan from an illegal take (from unknown locations) were investigated to confirm species identity. They had been identified as Fraser's dolphins by the Taiwanese authorities. Genetic analysis suggested that the confiscated samples were not Fraser's dolphin but more likely of a species in the genus *Stenella*, possibly *S. longirostris*. Further analyses and sequencing is planned to resolve this question. These results were presented at regional meetings in Taiwan and Japan and a report on the status of these species for Taiwanese authorities in preparation. A final report will be submitted to the IWC in June 2014.

In discussion it was noted that although the results were preliminary, they served to emphasise the lack of reference sequences for many genes. The Committee **commends** the work by Chen and Hoelzel and **emphasises** the efficient use of a relatively modest grant.

Porter provided an update on an ongoing project entitled 'A Pilot Study to Identify the Extent of Small Cetacean Bycatch in Indonesia using Fisher Interview and Stranding Data as Proxies'. Recent activities include a workshop (November 2013) where participants were trained to identify evidence of bycatch in strandings events. Interviews of fishers (50 per site) were completed at two sites: Paloh and Adonara. The Paloh area fisheries focus on coastal areas using gillnets as the main fishing gear and interviews suggest that the species most effected are the finless porpoise and the Indo-Pacific humpback dolphin (*Sousa chinensis*). The Adonara fisheries operate both inshore and offshore with pole and lines and purse seine as the main gears utilised. The cetacean species most effected were noted to be the bottlenose dolphin (*Tursiops spp*), the spinner dolphin (*Stenella longirostris*),

some unidentified 'black fish' (and sperm whales). Data analyses are still underway and the final report will be submitted by the first week of June 2014.

In discussion Porter clarified that dolphins were actively targeted for consumption in some areas but were opportunistically used at other sites when landed. The use of terminology associated with catches was also discussed, with the need for care and consistency emphasised. It was suggested that the term 'takes' and not 'bycatch' be used in this context.

14.4 Progress on previous recommendations

14.4.1 Vaquita

Great concern over the status of this species has been expressed for many years by the Committee. At last year's meeting the Committee was (1) advised that the best 2013 abundance estimate for the critically endangered vaquita, long a topic of this Committee, was 189 animals and (2) commended Mexico's establishment of a new Advisory Commission of the Presidency of Mexico for the Recovery of the Vaquita (CAP). Rojas-Bracho reported that CAP held its fourth meeting in April 2014 where Advisory Commission members were advised of a recent dramatic escalation of illegal fishing and trade of totoaba (*Totoaba macdonaldi*), a critically endangered CITES Appendix I species, in the Upper Gulf of California. This fishing involves the use of large-mesh gillnets which have a high entanglement risk for vaquita. Demand is driven by the high price of totoaba swim bladders in Asian markets. The actions by the Mexican Government to combat this fishery were presented and discussed during the CAP meeting as were further measures to replace gillnets with alternative light trawl gear and to strengthen enforcement.

The Committee also received information on the Second Meeting of the Steering Committee of the Vaquita Acoustic Monitoring Program, which met in Ensenada in April 2014, to review and evaluate technical aspects of the passive acoustic monitoring project and to review results to date. The monitoring array performed well and acquired sufficient data to detect a 4%/year increase in over a 5-year interval were such an increase to occur. Alarming, mid-project results indicate a substantial decline in vaquita numbers since 2011. Raw data indicate declines of 7.5% and 14.9% from 2011 to 2012 and from 2012 to 2013, respectively. Assuming a 14.9%/yr decline, from the 2013 estimate of 189 individuals, the population could be reduced to fewer than 100 individuals in the next two years. The Steering Committee agreed that these estimated annual rates of decline from 2011 to 2013 are so severe and the vaquita's status so serious that immediate action is essential to save this species. To confirm its findings, the Steering Committee is planning an immediate review of the data, analyses and preliminary findings by a small group of experts before the next CAP meeting in July 2014.

The Committee **reiterates** that the situation for the vaquita is extremely grave and is especially exacerbated by the totoaba fishery. It **expresses grave concern** that the resurgence of illegal totoaba fishing with large mesh gill nets is driving the vaquita more rapidly toward extinction. The Committee **supports** the actions taken and recommendations made by the CAP at its Fourth Meeting and **recognises and commends** the efforts being made by the Mexican Government to combat the illegal fishing of totoaba.

Recalling Committee recommendations from 1991, the Committee **recommends** that further action be taken to stop vaquita entanglement by fully enforcing the closure of the totoaba fishery and that immediate action be taken to stop the illegal shipment of totoaba across the US border.

The Committee **recommends** that the Governments of Mexico and the United States consult on this continuing illegal international trade in CITES Appendix I totoaba and, as necessary, raise it to CITES and its Party government to highlight the effect of this trade in causing additional losses of the critically endangered vaquita, with the goal of enhancing enforcement efforts and awareness.

The Committee **emphasises** that immediate implementation by the Government of Mexico of its strategy to replace gillnets with alternative fishing gear, as required by NOM-002-SAG-PESC-2013, is **extremely urgent**, particularly given the recent major expansion of illegal totoaba fishing and the preliminary results of the acoustic monitoring program, which indicate a rapid decline in vaquita abundance.

The Committee also **reiterates** its previous recommendations (IWC, 2011a; 2012a) to continue research on technologies to replace gillnetting for finfish or otherwise to remove all gillnets from the vaquita's entire range (IWC, 2008d; 2009c; 2010d; 2011d; 2012e; 2013e; 2014h).

The Committee **encourages** the Government of Mexico to maintain and, as necessary, refine or expand the acoustic monitoring programme as the only feasible way of evaluating the effectiveness of the recovery plan contained in the federal Action Program for the Conservation of Vaquita (PACE-Vaquita). The Committee **strongly endorses and applauds** the work of the team (Coordinación de Investigación y Conservación de Mamíferos Marinos) at CONANP for the field work and data analysis and of the steering committee for the review and evaluation of the monitoring programme.

14.4.2 Hector's dolphin

Currey provided a summary of the Government of New Zealand Ministry for Primary Industries (MPI) science and management actions for Hector's (*Cephalorhynchus hectori*) and Maui's (*Cephalorhynchus hectori maui*) dolphins. The decline of Maui's dolphin is demonstrated by multiple methods. Both the East Coast of the South Island (ECSI) and West Coast South Island (WCSI) Hector's dolphin populations are probably also in decline, although evidence is inconsistent and trends not entirely clear. Since 2008 there has been a substantial reduction in set net effort on the WCSI, while on the ECSI fisheries interactions have declined following the extension of set net area closures. The population of Hector's dolphins along the South Coast of the South Island is small and genetically isolated, but the trend in abundance is unknown.

The Committee **respectfully requests** that the New Zealand government provide updates of the MPI report on a regular basis.

Annex L provides details of criticism by Slooten of aspects of the report relating to abundance and distribution.

Mackenzie and Clement (2014) reported the results of an aerial survey program to estimate the abundance and distribution of the ECSI population of Hector's dolphins between Farewell Spit and Nugget Point and offshore to 20

nm (covering ~42,677 km²). The estimates suggest substantially higher numbers in both inshore and offshore areas than previously thought. The discrepancy is more likely attributable to differences in survey methodology (i.e., boat versus aerial surveys) and increased survey effort in offshore areas, rather than to an increase in population size or a change in distribution.

The Committee **agrees** that this matter deserves closer scrutiny than was possible in the time available at this year's meeting. Next year the sub-committee will make provision to ensure appropriate evaluation of abundance estimates.

14.4.2.1 MAUI'S DOLPHIN

SC/65b/SM8 presents estimates of the effectiveness of the extensions to protected areas for Maui's dolphin implemented in 2012 and 2013 in terms of reducing bycatch. An 'Expert Panel' of scientists, convened by the New Zealand government in 2012, estimated that five Maui's dolphins were killed each year in trawl and gillnet fisheries (Currey *et al.*, 2012). The level of trawl mortality is unchanged and continued dolphin deaths in gillnets are due to a lack of protection in some areas and incomplete protection in others. The estimated number of bycatch events has decreased from 5 per year to 3-4 per year, reducing the total level of bycatch from >75 to >54 times the safe level estimated using a PBR (Potential Biological Removal). Detailed information on strategies to reduce bycatch below PBR are given in the document and summarised in Annex L.

SC/65a/SM11 recognised the efforts of the Government of New Zealand to date, but provided a critique of the current protection measures stating that they are insufficient. Detailed information is given in the document and summarised in Annex L.

In discussion it was noted that the current management situation falls short of that required to reverse the Maui's dolphin decline. Since the publication of the Expert Panel report (Currey *et al.*, 2012) the New Zealand Government had closed additional fisheries, and a reduction in the number of predicted fisheries interactions is expected. It was noted that bycatch numbers would not be reduced to zero even with the most recent increased area closures.

The Committee **commends** the New Zealand Government for maintaining initial and interim protection measures for Maui's dolphin, and adding an additional 350 sq. km set net restriction. However, the Committee **emphasises** that these measures fall significantly short of those previously recommended (IWC, 2013a; 2014c). The Committee **reiterates** its **extreme concern** about the continued decline of such a small population as the human-induced death of even one dolphin would increase the extinction risk for this subspecies. It also **reiterates** that rather than seeking further scientific evidence it is of highest priority to take immediate management actions that will eliminate bycatch of Maui's dolphins. This includes full closures of any fisheries within the range of Maui's dolphins that are known to pose a risk of bycatch of small cetaceans (i.e. set net and trawl fisheries).

The Committee **re-emphasises** that the critically endangered status of Maui's dolphin and the inherent and irresolvable

uncertainty surrounding information on small populations, require the implementation of precautionary measures.

Ensuring full protection of Maui's dolphins in all areas throughout their habitat, together with an ample buffer zone, would minimise the risk of bycatch and maximise the chances of population increase. The Committee **notes** that the current range of Maui's dolphins comprises the area from Maunganui Bluff in the north to Whanganui in the south, offshore to 20 nautical miles and including harbours. This range reflects all available sightings and strandings data for Maui's and Hector's dolphins along the West Coast of the North Island. The Committee **notes** that data from Hector's dolphins off the South Island, with most sightings in waters less than 100 m deep and less than 20 nm offshore support our understanding of the offshore distribution of Maui's dolphins and the recommendation that within this defined area, fishing methods other than set nets and trawling should be used.

The Committee **urges** the New Zealand Government to **commit** to specific population increase targets and timelines, and **respectfully requests** that reports be provided annually on progress towards conservation goals.

14.4.3 Beaked whales

SC/65b/SM01 provided a short review of strandings of Gervais' beaked whale (*Mesoplodon europaeus*) in the Atlantic Ocean collected since 1995 and SC/65b/SM02 presented stranding records in European waters of Sowerby's beaked whale (*Mesoplodon bidens*) since 1825.

See Annex L, item 6.1 for new information on Mediterranean beaked whales. See also the relevant discussions on beaked whales and anthropogenic noise in Annex K, items 8.3 and 9.4.

14.4.4 White whales²⁴ of the Okhotsk Sea

SC/65b/SM14 provided information on recent and expanding captures of white whales in the western Okhotsk Sea (Russia). Recent studies have identified separate demographic units within the Western-Okhotsk population, including the summer aggregation in Sakhalin-Amur region (details on abundance are provided in item 8.4 of Annex L) with Potential Biological Removal (PBR) estimated as 42 (SC/65a/SM23).

Last year (IWC, 2014c), the Committee agreed that the current management scheme for live-capture of white whales in the Sea of Okhotsk was very likely to lead to unsustainable levels of removals, placing at least the Sakhalin-Amur summer aggregation in Sakhalinsky Bay at high risk of depletion.

The Committee **expresses strong concern** given the estimated PBR of 42, that the removal of 81 living white whales, with an additional 12 confirmed and over 30 suspected deaths in summer of 2013, is unsustainable for this local summer aggregation and **reiterates** that removals should be reduced to at least a level that is consistent with available scientific data and that the four summer aggregations in the North-Okhotsk subzone should be managed separately through separate quotas for Sakhalin-

²⁴ 'White whale' is the official IWC common name but the species is also known as 'beluga' or 'belukha' in some parts of the Arctic.

Amur region, Ulbansky Bay, Tugursky Bay and Udskeya Bay (IWC, 2014c).

The Committee also **supports** the continuation of the white whale research projects conducted by the A.N. Severtsov Institute and the Marine Mammal Council and **recommends** expanding research efforts into all areas of potential beluga removals.

14.4.5 Killer whales

14.4.5.1 RUSSIAN FAR EAST

SC/65b/SM07 provided information on killer whales in the Russian Far East, including details of recent captures. Six killer whales were live-captured in different areas of the Russian Far East from 2002-2011 and seven more were reported captured in the western Okhotsk Sea in 2012-2013. Two of these were transported to China for public display and another two are suspected to be in Moscow; the fate of the remaining three animals is unknown.

The Committee discussed its concern about these captures, particularly the uncertainty of ecotype identification. There is evidence that resident and transient killer whales belong to reproductively isolated populations (SC/65b/SM15, Filatova *et al.*, 2014; Ivkovich *et al.*, 2010), mirroring the situation in the eastern North Pacific (Ford *et al.*, 1998; Saulitis *et al.*, 2000). Based on genetic data similar to that reported in SC/65b/SM07, 'Resident' and 'Transient' killer whales are currently recognised as unnamed subspecies by the Society for Marine Mammalogy Committee on Taxonomy (List of marine mammal species and subspecies. Society for Marine Mammalogy)²⁵ and some have suggested that these ecotypes qualify as full species (Morin *et al.*, 2010a).

No reliable abundance estimates are available for either ecotypes in the Okhotsk Sea but the available information (e.g. SC/65b/SM07) raises concern that local stock size is fairly small and that only transients have been live-captured in this region. Different killer whale ecotypes are not officially recognised in Russia, and consequently they are not treated as different management units. Currently, the total allowable take for 2014 is zero, but this will likely be reviewed before the 2014 season.

The Committee **reiterates** its longstanding recommendation that no removals of small cetaceans (live capture or deliberate killing) should be authorised until a full assessment of sustainability has been completed and **recommends** transient and resident killer whales be managed as distinct units and that studies in the western Okhotsk Sea be continued and be expanded.

14.4.5.2 ANTARCTIC KILLER WHALES

Six papers were presented on six ongoing projects (including SORP) on Antarctic and sub-Antarctic killer whales. All details are provided in the Annex L, item 8.5.2.

The Committee was also informed that Italian National Antarctic Research Programme (PNRA) will conduct research on killer whales in Terra Nova Bay (Ross Sea) to assess the role and dynamics of killer whales in this highly productive local marine ecosystem.

The Committee **recognises** the importance of these projects on Antarctic and Sub-Antarctic killer whales, **encourages**

their continuation and **recommends** any further studies consider any impacts of tagging as part of their ongoing work.

14.4.5.3 CARIBBEAN KILLER WHALES

A recent paper on killer whales in the Caribbean Sea (Bolaños-Jiménez *et al.*, 2014) summarises records there and indicates their widespread and year round occurrence. Preliminary morphological analysis suggests that Caribbean killer whales exhibit both characteristics typical of Type 2 killer whales in the North Atlantic and those typical of 'offshore' killer whales in the northwest Pacific.

14.4.6 Irrawaddy dolphin (*Mekong and Ayeyarwady dolphins*)

An update was provided on Irrawaddy dolphins in the Mekong and Ayeyarwady Rivers based upon two meetings organised by WWF-Cambodia in March 2014. The number of dolphins in the Mekong River has declined to well below 100 and their survival is very much in doubt. The most recent reported counts in the Ayeyarwady River have been in the order of only 70 individuals and mortality appears to have increased in the last few years. Bycatch in gill nets remains the most serious problem. The construction of any large hydropower projects in the Mekong basin, especially mainstem dams, will have very serious impacts on the population of Irrawaddy dolphins. The proposed Don Sahong Dam is of immediate concern because Lao PDR has announced it will begin construction of the dam in the near future. A WWF-Cambodia risk assessment found that the extinction risk posed by the Don Sahong dam to the trans-boundary sub-population – the last remaining dolphins in Lao PDR – is 'very high' and the risk to the overall Mekong population is 'high' (Ryan *et al.*, 2014).

The Committee again **re-emphasises** that the situation in Laos and Cambodia is of **serious concern** and that without urgent intervention in the trans-boundary pool, and the surrounding area, the dolphins there will be eradicated.

Effective enforcement of gillnet fisheries ban is essential to the survival of dolphins throughout their remaining Mekong River range and the Committee **recommends** that the governments of Cambodia and Laos give the highest priority to effective enforcement of existing dolphin conservation laws. The Committee **notes with concern** the assessment of the risk of the Don Sahong dam to the transborder sub-population and the Mekong River population as a whole, and **calls** for full and transparent assessment of the environmental impacts of this and other less destructive hydropower options.

The Committee will receive a further update on the ongoing management actions put in place to mitigate threats, including widespread electro-fishing practices next year.

14.4.7 Yangtze finless porpoise

SC/65b/SM22 provided recent information on the Yangtze finless porpoise (*Neophocoena asiaeorientalis asiaeorientalis*), red-listed by IUCN as a Critically Endangered subspecies endemic to Yangtze River system in China. The population in the mainstem of the Yangtze (Yichang to Shanghai) is estimated to have declined from more than 2,500 in 1991 (Zhang *et al.*, 1993) to 505 now (Mei *et al.*, 2014); data suggest a reduction by more than half between 2006-2012 with an estimated probability of

²⁵ <http://www.marinemammalscience.org> consulted on 25 May 2014

extinction in the next 100 years of 86%. Bycatch is considered the main cause of the decline. Ship strikes have also increased in recent years. Lack of enforcement of regulations as well as a lack of awareness among fishermen are considered major obstacles to success of conservation measures. The authors emphasised the need for immediate *in-situ* conservation actions to save 'seed populations', increased *ex-situ* conservation efforts, and strengthened national protective legislation.

The Committee **is concerned** that given the scale of anthropogenic pressures from *inter alia* bycatch, vessel traffic, sand mining and pollution, preventing the extinction of this subspecies will be a daunting challenge. Our concern is heightened because the same decline was witnessed with the decline and extinction of the baiji. Support from government officials at the highest levels, regional and national, is essential. Current conservation measures include reserves that are not appropriately designed or not adequately enforced.

Given its **grave concern** about the rapid, ongoing decline of Yangtze finless porpoises throughout their range, the Committee **recommends** that stronger measures be taken immediately, beginning by upgrading the subspecies to State I Protected status in Chinese legislation and implementing a national action plan with the necessary policy and financial support.

The Committee further **recommends** that all effort be made to protect Yangtze finless porpoises in their natural habitat. These include: (a) identifying river and lake segments with the highest porpoise concentrations, enforcing appropriate protection measures (including fishing bans) there year-round; (b) vigorously enforcing basin-wide prohibitions on electro-fishing and other fishing activities known or suspected to threaten porpoises; (c) vigorously enforcing regional and seasonal closures of sand-mining; (d) strengthening pollution control measures and (e) ensuring that before any further modification of the natural flow regime (or other natural features) of the Yangtze ecosystem are allowed to take place, the implications for finless porpoises are investigated and taken into account.

The Committee **recommends** that the Secretariat send a letter to the appropriate Chinese Government authorities, drawing their attention to these recommendations.

14.4.8 Franciscana

The franciscana is endemic to the eastern coasts of Brazil, Uruguay and Argentina, and is regarded as one of the most threatened small cetaceans in South America due to high bycatch levels as well as increasing habitat degradation, especially in the inshore and estuarine portions of its range.

SC/65b/SM18 reports on 9 days of helicopter experiments partially funded by the IWC Small Cetacean Research Fund to evaluate availability bias in franciscana observations made from an aerial survey platform. Results showed that availability bias is underestimated when using data from surface platforms, resulting in overestimation of abundance. The Committee **recommends** that estimates of availability bias derived from aerial, rather than surface platforms be used when analysing aerial survey data for abundance estimation.

Cunha *et al.* (2014) (also discussed in Annex I, item 3.1.1) suggests that there is substructure within each of the four

existing Franciscana Management Areas (FMAs, Secchi *et al.*, 2003). The paper recommends division of these areas into smaller management units as data indicate very limited movement of franciscanas between sub-areas and raise concerns over the effects of localised bycatches.

The Committee **expresses its concern** regarding the increase of reported franciscana entanglements in sub-regions within FMA I. The Committee **recommends** that the impacts of bycatch and human-related mortality on franciscanas within sub-regions be assessed and mitigated. It further **recommends** the assessment of finer-scale management area boundaries and that FMA definitions be supported to the greatest extent possible by analyses of both nuclear and mitochondrial markers and other indicators. The Committee **agrees** that the goal of species conservation is to maintain viable Franciscana populations in all areas where they occur.

The Committee **reiterates** its previous recommendations:

- (1) on the need to gather additional basic data on demography and life history, so that the status of each management unit can be evaluated and appropriate conservation measures designed and implemented;
- (2) the need for bycatch to be estimated in additional areas and for assessment of other possible threat factors, such as underwater noise, chemical pollution from coastal development and industrial and human waste discharge, oil and gas exploration activities and vessel traffic; and
- (3) the need for international collaboration to continue and expand the investigations into population structure and to assess its implications for conservation, especially the strengthening of the regional collaboration between Argentina, Uruguay and Brazil to implement conservation management actions that address bycatch and other threats.

14.4.9 Amazon River dolphins: boto and tucuxi

SC/65b/SM24 provides an update on more than 15 scientific expeditions conducted by regional NGOs between 2006 and 2014 in the Amazon River. These have recorded sightings of the three species recognised (*I. geoffrensis*, *I. boliviensis*, *S. fluvialilis*), as well as the recently described but not yet evaluated Araguaia dolphin (*Inia araguaiaensis*) over 5,700 km of the wider Amazon basin. The authors encourage strengthening of regional collaboration to manage direct threats, such as mercury contamination associated with mining and the hunting of dolphins for use as bait in the piracatinga (*Calophysus macropterus*) fishery.

SC/65b/SM10 summarised recent efforts by the Brazilian government to limit the illegal use of river dolphins as bait in piracatinga traps. Piracatinga are distributed throughout the Amazon Basin, occurring in Brazil, Bolivia, Colombia, Peru and Venezuela, highlighting legal, enforcement and institutional challenges and approaches. See Annex L, item 8.9 for additional details. Additional attention was drawn to dolphin watching and hand feeding tourism activities in Brazil as described in SC/65b/WW1 (see Annex M, item 5).

The Committee **commends** the Government of Brazil for responding to the current situation, **noting** that emerging cooperative efforts amongst the range states of the Amazon basin present a cause for optimism and that the Brazilian Ministry of Foreign Affairs could play a role in encouraging cooperation with other governments.

The Committee **encourages** further coordination between governments as a means to strengthen the effectiveness of conservation actions. The Buenos Aires Group was recognised as a useful caucus for discussions on conservation actions for the Amazon River dolphins.

The Committee once again **reiterates** its **serious concerns** about the potential population implications of the intentional killing of both botos and tucuxis for use as bait in the piracatinga fishery. It expresses **support** for the priority actions to assess and mitigate the capture of dolphins for bait contained in the Brazilian National Action Plan for Small Cetaceans and **reiterates its previous recommendation** that an international scientific workshop be organised involving scientists and managers from the range states, with the goal of addressing research and conservation priorities, standardising methodologies and planning long-term strategies.

In particular, the Committee **calls upon** the relevant authorities in each range state to continue and strengthen their efforts to:

- (1) Assess and monitor the impact of intentional and incidental river dolphin capture relative to the density of local populations;
- (2) Evaluate and monitor the use of botos and tucuxis as bait in fishing for piracatinga; and
- (3) Test alternative baits (e.g. slaughter house waste products) for use in piracatinga fishing.

The Committee **encourages** the presentation of a report next year on progress in the development and implementation of an inspection plan to combat the targeted catch of Amazonian dolphins for bait.

14.4.10 Harbour porpoise

SC/65b/SD4 that describes population differentiation of Baltic Sea harbour porpoises using RAD-tag genotyping. Full technical details can be found in the report of Stock Definition Working Group (Annex I, item 3.2.1). Participants noted that this is a promising method for the future.

14.4.11 Humpback dolphins

An expert workshop on ‘Sustainable Fisheries and the Conservation of the Critically Endangered Taiwanese White Dolphin (TWD) (*Sousa chinensis*)’ in Taiwan (April-May 2014) conducted an assessment of TWD population status, using three approaches, each of which suggested the TWD population is declining. The workshop made a number of recommendations and welcomed the recent decision of the Government of Taiwan to designate ‘Major Wildlife Habitat’ along a stretch of the dolphins’ known current range in the nearshore waters of the west coast of Taiwan, but also highlighted the need to implement its recommendations beyond the proposed area of protection. The workshop suggested a management target of recovering the population to 100 dolphins by the year 2030.

The Committee **endorses** the following recommendations by the workshop:

- (1) immediate banning of all gill and trammel nets within the entire known habitat of the Taiwanese white dolphin;
- (2) compensation for fishers willing to engage in alternative livelihoods;
- (3) compensation to aid in the transition to alternative

fishing gear that is both sustainable and dolphin-friendly, such as handlines;

- (4) a strict enforcement of the existing inshore (inshore of 3nm) trawler ban.

The Committee also discussed three candidate wind farms planned for the Eastern Taiwan Strait, one of which overlaps with the northernmost range of the Taiwanese white dolphin. Such threats were a global concern for coastal small cetaceans and agreed that future meetings of the sub-committee should consider the impact of offshore renewables and land reclamation on small cetaceans. It **recalls the advice** provided by the Committee with respect to marine renewables provided in IWC (2013a) and **commends** this to the appropriate authorities.

The Committee received a summary of a report from a recent workshop on Marine Protected Areas (MPAs) for the Indo-Pacific humpback dolphin (*Sousa chinensis*) in the East Asia Ecoregion (January 2014). This workshop focused on the usefulness of establishing an East Asian network of MPAs. The Committee **welcomes** the positive steps taken at this workshop towards better protection for populations of *Sousa chinensis* which are under pressure from a multitude of threats associated with resource competition, coastal development and habitat loss throughout the East Asia region. The Committee **highlights** the critically endangered status of Taiwanese white dolphin and stressed the need for expediency in MPA designation and other management strategies.

The question of taxonomy is dealt with under Item 26.

14.4.12 Japanese drive fishery

In 1975, 1980, 1990, 1992, 1993 and 1996 the Commission passed resolutions on the Japanese drive fisheries in general or specifically on actions to better assess and prevent further depletion of striped dolphins taken in these fisheries. Those resolutions were based on the discussions and concerns related to the drive fisheries raised in the sub-committee. Last year, the Committee re-iterated a number of recommendations (IWC, 1992; 1993; 1998b) including the that (a) up-to-date assessments of these exploited populations be undertaken, including studies of population structure and life-history; (b) up-to-date data on struck and lost rates, bycatch rates, directed hunting effort, stock identity and reproductive status and age composition of catches be collected and made available; (c) catch limits take into account struck and lost bycatch rates and be based on up-to-date population assessments, and be sustainable with allowance for population recovery.

There is no struck and lost rate problem in the drive fisheries. However, there is an important related issue of the total removals in the drive fisheries. These concerns relate to the long holding period before the remaining dolphins that are not ultimately removed are released. This long holding period will lead to cryptic mortality (unobserved, unrecorded deaths) including the following: (1) stress caused by holding the animals for extended periods prior to release, (2) serious injury while held captive, (3) disruption of reproduction during the drive and during holding and/or handling (e.g. abortions caused by stress and mother/calf separation leading to the death of the calf) (Kita *et al.*, 2013) and (4) post-release deaths (e.g. due to pneumonia). These types of cryptic mortality are not estimated or counted against annual catch

limits or included in assessments of the effects of drive fisheries on the dolphin populations. Further information is provided in Annex L.

The Committee **agrees** the issue of total removals in the drive fisheries needs to be more critically examined and incorporated into population assessments. Based on detailed information provided in Annex L concerning live captures of bottlenose dolphins during the Taiji hunt and export to *inter alia* China (Zhang *et al.*, 2012), the Committee **also agrees** that the issue of live removals in drive fisheries must also be taken into account in assessments and notes the lack of current data on either stock identity or stock size for the bottlenose dolphins in waters off Taiji. Finally, the Committee noted that stress experienced during long processing time of captured animals (up to 5 days) will increase the likelihood of post-capture mortality (see Annex L).

Based on the foregoing information, the Committee **reiterates its previous concerns and recommendations** that there is an **urgent need** for an up-to-date assessment of the targeted populations. This is especially needed for the common bottlenose dolphins subject to exploitation in the Japanese drive fisheries and live captures. Any new assessment must include, as indicated above, explicit consideration of cryptic mortality and subsequently consider the sustainability of removals for international trade.

Regarding the concerns about cryptic mortality in the drive fisheries in Japan, Kishiro noted that at least the animals found to have died during the period prior to release were actually counted, and included in the number of catch against the catch limit in the drive fishery, even though these animals were not directly killed and landed.

14.5 Takes of small cetaceans

14.5.1 New information on takes

The Committee received from the Secretariat the summary of catches of small cetaceans in 2013 extracted from this year's online national Progress Reports (see Annex L, Appendix 3, table 1).

14.5.1.1 DIRECT TAKES

Funahashi presented a table of direct takes of small cetaceans in Japan from 2002 to 2012, together with the catch limits for each species from 2007 to 2013 (Annex L, Appendix 3, table 2). The figures were obtained from websites of the Government of Japan. The catch limits given in the table are by season but the catch numbers are by calendar year.

The Committee **reiterates** its long standing recommendation that no small cetacean removals (live capture or directed harvest) should be authorised until a full and complete assessment has been made of their sustainability.

SC/65b/SM17 reports on small cetacean landings recorded in Dixcove Port (Ghana) in 2013-14. Details are given in Annex L. This information raises serious concern for these populations. Animals were mostly captured in large-mesh gillnets of the primary artisanal fishery. There was also evidence of at least occasional directed captures. The products was traded for human consumption, as previously reported (Debrah *et al.*, 2010). The authors stress that sampling has to be improved, possibly by providing support to biology/fisheries faculty students trained to photograph and sample landings. The proportion of total catches the

figures in the paper represented are unclear but the authors state that there are many deficiencies in the current monitoring system, including focal instead of national coverage and discontinuous monitoring effort over time. The Committee **thinks** the authors for this important information and **expresses serious concern** over the threat to these populations.

The Committee **welcomes** received new information on the release of three Indo-Pacific bottlenose dolphins in 2013 in Jeju-do, Korea. The animals appear to be interacting successfully with wild population. The overall population size was estimated at 104 and the population is thought to be stable.

14.5.1.2 ACCIDENTAL TAKES

SC/65a/SM05 documents the ongoing threat from illegal large-scale driftnetting to cetacean populations in the Mediterranean. Illegal driftnetting continues in Albania and Tunisia, at a potentially significant rate, with unconfirmed indications of illegal activity in Italy. The authors recommend further research in order to better understand the threat from driftnetting, including that (i) methods be developed and applied to estimate driftnet-related mortality of cetaceans in the Mediterranean and the impact on populations, giving special attention to areas where driftnetting overlaps with known concentrations of cetaceans; (ii) scientists and other stakeholders collaborate to conduct a regional examination of the impacts of European small-scale driftnet fisheries on cetacean populations; and (iii) researchers and relevant national and international agencies collaborate to examine the extent of regulation and impacts of large-scale driftnetting within EEZs globally. Additional information on this issue can be found in Annex L, section 9.1.2.

The Committee **welcomes** the recent improvements in the implementation of the ban and **expresses concern** over the ongoing illegal driftnetting and **recommends** that countries increase enforcement capacity and penalties for any illegal, unreported and unregulated (IUU) fishing. In addition to existing EU legislation, all Mediterranean countries are party to the General Fisheries Commission for the Mediterranean (GFCM) which bans the use of large pelagic driftnets (>2.5 km long and mesh size >10 cm).

The Committee **agrees** that improving the identification of ports and areas affected by the illegal driftnet fishery was of considerable importance and should be pursued further.

From the progress reports, the Committee noted that the bycatch of finless porpoises in South Korean waters was still high. Acknowledging previous recommendations, the Korean Government has started a monitoring and mitigation programme on the stow net fisheries which are responsible for 95% of finless porpoise bycatch. The Committee **looks forward** to results of the programme next year.

14.5.2 Follow up on the proposal for a Workshop on 'poorly documented hunts of small cetaceans for food, bait or cash'

Limited progress had been made on this standing agenda item in the intersessional period. The sub-committee decided to pursue this further by producing a scaled down agenda from that proposed last year with the intention that this may provide a structure for a series of regional workshops, including South East Asia, Africa and South America.

New research in Southeast Asia, some of which has been supported by the Small Cetacean Voluntary Fund, has led to an opportunity to organise the first workshop there (Annex L, Appendix 4). Members of the steering group will work to formalise a list of attendees and a detailed agenda. The Committee **welcomes** this new development.

14.6 Update on proposed joint workshop on monodontids

Bjørge reported that the proposal for a global review of Monodontids was discussed at the NAMMCO Council meeting in February 2014. The Council decided to convene a workshop to undertake a global review of narwhal and beluga. This will not be an IWC workshop. The workshop will be convened in connection with the meeting on Marine Mammals of the Holarctic in Russia in 2016.

14.7 Conservation and Management plans

This is considered under Item 21.

In addition, the Committee **agrees** to trial a new intersessional approach for situations that are considered high priority from a conservation perspective at the species or population level, especially where the indications are that time is short and no mitigation actions are in place. An intersessional ‘task team’ of appropriate experts will be identified from the sub-committee on small cetaceans. Task teams would undertake a thorough review of the situation, consulting with local research groups, authorities and others as appropriate, provide written information to the relevant authorities (through the chairs of the sub-committee and Committee in consultation with the Secretariat) if required, and provide scientific or mitigation advice as appropriate. Task Teams would report back to the sub-committee on progress at its next meeting. It was suggested that budgetary needs could be evaluated by the existing Small Cetacean Conservation Research Fund Review Group (http://iwc.int/sm_fund). Work will continue intersessionally to better define this task team approach.

14.8 Other information on small cetaceans

SC/65b/SM12rev describes two unknown beaked whale FM pulse types (Antarctic BW29 and BW37) recorded during the 2014 IWC-SORP-ABWP South American Consortium voyage.

SC/65b/SM3 provided information on seven Longman’s beaked whales (*Indopacetus pacificus*) that stranded in New Caledonia during November 2013, the first mass stranding recorded for this species.

SC/65b/SM27 reviewed the information on cetacean strandings and mortality in Venezuela between 1988 and 2014.

14.9 Workplan and budget requests

Last year, two previously identified priority topics, a review of Southern Hemisphere Ziphiids and an assessment of *Tursiops* systematics and associated conservation issues were deferred. The Committee **agrees** that the former remains a priority that should be addressed when the Scientific Committee next meets in the Southern Hemisphere.

There was considerable discussion over whether the *Tursiops* review was an appropriate priority topic for next year as discussed in detail in Annex L, item 14.9. It was decided to advance the discussion intersessionally.

Recognising that the venues for the 2105 and 2016 Annual Meetings are not yet known, Table 17 presents a tentative two-year workplan for small cetacean work.

Table 17

Overview of the workplan as it relates to small cetaceans

Topic	SC66a 2015	SC66b 2016
Main topic to be decided by December 2014	<i>Tursiops</i> systematic or regional assessment of the status of small cetaceans	Depends on what happens in 2015 and the venue for 2016
Voluntary fund for small cetaceans conservation research fund	Continue	Continue
Review of previous recommendations (priority will be given to vaquita, Hector's and Maui's dolphins, franciscana, beluga, river dolphins)	Continue	Continue
Review on takes of small cetaceans.	Continue	Continue

15. WHALEWATCHING

The report of the Committee on whalewatching is given as Annex M. Scientific aspects of whalewatching have been discussed formally within the Committee since a Commission Resolution in 1994 (IWC, 1995). The Commission also has a Standing Working Group on Whalewatching that reports to the Conservation Committee (e.g. see Item 15.3.3).

15.1 Assess the impact of whalewatching on cetaceans

SC/65b/WW01 described inter- and intraspecific behaviours of pilot whales (*Globicephala macrorhynchus*) from the Canary Islands, Spain, where their behaviours when interacting with swimmers were recorded, and of botos (*Inia geoffrensis*) in Amazonas state (Brazil), where tourists feed and interact but do not swim with the animals. Behaviour was categorised based on *a priori* ethograms and the risk they posed for physical harm to either humans or cetaceans.

Roughly a quarter of the pilot whales reacted neutrally or avoided swimmers; the others initiated one or more interspecific behaviours. Pilot whales were assumed to be disturbed by human swimmers to some extent, although their overall reaction was interpreted as ‘indifferent’. The Amazon botos (all males), were attracted to people. This is an unnatural association, as they are generally solitary. The dolphins performed risky behaviours during all encounters and initiated agonistic behaviours towards conspecifics, which could compromise their health and increase stress as well as pose health risks to humans at the provisioning sites. Licensing of operators and regulation of feeding is being experimentally implemented. The authors’ recommendations are listed in Annex M, item 5.

The Committee welcomes this information and requested that Ritter report back on the implementation of regulations and licensing of boto feeding operations in Brazil. Discussion of the paper is found in Annex M, item 5, including consideration of the subjectivity of assigning behaviours to categories such as ‘risky’ and ‘not risky’. The Committee

agrees that researchers conducting impact studies with specific species should work to standardise ethograms to ensure comparability of results.

Last year, the Committee had recommended that an international scientific workshop be organised involving scientists and managers from the boto range states, with the goal of addressing research and conservation priorities, standardising methodologies and planning long-term strategies (IWC, 2014c). Given concerns expressed in SC/65b/WW01, which could make the animals more susceptible to hunting, the Committee **reiterates** this recommendation.

SC/65b/WW02 summarised three papers addressing the impacts of whalewatching on cetaceans: Luis *et al.* (2014) documented the vocal responses of dolphins in a control setting (no vessels) and in the presence of different vessel types, including dolphin watching vessels, in the Sado Estuary, Portugal; Christiansen *et al.* (2013) evaluated the energy budgets for Icelandic common minke whales, using both field observations and a step-wise modelling approach; and Perrtree *et al.* (2014) showed that begging and other abnormal behaviour can persist more than 20 years after banning food provisioning, strongly suggesting that this activity could have long-term detrimental behavioural impacts on cetaceans.

In 2012, the Committee expressed concern over the impacts of ineffectively managed dolphin watching in Bocas del Toro, on the Caribbean coast of Panama, and recommended continued monitoring of the impacts of dolphin watching activities on this population (IWC, 2013f). This recommendation was ‘strongly’ reiterated at SC/65a (IWC, 2014i). The resident bottlenose dolphin population in the entire archipelago of Bocas del Toro is probably less than 250 dolphins of which some 105 frequent Dolphin Bay, where dolphin watching activity is concentrated.

SC/65b/WW06 presented data collected by boat-based surveys monitoring dolphin behaviour in the presence and absence of dolphin watching boats. There were significant differences in dolphin reaction to the research (86% neutral) and dolphin watching boats (80.6% neutral). ‘Negative’ reactions to boat presence increased four-fold as the number of dolphin watching boats increased from one to more than three. When multiple boats were present, a significant positive correlation was found between diving frequency and boat presence. In contrast, foraging and social behaviours were significantly negatively correlated with an increase in boat presence.

The Committee **welcomes** this update on the situation in Bocas del Toro and **reiterates its continued and extreme concern** regarding the lack of enforcement of regulations (IWC, 2013f; 2014i). It noted with concern that the boat presence (up to 39 boats on one group) reported in SC/65b/WW06 was in the tourist low season; in high season, boats can number up to 100 or more. In addition, in the last three years (2012-2014), 10 dolphins have died in Dolphin Bay due to boat strikes.

The Committee **emphasises** that situations of extreme concern like Bocas del Toro, where recommendations need to be directly communicated with governments, need a more focussed mechanism to bring them to the attention of the

Standing Working Group on Whalewatching and the Conservation Committee, than a simple presentation of the Scientific Committee report.

The Committee **endorses** the following recommended mitigation measures from SC/65b/WW06, which are consistent with the IWC Guiding Principles (see SC/65b/WW04): (1) licensing should be limited and license issuance should be regularly re-evaluated; (2) operator training workshops and a certification program for best dolphin watching practises should be developed and implemented; (3) a maximum of two dolphin watching boats should follow a single group of dolphins at one time; (4) new boats arriving and encountering a dolphin group should remain outside a ‘waiting zone’ of 300m, and allow a 30min ‘resting time’ before approaching dolphins after a previous interaction; and (5) arriving boats should either stop in the ‘waiting zone’ if other boats are already present, or move to other parts of the bay to look for a different group of dolphins. The Committee also **agrees** that speed restrictions and propeller shrouding can reduce collision risk and severity between dolphin watching boats and cetaceans.

The Committee **agrees** that responsible whalewatching operators from other areas, using best practises and making efforts to be sustainable in their operations, should attend Bocas (and other area) training workshops, where they could be helpful advocates for encouraging sustainable dolphin watching practises. All stakeholders, (e.g. hotel operators, airlines) should be involved in workshops to help ensure the widest possible buy-in to any management regime.

Further discussions are detailed in Annex M, item 5.

15.2 Review whalewatching in the Mediterranean and Red Seas

Annex M, table 1 is a summary from O'Connor *et al.* (2009) on worldwide tourism and expenditure on whalewatching.

It was noted that in general, the response to requests for input on whalewatching in the region of the Committee’s meeting was insufficient for a comprehensive and up-to-date review. The Committee therefore **agrees** that the process would be improved if individuals are tasked in advance with compiling a basic review of the industry in the region of the next year’s meeting. The review should be widely distributed (see Annex M) for comment and revision in advance of submission as a document for the Committee; the Conservation Committee could be approached for help with this distribution. Kaufman, Weinrich, and Alisa Shulman-Janiger volunteered to draft the review for the 2015 Annual Meeting should the northeastern Pacific be the appropriate region.

15.3 Review reports from intersessional working groups

15.3.1 Modelling and Assessment of Whalewatching Impacts (MAWI) steering group

SC/65b/WW08 summarised the progress with MAWI, established last year, to date. The group was tasked to define specific research questions and hypotheses that would best advance understanding the impact of whalewatching, identify whalewatching locations that would be most suitable and amenable for targeted studies addressing these questions, and summarise the current modelling tools available to analyse the data that will be collected.

Suitable locations should be in accessible areas where: the potential for whalewatching exists; has not yet started or is in

its infancy; control areas can be established; there is an elevated site in near proximity allowing for land-based observations; and some data on the target species exists. See Annex M, item 7.1 for details.

A variety of data collection methods have been used when analysing the impacts of whalewatching vessels on cetaceans. The variety of statistical approaches used to estimate the effects of whalewatching on cetaceans appear to have been determined by the researchers' skill sets, the question under consideration and/or the nature of the data collected. The approaches can be divided into roughly four categories: (1) comparison of groups; (2) regression methods; (3) Markov-chains; and (4) modelling and simulation. The approaches are detailed in Annex M, item 7.1.

The MAWI steering group will be presenting a symposium and small workshop at the 2014 International Marine Conservation Congress in Glasgow (18 August 2014), to receive input and feedback from the wider marine conservation community. The Committee **welcomes** this paper and looks forward to further discussion at the 2015 Annual Meeting.

15.3.2 Background document for Guiding Principles

SC/65b/WW04 reported on the intersessional working group on Guiding Principles development. The group was tasked to develop a 'background document' to annotate the Guiding Principles, with an explanation of their origin and evolution, as well as definitions of terms and other explanatory background. Details on annotations and discussions are noted in Annex M, item 7.2.

15.3.3 Five-Year Strategic Plan Whalewatching Handbook

Rojas-Bracho presented an outline of the Handbook. A chapter involving significant input from the Committee will be on the Role of Science. This chapter will be amongst the longest in the Handbook and will focus on a number of overlapping themes aimed at providing advice on threats and mitigation measures, and evaluating whether measures are working or are likely to work. It will highlight strengths and weaknesses of various management approaches by operation type and circumstances, as well as species.

The chapter on Management, although not within the Committee's remit, still will be based on the best available science and therefore will require the Committee's input. It will include the Guiding Principles, developed at the 2015 and 2016 Annual Meetings. See Annex M, item 7.3 for discussion.

There was a general desire expressed by the Committee for clarification of the relationship between the Commission and the Committee regarding the development of the Handbook. The Whalewatching Sub-Committee Co-Convenors will work with the chair of the Conservation Committee to address this concern. The Committee **agrees** that a budget request for assistance with developing the Handbook should be forwarded to the Standing Working Group on Whalewatching for consideration and submission to the Commission.

15.3.4 Swim-with-whale operations

SC/65b/WW03 updated earlier work using web-based searches in English for swim-with-whale operations. Commercial operations increased from 67 as compared to 44 in 2005 and 21 in 2003. Sources of positive and negative bias in data collection, plans for future reviews of swim-with-

whale operations and general discussion are in Annex M, item 7.4.

15.3.5 In-water interactions

A study is underway in Dominica focusing on sperm whale swims and additional work on ethograms is being undertaken.

15.4 Consider information from Platforms of Opportunity of potential value to the Scientific Committee

SC/65b/WW05 reported on *Whale and Dolphin Tracker* (WDT), a web-application for recording cetacean sighting data in real-time. It presented the occurrence of encounters with several cetacean species from data collected on platforms of opportunity using WDT from tour vessels off Maui, Hawaii. This customisable web-application was developed in-house by the Pacific Whale Foundation. Preliminary results indicate that WDT can be a cost-effective web-based data management system providing a large amount of good quality data (including effort). Details and discussion are in Annex M, item 8. The Committee **thanks** the authors for this paper and the work done on WDT.

SC/65b/WW07 proposed guiding principles for data collection from platforms of opportunity, to be hosted by the Commission website, to help ensure a higher standard of data from whalewatching vessels. Basic parameters any data collection system should include were listed, along with explanations on why these parameters are important to record. It also addressed multi-layered data quality control, an important aspect of citizen science. Details and discussion are in Annex M, item 8. The Committee **agrees** that the guiding principles presented in SC/65b/WW07 should be refined and then added to the website. It also **recommends** that the final data collection guiding principles be added to the Handbook. The Committee **agrees** to establish an intersessional working group whose task would be to finalise the guiding principles for SC/66a, with Rose as convenor and a diverse composition, including at least one operator and one researcher who uses data from platforms of opportunity (see Annex M, table 2).

15.5 Review whalewatching guidelines and regulations

Carlson noted that the 2014 update of the Compilation of Worldwide Whalewatching Regulations would be submitted for inclusion on the Commission's website by September 2014.

SC/65b/WW02 summarised Dimmock *et al.* (2014), a study of the perspectives of two stakeholder groups (resource managers and commercial whalewatching operators) in relation to industry knowledge and information exchange. See Annex M, item 8.

SC/65b/WW09 evaluated the level of whalewatching guideline compliance and the effects of compliance, or lack thereof, on dolphin behaviour in Bocas del Toro (and see Item 15.1). A total of 63 dolphin encounters were recorded from June through September 2013. During all of the dolphin encounters where dolphin watching boats were present, Panama's 100m minimum distance regulation was violated at least once. Operators violated other regulations regularly. Results of the study and levels of non-compliance are detailed in Annex M, item 8.

The authors noted that sustainable tourism and training workshops for the community and boat operators are urgently needed in Bocas del Toro and recommended that all dolphin

watching vessels place the regulations in a visible location on board their vessels, so tourists can be aware of the regulations. In accord with its recommendation under Item 15.1, the Committee **endorses** these recommendations and **agrees** that research on dolphin watching impacts and community engagement in Bocas del Toro is important and should continue identifying funding sources should be a priority.

15.6 Consider emerging whalewatching industries of concern

15.6.1 Review of workshops in Oman

Last year, the Committee received an update on the development of whalewatching guidelines, an effort undertaken as a multi-stakeholder initiative by Environment Society of Oman (ESO) and funded by the Commission. The initiative included a series of workshops held over the past year focusing on delivering and demonstrating whale and dolphin watching guidelines and on-water training sessions. Several ministries were consulted during the process and the team visited with operators in Muscat, Salalah and Dhofar. Continued funding support is requested to consolidate this work, including development of an Oman Whalewatchers' Association.

The Committee thanked Wilson for a further update and greatly **welcomes** the positive nature of developments in Oman, which were partially in response to the recommendation of the Committee (IWC, 2013f). Continuation of training workshops is especially urgent in areas where operators are targeting Arabian humpback whales and local populations of *Sousa*. The Committee **recommends** that this work continues and be funded for at least the next two years and **agrees** to keep this as a standing item on the agenda.

15.7 Other issues

The Committee considered several strategies that might make Committee recommendations more visible and effective, especially urgent statements involving highly endangered or isolated cetacean species/populations (see also Annex M, item 5). These include: extracting and combining recommendations in a separate short document, enabling follow-ups by introducing a new agenda item ('progress on previous recommendations') on the agenda of the sub-committee on whalewatching, and establishing intersessional groups with terms of reference related to promoting recommendations beyond the Commission.

The Committee **agrees** to add 'progress on previous recommendations' to the agenda (see Annex M, item 12). In discussion at plenary, the Committee noted that a model highlighting and progressing recommendations on particular issues of concern had been discussed by the Small Cetaceans Sub-committee (Annex L, item 8) and would be a useful model. The Committee **agrees** that an intersessional group to discuss highlighting and progressing recommendations be formed, using Bocas del Toro as an example, to report back to the Committee at the 2015 Annual Meeting.

Funahashi presented information that in June 2014, local whalewatching associations, operators, guides and industry-related personnel will form the Japan Whale-Dolphin Watching Council from seven areas, to promote a responsible, sustainable whalewatching industry in Japan.

The Committee **welcomes** this information and **endorses** the formation of the Council. The Committee **recommends** that the council expand its membership by contacting established operators in other regions of Japan. It was also suggested that the council contact established operators in other countries. Funahashi agreed to draft a document describing the council and its goals for global distribution via Committee members.

Carlson updated Robbins' work to identify data sources from platforms of opportunity of potential value to the Scientific Committee. There have been delays in its development, but it should be online in the near future.

Attention of the Committee was drawn to a new publication for which several members of the Committee are chapter authors and/or editors. Details can be found in Annex M, item 11.

15.8 Workplan

The detailed workplan is given in Annex M, item 12. Table 18 provides a short overview

Table 18

Overview of the workplan as it relates to whalewatching

Topic	SC66a 2015	SC66b 2016
Assess the impacts of whalewatching on cetaceans	This is the ongoing and primary aspect of the work on this topic.	Continue
Review progress on the Commission's five-year strategic plan including the Handbook	Review the work of an intersessional working group. As the Handbook is an online 'living' document then it is anticipated that this will be ongoing work although the initial work will be the most intense.	Continue
Review work of intersessional steering groups	These are listed in Annex M, table 2	Continue
Review whalewatching in the region of the meeting	The next meeting venue is unknown but this is an ongoing item	Continue
Consider information from platforms of opportunity	Finalise standard elements and guidelines including data collection items to be hosted on the IWC website	Review progress and modify if required
Review whalewatching guidelines and regulations	Ongoing work –the most recent compilation is submitted to the IWC Secretariat and included on the IWC website	Continue
Emerging whalewatching industries of concern	Ongoing work	Continue
Progress on previous recommendations	Ongoing work	Continue

16. DNA TESTING (DNA)

The report of the Working Group on DNA is given as Annex N. This particular agenda item has been considered since 2000 in response to a Commission Resolution (IWC, 2000).

16.1 Review genetic methods for species, stock and individual identification

SC/65b/DNA01 was prepared in response to a recommendation from the JARPA II Review Workshop that

a revised paper be submitted that explains in more detail how far the IWC guidelines for DNA data quality control were able to be followed (SC/65b/Rep2 p.15). SC/65b/DNA01 presented a full description of the protocol used by the Institute of Cetacean Research for the genetic analyses in the context of the IWC guidelines. The Committee **welcomes** this document and **agrees** that it responds appropriately to the recommendation.

SC/65b/BRG04 presented an estimate of the genome size of the bowhead whale using flow cytometry. The mean genome size (C value) was estimated to be 2.93 picograms (2.87 gigabases, Gb). This was the first direct genome size estimate for a baleen whale, and is the lowest value reported for any cetacean. It is near the low end of values reported for cetartiodactyls and is relatively low for mammals. The relatively small size of the genome of bowhead whales could be associated with metabolic rate, oxygen exchange, or simply a plesiomorphic trait shared in common with other basal cetartiodactyls.

The Committee noted that the two suggested explanations are not mutually exclusive, i.e. it can be at the same time plesiomorphic and adaptive. It was also noted that differences between directly estimated (from flow cytometry) and indirectly estimated (from sequence) genome size are considered primarily due to removal of highly repetitive sequences not included in sequence-based estimates. Details of this paper and the discussion are found in Annex N.

SC/65b/BRG09 reported progress on the transcriptome sequence of the bowhead whale. This study compared two methods of RNA sequence to characterise the bowhead whale transcriptome including polyA RNA isolation and RiboZero which does not involve the capture of a RNA molecule by the end of its 3' tail. The study sequenced the transcriptome from pituitary gland, adolescent testis, vibrissa follicle, mesenteric lymph node, and spleen using the RiboZero protocol and the heart, cerebellum, liver, adolescent testis, and retina from 2011 using the polyA protocol for a total of 51,637,573,518 bp of sequence. The data are being explored for the discovery of SNP loci for population genetic studies.

The Committee **commends** the large amount of work undertaken and notes the valuable data being produced in this study. It was noted that SNP discovery using genome and transcriptome sequence has some advantages over the use of anonymous loci, but that there are also some difficulties with this approach. Details of this paper and the discussion are found in Annex N.

SC/65b/BRG13 summarised results from a bowhead whale genetics project. The project had two parts, development of an mtDNA database and identification of SNP loci including the development of a SNP database. Regarding mtDNA loci a total of 570 whales have been sequenced for HVR1, 480 for ND1, and 389 for cyt-b. A total of 155 SNP loci were identified for bowhead whale, including 99 new SNPs reported in SC/65b/BRG13, 14 sex-specific SNPs reported in SC/65a/BRG22 and 42 from the literature (Morin *et al.*, 2010b). It was reported that the data in these databases will continue to be used for monitoring stock structure, population size estimates, and estimates of historical demography. Work is ongoing to fill the gaps in the database.

The Committee again **commends** the amount of work undertaken in this study. The authors clarified that the transcriptome upon which the SNP loci were identified was based on multiple individuals (all from the BCB stock), multiple sexes, and multiple tissues.

In discussion, the Committee was informed that most but not all of the mtDNA sequences are from bowhead whale tissues obtained from the aboriginal harvest in Alaska and the sequences are linked to the tissue sample by a unique identifier code. Tissues are archived at the Department of Wildlife Management, North Slope Borough, Barrow, AK, with duplicate samples archived at the Southwest Fisheries Science Center (National Marine Fisheries Service, NOAA) in La Jolla, CA. Published sequences are deposited on *GenBank* and publicly available.

16.2 Review results of the amendments of sequences deposited in *GenBank*

Last year, the Committee agreed that the list of accession numbers involving inconsistencies due to a lag in the taxonomy recognised by *GenBank* or uncertainty in taxonomic distinctions currently under investigation (IWC, 2014j) should be sent to *GenBank* with a letter explaining the background and the main reasons for the inconsistencies (IWC, 2014c, p.56).

Cipriano informed the Committee that he had sent the list and letter to *GenBank* during the intersessional period. A positive response was received informing that *GenBank* is willing to work with the IWC on this particular problem, and requested further explanations on the list received on accession numbers associated with problematic taxonomic designations. The Committee **agrees** that Cipriano should continue to work with *GenBank* during the next intersessional period to facilitate the work by *GenBank* staff on the correction of the inconsistencies based on the list sent.

In discussion the Committee was further informed that the NCBI staff is already making changes to taxonomy fields of sequences in *GenBank* on the advice of the Scientific Committee and that additional changes needed in *GenBank* annotations include a mechanism for providing clear and consistent geographic source information. Situations where taxonomy is in flux (such as the revision of cetacean species and subspecies names currently underway) would also benefit from continued dialogue between the Scientific Committee and NCBI.

The Committee also suggested further discussion by the Committee on issues regarding new species descriptions and taxonomy of baleen whales.

16.3 Collection and archiving of tissue samples from catches and bycatches

The Committee previously endorsed a new standard format for the updates of national DNA registers to assist with the review of such updates (IWC, 2012a, p.53), and the new format worked well the last two years. This year the update of the DNA registers by Japan, Norway and Iceland were based again on this new format. Details are given in Appendices 2-4 of Annex N for each country, respectively, covering the period up to and including 2013. The Committee **thanks** the countries involved for providing this information.

16.4 Reference databases and standards for diagnostic DNA registries

Annex N, Appendices 2-4 summarise the status of mtDNA and microsatellite analyses of the stored samples for Japan, Norway and Iceland, respectively. In almost all cases, the great majority of samples have been analysed for at least one of either mtDNA or microsatellite and in most cases both. Work on unanalysed samples is continuing. Details of the exact number of samples collected and analysed are provided in Annex N.

The Committee **appreciates** the efforts of Japan, Norway and Iceland in compiling and providing this detailed information of their registries.

16.5 Workplan

The workplan is discussed in detail under Annex N.

Members of the Committee are encouraged to submit papers in response to requirements placed on the Committee by the IWC Resolution 1999-8 (IWC, 2000). Relevant information in documents submitted to other groups and sub-committees of the Committee will be reviewed next year. Results of the 'amendment' work on sequences deposited in *GenBank* will be reported next year.

17. SPECIAL PERMITS

17.1 Expert Panel Review of the results from JARPA II

This item was initially discussed by a working group (Annex O). Scientists from countries that made a statement at plenary that it was inappropriate for the SC to continue the review of the JARPA II programme under Annex P, did not participate in the discussion related to JARPA II agenda items (see Item 2). These scientists may not agree with any conclusions reached in this report under the relevant agenda items.

This agenda item is related to the Expert Panel Review of the results from JARPA II (SC/65b/Rep2).

The Expert Panel review took place in Tokyo from 24-28 February 2014 and followed the guidelines described in Annex P (IWC, 2013). The previous Chair of the Scientific Committee (Palka) chaired the review workshop. Typically, the chair of Special Permit reviews is the current Scientific Committee Chair. However, since the Chair of the Scientific Committee (Kitakado) is a member of the proponents, the Scientific Committee agreed last year that the previous Chair (Palka) would be an appropriate chair for this review workshop.

17.1.1 Expert Panel report

The Expert Panel was chaired by Palka and was comprised of the IWC Head of Science (in accord with the guidelines), 3 current members of the Committee, 2 scientists who rarely participate in the Committee and 3 scientists who have never participated. Expertise in all areas of the research programme was available. Thirty-eight papers were submitted by the proponents (SC/F14/J1-38), 8 papers submitted by other Scientific Committee members (SC/F14/O1-8), and 5 papers were submitted in response to the observer papers (SC/F14/R1-5).

The Panel report (SC/65b/Rep2) is divided into sections based on the stated objectives of the programme: monitor cetacean habitat; elucidate temporal and spatial changes in stock structure; monitor whale abundance trends; monitor krill abundance and feeding ecology of whale stocks; monitor effects of contaminants on cetaceans; model competition

among whale species; and improve management procedure for Antarctic minke whales. Each of these sections contained the proponents' summary of their results followed by a review from the Panel that included specific technical recommendations. The final section presented the Panel's general overview and conclusions containing recommendations divided into short, medium and long-term.

The report is a long and detailed review. What follows here is a short Panel Chair's summary of only the broad conclusions. The Panel emphasised that its task was to provide an objective scientific review of the results of JARPA II; its task was not to provide either a general condemnation or approval of research under special permit.

Before considering individual objectives, general comments applicable to all aspects of the programme are identified. The Panel noted that the general and extremely broad nature of the objectives and its ongoing nature made it difficult to fully review how well the programme met its own objectives. It recommended refined objectives and sub-objectives with timelines for progress be developed to provide a basis to more easily assess if the objectives have been met.

Data collection disruption due to weather, ice conditions and increasing sabotage activities by protestors resulted in not achieving the designed sampling scheme for some years, and the Panel was concerned that this could severely compromise the ability of the programme's objectives to be met. The Panel recommended that an explicit protocol be developed to specify *a priori* how the design could be modified if disruption by protestors occurs; simulation studies based on existing data should assist in this.

The Panel recognised that this was the first period of the JARPA II programme but noted that the programme arose out of the long JARPA programme and that many of the papers analysed data from both programmes. The Panel welcomed the considerable work that was put into field and laboratory work and the development of papers, particularly those addressing recommendations made in previous JARPA reviews. However, the Panel recommended that considerably more effort and resources be put into the analytical side of the programme, both via more thorough analyses of individual datasets and through better integration amongst the datasets to integrate the information available from the various aspects of the programme.

The Panel recognised an important component of any programme is archiving data and samples. It agreed that a number of questions potentially could be addressed with material that may have been preserved from the historical commercial catch. While reports from JARPA and JARPA II detailed the availability of tissue samples, no similar information was available from the historical catch. The Panel recommended a detailed list of available historical samples be produced.

While the Panel agreed broadly with the conclusion that JARPA II catches will not adversely affect the stocks in the research area, it also noted that the most appropriate way to assess the impact of future Special Permit catches on stocks is within the framework of an RMP-type process; that approach explicitly accounts for uncertainty.

In regards to the monitoring the cetacean habitat objective, the Panel agreed that the monitoring of the whale habitat is

relevant to all of the objectives. Unfortunately this work has been limited. If the programme is to meet its own objectives, the Panel recommended the collection of the full suite of oceanographic data be resumed and the proponents should incorporate other oceanographic and related data that may exist within other international programmes to form a more comprehensive dataset. In addition, the proponents could develop a method to make their data available to other international programmes.

In regards to the temporal and spatial changes in the stock structure objective, the Panel agreed that considerable progress has been made in understanding stock structure within the research area. However, it drew attention to the fact that the programme incorporated little information from outside the research area. For Antarctic minke whales, the Panel welcomed the innovative integrative approach used which incorporated genetic and non-genetic data and it recommended consideration of other potential hypotheses. The Panel welcomed the examination of stock structure of several of the species by integrating data from biopsy samples collected during JARPA and JARPA II with other data collected within the Antarctic and lower latitudes. The Panel suggested increasing the sample sizes by using biopsy samples collected by other programmes (e.g. SOWER) and from earlier commercial whaling, if available.

In regards to the monitoring abundance trends objective, sightings data analyses and statistical catch-at-age analyses (SCAA) were used. The Panel agreed that survey results from the JARPA and JARPA II programmes contribute significantly to the objectives of the programme. The survey work represents a considerable expenditure of research time and a large dataset for long-term monitoring. The Panel agreed that the papers on Antarctic minke whales (SC/F14/J3) and humpback whales (SC/F14/J4) had adequately addressed most of the concerns raised in the JARPA review meeting. In terms of future field work, the Panel recommended consideration of the use of Independent Observer mode in future surveys to address the issue of $g(0)$ and the collection of killer whale ecotype data.

The Panel noted that the SCAA analyses, whilst using data from JARPA and JARPA II, has been directed by the Scientific Committee and was undertaken by non-proponent scientists. The Panel agreed that the SCAA model is both the best currently available model for examining stock dynamics for the minke whales in the JARPA II area, and that the model performed well in this regard. The Panel noted that certain results from the SCAA model may not be consistent with inferences developed from other components of JARPA II or may suggest potential revisions to the design of JARPA II itself. These points concerned *inter alia* MSYR, stock structure and growth rate changes.

Examining and understanding the distribution of whale species and the reasons for any changes in distribution is central to the objectives. The Panel recommended that more robust and comprehensive analyses of the existing data be undertaken that incorporate many more potential explanatory variables. In addition, a more rigorous area occupancy analysis should be undertaken that incorporates recent advances in spatial modelling. The distributional information was used to formulate their 'competition' hypotheses. The Panel agreed that a conceptual model for such competition

should be developed. Additional field efforts will be needed to develop plausible hypotheses, such as focused studies of prey density and swarming behaviour in relation with local whale distribution and abundance or comparison of stomach contents in areas where both species overlap, and in areas where they segregate.

In regards to the monitoring krill abundance objective, the Panel recommended that future krill surveys should be frequent because the density of krill in any given stratum may vary significantly from year to year, and the objectives of JARPA II require an area-based time-series view of how the prey field changes over time. The JARPA II study area is very large, and it is probably not possible to survey the entire study area every year with a single survey vessel. Thus, the Panel recommended either using multiple survey vessels to synoptically cover the JARPA II study area every 1-3 years or using one vessel to survey alternating halves of the study area every year.

In regards to the monitoring feeding ecology of whale stocks objective, the Panel agreed that this work was central to achieving several of the objectives. The Panel agreed that the approach to the feeding ecology study developed by the proponents during the Workshop to address some shortcomings was a useful way forward. The Panel also recommended the work be extended by computing a time series of Monte Carlo results for the total potential consumption of krill using abundance estimates of minke whales and the uncertainties around these estimates. These Monte Carlo results can also be used to re-evaluate the future research and sampling in JARPA II.

In regards to monitoring whale biological parameters, the Panel noted that these analyses assumed that the sampling scheme was broadly representative of the population and was related to the stock structure hypotheses agreed at the JARPA review rather than those that were subsequently presented to this meeting. In regards to the age at sexual maturity and pregnancy rates, the Panel recommended additional analytical work before conclusions can be drawn. The Panel welcomed the work presented on the evaluation of the use of aspartic acid racemisation as an alternative approach to estimating age and made a number of recommendations for an updated paper and future work.

In regards to the studies on nutritive condition, the Panel recognised that the factors considered in the models arose primarily from discussions within the Scientific Committee and were not derived from biological hypotheses. The Panel recommended a conceptual model of the system be developed and then used to identify a set of covariates to consider in the model. The Panel also noted that it is inappropriate to automatically select the 'best model' because such a model can lead to covariates being selected for which there is no reason that they are related to response variable. Despite the complexity of the analyses and the protracted discussion of appropriate statistical techniques, the Panel expressed the opinion that the 'weight of evidence' (i.e. the different measures consistently indicated that there was an overall decline in body condition of minke whales through the JARPA period), as well as the implications of such a result, warrant careful consideration in terms of cause.

Following the discussion at the JARPA review meeting and the advantages of considering lipid content of the blubber as

well as thickness, the Panel strongly recommended that any further studies should incorporate blubber lipid content analyses for all samples, and that the collection of current measurements also continue to ensure comparability with past and future data. The Panel also recommended that faecal samples (from the colon) be compared with stomach samples for species composition.

In regards to the monitoring effects of contaminants objective, the Panel noted the low levels observed, and therefore recommended lower priority for pollutant studies in the future and agreed that it would be sufficient to undertake pollutant analyses on a suitably chosen subsample at periodic intervals (say 3-5 years).

In regards to the model competition among whale species objective, the Panel recognised that this work is at a preliminary stage. The Panel stressed the fundamental importance of this work to most of the objectives of JARPA II. The Panel therefore recommended that considerably more effort be allocated to this aspect. The Panel recommended that simulations be used to determine the data needed to reliably distinguish among competing hypotheses to explain the available data, including the proponents' preferred option, competition among species. These simulations may also be used to identify (1) whether models are able to respond in predictable ways to known signals in the data and (2) the required level of precision in the data to parameterise them. The Panel emphasised that producing ecosystem models is a long-term exercise, which requires the integration of a large amount of data as well as ecological and biological knowledge of the system. The work conducted to date represented a useful start. To this end, the Panel recommended increased collaboration with other researchers from outside the JARPA II area to improve the modelling exercise.

In regards to the improve the management procedure for Antarctic minke whales objective, the Panel agreed that the information from JARPA and JARPA II, particularly with respect to stock structure and abundance will greatly improve any future *Implementation Simulation Trials*, should these ever be requested by the Commission. Similarly, SCAA and related analyses could be used to develop hypotheses related to carrying capacity, natural mortality and variation in birth rates. In principle, the work on ecosystem modelling could be used to develop a set of operating models that allow for competition. However, the ecosystem models need to be developed with sufficient resolution (e.g. age- and sex-structure for minke whales).

The Panel agreed that a number of aspects of the JARPA II programme are relevant to the several IWC resolutions and discussions.

Although a comparison of the utility of lethal and non-lethal sampling is not an objective of the JARPA II programme, the samples and data already collected to achieve the objectives can be analysed to investigate this general research question. The Panel recommended that the proponents examine the approaches for comparison used in the Icelandic programme and develop an approach to formally and objectively compare the results from different approaches in the light of the programme's objectives.

In conclusion, the Panel's Chair thanked the Panel, the proponent scientists and the observers for their constructive and patient approach to the workshop and the Fisheries Agency of Japan for providing excellent facilities and logistic support.

17.1.2 Response to Expert Panel report

Pastene presented an overview of SC/65b/SP01. This paper summarises the general response of the JARPA II proponents to the JARPA II Panel Review report (SC/65b/Rep2). The International Whaling Commission's Scientific Committee (IWC SC) convened a workshop to review the progress made in the research conducted under the Japanese Whale Research Program under Special Permit in the Antarctic-Phase II (JARPA II) in its first six years (2005/06-2010/11). The review followed the guidelines specified in the Annex P. An international Panel of experts (Review Panel) carried out the review on the basis of 38 scientific papers prepared by the proponents, eight prepared by IWC SC members and five prepared by the proponents in response to some of the documents from the IWC SC members. Scientists involved in the JARPA II research participated in the workshop only to present papers on particular agenda items and to respond to questions of clarification and substance regarding the work that had been undertaken or further work expected to be undertaken. The report of the Review Panel is presented in document SC/65b/Rep2. The present paper summarises the views of scientists involved in the JARPA II research on the evaluation and scientific suggestions from the Review Panel. Short-term recommendations offered by the Review Panel were responded to in different papers presented to sub-committees: SC/65b/EM1,2,3; SC/65b/IA1,2; SC/65b/SD1,2,3 and SC/65b/DNA1. The proponents agreed with most of the medium and long-term recommendations, and this paper shows the proponent's view and plan regarding those recommendations. This paper also offers some general comments on the JARPA II review process which could be considered to improve future reviews. The proponents consider that, in general, the Review Panel report represents a fair and balanced evaluation of the work conducted by the JARPA II in its first six years. The Review Panel welcomed the scientific contribution of JARPA/JARPA II. At the same time it identified those areas where further work is required and provided suggestions and recommendations that if correctly implemented, will contribute to improve analyses from the first six years of research as well as future research.

Some members of the Committee expressed concern about the JARPA II Expert Panel review, especially with respect to the Panel's ability to evaluate: (1) the utility of lethal research methods during the JARPA II programme; and (2) results based on combined data from both JARPA and JARPA II that formed the basis for a number of the documents reviewed by the Expert Panel, making a review of just the JARPA II programme somewhat difficult. These concerns are summarised in Annex O1.

In response to Annex O1, other members of the Committee stated that JARPA/JARPA II has provided substantial new knowledge related to the management of minke whales in the Antarctic and on the functioning of the Antarctic ecosystem and that much of this information could not have been obtained from non-lethal methods alone (see Annex O2).

In discussion of Annex O2, Wade noted that in response to the Expert Panel review, the proponents of JARPA/JARPA II authored papers that often concluded that they 'did not agree' with the advice provided. Wade stated that he did not find many of the revised analyses to be convincing and found the proponents had often not modified their analyses in response to recommendations from the Expert Panel but had instead agreed to disagree.

Pastene responded that several papers responding to the JARPA II review workshop had been prepared by Japanese scientists and presented in different sub-committees this year, mainly in the IA (biological parameters), EM (body conditions and stomach content trends) and SD (stock structure) sub-committees. Some of those analyses have been accepted while that for others further work has been required but this is normal in the scientific world. It is clear that many research topics from JARPA/JARPA II, for example body condition, biological parameters and stock structure, have promoted interesting and detailed scientific discussion in the Scientific Committee.

Wade provided several examples of how biopsy sampling could be effectively conducted in the Antarctic. These include the successful biopsy sampling of Antarctic minke whales in nearshore waters (A. Friedlaender pers. comm.; SC/65a/IA12) as well as the previous biopsy experiments during SOWER cruises that showed the practicality of biopsy sampling minke whales in offshore waters, as noted by Gales in his testimony to the International Court of Justice. Experiments in 2000 and 2008 on Japanese IDCR/SOWER cruises showed that Antarctic minke whales could be biopsied, that they could be biopsied at distances similar to the distance used to harpoon minke whales, and that the average time it took to biopsy a minke was approximately the same as the time it took to harpoon a minke whale, and much less considering the handling time of a harpooned whale (information taken from Ensor *et al.* cruise reports, 2001-2008). Moreover, the average time to biopsy an Antarctic minke whale was less than any other baleen whale (blue, fin, humpback, and right whales), and this was accomplished under difficult open ocean conditions. Given the success that JARPA II has had biopsy sampling other baleen whales, Wade thought there was no reason that Antarctic minke whales could not be biopsied in large numbers, if the effort was made to do so.

Pastene reiterated that the Scientific Committee has on several occasions recommended the use of multiple techniques, genetics and non-genetic, to resolve questions on stock structure (IWC, 2013a, p.10). Non-genetic approaches include morphometric analysis, which require lethal sampling. Biopsy sampling of Antarctic minke whales has proven to be difficult, particularly in offshore areas and for small schools (see details in Ensor *et al.*, 2004, p.17; Ensor *et al.*, 2001, p.14) for experiments based on IDCR/SOWER and Nishiwaki (2000) for experiments based on JARPA and JARPN). Even if biopsy sampling became possible under the more challenging conditions, he believes that it would still be difficult to collect the number of samples required for statistical analyses of stock structure.

Wade also debated the statement made in Annex O2 regarding the inadequacy of conducting organic pollutant (lipophilic) and trace elements pollutant analyses from biopsy

samples, stating that he has published three studies that used biopsy samples to examine organochlorine concentration in cetacean blubber.

Pastene clarified that his opinion was based on a comprehensive and detailed comparison between lethal and non-lethal techniques made by the Review Panel on the Icelandic Special Scientific Permit Review that concluded that the lethal sampling is more practical than the non-lethal sampling to investigate some pollutants in the common minke whale (IWC, 2014a, p.480).

Víkingsson highlighted the improvement in the working methods of the Committee concerning review of results from Special Permit programmes with the introduction of independent Expert Panels. He commended the high professional quality of the review of the Expert Panel of the JARPA II programme. While generally recognising the scientific value in the great amount of work conducted as a part of the program, the Panel criticised some parts of the analyses and made constructive suggestions for improvements. Víkingsson commended the wide-ranging combination of lethal and non-lethal research techniques used in JARPA II that had helped explain recent changes in the Antarctic ecosystem. Concerning the use of lethal and non-lethal methods, Víkingsson concurred with the suggestion of the Panel regarding further evaluation of the usefulness of biopsy sampling by direct comparisons of different research techniques applied on the same animals as done in the Icelandic research programme reviewed in 2013. Those studies had, for example, indicated variable utility of biopsies (skin and outermost blubber) in studies on diet composition and pollutant levels.

17.2 Review results from ongoing permits

The Committee has decided not to discuss annual cruise reports between the periodic reviews. Therefore, the cruise reports are briefly summarised below.

17.2.1 JARPN II

SC/65b/SP02 outlined the twelfth cruise of the full-scale JARPN II offshore component conducted in the western North Pacific. There were three main research components in the 2013 survey: whale sampling survey, dedicated sighting survey and whale prey survey. The whale sampling survey was carried out from 25 July to 7 October 2013. A total of 1,846n.miles was surveyed in a period of 65 days by the two SSVs. A total of three common minke, 100 sei, 28 Bryde's and one sperm whale was sampled by the SSVs. In August, common minke whales fed mainly on Japanese anchovy, mackerels and Pacific saury in sub-area 9. Sei whales fed mainly on mackerels followed by copepods from August to September in sub-areas 8 and 9. Bryde's whales fed mainly on krill followed by Japanese anchovy and mackerels in sub-areas 8 and 9 from late July to early October. Dominant prey species in the stomach of the sperm whale was various kinds of squids, which inhabit in mid- and deep-waters. Three dedicated sighting surveys were carried out from 18 May to 26 June in sub-areas 7 and 8, from 20 July to 23 August in sub-area 9 and from 12 September to 7 October in sub-areas 8 and 9. A total of 3,470, 987 and 539n.miles was surveyed during those surveys by the SVs, respectively. The whale prey survey was carried out from 24 July to 22 August. The survey was conducted concurrently with SSVs and NM in a part of sub-areas 8 and 9. The main purpose of the prey survey

in this year was recording of underwater behaviour of Bryde's and sei whales by using acoustic transmitters. Data obtained in this research will be used in the elucidation of the role of whales in the marine ecosystem through the study of whale feeding ecology in the western North Pacific.

There were two questions of clarification regarding this document on (1) whether the survey tracklines (depicted within the red block of fig 3.) were designed for abundance estimation and (2) how the survey tracklines were randomly started. In response, the authors stated that the survey tracklines in question were not designed for abundance estimation and that the starting points of the track lines were randomised following methods described in Matsuoka *et al.* (SC/65b/IA06).

SC/65b/SP03 outlined results of the ninth survey of the JARPN II coastal component conducted off Sanriku. The survey was carried out from 18 April to 3 June, using four small-type whaling catcher boats and one echo sounder trawl survey vessel. Sampling of common minke whales was conducted in coastal waters within 50 n. miles from Ayukawa port in the Sanriku district, and all animals collected were landed at the JARPN II research station established for biological examination in Ayukawa. A total of 7,188.3 n.miles (709.3 hours) was surveyed and 59 schools (59 individuals) of common minke whales were sighted. A total of 34 animals were sampled. Average body length of the animals was 5.02 m (SD: 1.12, $n=17$) for males and 5.21 m (SD: 0.60, $n=17$) for females. Dominant prey species found in the fore stomach of common minke whales collected in the Sendai Bay were juvenile Japanese sand lances, and those collected outside the Sendai Bay were Japanese anchovies. This suggests that common minke whales in the Sendai Bay and in the outside slope feed on different preys. Furthermore, common minke whales significantly fed on juvenile sand lances in 2012 and 2013, with the proportion of adult sand lance decreased in recent years. This result indicates that feeding habit of common minke whales in coastal waters off Sanriku changes year by year.

SC/65b/SP04 outlined the results of the JARPN II coastal component off Kushiro, northeast Japan (the sub-area 7CN) in 2013. The survey was conducted from 6 September to 25 October 2013, using four small-type whaling catcher boats as sampling vessels. During the survey, a total of 4,629.7 n. miles (451.8 hours) was searched, 126 schools/ 142 individuals of common minke whales were sighted and 58 whales were sampled. Average body length of sampled whales was 6.77m (SD=0.88, $n=41$) for males and 6.55m (SD=1.39, $n=17$) for females, respectively; 27 of the 41 males (65.9%) and seven of the 17 females (41.2%) were sexually mature. The dominant prey species found in the stomach was Japanese sardine *Sardinops melanostictus* (63.8%), followed by walleye pollock *Theragra chalcogramma* (22.4%), mackerel *Scomber japonicus* (6.9%), krill *Euphausia pacifica* (5.2%) and Japanese common squid *Todarodes pacificus* (1.7%). In the 2013 survey, Japanese anchovy *Engraulis japonicus* and Pacific saury *Cololabis saira* could not be found in the stomach. From late 1960s to 1987, Japanese sardine and mackerel were recorded as the major prey species of common minke whales taken by the commercial whaling. But, when the coastal component off Kushiro started in 2002, Japanese anchovy was the major prey species found in the stomach, and dominance of the Japanese anchovy was

continued until 2011 survey. In 2012, Japanese sardine and mackerels were detected again from the stomach by the survey, and in the present survey, Japanese sardine became the most dominant prey species. Conversely, Japanese anchovy was not present. Apparent change in the dominant prey species from Japanese anchovy to Japanese sardine observed here suggested that the distribution and amount of those prey species in the coastal waters off Kushiro were changed, and the stomach contents of the whales could reflect those environmental changes. Such information is valuable in considering the habit of the whales and environmental change in the region, and will contribute to the objectives of the JARPN II feeding ecology and ecosystem studies.

In discussion, the high number of humpback whale sightings in fig. 4 of the paper was noted and it was asked if this represented an increase over what had been observed in past surveys. The authors stated that at the start of the programme in 2002 there was a lower number of humpback whales sighting but beginning about 3-4 years ago the number of humpback whale sightings increased. In discussion, it was postulated that the increased number of humpback whale sightings may be related to changes in oceanographic conditions and available prey species. It was then asked if fluke photographs for photo-identification purposes are being collected. The authors confirmed that fluke photographs are being collected but that humpbacks in this area do not regularly fluke-up dive.

Finally, it was asked if the changes in the diet composition of minke whales as depicted in fig. 6 of the paper were correlated with changes in body condition. The authors stated that an analysis of this type was pending.

17.2.2 JARPA II

SC/65b/SP05 report the results of the 2013/14 survey of the Second Phase of the Japanese Whale Research Program under the Special Permit in the Antarctic (JARPA II). Two dedicated sighting vessels (SV), one sighting and sampling vessels (SSV) and one research base vessel engaged in the research for 70 days, from 3 January to 13 March 2014 in Areas V (130°E - 170°W) and VI West (VIW: 170°W - 145°W). Unfortunately the research activities were interrupted several times by an anti-whaling group which directed violent sabotage activities against Japanese research vessels in previous seasons. As a result the planned dedicated sighting survey was cancelled in the whole research area because the two SVs had to be dedicated to security tasks. The total searching distance was 3,182.0 n.miles by the SSV, which was approximately one-third of the searching distance in 'normal' years. Seven species including five baleen (blue, fin, sei, Antarctic minke and humpback) and two toothed (sperm and southern bottlenose) whales were sighted during the research period. A total of 313 schools (531 individuals) of Antarctic minke whales were sighted. It was the dominant species in the research area followed by the humpback whales (82 schools/133 individuals) and fin whales (45/99). The number of sightings of the Antarctic minke whales was about 4.0 times higher than that of humpback whales. A total of 251 Antarctic minke whales was sampled which were examined on board the research base vessel except one whale was lost during the transfer to the research base. Of 250 Antarctic minke whales, 125 were male (50.0%) and 125 were female (50.0%). Photo-id experiments were conducted and a total of two blue whales were photographed. Oceanographic surveys

to investigate vertical sea temperature profiles were also implemented using XCTD system. The research activity of the SSV was also interrupted several times. This situation was continued over three seasons from the 2011/12 surveys. The authors concluded that this represents a great loss for the Antarctic whale research and management under the IWC SC objectives.

17.3 Review of new or continuing proposals

17.3.1 JARPA II

In light of the announcement by Japan to cancel the JARPA II programme in the 2014/2015 season in accordance with the 31 March 2014 Judgment of the International Court of Justice (ICJ), there was no discussion of JARPA II under this agenda item.

In the 2014/2015 season, Japan will undertake a sighting survey in the Antarctic areas previously covered by the JARPA II activities.

17.3.2 JARPN II

The Committee was advised that following the 31 March 2014 Judgment of the ICJ regarding activities related to JARPA II, the Government of Japan voluntarily reviewed JARPN II. This voluntary review resulted in the reprioritisation of the research focus as well as recalculation of sample sizes to be pursued during the 2014 JARPN II survey.

Some members of the Committee recognised that substantial effort went into the design and planning of JARPN II. Changes in the allotment of lethal versus non-lethal approaches as well as recalculation of sample sizes may impact achieving the stated objectives of the JARPN II programme and that such changes must be accompanied by a scientific justification. Further, some members of the Committee expressed uncertainty about whether the stated changes represent a modification of the existing JARPN II programme or if this needs to be viewed as a 'new' programme.

In response, the proponents of JARPN II stated the overall objectives of the programme remain the same, focusing on the study of interactions between whales and fisheries in the coastal area and interactions among whale species in the offshore area as well as a contribution to the management of whales. The recalculation of sample sizes for target species was conducted to assess the appropriateness of the current target sample sizes (see below) and the non-lethal components of the programme were strengthened in order to address concerns raised by the ICJ in its consideration of JARPA II.

With respect to the 2014 JARPN II Offshore Component, keeping in mind the desire of the Government of Japan to balance scientific objectives with advice stemming from the ICJ decision, the following rationale was provided:

- (1) Allocation of some samples to non-lethal means was decided by the Government of Japan based on advice/suggestions from the ICJ.
- (2) Sampling of sperm and common minke whales was suspended because their role in the study of interactions between whales and fisheries in the coastal waters (a prime objective of the 2014 survey) seems to be limited.

- (3) Sei whale sample size of 100 (as in the original plan, see below) of which 10 will be studied using only non-lethal methods.
- (4) Bryde's whale sample size of 50 (as in the original plan, see below) of which 25 will be studied using only non-lethal methods. A larger number of Bryde's whales were allocated to non-lethal methods because they are better studied than sei whales through *the Comprehensive Assessment and the Implementation Review*.
- (5) A study for verifying the feasibility of using non-lethal method will be carried out and results of the study could be reflected in the future research programs.

With respect to the 2014 JARPN II Coastal Component, and keeping in mind the desire of the Government of Japan to balance scientific objectives with advice stemming from the ICJ decision, the following rationale was provided:

- (1) Allocation of some samples to non-lethal means was decided by the Government of Japan based on advice/suggestions from the ICJ.
- (2) Minke whale sample size of 114 (57 in each of the spring and autumn season as recalculated with the latest information, see below) of which 12 (6 in each of the periods) will be studied using only non-lethal methods.
- (3) A study for verifying the feasibility of using non-lethal method will be carried out and results of the study could be reflected in the future research programs.

When developing the JARPN II research programme, sample sizes of target species necessary for the estimation of food consumption by cetaceans were calculated with the method employed under the Norwegian research (Government of Norway, 1992, SC/44/NAB18) taking into account the following information derived from its past research:

- (1) Composition of prey species (%)
- (2) Average weight of each prey species in the stomach contents (kg)
- (3) SD and CV of the compositions and weights

Sample sizes were calculated with a condition that the stomach contents of a target prey species be calculated, with CV=0.2, for each year.

Re-calculation of the sample sizes for the 2014 JARPN II survey was made in the same manner as above while also incorporating the latest information derived from the ongoing JARPN II research. The results of these recalculations are as follows:

COASTAL COMPONENT

Ayukawa (Spring) - Re-calculation of the sample size for Minke whale was made for the main prey species (juvenile sand lance) with CV=0.2 for each year using the results of the latest JARPN II research (Coastal Component conducted in Ayukawa) in 2003-2010. The result of the re-calculation was 57 (the average during the research period).

Kushiro (Autumn) - Re-calculation of the sample size for Minke whale was made for the main prey species (Japanese anchovy and walleye pollock) with CV=0.2 for each year using the results of the latest JARPN II research (Coastal Component conducted in Kushiro) in 2002-2010. The results of the re-calculation was 50 for Japanese anchovy (2002-2007) and 57 for walleye pollock (2008-2010). Taking account the recent possible change of the distribution of prey

species, the sample size has been set 57 for walleye pollock (the average during the research period).

OFFSHORE COMPONENT

Bryde's whale - Re-calculation of the sample size was made for the main prey species (Japanese anchovy and krill) with CV=0.2 for each year using the results of the latest JARPN II research (offshore) in 2000-2012. The results of the re-calculation was 75 (the average during the research period).

Sei whale - Re-calculation of the sample size was made for the main prey species (copepods, Japanese anchovy and krill) with CV=0.2 for each year using the results of the latest JARPN II research (Offshore Component) in 2002-2012. The results of the re-calculation was 135 (the average during the research period).

With respect to Bryde's and sei whales, the Government of Japan decided to maintain the sample sizes as originally calculated since recalculation for those species showed the need for substantial increases of sample sizes. The Government of Japan considered that such increases could be regarded as revisions of the programme and therefore should be examined after the due process including review of results that is planned in 2016 for the 2nd period of JARPN II (2008-2013).

In discussion, the Committee **recommends** that the proponents of JARPN II develop a more comprehensive document for review at the 2015 Annual Meeting that details how the above recalculations of sample size and changes in allotments of lethal versus non-lethal methods fit with achieving the overarching programmatic objectives. This recommendation is made because the written information available to the Committee was not sufficient to evaluate whether the numbers of animals to be taken had been adequately justified in relation to the specific objectives of the research.

Further, the Committee recalled that the last JARPN II expert review in 2009 (IWC, 2010a) called for certain analyses to be performed to determine appropriate sample sizes for the JARPN II programme. The Panel concluded that it could not complete its review until this information (among other items) was supplied. The Committee (IWC, 2010b) subsequently expressed concern that the Panel was not provided with the information and guidance necessary to review programme progress and to draw conclusions regarding the appropriateness of programme sample sizes. The requested analyses were not performed and the review could not be completed.

Finally, some members of the Committee expressed concern that the effectiveness of non-lethal methods was directly related to effort. That is, non-lethal methods are likely to be more effective given a high level of effort and more likely to be ineffective given a low level of effort. Given this concern, evaluating the utility of lethal versus non-lethal methods is not possible.

17.4 Workplan (and see Table 19)

17.4.1 Planning for a periodic review of JARPN II

According to the procedure outlined in 'Annex P', the JARPN II programme is due to a periodic review in 2016.

The next step of this review process (revised in accord with discussions under Item 27.2) is that the proponents make the

data description document available two months before the next annual meeting. Requests for use of the data will be made one month in advance of the 2015 annual meeting. The data will be available in electronic form one month after the end of the Annual Meeting. Then the proponents will send a document to the Secretariat describing the analytical methods

Table 19

Overview of the tentative workplan as it relates to special permits.

Species / area	Interseasonal 2014-15	SC66a 2015	Interseasonal 2015-16	SC66b 2016
New Japanese Antarctic proposal	Follow 'Annex P' with expert workshop early 2015,	Review of expert workshop; Committee comments.	Depends on discussions at SC66a,	Depends on discussions at SC66a,
Regular review of JARPN II	Submission of data description document 2 months before annual meeting; data requests data 1 month before meeting,	Discussion of any data requests.	Follow 'Annex P' with expert workshop early 2016,	Review of expert workshop; Committee comments

to be discussed at the Workshop. This will happen nine months prior to the next Annual Meeting; i.e. the beginning of September. Based on the description of analytical methods, the Steering Group (Chair, Vice Chair, Head of Science and the last four Scientific Committee Chairs) will begin the process of identifying experts to participate in the Workshop. Given his involvement in the programme, the Scientific Committee Chair, Kitakado, will not take part in the Steering Group. Palka (as immediate past Chair) will act on his behalf.

Japan announced that the Government of Japan will meet the necessary costs for organising the Workshop to be held in Tokyo in January/February 2016, which includes the cost for the meeting venue and other miscellaneous costs other than the travel/stay costs for the participants. Travel/stay costs for the participants at the Workshop (8-10 invited experts and a representative from the IWC Secretariat) are expected to be met by IWC.

The Committee **agrees** to submit a budget request for the 2015/16 interseasonal period to cover the travel and stay of the expert panel (see Item 26).

17.4.2 Planning for review of future Japanese Special Permit research in Antarctic

Japan announced that the Government of Japan plans to issue a Special Permit for a new research programme in the Antarctic starting in the season 2015/16. Japan wishes this programme to be reviewed at the 2015 Annual Meeting, in accordance with 'Annex P'.

The new proposal will be reviewed under the process stipulated in the Annex P. Japan will submit a new proposal to the chair of the Scientific Committee no later than six months before the next Annual Meeting of the Scientific Committee in 2015 (October/November 2014). The proposal should then be reviewed by a small specialist workshop with a limited but adequate number of invited experts. The Workshop should be organised at least 100 days before the Annual Meeting in 2015 (January/February 2015). Results of

the Workshop should be duly submitted to the next Annual Meeting of the Committee in 2015 for its final review.

The Government of Japan will meet the necessary costs for organising the Workshop to be held in Tokyo in January/February 2015, which includes the cost for the meeting venue and other miscellaneous costs other than the travel/stay costs for the participants. Travel/stay costs for the participants at the Workshop are expected to be met by IWC.

The Committee **agrees** to submit a budget request for the 2014/15 intersessional period to cover the travel and stay of the expert panel (see Item 26).

18. WHALE SANCTUARIES²⁶

The issues to discuss under this Item were to facilitate the decadal review of the existing Southern Ocean Sanctuary (SOS) and the review of the proposed South Atlantic Whale Sanctuary (SAWS). Kitakado read out instructions from the Chair of the Commission that the decadal review of the SOS and review of the proposal for SAWS should follow the existing instructions and guidance from the Commission for the review of Sanctuaries. The terms of reference for discussions this year are given in Annex R.

18.1 Preparation for the regular review of the Southern Ocean Sanctuary

The Chair of the Commission had noted in a letter to the Chair of the Committee that the Commission has not yet agreed scientific objectives for the Southern Ocean Sanctuary as requested through the 2004 review, but that these were expected to be discussed at the Commission meeting in September 2014. She suggested that the Committee may wish to commence its review process by assembling information necessary to establish scientific objectives. The Commission would then provide further advice regarding review of the Southern Ocean Sanctuary.

Some suggestions for the review process were presented in SC/65b/O1. This summarised the previous review of the SOS in 2004 and in particular noted the difficulties of conducting a review without fully specified objectives. In 2004 the Scientific Committee had developed a series of recommendations that, once the overall objectives of the SOS have been refined, would allow these objectives to be evaluated, and would facilitate evaluation in future reviews. These recommendations were endorsed by the Commission in 2004.

Based on the direction from the Chair of the Commission, the Committee **agrees** to establish an intersessional email group (comprising Zerbini (chair), Bjørge, Donovan, Double, Fortuna, Hall, Jackson, Kitakado, Palka and Robbins) to assemble scientific information that might assist the Commission to establish scientific objectives for SOS. The review from 2004 will provide a useful background document for starting this work. Other relevant information on whales in the Southern Ocean had been compiled for the IWC-CCAMLR workshop in 2008. The group should focus on existing information from the Committee's reports, assessments and National Progress Reports rather than

seeking the latest updates from the many active national research programmes in the SOS area, which would be a major task. The report from the group should provide a summary of information on distribution, migration, current abundance, status and trends, threats, and catches by species/stock in the Southern Ocean Sanctuary. In addition, the report should **reiterate** the Committee's recommendations from the 2004 review to facilitate reviews of Sanctuaries and Sanctuary proposals (item B, numbers (1)-(7) in Appendix 1) and outline how the information provided relates to these recommendations. The report of this email group will be circulated for information of the members of the Committee and submitted to the Commission three weeks before IWC65.

The Committee **agrees** that there was a need for more discussion of the review process. There were differing views on the merits of the proposals in SC/65b/O1 and the success of the process in 2004. The Committee **agrees** these discussions can better take place at the 2015 Annual Meeting following elaboration of objectives and guidance from the Commission.

18.2 South Atlantic Sanctuary proposal

The head of delegation for Brazil (Secretary of Biodiversity and Forests, Roberto Cavalcanti) summarised the proposal for a South Atlantic Whale Sanctuary (IWC/65/8 Rev1). He stressed that the IWC is not dealing with a new proposal and that the Commission had been considering this matter for more than a decade. During this period the amount of scientific research in the South Atlantic has increased and the new proposal reflects this. The new version of the proposal is intended to address the guidelines for reviews in Annex R. The SAWS proposal is consistent with modern and emerging management practices including protected areas, and provides an opportunity for countries with different management regimes to co-ordinate activities to address emerging issues. To give just one example, there are relatively few ports and generally low levels of ship traffic in the South Atlantic but this is set to expand considerably. The co-ordinated approach provided within SAWS will thus help to address existing and emerging environmental and anthropogenic threats such as shipping while finding a balance with the needs of conservation and industrial development. The primary goal of the SAWS is to promote the biodiversity conservation, non-extractive and non-lethal utilisation of whale resources in the South Atlantic Ocean. To achieve this goal, specific objectives are described in IWC/65/8 Rev1. The proposed SAWS is intended to promote cooperation well beyond the strict interpretation of preventing commercial direct takes from impacting cetacean populations, including support for the coordination between MPAs established at national levels or under other relevant international initiatives, such as the World Heritage Convention and UNESCO Man and the Biosphere programme.

Iñiguez noted that Argentina had been a proponent of SAWS with Brazil when it was presented for the first time 13 years ago. Later on South Africa and Uruguay also sponsored this proposal. The last review of the SAWS was in Ulsan, Korea

²⁶ The Committee had established an *ad hoc* working group chaired by Zerbini and Hall to discuss this item at times when there were no other sessions taking place to allow full participation of those who wished to

attend. It was agreed to incorporate the report of that group in full into the Committee's report here.

in 2005 (IWC, 2006) and subsequently the proponents incorporated the changes requested by the Commission. He added that large whale species were exploited by commercial whaling in the South Atlantic until the mid-1980s. Hunting occurred along migratory routes in addition to feeding and breeding grounds, reducing some populations to very small numbers (e.g. Antarctic blue whales, southern right whales, and humpback whales). Even though whale populations are currently protected, they face other threats including ship strikes, emerging disease, pollution, hydrocarbon exploitation and exploration, entanglement and climate change. The Chairman's report of the Thirty-Fourth Annual Meeting identifies the prime objective of a sanctuary as a place where individual or groups of whale populations are protected from whaling for a specified period with additional objectives related to information and research interests. He noted that the objectives of the SAWS had already been outlined by Cavalcanti and that the SAWS will provide the framework to coordinate and cooperate on cetacean research, conservation and management in the South Atlantic. The proposal was being submitted to SC65b in the hope that, consistent with its mandate and competences, the Scientific Committee will provide its contribution to improve the proposal as requested by Commission.

In discussion, some members noted that the measures contained in the proposed Schedule amendment that would establish the SAWS would only prohibit whaling. The amendment text does not include any of the other scientific objectives such as the coordination of research. The review of the Southern Ocean Sanctuary had been difficult because the objectives were not clearly specified. The lack of objectives within the proposed Schedule amendment text would make the SAWS difficult to assess following the terms of reference for the review process.

In response, it was noted that the Schedule amendment was just one of the points that needed to be addressed to establish the Sanctuary and that the Schedule contains those regulations applicable to whaling which are mandatory. Previous IWC reviews of sanctuaries had emphasised the need for clear objectives and the SAWS proposal had learnt from this by specifying detailed objectives.

In discussion of one of the primary objective of SAWS (maximise the rate of recovery of depleted whale populations towards their natural carrying capacity levels, and to monitor and maintain these populations at these levels), it was noted that further details of the monitoring plan were needed in order to evaluate whether the monitoring was likely to be successful in assessing whether the objectives had been achieved. In addition, changes to the environment, and particularly the impact of commercial fisheries, are likely to prevent whale populations recovering to natural carrying capacity, since this will have changed. The proposal should give more details of the proposed monitoring programme, including how carrying capacity will be assessed to take into account multi-species effects of mid-latitude fisheries.

In response, it was noted that the proposal mentions that carrying capacity will have been affected by human activities and therefore the objective is not necessarily to return to pre-whaling population levels. The way in which human impacts may have affected carrying capacity is complex and would need the kind of coordinated research outlined in the proposal

to address these questions. For MPAs, this level of detail is generally developed once the MPA is established. The SAWS contains some of the best monitored whale populations in the world. The Committee could assist in helping to define objectives in relation to environmental change, and refine monitoring programmes, once the SAWS was in place and a monitoring framework had been established.

The proposal describes general features of critical habitat but it was suggested that insufficient detail was provided in order to provide advice on whether the sanctuary addresses the issue of critical habitat and non-critical whale habitat. The Committee **advises** that a revised proposal, with more detail on the issue of monitoring and objectives with respect to carrying capacity and on critical habitat, would assist with the review. The Committee would also **welcome** further details on how potential threats might be addressed in collaboration with other international bodies.

In 2004, the Committee agreed that the involvement of independent external reviewers in the review of the SOS had been largely positive and that involvement of external reviewers should continue, both for future reviews and reviews of future Sanctuary proposals. It was agreed that external experts should be involved in the SAWS review process but there were different views on the success of the process used to review the SOS in 2004. Some members noted that they did not support the method used in 2004 if the external reviewers operated independently from the Scientific Committee. Therefore, these members only support the use of external reviewers in the upcoming review of the SAWS if they work in conjunction with the Committee. It was suggested that the review process should be initiated with a workshop or pre-meeting including selected invited experts and members of the Scientific Committee, followed by the review by the full Committee. The Committee **requests** further clarification from the Commission at IWC65 on recommendations for the SAWS review process. Based on any advice from the Commission, the Committee could then finalise the details of the review process at the 2015 Annual Meeting such that the review can be completed at the 2016 Annual Meeting.

18.3 Workplan

The Committee developed a draft workplan, **recognising** that the workplan may be modified under new guidance from the Commission at IWC65. The overview of future work on sanctuaries is given as Table 20.

Table 20

Overview of the tentative workplan as it relates to sanctuaries

Task	SC66a (2015 Annual Meeting)	SC66b (2016 Annual Meeting)
Review of methods for reviewing sanctuary proposals and periodic reviews of existing sanctuaries	Receive and act in line with advice provided by the Commission at IWC 65	Perhaps review how new process (if given) performs.
Periodic review of Southern Ocean Sanctuary	Receive advice from Commission on objectives. Finalise details of review process	Finalise review
Review South Atlantic Sanctuary proposal	Perhaps receive revised proposal. Finalise details of review process	Finalise review

19. SOUTHERN OCEAN RESEARCH PARTNERSHIP

The Scientific Committee received 22 documents detailing progress on the five major projects of the Southern Ocean Research Partnership (IWC-SORP). These included: (1) the Antarctic Blue Whale Project; (2) Distribution, relative abundance, migration patterns and foraging ecology of three ecotypes of killer whales in the Southern Ocean; (3) The foraging ecology and predator-prey interactions between baleen whales and krill: a multi-scale comparative study across Antarctic regions; (4) The distribution and extent of mixing of Southern Hemisphere humpback whale populations around Antarctica? Phase 1: East Australia and Oceania; and (5) Acoustic trends in abundance, distribution, and seasonal presence of Antarctic blue whales and fin whales in the Southern Ocean. All of these projects are still on-going and contributing to the work of five sub-committees and working groups. The Scientific Committee **welcomes** the scientific information contributed by on-going IWC-SORP research projects and **recommends** their continuation.

The Committee **expresses concern** that there are few funds remaining in the IWC-SORP budget, including the funds necessary to maintain centralised project coordination. It therefore **recommends** the continuation of a funded coordinator within IWC-SORP in order to sustain the momentum of this large collaborative research effort, to ensure the communication of high-calibre scientific research to the Committee, and to leverage future funding to the project (see Item 26). It also **urges** the Commission to review the funding status of IWC-SORP and to facilitate sustainable support for these long-term research initiatives.

20. IWC LIST OF RECOGNISED SPECIES

Mendez *et al.* (2013) described multiple lines of evidence to re-evaluate the genus *Sousa* and four species, one still unnamed, were recognised. *Sousa* exhibit some of the greatest degrees of genetic differentiation yet observed in small cetaceans, indicating that migration events are either very infrequent or may no longer occur. The Mendez *et al.* re-evaluation was accepted by the Society of Marine Mammalogy (SMM) Taxonomy Committee and the Committee **agrees** that the IWC list of recognised species should be amended accordingly:

Sousa teuszii (Kükenthal, 1892) Atlantic humpback dolphin

Sousa chinensis (Osbeck, 1765) Pacific humpback dolphin

Sousa plumbea (G. Cuvier, 1829) Indian Ocean humpback dolphin

Sousa un-named species. From Australia²⁷

The Committee **appreciates** the work of the SMM Taxonomy Committee and **agrees** that this should be reviewed annually in the context of the IWC list to keep them synchronised.

²⁷ The new species from Australia will soon be named and published. Therefore, both the scientific names and common names should be examined again at the next SC meeting.

21. CONSERVATION MANAGEMENT PLANS

The Committee had discussed CMPs in the context of large whales last year (IWC, 2014). This year, there was discussion of the concept of threat-based CMPs that they can apply to a single threat requiring international coordination and affecting multiple species or large habitats. The Committee **reiterates** its recommendation of last year for a review of the template and criteria to enable better consideration of the options for a threat based approach. The Committee **agrees** that the issue of marine debris is appropriate for consideration as a first threat-based CMP.

With respect to small cetaceans, the Committee **agrees** that CMPs for some threatened species and populations would be highly beneficial and would allow coordination of efforts. Their implementation is more problematic when species ranges are limited to a single country, as with the vaquita, Maui's dolphin and Yangtze finless porpoise. The situations of the boto and the franciscana might make them appropriate candidates to be suggested for CMP development.

22. UPDATED LIST OF ACCEPTED ABUNDANCE ESTIMATES

The Committee received an update on the work being undertaken by Allison to complete the list of accepted abundance estimates. A number of issues that require clarification had arisen during the year and it was agreed to establish an intersessional group to assist in this work (Allison, Brownell, Butterworth, Donovan, Gunnlaugsson, Kitakado, Palka, Wade, and Witting).

23. RESEARCH AND WORKSHOP PROPOSALS AND RESULTS

23.1 Review results from previously funded research proposals

Progress on Research Proposals and Workshops funded last year (for details see IWC, 2014, pp. 66-70 and carryovers from the previous year were primarily discussed in the appropriate sub-groups. Table 21 summarises the results of the items allocated funds under the 2013 Scientific Committee budget (see IWC, 2014, pp. 66-70) plus one project that was originally funded in 2012. All projects were completed successfully and made a major contribution to the Committee's work (see the relevant sub-group Annexes for details) apart from two workshop that will be held after the close of this meeting (BRG-2 and E-5) and one project that is ongoing (E-3).

23.2 Review workshop proposals for 2014/15

The Workshop proposals for the 2014/15 period are discussed under Item 26 and summarised in Table 22. The Committee **notes** that these Workshops are essential to it being able to meet its proposed two-year workplan discusses under Item 24.

Table 21

Progress on workshop and research proposal agreed last year

Number	Title	Status
(16) from 2012 (IWC, 2013)	Review and guidelines for model-based and design-based line transect abundance estimates	Completed (SC/65b/RMP11)
AWMP-1	AWMP Workshop on developing SLAs for the Greenlandic hunts	Completed (SC/65b/Rep06)
AWMP-2	AWMP developers fund	Completed (SC/65b/AWMP03 and 04)
BRG/AWMP/1	Gray whale rangewide Workshop	Completed (SC/65b/Rep08)
BRG-1	Southern right whale kelp gull Workshop	Workshop in August 2014
E-1	State of the Cetacean Environment Report (SOCER)	Completed (SC/65b/E01rev)
E-2	POLLUTION 2020	Completed (SC/65b/Rep05)
E-3	Complete implementation of the CERD website	Ongoing
E-4	Joint IWC/IQOE Workshop predicting soundfields-global soundscape modelling	Completed (SC/65b/Rep03rev)
E-5	2 nd phase Workshop on marine debris	Workshop in August 2014
HIM-1	Ship strike data coordinator	Completed (SC/65b/HIM04, 05, 09)
IA-2	Statistical catch-at-age issues for further investigation	Completed (SC/65b/IA03)
IA-3	2014 IWC-POWER North Pacific survey	Completed (SC/65b/Reps 01, 09, SC/65b/IA05, 011)
RMP-1	Intersessional Workshop on North Atlantic fin whales	Completed (SC/65b/Rep07)
RMP-2	Pre-meeting on North Atlantic minke <i>Implementation Review</i>	Completed (Annex D, Appendix 5)
RMP/AWMP/SD	Simulations to evaluate power and precision of genetic clustering at critical [demographic] dispersal rates	Completed (SC/A14/AWMP-RMP01, 05)
RMP/AWMP-1	Joint AWMP-RMP Workshop on stock structure hypotheses for North Atlantic common minke whales	Completed (SC/65b/Rep04)
RMP/AWMP-2	Computing support for RMP and AWMP	Completed (Annexes D and E)
SH-1	Minimum abundance estimates of Breeding Stock D humpback whales	Ongoing
SH-2	Modelling work to complete assessments of Breeding Stocks D, E and F	Completed (SC/65b/SH04rev)
SH-3	Antarctic Humpback Whale Catalogue	Completed (SC/65b/SH03)
SH-4	Comparison of JARPA II photographs to Antarctic Blue Whale Catalogue	Completed (SC/65b/SH20)
SH-5	Southern Hemisphere Blue Whale Catalogue 2012/13	Completed
SH-6	Pre-meeting to complete the assessment of Breeding Stocks D/E/F	Completed (Annex H)
SP-1	Expert Workshop to review JARPA II	Completed (SC/65b/Rep02)

Table 22

Workshop proposals agreed during this meeting

RP nos*	Title	Relevance	Up to SC66a		Up to SC66b	
			Date	Venue	Date	Venue
AWMP1	AWMP Workshop to Develop SLAs for the Greenland Hunts	AWMP	?6-10 January 2015	Copenhagen	Early 2016	Copenhagen
BRG3	Workshop to forward the modelling process to understand the status of gray whales across the North Pacific	BRG, AWMP, E	24-26 March 2015	La Jolla		
E7	CERD pre-meeting	E	Prior to SC66a	TBD		
E8	Investigations of large mortality events and mass strandings	All (incl. SM)			Late 2015	San Francisco
EM2	CCAMLR-IWC Workshop on the development and application of multi-species models to the Antarctic marine ecosystem: pre-meeting	EM			Prior to SC66b	TBD
HIM2	Preventing the Entanglement of Whales in Fishing Gear	HIM, COMM			April 2016	TBD
IA1	IWC-POWER planning and Technical Advisory Group meetings	IA, BRG, RMP	October 8-12 2014	Tokyo	October 2016	Tokyo
RMP2	Evaluating abundance estimates: diagnostics and testing	All (incl SM)				
RMP3	Workshops to further progress on the <i>Implementation Reviews</i> for the North Atlantic minke and fin whales	RMP, AWMP	?16-20 February 2015	Copenhagen	?Spring 2016	Copenhagen
SP1	WS for periodic review of JARPN II	SP			Early 2016	Tokyo
SP2	WS on Review of New Special Permit Proposals	SP	Early 2015	Tokyo		
E6	Climate Change meeting	E	19-20 August 2014	Glasgow		

* The full proposals are available as numbered documents: SC/65b/AWMP-RP1 etc.

24. COMMITTEE PRIORITIES AND INITIAL AGENDA FOR THE 2015 AND 2016 MEETINGS

Table 23 provides an overview of the main items for consideration based upon the workplans developed by the sub-groups and discussed in detail in their reports and in the relevant Items in this report. The Committee emphasises that much of its work is iterative and thus depends on progress made intersessionally and at Annual Meetings. The progress made is also integrally related to budget requests (see Item 26).

Table 23

Priorities for Committee work in 2015 and 2016

Topic	SC66a 2015	SC66b 2015
RMP-related matters		
Evaluate energetics based model	Review progress	Review results
Evaluate <i>CLA</i> performance	Review results when density-dependence acts upon natural mortality; Evaluate Norwegian <i>CLA</i> proposal	Complete if not done at SC66a
Other <i>CLA</i> related tasks	Review progress	As above
Abundance estimates	Hold pre-meeting on Diagnostic software to assist in evaluating design-based estimates	As above
Common minke whales (WNP)	Review results	As above
	Review hybrid RMP variants & research proposals if submitted; agree abundance estimates for use in actual applications of the RMP	Complete if not done at SC66a
Common minke whales (NA)	Assign plausibility to trials; review trial results; complete <i>Implementation Review</i> ?	Complete <i>Implementation Review</i> (if needed)
Fin whales (NA)	Review trial results;	Complete <i>Implementation Review</i> (if needed)
	Assign plausibility; finish <i>Implementation Review</i> ?	
Sei whales (NA)	Decide to initiate or not pre-implementation assessment	Pre-implementation assessment (if agreed at SC66a)
Bryde's whales (WNP)	Review new information	Review new information
HIM-related matters		
Reviews of mitigation measures for ship strikes and entanglement	Produce simple summary information and advice table	Finalise if not completed at SC66a
Entanglement	Continue to examine new information on rates, risks and mortality and provide advice	Continue to examine new information
Entanglement (support Commission initiatives)	Communication of key issues; advice for specific CMPs; review recommendations from workshop; work with other organisations	Continue to support
Ship strikes	Continue to examine new information on rates, risks and mortality and provide advice	Continue to examine new information
Ship strikes (database)	Update and improve database, including review process and criteria	Continue
Ship strikes (support Commission initiatives)	Communication of key issues; advice for specific CMPs; review recommendations from workshop; work with other organisations	Continue to support
AWMP-related matters		
Validate <i>Humpback SLA</i>	Receive report formally	No
<i>SLA</i> for bowhead whales	Expect to finalise <i>SLA</i> recommendation	Finalise <i>SLA</i> recommendation if needed
<i>SLA</i> for common minke whales	Review progress; Developers' work	Hope to finalise <i>SLA</i>
<i>SLA</i> for fin whales	Review progress	Review progress; Developers' work
Annual review of catch limits	Complete	Complete
<i>Implementation Reviews</i>	None scheduled	Prepare for gray whale <i>Implementation Review</i>
Whale stocks-related matters		
Antarctic minke whales	Try to finalise the in-depth assessment with a focus on the Indo-Pacific region	Finalise if not completed at SC66a and [consider how to] address the remainder of the Antarctic
Southern Hemisphere humpback whales	Undertake review and synthesis of the completed 8-year circumpolar assessment. Begin to evaluate data requirements and process for future assessments.	Complete evaluation and determine future workplan
Southern Hemisphere blue whales (including pygmy blue whales)	Review available existing and new information on stock structure abundance etc. and determine feasibility of conducting area-based assessments with an associated workplan	Depends on workplan developed in 2015
North Pacific sei whales	Begin in-depth assessment	Complete in-depth assessment
North Pacific gray whales	See detailed workplan provided in Annex F	Continue and possibly complete
Southern right whales	Focus on reviewing new information, e.g. with respect to matters related to CMPs	Continue to review new information and develop workplan with respect to future updated assessments
North Atlantic right whales	Review new information. Determine when to undertake a new assessment and develop workplan.	Depends on outcome of discussions in 2015.
North Pacific right whales	New information expected from the Sea of Japan/Kamchatka region. Determine when to undertake an assessment and develop workplan.	Depends on outcome of discussions in 2015.
North Atlantic bowhead whales	Continue to review new information.	Continue to review new information and develop a workplan towards eventual assessment.
Okhotsk Sea bowhead whales	Review new information.	Continue to review new information and develop a workplan towards and eventual assessment.
Arabian Sea humpback whales	Review new information expected from several research initiatives. Continue to assist in efforts to develop a CMP.	Depends on outcome of discussions in 2015.
Sperm whales	Review information and develop a workplan	Depends on outcome of discussions in 2015.
Stock definition-related matters		
Terminology review and unit-to-convert	Continue with a focus on examining terms used for small cetaceans. Try to finalise an initial list for use by the Committee.	Finalise if not completed at SC66a.

Topic	SC66a 2015	SC66b 2015
Updates to genetic data analysis and DNA data quality guidelines	This is part of maintaining an online and evolving set of guidelines.	Review to see if updates are required
Statistical and genetic issues concerning stock definition	Continue to review technical issues regarding papers submitted to all sub-groups of the Committee.	Continue.
Testing of Spatial Structure Models (TOSSM)	Examine the future application of TOSSM datasets; advance the use of TOSSM to provide guidelines for setting subarea boundaries for assessment.	Continue based on discussions at 2015
Environmental concerns-related matters		
POLLUTION 2020	Refine population modelling approach; finalise priority contaminants list for future studies.	Continue to refine modelling approach; in utero transfer analyses and modelling
Oil spills	Review new information	Plan for an oil spill workshop
Contaminant threat information	Focus sessions on regional trends and POPs in cetaceans	Data integration and mapping
CERD	Pre-meeting. Data input and website management.	Improved communications on disease issues
Strandings and mortality events	Plan intersessional workshop; review new information	Receive report of intersessional workshop; review new information
Anthropogenic sound	Continue work on soundscape mapping; plan for 'masking' focus at SC65b. Review new information	Continue work on soundscape mapping; focussed sessions on 'masking'; plan for 'stress and sound' workshop; focus session on effectiveness of marine mammal observers in mitigation
Ecosystem modelling-related matters		
Co-operation on ecosystem model development	Discuss how best to further the long-term scientific exchange between IWC SC/EM and SC-CCAMLR WG-EMM	Receive results of Joint CCAMLR-IWC Workshop and continue
Processes in ecosystem model development	Receive results of IWC funded project to use tagging data to incorporate into models	Review progress and continue
Ecological change in the Southern Ocean	Review new analyses of the minke whale body condition and stomach content data to further examine temporal trends	Continue if necessary
Effects of long-term environmental change	Review work of intersessional group to determine suitable long time datasets and determine workplan	Depends on discussions at SC66a
Small cetacean-related matters		
Main topic to be decided by December 2014	<i>Tursiops</i> systematic or regional assessment of the status of small cetaceans	Depends on what happens in 2015 and the venue for 2016
Voluntary fund for small cetaceans conservation research fund	Continue	Continue
Review previous recommendations	Continue (priority will be given to vaquita, Hector's and Maui's dolphins, franciscana, beluga, river dolphins)	Continue
Review on takes of small cetaceans.	Continue	Continue
Whalewatching-related matters		
Assess the impacts of whalewatching on cetaceans	This is the ongoing and primary topic.	Continue
Review progress on the Commission's five-year strategic plan including the Handbook	As the Handbook is an online 'living' document then it is anticipated that this will be ongoing work although the initial work will be the most intense.	Continue
Review work of intersessional steering groups	These are listed in Annex M, table 2	Continue
Review whalewatching in the region of the meeting	The next meeting venue is unknown but this is an ongoing item	Continue
Consider information from platforms of opportunity	Finalise standard elements and guidelines including data collection items to be hosted on the IWC website	Review progress and modify if required
Review whalewatching guidelines and regulations	Ongoing work –the most recent compilation is submitted to the IWC Secretariat and included on the IWC website	Continue
Emerging whalewatching industries of concern	Ongoing work	Continue
Progress on previous recommendations	Ongoing work	Continue
DNA-related matters		
Progress on genetic methods	Ongoing work	Continue
Amendments to <i>GenBank</i>	Ongoing work	Continue
Progress on archiving of samples from catches and bycatches	Ongoing work	Continue
Reference databases and standards for diagnostic registers	Ongoing work	Continue
Special Permit-related matters		
New Japanese Antarctic proposal	Follow 'Annex P' with expert workshop early 2015	Review of expert workshop and comments by Committee.
Regular review of JARPN II	Consider requests for access to data	Discussion of any data requests.
Sanctuary-related matters		
Consider review methods	Receive and act in line with advice provided by the Commission at IWC 65	Perhaps review how new process (if given) performs.
Periodic review of Southern Ocean Sanctuary	Receive advice from Commission on objectives. Finalise details of review process	Finalise review
Review South Atlantic Sanctuary proposal	Perhaps receive revised proposal. Finalise details of review process	Finalise review

25. DATA PROCESSING AND COMPUTING NEEDS FOR 2014/15

Allison reported on the computing needs and requirements identified for the forthcoming year. These are summarised in Table 24.

Table 24
Computing tasks for 2014/15

REVISED MANAGEMENT PROCEDURE (RMP) – GENERAL ISSUES

- (1) Evaluate the performance of the *CLA* for trials when natural mortality rather than fecundity is density-dependent (Annex D, Items 2.3 and 2.4);
- (2) Address the remaining tasks related to testing the *CLA* (Annex D, Item 2.5);

RMP – IMPLEMENTATION-RELATED MATTERS

North Atlantic fin whales

- (1) assemble data for the combined sub-area EG+WI (stock structure hypothesis VII) (Annex D, Item 3.2.1)
- (2) update the catch series to include incidental catches off Eastern Canada (Annex D, Item 3.2.1)
- (3) finalise the initial validation of the code (Annex D, Item 3.2.1)
- (4) continue to work towards conditioned *Implementation Simulation Trials* (Annex D, Item 3.2.2)

North Atlantic minke whales

- (1) Finalise the catch series (commercial and aboriginal) catch series (Annex D, Item 3.3)
- (2) Code finalisation and conditioning (Annex D, Item 3.3)
- (3) Conduct projections and circulate results (Annex D, Item 3.3)

North Atlantic sei whales

- (1) Summarise information on the distribution of sei whales from catch records (Annex D, Item 3.4.2)

Western North Pacific minke whales

- (2) Run ‘hybrid’ versions of RMP variants if requested by Japan, to allow evaluation of candidate ‘variants with research’ (Annex D, Item 3.1);

AWMP

- (1) Validate and confirm results for the *Humpback SLA*
- (2) Provide operating model to developers for common minke whales and possibly fin whales (See also related tasks under RMP).

IN-DEPTH ASSESSMENT

- (1) Validation of the 2012 and 2013 POWER cruise data
- (2) Further validation and correction of IDC/SOWER data if the problems are elucidated (item 10.13.8)
- (3) Complete validation of the 1995-97 blue whale cruise data and incorporate into the DESS database (carried over).

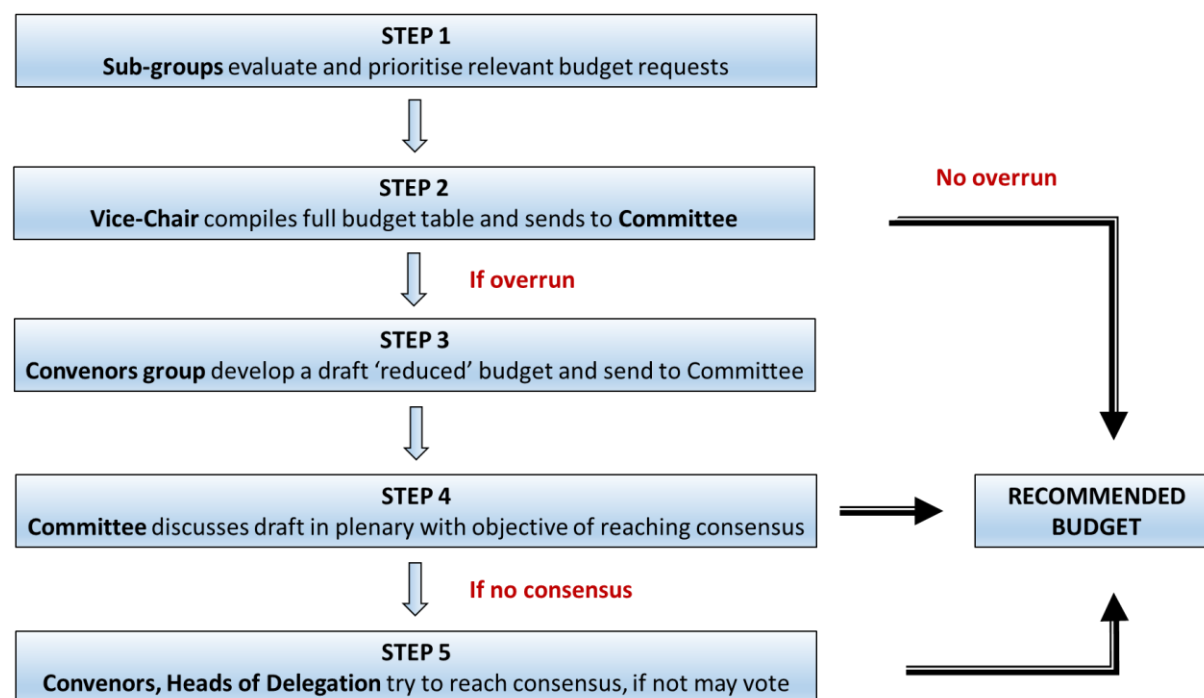

Fig. 4. Summary schematic of the budget process

26. FUNDING REQUIREMENTS FOR 2014/15 AND 2015/16

The Committee noted that this year it was expected to put forward a budget for a two-year period. In doing so it **draws the Commission's attention** to the unavoidable mismatch between the Scientific Committee year (May-June year 1 to May-June year 2), the Commission's biennial period (September year 1 - September year 3) and the Commission's financial year (1 January - 31 December). This makes planning rather more difficult, and is particularly difficult when the tasks undertaken are iterative i.e. the work needed in year 2 is heavily dependent on the results of year 1. This timing difference can be problematic if funded work is expected to be carried out in the period between the close of the Scientific Committee meeting and the adoption of the budget by the Commission which comes into force on the following 1 January (i.e. 6 months after the Committee meeting).

In response to discussions last year, the Committee discussed the process of developing a budget early in the plenary. As part of that discussion it received a report from the Secretary on the background to the IWC process and comparative information from other organisations (SC/65b/SCP02) as well as other discussion papers (SC/65b/SCP03 and 04).

After some discussion, the Committee **agrees** to the process given in Annex S and summarised in Fig.4. The approach agreed for the intersessional period and next year, based upon the experience gained this year, is given under Item 27.3.

Using the approach in Annex S, and following up to step 4, the Committee **recommends to the Commission** the budget request shown in Table 25, following discussion within sub-groups and a suggestion from the Convenors that was adopted by consensus.

The Committee notes that *pro formas* for all of the funding requests received are available on the Scientific Committee website. The Committee **thinks** the Convenors (and especially the Vice-Chair) for their hard work in developing the proposed draft and for the explanatory text. As the expected budget of £315,800 was exceeded in 2014/15, the explanation for the proposed reduced budget is given below (by project order in relation to the table).

26.1 Rationale for the reduced budget items

RMP-RP4. EVALUATION OF DENSITY DEPENDENCE PARAMETERS FOR INCLUSION IN RMP TESTING BASED ON ENERGETICS MODELLING.

The Committee **agrees** that this project can be spread over two years with no impact on its outcomes. The results can thus be considered at the 2016 meeting.

RMP-RP5. GENETIC ANALYSIS TO AID THE FORMULATION OF STOCK HYPOTHESES FOR PRE-IMPLEMENTATION ASSESSMENT OF N. ATLANTIC SEI WHALES.

The Committee **agrees** that this has scientific merit. However, there had not been time for it to be fully discussed during the sub-committee meeting. The Committee **agrees** that a revised proposal be resubmitted for consideration next

year with the possibility that funding may be allocated then, following the process agreed under Item 24.3.

BRG-RP2-SOUTHERN RIGHT WHALE MORTALITIES AT PENINSULA VALDES: REQUESTED BUDGET FOR POPULATION AND HEALTH MONITORING RESEARCH.

In discussing this project the Committee made two general observations.

- (a) The Committee has always strongly encouraged long-term monitoring programmes and recommended their continuation. However, given the nature of the Scientific Committee budget, its policy has been only to support such programmes financially if there was an emergency funding situation in a single year (as was the case for southern right whales off South Africa).
- (b) This project is of importance for the Conservation Management Plan for South Atlantic right whales approved by the Commission through the Conservation Committee, which receives some partial funding through the CMP fund.

The Scientific Committee is of course recognises the importance of CMPs and is pleased to provide scientific and technical advice on the relevant components of them. However, it notes that (a) CMPs may have many scientific actions within them and (b) that the number of CMPs is expected to increase. It **requests** that the Commission considers whether funding requests for scientific actions of CMPs, especially with respect to long-term programmes such as monitoring, are expected to be considered under the Scientific Committee's regular budget allocation. It notes that, if this is the case, then this may cause difficulties for the Committee to achieve its workplan in the future unless the regular budget allocation is increased.

The Committee recognises that the current worldwide economic situation can cause serious problems for long-term studies and monitoring programmes. It also recognises the present die-off situation in Peninsula Valdes. Recognising that the three components of the project (i.e. aerial survey, photo-identification and post-mortem inspections on stranded animals) also have a strong scientific importance and that their interruption could jeopardise the scientific objectives of the project, it **agrees** to allocate the related amount for those components (£13,000) for 2015.

The Committee had considered the option to split the funding over two years but **agrees** that this was inappropriate as it would affect the aerial survey component and therefore the achievement of the scientific objectives of the project.

BRG-RP4 - IDENTIFICATION OF SNP LOCI IN GRAY WHALES USING NGS SEQUENCING APPROACHES AND GRAY WHALE SAMPLES FROM ACROSS THE NORTH PACIFIC

The Committee **agrees** that this proposal has scientific merit. However, there had not been time for it to be fully discussed during the sub-committee meeting. The Committee **agrees** that a revised proposal be resubmitted for consideration next year with the possibility that funding may be allocated then, following the process agreed under Item 24.3.

Table 25

Summary of budget requests for the 2014-16 period. For explanation and details of each project see text.

RP nos*	Title	Relevance	2015	2015 reduced	2016	2016 reduced
AWMP1	AWMP Workshop to Develop SLAs for the Greenland Hunts	AWMP	7,000	7,000	7,000	7,000
AWMP2	AWMP developers fund	AWMP	7,000	7,000	7,000	7,000

* The full proposals are available as numbered documents: SC/65b/AWMP-RP1 etc.

SH-RP7-SOUTHERN OCEAN RESEARCH PARTNERSHIP (IWC-SORP) COORDINATION.

In discussing this proposal, the Committee made the following general observations.

(1) The nature of this proposal is somewhat different to proposals usually received by the Committee. The initial proposal appeared to be primarily an administrative role with a fund-raising component. After seeking clarification, it was found that some 90% of the proposed activities were more science-related. The Committee **seeks guidance** from the

Commission as to whether this type of administrative request is appropriate for consideration under the regular Scientific Committee budget in the future.

(2) The Committee is also aware that the Commission has a voluntary SORP fund generously initiated by the Australian Government that may also be appropriate for this kind of request. The Committee **urges** other SORP member countries to consider additional voluntary contributions to that fund. It was noted that since its

inception after a similar generous major contribution from Australia, the Small Cetaceans Voluntary Conservation Research fund has received some £170,000.

Having said that, the Committee **recognises** the valuable scientific work being undertaken as SORP projects (see Item 19) and the urgency of the situation (the coordinator contract will expire soon and there is little money in the SORP fund). It **agrees** to fund the 90% activities that are more science-related for the 2015 period on the expectation that further SORP funds will be generated during the 2015 period to pay for future years. The Committee notes that the Commission does not pay 'salary-on costs' so that these have been removed from the budget.

EM-RP1. USING BALEEN WHALE TAG DATA TO INFORM ECOSYSTEM MODELS.

This is a voluntary rearrangement of the project budget over the two years. The total budget of the project remains unchanged.

E-RP6. CLIMATE CHANGE MEETING (AUGUST 2014).

This activity does not fall under the 2015-2016 Scientific Committee budget. It is proposed that this is partially funded from a small projected underspend of the 2014 budget.

SH-RP5. PHOTO-IDENTIFICATION ANALYSIS OF BLUE WHALES FROM THE NEWLY DISCOVERED FORAGING GROUND IN THE SOUTH TARANAKI BIGHT (NZ).

This Committee **agrees** that this project falls under the category of an 'unsolicited' research proposal and had not therefore complied with the correct process (IWC, 1996b). It **agrees** that it should be resubmitted following the appropriate mechanism and timetable (see Item 24.3).

26.2 Summary information on all of the proposals received

(1) AWMP-RP1 WORKSHOP ON DEVELOPING SLAS FOR THE GREENLAND HUNTS FOR BOWHEAD, MINKE AND FIN WHALES

The Commission has requested that the Committee provide it with aboriginal subsistence *Strike Limit Algorithms* (SLAs) for use by 2018, i.e. the Committee must target being able to recommend SLAs to the Commission by no later than the 2017 Annual Meeting. The Committee has identified completion of the development of long-term SLAs for these hunts as high priority work. In order to meet the proposed timeframe, an intersessional Workshop is required. The focus of the proposed Workshop is to: (1) Review the performance statistics and plots for revised candidate *Strike Limit Algorithms* for bowhead whales off West Greenland; (2) Identify a work plan to which will allow the Committee to recommend a *Strike Limit Algorithm* for this hunt; (3) Review the performance of initial candidate *Strike Limit Algorithms* for minke whales off West Greenland and advice on how these SLAs can be adjusted to perform better; (4) Review a draft trials structure for fin whales off West Greenland which can be used to evaluate SLAs for this hunt.

The Workshop will be held in early 2015 in Copenhagen, Denmark. It is intended to hold this back-to-back with the RMP workshop on fin whales to save travel costs given some common participants.

(2) AWMP-RP2 AWMP DEVELOPERS' FUND

The developers fund has been invaluable in the work of SLA development and related essential tasks of the SWG. It has

been agreed as a standing fund by the Commission. It has been proved to be of great value in ensuring progress throughout the SLA development period for the Alaskan and Chukotkan hunts as well as recent work on the PCFG and Greenlandic hunts, including the completion of the *Humpback SLA* at the present meeting. The primary development tasks now facing the Committee are for the remaining Greenlandic fisheries.

(3) BRG-RP1 DEVELOPMENT OF AN SEX- AND AGE-STRUCTURED POPULATION DYNAMICS MODEL FOR NORTH PACIFIC GRAY WHALES

This proposal is essential to the workplan agreed by the sub-committee on BRG for gray whales and it is connected to the workshop proposal BRG-3. SC/65b/BRG1 presented to this meeting provides an outline of simple modelling framework based on the discussions at the workshop and explains how it could be implemented for hypothesis 3a. The aims of this project are to implement the model of SC/65b/BRG1, and to extend this model to include age- and sex-structure and apply it to the data available for the North Pacific gray whales. The results of the modelling will be presented to a planned intersessional workshop (scheduled for April 2015), the model specifications and data updated based on the outcomes from the workshop and results presented to the SC/66a.

(4) BRG-RP2 SOUTHERN RIGHT WHALE MORTALITIES AT PENÍNSULA VALDÉS: POPULATION AND HEALTH MONITORING RESEARCH (AND SEE ITEM 26.1)

The high mortality of right whales at Península Valdés prompted the IWC Scientific Committee to convene a workshop of specialists in Puerto Madryn, Argentina in March 2010 (IWC, 2010b for further details). In fact, the mortality reported for 2012 at Peninsula Valdés (116 dead whales including 113 newborns) is the highest mortality ever recorded for the species. Among the actions agreed in the Conservation Management Plan (CMP) for southern right whales, top priority was given to 'ensure long-term monitoring of abundance, trends and biological parameters' (objective MON-01) and to 'develop and implement a strategy to minimise kelp gull harassment' (objective MIT-02).

The objective of this proposal was to request funds for the continuation of the four research programmes and projects described below, in order to understand the effects of the increased mortality rates on the population dynamics and to make progress to address the kelp gull harassment issue in the context of the current southern right whale die-off at Península Valdés.

(5) BRG-RP3 WORKSHOP TO FORWARD THE MODELLING PROCESS TO UNDERSTAND THE STATUS OF GRAY WHALES ACROSS THE NORTH PACIFIC

This work is an integral part of the assessment process set in place by the Committee last year. It is of particular importance to: (1) the assessment of the status of gray whales in the North Pacific (BRG); (2) the management of subsistence whaling in the North Pacific in conjunction with the work of the AWMP SWG; (3) the evaluation of threats to gray whales in the North Pacific and the determination of future management advice (BRG); (4) the provision of advice in accord with the Commission's Arctic Workshop (E); (5) the western gray whale Conservation Management Plan endorsed by the Commission. This technical workshop will review the results of the work of Punt (BRG-1) and the Steering Group with respect to modelling the situation of gray

whales across the North Pacific. It will *inter alia* review trial structure, conditioning and initial model results from age-aggregated and age-structured models and work towards incorporating any new data obtained as part of the workplan. The results of this workshop will be presented to SC/66a.

(6) BRG-4 IDENTIFICATION OF SNP LOCI IN GRAY WHALES USING NGS SEQUENCING APPROACHES AND GRAY WHALE SAMPLES FROM ACROSS THE NORTH PACIFIC (AND SEE ITEM 26.1)

One of the recommendations made at the Rangewide Workshop on gray whales (SC/65b/Rep08) was to develop a panel of Single Nucleotide Polymorphism (SNP) markers for use with gray whales. This project proposal (2016 budget) aims to: (1) Utilise next generation sequencing approach to identify a panel of SNPs for use with gray whales; and (2) Conduct genotyping by sequencing for 200 samples from three. Expected outcomes are: (1) Assessment of population structure of gray whales utilising SNPs; (2) results can be compared to those generated using microsatellites to evaluate whether both approaches provide consistent results.

(7) E-RP1 SOCER REPORT

SOCER is a long-standing effort to provide information to Commissioners and Committee members on environmental matters that affect cetaceans in response to several Commission resolutions. Funds are for salaries, library services, and printing. The focus topic for 2015 will be the Pacific Ocean, and the Arctic Ocean in 2016, together with a section on issues of global concern.

(8) E-RP2 POLLUTION 2020

POLLUTION 2000+ has been a flagship programme of the Committee and the Commission has supported it and continued work on pollution in several Resolutions. POLLUTION 2020 is in effect Phase III of POLLUTION 2000+. POLLUTION 2020 will focus on the biennium 2015-2016 on three objectives. (1) To prioritise a list of 'contaminants of concern' for cetaceans (2015 activity) through a questionnaire to a range of acknowledged experts in the field to identify which contaminants are of highest priority and should thus be the focus of future modelling efforts. The output will be the collated results of the survey, with a prioritised tabulation of the listed contaminants. (2) To carry out a literature review and construct a database of appropriate dose-response relationships for the priority chemicals identified in (1) above (2015 activity). The output will be a database of dose-response relationships (in the form of a set of concentration-response functions with associated variability estimates) for the highest priority contaminants, where appropriate data are available. (3) To clarify the areas of uncertainty in the sPOCK population model already developed last year in terms of the amount of contaminants transferred from the female to the foetus *in utero* (2016 activity). The output will be an estimate, with uncertainty, of the proportion of contaminants transferred to the offspring *in utero*. This will replace the current single arbitrary point estimate of 0.6.

(9) E-RP2B CONTAMINANT STATUS, TRENDS AND RISK ASSESSMENTS IN CETACEANS

This item addresses the agenda item on Pollution and builds upon the work undertaken by POLLUTION 2000+ to provide an analysis of the trends and status of contaminants of concern in cetaceans globally. Its objectives are: (1) to collect status and trends contaminant data of cetaceans globally

through country/region points of contact that were identified as part of POLLUTION 2000+ work (IWC, 2010b) - this will be accomplished through a focus meeting at the 2015 Annual Meeting and cetacean contaminant data available for use in trend and status analyses will be identified by 2016; and (2) to collate data and evaluate comparability of data sets among nations/regions/studies, including geospatial analyses to determine areas or species of concern and assess health and risks to cetaceans. This activity will occur intersessionally and be presented at the 2016 Annual Meeting.

(10) E-RP3 SOUND FIELD MAPPING IN DATA-POOR AND DATA-RICH PRIORITY REGIONS (AND SEE ITEM 26.1)

This project aims to assess the feasibility of sound field mapping in data-poor and data-rich areas. This project will follow two approaches: (1) in a high priority region where limited or no sound mapping products exist, preliminary regional to ocean basin scale mapping products should be produced - baseline status and trend analyses should be conducted in these regions, and where there is limited collection of acoustic data, efforts to obtain this data should be expanded; (2) in a region(s) with high quality data to support high resolution predictive sound mapping, case studies should be conducted quantifying uncertainty in predicted sound levels, model sensitivity to varying input parameters, and ideally, verification or comparison of model results with empirical data.

(11) E-RP4 MASKING AND SHIP NOISE (AND SEE ITEM 26.1)

'Masking' will be considered as either a one-day pre-meeting or a focus area at a future Scientific Committee meeting (biennium 2017-2018), with a particular emphasis on theoretical and field studies to assess how anthropogenic noise could mask biologically important signals used by cetaceans for vital life functions.

(12) E-RP5 WORKSHOP ON ANTHROPOGENIC NOISE AND STRESS (AND SEE ITEM 26.1)

In recent years, there has been a growing recognition that anthropogenic noise can cause physiological stress in marine mammals. This is an active research area, but much of the specialised research results have not yet been presented to the Scientific Committee. The proposal will be for an IWC-hosted intersessional workshop on noise and stress during the biennium 2017-2018.

(13) E-RP6 CLIMATE CHANGE MEETING (AND SEE ITEM 26.1)

The IWC Scientific Committee Steering Group meeting on Climate Change is intended to facilitate the ongoing work by the Scientific Committee on climate change. The meeting would review the topic, including the latest work from other IGOs (for example by the Convention for Migratory Species, IUCN and ACCOBAMS) and the latest pronouncements from the IPCC and produce a proposed process for the future engagement in this topic by the SC. The meeting will be held in conjunction to the International Marine Conference occurring in Glasgow in August 2014.

(14) E-RP7 CERD PRE-MEETING

Objectives of this 1-day pre-meeting of the Cetacean Emerging and Resurging Diseases (CERD) working group will be (1) to review website progress and (2) to develop plans for future work on cetacean emerging and resurging diseases including the possibility of health mapping and consistent reporting standards. This will be held prior to the 2015 Annual Meeting.

(15) E-RP8 INVESTIGATIONS OF LARGE MORTALITY EVENTS AND MASS STRANDINGS

The Workshop will bring together biologists, veterinarians, and stranding network investigators from various countries to facilitate the collaboration and coordination between national and regional programmes on responses to and investigations of unusual or large scale mortality events, mass strandings, and disease events. The goals of the workshop are: (1) to establish common terminology, (2) to facilitate consistency in investigation techniques, (3) to identify common issues and share information on potential solutions relative to causes, responses, and mitigation, and (4) to promote international data sharing and mutual aid particularly for mass strandings and large mortality events. The final agenda will be finalised intersessionally and discussed at the 2015 Annual Meeting. This 3-day Workshop will be by invitation and will be held in conjunction to the 2015 Biennial Meeting of the Society for Marine Mammalogy (SMM) in San Francisco, CA. Its final report will be presented at the 2016 Annual Meeting.

(16) EM-RP1 USING BALEEN WHALE TAG DATA TO INFORM ECOSYSTEM MODELS

A central focus this year was discussing methods to model competition and competitive interactions between whales. Within this project preliminary analysis on fine-scale and satellite tag data will be conducted and this information will be used to develop individual-based models of cetacean foraging and generate specific hypotheses regarding competition between species from fine-scale foraging observations. The project objectives are: (1) estimates of feeding costs for a range of baleen whales species; (2) measures of how feeding costs change as a function of prey density; (3) analysis of movement patterns, habitat use and foraging bout duration from satellite-linked tags using state-space models. Objectives 1 and 2, including reports to the Committee will be completed by 1 June 2015. Objective 3, including reports to the Committee and manuscript submission will be completed by 1 June 2016.

(17) EM-2 CCAMLR-IWC WORKSHOP ON THE DEVELOPMENT AND APPLICATION OF MULTI-SPECIES MODELS TO THE ANTARCTIC MARINE ECOSYSTEM

The Joint CCAMLR-IWC Workshop on the development and application of multi-species models to the Antarctic marine ecosystem aims to foster collaboration between the two Committees in the development and application of multi-species models to the Antarctic marine ecosystem. The outcome from the workshop will be a set of specific and detailed proposals on the way forward in regard to both data collection and analysis, so as to move towards the development of tactical multi-species/ecosystem models of pertinence to the provision of scientific advice which addresses the objectives of both Commissions. It is proposed that this 2-day Workshop is convened in advance of the 2016 Annual Meeting.

(18) HIM-RP1 SHIP STRIKE DATABASE COORDINATOR

The ongoing development of the IWC ship strike database requires data gathering, communication with potential data providers and data management. Co-ordinators were appointed last year and the Committee agreed this should continue and a list of tasks was developed. It relates directly to the Commission's Conservation Committee working group on the topic.

(19) HIM-RP2 PREVENTING THE ENTANGLEMENT OF WHALES IN FISHING GEAR

This workshop responds directly to recommendations made in two previous Commission workshop reports and is of interest to the Commission's Working Group on Whale Killing Methods and Associated Animal Welfare Issues. Its overall objective is to identify methods and encourage further research into ways to prevent the entanglement of large whales; the funds here are for the scientific component of the topic. Detailed Terms of Reference will be finalised at the 2015 Annual Meeting of the Scientific Committee. The scientific output will inform a series of technical recommendations and policy advice to allow the Commission to develop a work programme to prevent entanglement.

(20) IA-RP1 2015-2016 IWC-POWER NORTH PACIFIC SURVEY

The Committee has strongly advocated the development of an international medium- to long-term research programme involving sighting surveys to provide information for assessment, conservation and management of cetaceans in the North Pacific, including areas that have not been surveyed for decades. The Committee has developed objectives for the overall plan and this money will fund the continuing work initial phase and progress on developing the medium-term phase. The amount of money is extremely small when seen in the context of Japan providing the vessel and associated costs for two years as it has in the past. The IWC contribution is for (1) IWC researchers and equipment, and (2) to allow the Committee's Technical Advisory Group to meet to review the multi-year results thus far and develop the plans for the next phase of POWER based on the results obtained from Phase I and (3) to enable analyses to be completed prior to the 2016 Annual Meeting.

(21) IA-RP2 ASSESSMENT MODELLING FOR IN-DEPTH ASSESSMENTS OF ANTARCTIC MINKE AND NORTH PACIFIC SEI WHALES

During 2015, the Committee will be starting an in-depth assessment of the North Pacific sei whales and will also be completing the in-depth assessment of the Indo-Pacific Antarctic minke whale. The project involves developing population dynamics models as required to progress the work on the In-depth Assessment sub-committee. The funds of this proposal will then be used between the 2015 and 2016 annual Scientific Committee meetings to implement the assessment model (including statistical catch at age assessment model for Antarctic minke whales) and conduct the runs. Results, including software and associated data files used to create the assessments, will then be submitted to the Committee during the 2016 annual meeting.

(22) RMP-RP1 TESTING PROPOSED NEW GUIDELINES FOR EVALUATING SPATIAL MODEL-BASED AND DESIGN-BASED ABUNDANCE ESTIMATES

This pre-meeting is relevant to all groups of the Scientific Committee. It is the point of delivery for intersessional work which comprises proposing updated guidelines (see RMP-2) for evaluating design- and (spatial-)model-based abundance estimates, and developing software for a diagnostic check on design-based estimates that have applied when the underlying criteria are not strictly met. The main objectives are: (1) to test the proposed new guidelines (see RMP-2) against several test cases of model-based abundance estimates made specifically for and during the workshop; (2) to demonstrate and discuss the proposed diagnostic software with a wider Committee audience involved in basic line-transect

abundance estimation. This will be a 2-day pre-meeting prior to the 2015 Annual Meeting by invitation only for objective (1) and the start of objective (2); and a half day on the first day of the 2015 Annual Meeting for delivery of objective (2) open to more general SC audience.

(23) RMP-RP2 EVALUATING ABUNDANCE ESTIMATES: DIAGNOSTICS AND TESTING

Abundance estimates are central to the Committee's work. Spatial modelling is a powerful tool for abundance estimation which, in principle, can: (a) be used in many cases where design-based estimates are inappropriate; (b) overcome some bias associated with uneven survey coverage; and (c) deliver more stable CVs than a standard design-based analysis even when the latter is appropriate. However, spatial modelling requires expertise both to use and to assess. Hence it is important to have clear guidelines both for assessing new abundance estimates made specifically with spatial models, and for handling the situation where a simple design-based estimate has been applied without its assumptions being met; in this latter case some diagnostic software is desirable. The general idea is that surveys with dense and evenly-distributed coverage should readily pass the diagnostic tests, whereas surveys with low or badly imbalanced coverage should raise a flag. Deliverables include software (R package of automated diagnostics based on results of automated trial fits of spatial models), workshop preparation and delivery (see RMP-1), and proposals for new guidelines in the form of a paper to the 2015 Annual Meeting.

(24) RMP-RP3 WORKSHOPS TO FURTHER PROGRESS ON THE IMPLEMENTATION REVIEWS FOR THE NORTH ATLANTIC MINKE AND FIN WHALES

Objectives of these back-to-back workshops are for fin whales: (1) review the conditioning of the initial trials; (2) update the specifications of the trials by defining a full set of sensitivity tests and (3) specify the management variants to consider intersessionally for fin whales. For common minke whales they are: (1) to review the conditioning of the trials; and (2) specify the management variants to consider intersessionally for common minke whales. The outcomes will be: (1) if all the trials for the minke whales can be conditioned successfully, the Committee should be in a position to complete the *Implementation Review* of the North Atlantic minke whales at the 2015 Annual Meeting; (2) if all the initial trials for the fin whales can be conditioned successfully, the Committee should be in a position to finalise the trial specifications for the North Atlantic fin whales at the 2015 Annual Meeting and complete the *Implementation Review* at the 2016 Annual Meeting. The proposal includes contingency funding for additional workshops in early 2016 in the event that it is not possible to complete the *Implementation Reviews* for North Atlantic minke and fin whales in 2015. This will be a five-day workshop held in March 2015 in Copenhagen.

(25) RMP-RP4 EVALUATION OF DENSITY DEPENDENCE PARAMETERS FOR INCLUSION IN RMP TESTING BASED ON ENERGETICS MODELLING (AND SEE ITEM 26.1)

The Committee has recognised the importance of the relationship between $MSYR_{1+}$ and $MSYR_{mat}$ in an RMP context and has agreed that it is desirable to explore the relationship arising out of the energetics-based model results further. This work is necessary before any conclusions or the need for additional RMP/CLA-related trials are considered.

To this end the Committee developed a two-year workplan and this project addresses three elements of that workplan.

(26) RMP-5 GENETIC ANALYSIS TO AID THE FORMULATION OF PLAUSIBLE STOCK HYPOTHESES FOR NORTH ATLANTIC SEI WHALES (AND SEE ITEM 26.1)

A Steering Group (SG) has been given the task of investigating the feasibility of conducting a pre-*Implementation assessment* of North Atlantic sei whales. The further genetic analysis identified in this project will aid the formulation of plausible stock hypotheses for this species. A total of 172 samples from the Eastern, Central and Western North Atlantic have been identified, the analysis of which is likely to inform on potential stock structure. The project involves the generation of ddRAD-based SNP genotypes from the available tissue samples by the Marine Evolution and Conservation Group at University of Groningen in the Netherlands.

(27) RMP-RP6 ESSENTIAL COMPUTING FOR RMP

This is to provide essential assistance to the Secretariat with the large computing tasks it is facing in the coming year (see Item 25).

(28) SC FOLLOWING UP FROM WORKSHOP AND COMMITTEE RECOMMENDATIONS

This is a new budgetary line necessary in the second year (2016) of the Scientific Committee biennial budget to accommodate additional work that is generated by meetings, workshops and projects funded and concluded in the first year (2015). This budgetary line can also accommodate new project proposals generated during the 2016 Scientific Committee meeting.

(29) SH-RP1 REVIEW & SYNTHESIS OF THE RESULTS OF THE COMPREHENSIVE ASSESSMENT OF SOUTHERN HEMISPHERE HUMPBACK WHALES

This project will provide a summary overview of results arising from the Comprehensive Assessment of Southern Hemisphere humpback whales, in three parts: (1) assessment of findings by breeding sub/stock; (2) identification of data gaps during the assessment process (including recommendations for future work); (3) methodological developments in terms of analysis and other informative parameters over the period of the assessment (e.g. direct integration of mark recapture into models, N_{min} etc.).

(30) SH-RP2 MODELLING SUPPORT/ SOUTHERN HEMISPHERE HUMPBACK WHALES

This project will undertake modelling studies to assist the development of future syntheses of assessments of Southern Hemisphere humpback whales and optimised monitoring of these populations. It will contrast the relative information content of alternative data monitoring approaches to inform on the reliability of current predictions of population trends (and hence on the appropriateness or otherwise of the present population modelling framework).

(31) SH-RP3 RESEARCH CONTRACT 16, ANTARCTIC HUMPBACK WHALE CATALOGUE

The Antarctic Humpback Whale Catalogue (AHCW) collates photo-identification information from Southern Hemisphere humpback whales. Increasing awareness of the project among research organisations, tour operators and other potential contributors has widened the scope of the collection; research efforts in areas that had not previously been sampled have extended the geographic coverage. The AHCW has doubled in size in the past five years and grown by more than 10% in

the past year, substantially increasing the time required to analyse photographs. In addition to these requested IWC funds, additional funds from other sources will be sought.

(32) SH-RP4 SOUTHERN HEMISPHERE BLUE WHALE CATALOGUE 2012/2013

The Southern Hemisphere Blue Whale Catalogue (SHBWC) is an international collaborative effort to facilitate cross-regional comparison of blue whale photo-identifications catalogues. In 2006, the Committee agreed to initiate an in-depth assessment of Southern Hemisphere blue whales and in 2008, it endorsed a proposal to establish the SHBWC. Currently the SHBWC holds photo-identification catalogues of researchers from major areas off Antarctica, Australia, Eastern South Pacific and the Eastern Tropical Pacific. Results of comparisons among different regions in Southern Hemisphere will improve the understanding of population boundaries, migratory routes and model abundance estimates. In addition, assessment of blue whales and estimates abundance of populations will require improving software capabilities to access encounter histories of individuals.

(33) SH-RP5 - PHOTO-IDENTIFICATION ANALYSIS OF BLUE WHALES FROM THE NEWLY DISCOVERED FORAGING GROUND IN THE SOUTH TARANAKI BIGHT (NZ)

This project falls under the category of 'unsolicited project' and should be resubmitted according to the existing Scientific Committee rules of procedure.

(34) SH-RP6 PRIORITY TASKS TO SUPPORT THE REGIONAL CONSERVATION EFFORT OF ARABIAN SEA HUMPBAC WHALES

This project will help further two priority activities that were identified by the Committee for the improving conservation and research of Arabian Sea humpback whales for which the Committee has expressed serious concern in the past. These priorities are: (1) genetic analyses of archived samples; and (2) Kutch and Saurashtra coasts of Gujarat, India Exploratory Surveys. Reports will be submitted to the 2015 Annual Meeting and will be used to examine the funding requested for 2016.

(35) SH-RP7 SOUTHERN OCEAN RESEARCH PARTNERSHIP (IWC-SORP) (AND SEE ITEM 26.1)

The Southern Ocean Research Partnership (IWC-SORP) was endorsed by the IWC in 2009 and is now fully part of the IWC process. The Partnership includes 11 member States. SORP delivers Southern Ocean whale research, fully aligned with IWC priorities, and benefits from large scale collaboration. Approved funding is to employ an IWC-SORP coordinator for the period of one years (without ineligible local taxes and benefits) to (1) ensure, facilitate and implement continued delivery of high calibre science; (2) ensure the communication of high-calibre scientific research to Scientific Committee, IWC and the wider scientific community; and thus; (3) sustain the momentum of the collaborative research effort and (4) leverage future funding for IWC-SORP.

(36) SP-RP1 EXPERT WORKSHOP TO REVIEW JARPA II

The Committee has agreed a procedure for periodic and final reviews of results from Special Permit research (IWC, 2013g). This procedure outlines an intersessional review meeting by an expert panel in accordance with the 'Annex P' process agreed by the Commission. The report from the intersessional expert meeting will be reviewed and discussed at the 2015 Annual Meeting. The experts to the review

workshop will be identified by September 2014 and the expert workshop will be convened during four days in February/March 2015. The requested funds are for travel for the invited experts.

(37) SP-RP2 WS ON REVIEW OF NEW SPECIAL PERMIT PROPOSALS

Japan announced that the Government of Japan will issue a Special Permit for a new research programme in the Antarctic starting in the season 2015/16. Japan wishes this programme to be reviewed at the 2015 Annual Meeting, in accordance with the 'Annex P' process agreed by the Commission. In accordance with the provisions for the review process stipulated in the Annex P, Japan will submit a new proposal to the chair of the Scientific Committee no later than six months before the next Annual Meeting of the Scientific Committee in 2015 (October/November 2014). The proposal should then be reviewed by a small specialist workshop with a limited but adequate number of invited experts. The workshop will be held in Tokyo in January-February 2015.

(38) WW-RP1 EMERGING WHALEWATCHING INDUSTRY IN OMAN

The goals of this three year project (2014-2016) are to improve, educate and stimulate the emerging cetacean watching industry in Oman, especially in areas where Arabian Sea humpback whales are sighted. The ultimate outcome is to raise the standards of cetacean watching tourism in Oman in order to actively support conservation of cetaceans and their habitat by: (a) maximising industry benefits; (b) enhancing industry standards; (c) minimising impacts to cetaceans; and (d) obtaining information on cetacean distribution and occurrence. The main task for Years 2 and 3 (2015 and 2016) is to promote a responsible and sustainable approach to dolphin/whale watching. This will be achieved by: (a) continuing hands-on training of operators by area and priority species; (b) identifying a liaison among operators who will represent the industry to continue to monitor guidelines and compliance; (c) continuing to support the data collection process during training exercises to increase knowledge of cetacean occurrence for science and management; and (d) discussing the development of a cooperative of operators with mutual benefit to all members.

26.3 Unspent and unallocated budget monies

Over the years, the money allocated to Scientific Committee work has inevitably been based on requests that involved a degree of 'informed guesswork' when putting together proposals. Previously, in the Commission's accounts this money had been held with the expectation that it might be spent in the future but these assumptions were unfortunately not reviewed annually. In the last 12 months, the Secretariat has been carefully reviewing and updating its financial procedures. This has now enabled detailed information on status of all IWC projects including those taking place through the Scientific Committee budget. This review has provided an accurate estimate of the extent of any monies remaining unspent from previous allocations.

Whilst the annual average may not seem so large, this has generated a large total amount of no longer allocated funds over the last ten years amounting to £135,000. This amount has arisen from a combination of underspends (some 'small' from overestimating IP costs at workshops, some 'large' from cruise participants being funded in kind therefore not requiring the grants that had originally been budgeted for) and

from projects where funding was originally allocated, postponed and ultimately did not take place (e.g. some Workshops). The £135,000 does not include money that is for ongoing projects earmarked for spending in the next two years but not yet completed.

Improved procedures are now in place so that in future each research budget item code will be reviewed biennially such that large amounts cannot accumulate. A document will be presented to the Scientific Committee showing the actual amounts allocated to a project, spent at the time the document is compiled and projected to be spent by the end of the financial year.

The Bureau of the Commission has indicated that there will be a discussion of how to deal with this unallocated amount at the Annual Meeting in September 2014. There are a number of possibilities. For example, it may be considered that the Commission funds particular items, not absolute amounts – it therefore follows that underspends should be returned directly to the Commission's general funds. Alternatively, there may be a view that these funds were allocated to the Scientific Committee and that they should be used primarily for scientific work. The unallocated monies relate to work similar to that now being carried out by the Committee. Clearly, how to deal with this is a Commission decision.

However, it seems appropriate for the Committee to provide some views on how the matter might be dealt with to assist the Commission in its discussions. One suggestion by the Committee and a variant on that is provided below.

The Committee's requirements can vary considerably from year to year depending on its workplan and priorities – in most years the desired budget has exceeded the amount of funds expected to be received but the extent of the difference vary considerably ranging from around £20,000 to as much as around £180,000 last year.

The Committee **fully recognises** the current economic situation and also **recognises** its responsibility to ensure that funded work is directly relevant to its agenda and workplan as agreed by the Commission. It therefore does not seem appropriate to suggest that all of the money should be allocated to the Scientific Committee to spend in a short time period. The principle that expenditure should be on value-for-money projects that directly support the Committee's ability to meet its agreed workplan and supply the best advice to the Commission remains.

The Committee therefore **respectfully suggests** that one option for a portion of the unallocated money could be for a special fund (say £50,000) to be established that would be available for the Committee²⁸ in addition to the money available through the Commission's regular budget (at present £315,800) to assist with the yearly variations in requirements. This money could only be used if the regular allocation was exceeded, and then only for essential work deemed necessary to meet the Committee's two-year

workplan. The fund could be topped up in the future in the event of any future underspends.

A second option or variant upon the first option is relevant if the Commission agrees that it is appropriate for the Committee to receive the full £135,000 allocation. Under this option, the full allocation could be 'protected' within the overall Commission budget. The first option could be maintained but the special fund could be 'topped up' to the chosen level (say £50,000) as necessary. The money would then provide assistance to the Committee over a long time period.

27. WORKING METHODS OF THE COMMITTEE

27.1 Increasing the support of the Scientific Committee on conservation related issues

Of 3,259 statements within the Committee's reports, they classified 76% as *scientific statements*, 10% as *conservation statements*, while *management* and *administrative* statements represented 7% each (tables 2 and 3 in SC/65b/SCP1). In addition to this, they also examined qualitative aspects in the wording of the reports that could be improved in relation to the strength, clarity or absence of statements. With respect to funding requirements, they classified a large proportion (62%) of the funding as directed towards scientific research, 18% as related to management and 11% as related to administrative matters, mainly IPs. They assessed that only 9% has been allocated to scientific work with a conservation perspective (fig. 5 of SC/65b/SCP1). The work of the sub-committee on small cetaceans was not included in these analyses because funding for this sub-committee has come exclusively from the Small Cetacean Voluntary Fund. This funding source varies significantly from year to year and cannot be considered as a stable fund.

A number of recommendations were proposed including: (1) clearly and consistently highlight conservation concerns that can improve and support the IWC conservation work or as guidance for Range States; (2) including clear statements to point out the delicate conservation status or increasing risk for cetaceans; (3) reiterate previous statements where necessary; (4) include a summary of the status of the species/subspecies/population and the action needed; (5) whenever there is no agreement among SC members over an important discussion, properly highlight the issue in the report; (6) increase the funding allocated for conservation-oriented research, such as investigation on conservation or mitigation measures; (7) include the budgetary needs of the standing sub-committee on small cetaceans into the general Committee budget; (8) consolidate the mandate of the standing sub-committee on small cetaceans by agreeing the terms of reference; (9) consider making the results of IWC workshops more accessible; and (10) make an annual compilation of concerns and recommendations to be forwarded by the Secretariat to contracting and non-contracting governments, intergovernmental organisations and other entities to be considered in the development of national and regional cetacean action plans as appropriate.

²⁸ And the responsibility of its Chair in accordance with recommendations from the full Committee.

In addition, it was noted that the topics for the Scientific Committee in its Rules of Procedure have not been updated for many years and it was suggested that these should be updated, and based on this review the Commission may wish to consider amending the Terms of Reference of the Scientific Committee.

In conclusion the authors noted that implementing these recommendations would make an important contribution to the long-term survival of cetacean species, sub-species and populations, where it is most needed.

The Committee **thanks** the authors for the extensive review, recognising that the system for classifying statements, actions and funding was inevitably somewhat subjective. In discussion a number of points were raised. Some members broadly supported the document and its recommendations. Other members commented in particular that the Committee works hard to cover a broad range of topics, most of which are aimed at assessing and improving status, taking into account the many different kinds of potential threats to cetaceans. They did not believe that it was helpful to try to separate out concepts of 'conservation' and 'management' or suggest that they were conflicting within the work of the Scientific Committee. They referred to a number of international definitions that treated sustainable use and associated management as part of 'conservation'. They also noted the value of collaboration among scientists who might be described as working mainly on 'management' or mainly on 'conservation' under the terms as defined by the authors, to improve both conservation and management. In response, it was argued that while both terms look to maintain viable cetacean populations, currently the Committee includes under agenda items 'management advice' and 'conservation advice' and that the differences between them is clear, being one aimed to direct takes of cetaceans while the other aimed to the rest of the threats.

With respect to small cetaceans, it was noted that although its budget was not included in the general budget request table of the Committee, the information was available within the reports. In particular, since the initial large donation from Australia, the fund had received some additional £170,000 in voluntary donations and had supported some excellent projects. The difficulties within the Commission over competency and small cetaceans are well known and resolving this is a matter for the Commission itself. In response it was noted that there is less stability when relying on a voluntary fund.

In conclusion, while different points of view had been expressed, the Committee broadly agreed with the need to:

- (a) work carefully to ensure consistency and clarity over its recommendations especially those the expressed concerns over status and threats that required action by the Commission and others;
- (b) improve communication with the Commission and others regarding the recommendations and concerns within its reports;
- (c) keep track of recommendations and ensure that they are referred to and/or repeated as necessary;

- (d) make workshop reports more accessible; and
- (e) consider updating the 'specific topics of current concern' in its Rules of Procedure as had also been suggested in the review of other organisations produced by the Secretary (SC/65b/SCP02).

The Committee noted that the Secretariat was working to improve communications about all aspects of the Commission's work including that of the Scientific Committee, especially by improving the website. It had introduced the concept of news boxes on specific topics and that will include the work and report of the Scientific Committee. In addition, it had started to build up a series of webpages dedicated to workshops to make their conclusions and advice more accessible. It also annually developed a list of work actions for the Committee members, Secretariat and interessional groups based on recommendations in the Committee's report and this could be expanded or a separate table be developed to refer to all recommendations.

The Committee **agrees** to keep this item on its agenda.

27.2 Data access under Annex P

In the run up to the JARPA II review, a request for access to the data was made as specified in Annex P through Data Access Protocol B. Unfortunately this process proved to be more time consuming and difficult than expected. This situation was caused by a number of different issues including: time zone differences; time for official response from data owners (according to Annex P allows up to 15 days which can become problematic if an exchange of views is required²⁹); better guidance on the level of detail required in a proposal; availability of DAG members (e.g. holidays, fieldwork, etc.).

After a discussion amongst DAG members and representatives of data requesters and data owners on this specific case), a proposal for a following way forward in regard to improving the efficiency of the process was developed as outlined below. The Committee **agrees** that this is trialled from now, noting that further improvements may be made in the light of experience.

- (1) Annex P specifies that a data description document is required at the Annual Scientific Committee Meeting prior to a review. This deadline should be advanced to **two months** before the Scientific Committee meeting. The preliminary data description document (which *inter alia* needs to broadly contain the types of data and the approximate sample size) will then be circulated to members of the Committee. The date for the final data description document remains as in Annex P (i.e. one month after the Scientific Committee meeting to allow for final checking of sample sizes etc.)
- (2) Members who wish to develop analyses for the review should then develop those requests for data access for submission as a document to the Scientific Committee **four weeks** before the Scientific Committee meeting. This will allow other members of the Scientific Committee (including the data holders) to consider alternative analyses.

²⁹ E.g. if the proposal contains unclear aspects, the data owner will reply asking to the DAG to obtain clarifications from the proponents; this can add additional 15-30 days between the first request of clarification and the final

response by data owners, via the DAG. If further clarifications are requested this multiplies.

- (3) Requests will then be considered at the Scientific Committee Meeting. Initially, data requesters, data owners and the DAG can discuss the request early in the Meeting. This will provide opportunities for clarification and possible amendment of proposed studies. If there is disagreement over (e.g. whether analytical methods are appropriate and within the terms of reference of the workshop), this will be referred by the DAG to the appropriate sub-committee or an *ad hoc* group. In the hopefully rare event that disagreement remain after the sub-group discussion, then the DAG will be authorised to take the final decision on the request. Data forms and requests can then be signed/authorised at the meeting.
- (4) In order to enable the DAG to function if one or more members are unavailable, the membership of the DAG (currently Chair, vice-Chair and Head of Science) will be expanded to include the Chair of the Scientific Permit working group and the Chair(s) of the most relevant sub-group(s). Any decisions (which should be few in view of the approach outlined above) can be taken with a quorum of three.
- (5) While Committee members can still submit requests after the meeting in accordance with the existing timeframe in Annex P, they should be aware that the process may take a longer time and the request may not be accepted.

This process requires only minor amendments to the existing process. The revised Annex P is given as Annex P.

27.3 Improving the Scientific Committee budget review process

Following the development of the budget as described under Item 26, the initial feedback on the experiences from various sub-groups showed how complex (and time-consuming) agreeing and prioritising items for the Scientific Committee budget can be.

The primary function of the Scientific Committee budget is to allow the essential work to take place that the Committee needs to fulfil its workplan as agreed by the Committee. It is not intended to be seen as a 'research fund' in the usual sense of the term. Should the Commission wish to establish a traditional research fund then it would be appropriate for this to be dealt with outside the Scientific Committee's regular budget and handled in a similar way to the Small Cetaceans Voluntary Fund.

In order to facilitate discussions next year on the budget process and build upon this year's experience, the Committee **agrees** to establish an intersessional working group (Members: Kitakado, Fortuna (Convenor), Donovan, Double, Holm, Jackson, Rendell, Roel, Rojas-Bracho, Ritter, Vikingsson, Walloe).

That group will:

- (1) receive comments from members on any aspect of the process received by 1 September 2014;
- (2) review and as appropriate modify revised proformas taking into account the discussions and experience this year by 1 November 2014 which will be placed on the IWC website and circulated to the Committee by 7 November 2014;

- (3) develop a discussion document to be available at least one month prior to the 2015 Annual Meeting that includes suggestions/proposals on:

- (1) advice for the Committee and sub-groups on broad 'principles' with respect to examining proposals including: further clarifying what falls into category (c) type requests (see below); the factors to be taken into account when accepting and prioritising proposals of different types (workshops, research, databases etc.); the linkage between agenda, workplan, and budget requests; how to handle 'conflicts of interest'; where flexibility or discretion is appropriate; how to present the results in the report etc.
- (2) proposals or options on the overall process including prioritisation across sub-groups and presentation of the budget to the Commission;
- (3) other related issues that might arise out of discussions within the group and suggestions received under Item 1.

In addition, the Committee notes that the types of requests received by the Committee can be considered to be of three broad types:

- (a) proposals developed directly from discussions within sub-groups that are focused to allow fulfilment of the two-year workplan – examples include targeted workshops and any associated analyses/programming;
- (b) ongoing issues that support the work of the Committee and for which data are freely available – this could include items such as databases, catalogues, IWC-designed multi-national long-term programmes;
- (c) research proposals, often for field work, that relate to broad Committee recommendations but do not arise directly out of a specific request from the sub-group during the annual meeting at which they are proposed, based upon its workplan.

Recognising that the borderline between the categories can be somewhat grey, the Committee notes that it has been receiving an increasing number that seem to fall into the last category. This is not to say that they are not a valuable contribution to the Committee's work but there has often been insufficient time (or detail presented in the request) to review them properly in the way that they deserve either from a scientific perspective (can they deliver and are they value for money?) or a priority perspective (how essential are they to an agreed workplan?).

The Committee recalled that the Committee in the past developed an approach for what at the time were called 'unsolicited' research proposals (IWC, 1996b, p.227) i.e. proposals not directly requested by the Committee but of relevance to its work. However, no requests under this system have been received for some time as scientists are aware that there is rarely money left in the Committee's budget. The process requires early submission such that the proposals get reviewed by a smaller group who then report to the Committee – the Committee has the final say as usual.

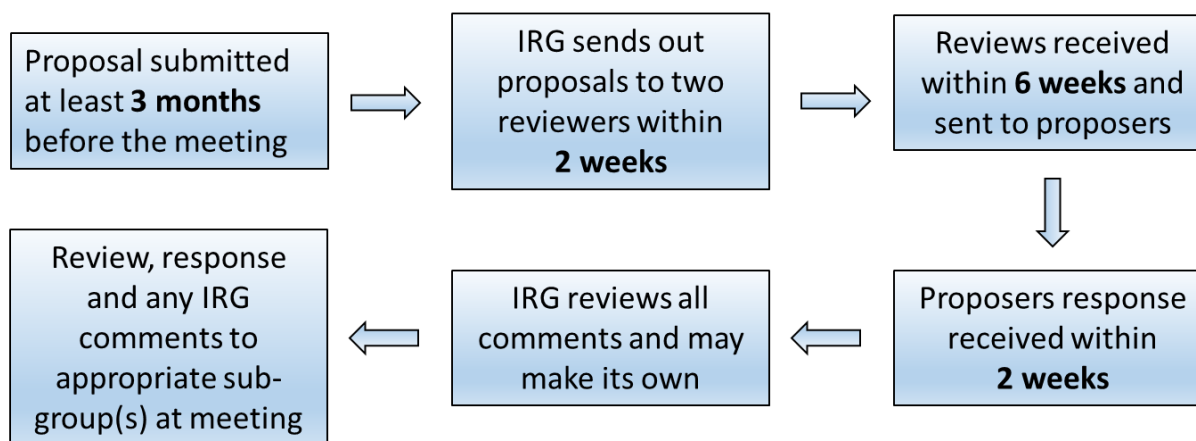

Fig. 5. Summary of the trial process

In parallel with the intersessional working group proposed above, the Committee also **agrees**, on a trial basis for the next intersessional period, the following process (and see Fig. 5) for proposals fitting within category (3) above, including proposals identified under Item 26 this year.

- (1) Proposals are submitted **3 months** in advance of the Committee meeting following a standard *pro forma* (see above);
- (2) Within **two weeks** of receipt of the proposal, an intersessional review group (IRG) comprising the Chair, Vice-Chair, Head of Science and the most relevant convenor(s) to a proposal will agree two anonymous reviewers (with some experience of the IWC) for each proposal with instructions to comment **within six weeks** on the following aspects (taken from IWC, 1996b):
 - (a) relevance to the work of the Committee;
 - (b) scientific quality of the project;
 - (c) scientific competence of the proposer(s);
 - (d) likelihood of meeting its objectives;
 - (e) feasibility of the proposed work schedule;
 - (f) reasonableness of the budget;
 - (g) multinational context.
- (3) The reviewers' comments will be sent to the proposers for comment when both are available and the proposer(s) will be given **three weeks** to respond;
- (4) The reviewers' comments, the views of the proposers and any views of the IRG will be provided to each sub-group at the annual meeting whose views on the proposal are given to the relevant sub-group when discussing proposals and prioritised budget requests.

28. ELECTION OF OFFICERS

The Committee **welcomes** the fact that Kitakado and Fortuna have agreed to continue in their roles. It notes that their three-year terms of office conclude at next year's meeting.

29. PUBLICATIONS

Donovan was pleased to report that the *Journal* was now set up to be completely online and free access. This covers all stages of the review process from submission of manuscripts to publication. This allows papers to be made available immediately they have been accepted and pages finalised

which will make the publication process much more efficient. He also noted that although the *Journal* will no longer be available in hard copy, members of the Committee attending Annual Meetings will continue to receive a hard copy of the supplement as agreed last year. All of the published *Journal of Cetacean Research and Management* (i.e. since 1999) and all of the *Reports of the International Whaling Commission* (i.e. the 48 volumes pre-1999) are now available on the IWC website.

The Committee **welcomes** this news and **thanks** Donovan and his team for their efforts. They **reaffirm** the importance of the *Journal* to the work of the Committee and **encourages** continued submission of papers to the *Journal*.

Donovan also reported on progress with digitising the entire set of papers submitted to the Committee since 1950 with a view to making them available online. This work has been progressing starting with the most recent years and he was now pleased to report that the complete set (over 8,600 papers) has now been digitised. The Secretariat are now focussing on how best to make these available online – this work is ongoing and should be completed before the next annual meeting of the Committee. A similar exercise is ongoing for papers submitted to the Commission.

In discussion, it was noted that as part of making the papers online, it was important that the agreed statement³⁰ on unpublished papers be highlighted when people downloaded papers, i.e.

³⁰Papers submitted to the IWC Scientific Committee are produced to advance discussions within that Committee; they may be preliminary or exploratory. It is important that if you wish to cite this/a paper outside the context of an IWC meeting, you notify the author at least six weeks before it is cited to ensure that it has not been superseded or found to contain errors.⁷

30. OTHER BUSINESS

There was no other business.

31. ADOPTION OF REPORT

The Committee adopted the report at 1700hrs on 24 May 2014, apart from the final items discussed during the last session. As is customary, those items were agreed by the Chair, rapporteur and Convenors. The Chair thanked the participants for their positive and co-operative attitude,

³⁰ <http://iwc.int/scientific-committee-handbook#five>

particularly given the sensitivity of some agenda items. He especially thanked the rapporteurs, Secretariat and Vice-Chair for their excellent assistance. Finally, he reiterated his thanks to the host government and the hotel for the excellent facilities which contributed greatly to the success of the meeting. The meeting thanked the Chair for his expert and fair handling of the meeting.

7.4 Consideration of how these may be incorporated into a modelling framework.....	25
8. DEVELOP MODELLING APPROACH/SCENARIOS	25
9. WORKPLAN UP TO 2014 IWC ANNUAL MEETING AND BEYOND	25
10. RECOMMENDATIONS.....	26
11. ADOPTION OF REPORT	28

The Workshop was held at the Southwest Fisheries Science Center, La Jolla California from 8-11 April 2014. The list of participants is given as Annex A.

1. INTRODUCTORY ITEMS

1.1 Convenor's opening remarks

Donovan and Punt (co-convenors) welcomed the participants. In particular they thanked the Southwest Fisheries Science Center for hosting the Workshop at its excellent facilities and in particular Dave Weller for co-ordinating the logistics. The objectives of the Workshop were to:

- (1) review available information (especially new telemetry, genetics and photo-ID data) and reappraise the population structure and movements of North Pacific gray whales with a focus on examining status;
- (2) develop a modelling framework to better assess the status of gray whales and the potential impact of human activities and possible changes in regime or climate – if possible such that some initial runs may be available for the 2014 Annual Meeting of the Scientific Committee.
- (3) provide information for updating the IUCN/IWC Conservation Management Plan for western gray whales and develop a mechanism for updating the plan.

1.2 Election of Chair

Donovan was elected chair.

1.3 Appointment of rapporteurs

Reeves co-ordinated production of the report assisted by Donovan, Cooke, Moore, Lang, Weller, Punt and Bradford.

1.4 Adoption of Agenda

The adopted Agenda is provided as Annex B.

1.5 Documents and data available

The list of documents is available as Annex C.

2. SUMMARY OF POPULATION MODELLING APPROACHES THAT HAVE BEEN OR MAY BE RELEVANT FOR NORTH PACIFIC GRAY WHALES

2.1 AWMP (including Pacific Coast Feeding Group or PCFG)

The AWMP trial approach has since 2011 included consideration of the Chukotkan hunt and the potential hunt by the Makah tribe off Washington State (IWC, 2012). The trials considered two plausible 'stocks': 'PCFG' and 'north'. PCFG whales are defined as gray whales observed (i.e. photographed) in multiple years between 1 June and 30 November in the PCFG area (IWC, 2011, p.22). Not all whales seen within the PCFG area (the precise boundaries are somewhat arbitrary as discussed in IWC (2011) at this time will be PCFG whales and some PCFG whales will be found outside of the PCFG area at various times during the year. The geographic regions considered were:

- (1) the 'north' area (north of 52°N, i.e. roughly northern Vancouver Island);
- (2) the 'PCFG' area (between 41°N and 52°N with the exception of Puget Sound); and
- (3) the 'south' area (south of 41°N).

The trials used to evaluate candidate *Strike Limit Algorithms (SLAs)* for the PCFG are based on operating models that include the 'north' and PCFG 'stocks', each of which is represented using age- and sex-structured population dynamics models (IWC, 2013). Allowance is made for immigration and emigration between the 'north' group and the PCFG group. The operating model allows for catastrophic mortality in 1999 and 2000 from the 'north' group given the large numbers of gray whales observed stranded along the coasts of Oregon and Washington in those years (Gulland *et al.*, 2005; Brownell *et al.*, 2007). A variety of levels for the annual rate of immigration from the 'north' to the PCFG was considered, along with the possibility of an immigration pulse into the PCFG in 1999 and 2000.

The catches accounted for in the operating model include aboriginal subsistence catches as well as incidental removals. The operating model allocated the catches to four types: (a) catches north of the PCFG area, (b) catches in the PCFG area during December to May, (c) catches in the PCFG area during June – November, and (d) catches south of the PCFG area. All of the catches north of the PCFG area were assumed to be 'north' group whales, the

catches from the PCFG area during June – November were all assumed to the PCFG group whales, and the other two types of catches were assumed to be from both stocks.

The values for the parameters of the operating model were estimated using Bayesian methods. Uniform priors were placed on the parameters on the model based on data for the eastern North Pacific stock of gray whales. The data used when fitting the model were the shore-based counts at Granite Point and Yankee Point (Laake *et al.*, 2012) and estimates of abundance based on mark-recapture data (Calambokidis *et al.*, 2012; IWC, 2013). It is well-known that it is impossible to develop a model of the eastern North Pacific gray whales which assumes that carrying capacity has been unchanged since the start of commercial whaling, and nevertheless fits the available abundance estimates (Butterworth *et al.*, 2002). Consequently, in terms of providing management advice for present whaling operations, the model projections are initiated in 1930 with the age-structure of a depleted population (IWC, 2013).

The process adopted for developing operating models for commercial whaling (IWC, 2005) and aboriginal subsistence whaling aims to identify a range of uncertainties, including those associated with stock structure, such that future information should reduce rather than increase the range. Consequently, the range of uncertainties considered during trials development should be inclusive. This process has been applied to the western North Pacific minke whales (IWC, in press), the western North Pacific Bryde's whales (IWC, 2008) and the North Atlantic fin whales (IWC, 2009), as well as for eastern gray whales and bowhead whales under the AWMP. Under the RMP, the trials based on the hypotheses developed to encompass the uncertainties are assigned plausibility ranks, and only trials which are not considered 'low plausibility' are used when selecting 'variants' (IWC, 2005). In addition to stock structure hypotheses, the trials include hypotheses related to productivity, to changes over time in carrying capacity and natural mortality, to time-trends in survey bias, and to the quality and quantity of data on which future management advice might be based.

2.2 Western North Pacific (Cooke model)

Cooke summarised the population modelling approach used for assessment of western North Pacific gray whales since 2004. The model has been applied to the group of whales studied on a summer feeding ground off Sakhalin Island. Photo-id data, supplemented with sex determinations from biopsies, collected under the Russia-US programme since 1994 were used to inform the model. The latest assessment was presented in SC/65a/BRG27 (using data through the 2011 season), where details of the model are to be found (see Item 5.1.1.1 for a summary of results).

The population model is stage-structured. The stages include: calves; each of the immature age classes by sex; mature males; and three stages of mature females: pregnant, lactating and resting. The minimum observed time between calvings is two years: the model allows zero or more additional resting years so that calving intervals of three or more years are also possible. The model is individual-based, so that it can be fitted to individual photo-id capture histories. A "capture" in this case means that a whale was photo-identified in a given year as either: (i) a mother with a calf; (ii) a calf with its mother; (iii) a calf on its own; or (iv) any other whale. These were the only categories of animal that were considered to be distinguishable with close to 100% reliability in the field.

The transition probabilities between stages are assumed to depend on various combinations of parameters to be estimated. The transition probabilities can vary between years and between individuals. Availability (sighting probability) can vary between years, stages and individuals. Variations between individuals are modelled by allowing individuals to have additional attributes, and stages in the model are replaced by stage-attribute combinations. Model selection using the AIC criterion is used to determine which parameters are allowed to vary over time.

The results of greatest potential ecological interest are the annual variations in population parameters. The analyses presented in SC/65a/BRG27 found strong indication of inter-annual variability in both calf (post-weaning) survival rates and calving intervals. The variations in these two parameters were significantly correlated with each other subject to a 2-year time lag.

The variations in parameters and the time lags between them potentially provide insights into the impact of external factors on the life cycle. For example, correlations have been identified using a similar model for South Atlantic right whales (Leaper *et al.*, 2006): between right whale calving intervals and environmental variables such as the ENSO (El Niño Southern Oscillation), water temperatures in the South Georgia feeding ground, and reproductive success of other species (fur seals, gentoo penguins) feeding in the same area.

Work is in progress to identify the ecological and climatic variables most strongly correlated with the demographic changes observed in Sakhalin gray whales. Understanding the ecological factors affecting the demography can also provide important background information when interpreting data on the possible impacts of anthropogenic factors such as acoustic disturbance on the feeding ground.

The main reason for using an individual-based model is not that the individual processes are necessarily the focus of interest, but that the longitudinal individual data from photo-id have been found to be extremely informative with respect to population parameters and their variations. In order to make maximal use of these data to draw inferences on population parameters, an individual-based model is required.

An application of the model that also uses data collected from eastern Kamchatka is contained in the latest report of the Western Gray Whale Advisory Panel¹ (iucn.org/wgwap/wgwap/meetings/wgwap_13). Those results were obtained by simply merging the available data sets as if they were from a single study. It is recognised that this is probably not a valid approach, and that it would be desirable, when using data from more than one location, for the model to take account of differences between locations. In the case of Kamchatka and Sakhalin, for example, there may be differences in the relative availability of the different population stages (for example, adults versus subadults). Furthermore, the observations off Kamchatka may include whales that do not “belong” to the group of whales summering off Sakhalin Island.

Work is in progress to extend the model to allow location-specific differences in the relative availability of the different population stages, and to allow data from locations where not all animals necessarily belong to the population of interest.

The Workshop **welcomes** this information and **strongly encourages** the continued development of the approach. It **reiterates** the importance of careful incorporation of all relevant data from Sakhalin and Kamchatka into the model (e.g. IWC, 2013).

3. STOCK STRUCTURE AND MOVEMENTS

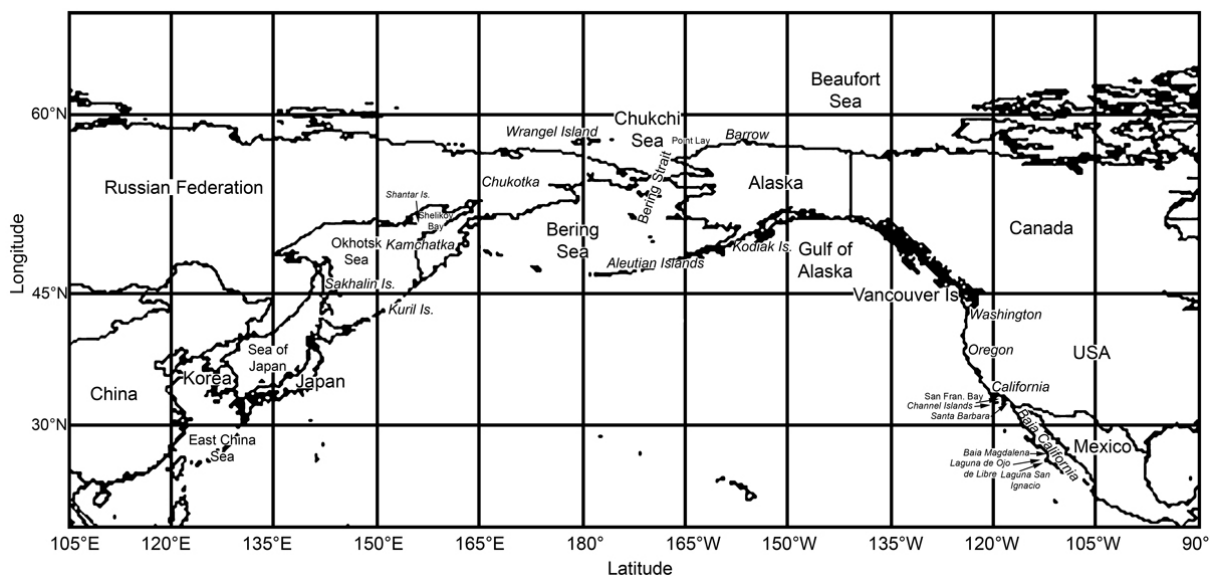

Fig. 1. Map of the North Pacific showing place names in the text.

3.1 Summary of existing hypotheses

Until recently, it was generally believed that there were two separate gray whale stocks in the North Pacific. According to that paradigm, the ‘eastern’ stock winters in Mexican waters, migrates along the North American coast and feeds during the summer and autumn in Arctic waters of Russia (primarily Chukotka) and the USA. This stock is considered to have recovered to around its pre-exploitation level (~20,000 individuals). The greatly depleted ‘western’ stock is considered to feed mainly in waters off Sakhalin Island, migrate along the coasts of Japan and possibly Korea and winter somewhere in the South China Sea (see Fig. 2 for a simple schematic). The AWMP *Implementation* for gray whales which evaluated and agreed the *Gray Whale SLA* (strike limit algorithm) agreed to a single eastern stock (IWC, 2001)

However, during the AWMP *Implementation Review* of eastern North Pacific gray whales in 2010 (IWC, 2011), which examined the subsistence hunts of gray whales off Chukotka and potentially Washington State, the

¹ www.iucn.org/wgwap/wgwap/meetings/wgwap_13

Scientific Committee agreed that there was sufficient evidence to consider the Pacific Coast Feeding Group (PCFG) of gray whales separately for management purposes related to the proposed Makah hunt and this evaluation was completed in 2012 (IWC, 2013), as defined above under Item 2.1.

In an effort to obtain more information about the southern migration route(s) and wintering area(s) of gray whales in the western North Pacific (WNP), a satellite telemetry project was undertaken in 2010 and 2011 by a team of Russian and American scientists (Mate *et al.* 2011). While the objective of the study was to document gray whale movements within the WNP, the three whales tracked for more than a few weeks travelled from the Sakhalin feeding area to the eastern North Pacific (ENP) (see Item 3.2.4).

Lang summarized the stock structure hypotheses put forward at the last IWC Scientific Committee meeting (IWC/65A/Rep 1 Annex I). These hypotheses are focused on the stock identity of the whales that feed off Sakhalin, and they did not address possible stock structure among whales considered part of the eastern North Pacific (ENP) stock. It was suggested that these existing hypotheses should be modified to include Kamchatka, as some data are available from this area. The addition of a model that incorporates multiple migratory routes in the western North Pacific was also proposed.

Fig.2. Schematic of the suspected distribution of what were thought to be two distinct populations of gray whales with little overlap (see text)

3.2 Review of available data and analyses

3.2.1 Genetic data on population structure

A small working group, consisting of Lang, Bickham and Urbán, was formed to summarize the available genetic data and analyses by region. A short summary is included as Table 1 and a full summary in Annex D.

Lang reviewed the results of previous genetic studies of gray whales that were relevant to stock structure. Recent studies investigating whether structure exists among feeding grounds used by ENP gray whales have found significant differences in mtDNA haplotype frequencies when PCFG whales were compared with whales sampled in other regions of the ENP stock's range (PCFG v. Bering and Chukchi Seas, Lang *et al.*, 2014; PCFG v. ENP migratory route, Frasier *et al.* 2011). No significant differences were detected when comparing microsatellite allele frequencies between the PCFG and whales sampled in the Mexican wintering lagoons (D'Intino *et al.* 2012) or between the PCFG and whales sampled in the Bering and Chukchi Seas (Lang *et al.* 2014). Structure on the ENP wintering grounds has also been investigated, with small but significant differences in mtDNA haplotype frequencies identified between cows (females with calves) sampled in two of the primary calving lagoons in Mexico and females sampled in other areas (Goerlitz *et al.*, 2003). A subsequent study by Alter *et al.* (2009), however, did not detect significant levels of mtDNA differentiation when comparing whales sampled in the three primary calving lagoons, although a small but significant departure from panmixia was detected between whales in two of the lagoons using microsatellites.

Comparison of whales feeding off of Sakhalin Island, Russia, with whales sampled on ENP feeding grounds and migratory routes have identified significant differences in both mtDNA haplotype and microsatellite allele frequencies (LeDuc *et al.*, 2002, Lang *et al.*, 2011). Between 1995 and 2007, 56 mother-calf pairs were sampled off Sakhalin; males sampled off Sakhalin were assigned as putative fathers for 46 to 50% of these calves (Lang *et al.*, 2010). Meschersky *et al.* (2012) analysed additional mtDNA sequence data, totalling ~2800 bps of sequence and including two protein-coding genes, generated from biopsy samples collected from whales encountered off Sakhalin Island, the eastern coast of Kamchatka, and the Russian Koryak coast as well as from samples collected as part of the aboriginal hunt in the coastal waters of the Chukotka Peninsula. Two sequence variants were found in relatively high frequencies among whales sampled off Sakhalin but only in low frequencies among the Chukotka whales.

Urbán reported that samples have been collected from gray whales in the Mexican lagoons over the last three seasons. Approximately 450 samples have been collected and 300 are being processed for mtDNA. Once produced, these data may provide additional insight into whether structure among lagoons exists.

Ilyashenko noted that approximately 150 samples collected from whales harvested in the Chukotka hunt had been sent to Japan for analysis; data are not currently available. Bickham noted that in addition to the samples analysed in Bickham *et al.* (2013), additional samples collected from whales off Sakhalin in 2012 ($n = 20$) and 2013 ($n = 9$) exist.

Lang reported that an analysis of relatedness among whales sampled off Sakhalin is ongoing; the primary objective of this work is to evaluate what proportion of the whales sampled off Sakhalin share a putative mother-offspring relationship with Sakhalin whales known to migrate to the eastern North Pacific. Similar studies to examine relatedness among sampled PCFG whales are also underway and will focus on examining internal recruitment into the group by identifying putative mother-offspring pairs among sampled whales.

Table 1

Summary of available samples of gray whales (not all have been analysed and there may be some overlap between studies included here). For details and further explanation see text and Annex D).

3.2.2 Osteological data comparing populations

Kato and Nakamura (doc for this meeting) reported initial results of osteological comparisons among five gray whales from Japan (1 mature, 4 immature), one from Korea (Andrews, 1914), one from California (Andrews, 1914) and five additional California specimens (body lengths 9.3–11.7m). They concluded that the specimens from Japan (all from the Pacific coast) were more similar to the California specimens than to the Korea specimen and thus inferred that the feeding range of ‘eastern’ gray whales has expanded to the coast of Japan (an idea also suggested by Nishiwaki and Kasuya, 1970).

The Workshop welcomed this initial analysis but cautioned against over-interpretation of the results given that (1) the sample size is small and there are the long temporal gaps in timing of collections and (2) the sample includes immature specimens and some skeletal and skull features are known to vary by age or stage. The Workshop **encourages** continuation of this work provided sufficient additional specimens can be identified.

In discussion, it was noted that bone material can also be used for stable isotope and DNA studies (see below).

3.2.3 Individual identification data (photo and genetic)

Research on gray whales in the western North Pacific has been ongoing since 1995, predominantly on the feeding grounds off north-eastern Sakhalin Island and more recently also off south-eastern Kamchatka. These studies monitor gray whales using photo-identification methods. Data have been collected primarily between July and September off Sakhalin, and July and August off Kamchatka. The Sakhalin catalogue contains about 230 whales. The Kamchatka catalogue contains about 155 whales, of which approximately 55% have also been sighted off Sakhalin. In addition to the Sakhalin and Kamchatka catalogues, opportunistic photographs exist for a number of other regions in the Okhotsk Sea, the northern Kuril Islands, Japan and China.

Research on gray whales in the eastern North Pacific has been ongoing since the late 1960s. Photo-identification data useful for analyses of stock structure have been collected in a number of areas including: (1) Baja California, Mexico (Urbán *et al.*, 2013), (2) the north-western USA and southern British Columbia, Canada (~ 41°-52°) (Darling *et al.*, 1984; SC/A14/NPGW03) and (3) around Kodiak Island, Alaska, USA (Gosho *et al.*, 2011).

The photo-catalogue from Mexico includes images obtained primarily between January and April from all of the major wintering lagoons including: (1) Laguna Ojo de Liebre (2001-2003, 2013), (2) Laguna San Ignacio (2005-2013) and (3) Bahia Magdalena (1998-2010, 2012-2013). Altogether, 6,900 individual gray whales have been photo-identified in these three study areas.

The photo-catalogue from the Pacific Northwest (PNW) contains ~1,500 ‘Pacific Northwest’ gray whales identified by a large number of researchers working in US and Canadian waters from California to Alaska, primarily between 1998 and 2013. The PNW catalogue focuses on gray whales that feed during the summer and fall in coastal waters between northern California and the Gulf of Alaska, the PCFG, but also includes some migrating whales identified in the spring (March to May) during their northward passage to high-latitude feeding grounds; there are some but fewer southbound sightings from December to February.

Gray whale photo-identification images have also been collected opportunistically during the past decade off southern California and off Alaska including Southeast Alaska, Kodiak Island and Barrow and vicinity. In addition some photographs are available from St. Lawrence Island and the SE Chukchi Sea (also see Item 3.2.6).

Table 2 provides a summary of the photo-id efforts across the North Pacific.

Ilyashenko reported that he has asked biologists working in Chukotka to try to obtain photographs of harvested gray whales for photo-id work even though this is difficult because carcasses on shore are generally not oriented in a convenient position and their flukes have been trimmed to facilitate towing to shore. This recommendation has also been made by the IWC Scientific Committee (e.g. IWC, 2009).

Results from photo-identification (Urbán *et al.* 2013, Weller *et al.* 2012), genetic (Lang, 2010; Baker *et al.*, 2002), and telemetry studies (Mate *et al.* 2011) have documented spatial and temporal overlap between western and eastern gray whales. Observations include: (1) six whales photo-matched from Sakhalin Island to southern Vancouver Island, (2) two whales genetically matched from Sakhalin to Santa Barbara, California, (3) 13 whales photo-matched from Sakhalin Island to San Ignacio Lagoon, Mexico, and (4) two satellite-tagged whales that migrated from Sakhalin Island to the west coast of North America. Despite this overlap, significant mtDNA and nDNA differences are found between whales in the western North Pacific and those summering in the eastern North Pacific (Lang *et al.*, 2011). Although it is clear that some whales feeding in the western North Pacific during the summer/fall migrate to the west coast of North America during the winter/spring, past and present observations of gray whales in the western North Pacific off Japan, Korea and China during the winter/spring suggest that not all gray whales in the WNP share a common wintering ground (Weller *et al.*, 2013). The possibility that not all whales migrate to the same grounds each winter was also raised.

Table 2.

* Some historic data to 1970s

In view of the evidence that at least some of the whales that summer off Sakhalin migrate to the eastern North Pacific in winter, the Workshop considered that a combined analysis of all available data to place bounds on the proportion of whales that move from Sakhalin to the eastern North Pacific and vice-versa would be useful. The Workshop **recommends** that such an analysis be performed, preferably before SC65b. It **requests** that curators of the different catalogues provide summary data as outlined under Item 10.4, if they have not already done so.

3.2.4 Telemetry data

ENP: MIGRATION AND FORAGING AREAS

The eastern gray whale population numbers around 21,000 whales and the population is censused from shore during its annual south-bound migration past Granite Canyon, central California (Laake *et al.*, 2012; Durban *et al.*, 2013). Mother whales (N=17) tagged by Oregon State University (Mate) in Baja California in April 2005 showed staggered departure times over a period of ~6 weeks. Additional tagging by John Durban *et al.* of whales in San Ignacio Lagoon (N=18) resulted in localized movements in Baja California and southern California. Travel speeds of adult females accompanied by calves were slower going north than single whales traveling south. Mothers with calves also travelled closer to shore than earlier (Phase A) north-bound single whales. Most tagged whales provided very few locations from British Columbia to Unimak Pass (Alaska), probably because wind-generated waves and swells compromised the antenna and saltwater switch. One whale ‘re-appeared’ after a period of more than a week without positions. By that time it was moving northeast along the Russian coast of the Bering Sea and subsequently continued through Bering Straits. The feeding destinations of 7 tagged whales were primarily in the Chukchi Sea between Barrow (Alaska) and Wrangel Island (Alaska), with arrivals to that region starting in mid-June. One tagged whale was killed by hunters in Chukotka. Five additional whales tagged by John Ford *et al.* (2013) in British Columbia remained in coastal waters while migrating north. Six whales tagged by NMML in the Alaskan Chukchi Sea and whales tagged by M.P. Heide-Jørgensen off Chukotka showed localized foraging. Six whales tagged by researchers from Alaska Department of Fish and Game (one off Tuktoyuktuk in Canada and five off Barrow) foraged in the Beaufort Sea, while one tagged off St Lawrence Island moved to the Russian coast during a 65-day track.

The Workshop **welcomes** a report from Ilyashenko that Litovka is planning to tag gray whales off Chukotka this year in collaboration with researchers from Europe.

PCFG: S & N MIGRATIONS, WINTERING AREAS, FORAGING AREAS

Mate *et al.* tagged 35 PCFG whales (see definition under Item 2.1) feeding during late autumn in coastal waters off Oregon and northern California, where whales seem to stage before the south-bound migration. Nineteen whales left the PCFG area with staggered departure dates over a period from late November to early February. Some tagged whales had returned to California waters from Mexico before other PCFG whales arrived in Baja California. There were several such ‘waves’ of Baja arrivals for each of the three years of tagging.

Table 3

Summary of telemetry information (see text)

¹ added data from Durban; ² added data from Ford (2013); ³ added data from 1 whale Quakenbush *et al.* (2013); ⁴ added data from 6 whales Quakenbush *et al.* (2013); ⁵ added data from NMML; ⁶ added data from Heide-Jørgensen *et al.* (2011); ⁷ transmitter stopped so may have been longer (as in previous year); ⁸ added data from CRC limpet tags, Ford *et al.*, 2013.

Seventeen tagged whales were tracked to the breeding and calving areas of Baja California, where most of them stayed in nearshore waters. Most of the whales began their southward migration near Pt. St. George, CA. However, in 2012 two of them travelled north to the Washington coast before migrating south. Another individual began its southerly migration from Pt. St George but reversed course near San Francisco Bay, CA, and travelled north to the northern Washington coast before again turning south and migrating to Mexico. One healthy-appearing male did not migrate south at all, instead remaining off northern California and Oregon for the duration of the winter, with two extended periods off Pt. St. George in October-February and February-May during its 382 day tracking period.

In Baja California, most whales spent extended time in the area offshore of Ojo de Liebre (ODL) lagoon and two whales passed farther south offshore of San Ignacio Lagoon en route to Magdalena Bay. Locations inside ODL lagoon accounted for 23% of all high-quality locations. No tagged whales had more than 69% of their high-quality locations within the lagoon. Eight of 17 whales did not have any high-quality locations within the lagoon.

Tagged whales arrived at the breeding grounds from late December to early March. Most of them spent an average of 21 days in reproductive areas before heading north on migration. One female and another whale of unknown sex remained in the breeding area for 2.5-3 times as long as other whales. These were likely both females that gave birth and then departed the lagoon area in late February or early March. The observed variability in arrival and departure times indicates that the entire population is never in the lagoon region at the same time. Thus, population estimates based on surveys in the breeding areas will severely underestimate the population if typical 'closed population' assumptions are made.

Twelve whales were tracked back to the 'Pacific Northwest' following their northbound migration from wintering areas off Baja California. Migratory routes were typically close to shore and followed the coastline. However, some whales in each year travelled directly across the California Bight, through the outer Channel Islands (Santa Rosa and Santa Cruz), rather than following the coastline. Most whales travelled continuously after starting their migration until they reached their destination. However, one whale stopped for 9 days near San Miguel Island in the California Channel Islands (where it was first photographed before the telemetry study) before continuing its

journey south. Ford *et al.* (2013) tagged three PCFG whales as they passed Vancouver Island migrating north. These three whales continued north exhibiting similar migratory speed and path as whales not thought to be PCFG whales until their tags stopped working in southeast Alaska.

Rather than migrating to the Bering, Chukchi and Beaufort Seas like the rest of the ENP population, tagged PCFG whales returned on their north-bound migration to traditional PCFG areas, although two went farther north to Icy Bay (60N) for variable periods before working their way farther south. Some of the emphasis in the data on foraging locations in the area of Pt. St. George reflects the large number of tag deployments there (23 out of 35 whales). Six whales recorded locations either inside (or adjacent to) the Makah Tribal U&A Fishing grounds during five months (Feb, Apr, May, Sep, Dec).

It has often been noted that the number of calves found at any one time in the three main Mexican lagoons is smaller than the total estimated calf production. The large proportion of tagged whale locations outside ODL lagoon during the breeding season suggests not only a greater amount of time spent outside the lagoon, but also that most of the population (and probably calves as well) can be outside lagoons at any point in time. In the case of eight whales, none of their good-quality locations were inside the lagoon. If some whales rarely if ever enter the lagoon, and others spend a large percentage of time outside the lagoon, it would be necessary to include offshore surveys to properly characterize the population's distribution during the breeding season. As relatively small areas, lagoons could serve to help drive genetic isolation of the PCFG whales (and possibly also Sakhalin whales) from other eastern gray whales. However, ODL is the largest of the three major lagoons and has peak populations of nearly ten times the estimated number of PCFG whales.

Gray whale calls have been recorded throughout the winter in the Beaufort Sea (Stafford *et al.* 2007), suggesting either that (a) some whales do not migrate or (b) there is considerable variation in the timing of migration into and out of the region, with the turnover ensuring that the area is never 'unused' by gray whales. Moreover, results from tagged PCFG whales provide unequivocal evidence that not all gray whales migrate to Mexico every year.

Re-sight photographs showed that tagged whales, whales that had shed their tags and untagged whales were often together in the Pt. St. George area (especially very late in the season). This mingling suggests that the movements of tagged whales represent, at least to some extent, the movements of some other, untagged whales.

WESTERN GRAY WHALES: N & S MIGRATIONS AND FORAGING AREA

Three of seven gray whales tagged at Sakhalin Island migrated to the ENP after staying at Sakhalin for several months after tagging (the tags on the others stopped transmitting prior to movement away from Sakhalin). They crossed the Bering Sea, using varying routes, timings and entry points through the Aleutian Islands into the Gulf of Alaska. Two of the whales entered the traditional coastal south bound migration route for 'traditional' ENP gray whales from late December to late January. These whales migrated at faster speeds than ENP whales. One male's transmitter was last heard along the Oregon coast in February while migrating south while a female migrated to Baja California where it spent 42 days and passed all three major calving areas before a return northbound. The latter involved a different route across the Bering Sea than the winter migration eastward and southward. The first arrival point on the Russian coast was the western? side of Kamchatka peninsula. The whale continued on to the NE coast of Sakhalin Island in mid-May, passing through what was characterized as heavy ice.

The Workshop **reiterates** the great importance of further telemetry studies, particularly off Sakhalin, Kamchatka and in the northern areas such as Chukotka and **recommends** that such work be undertaken.

3.2.5 Removals data (catch and incidental catch; strandings)

Uni (2008) analysed records of Japanese whaling along with recent sightings, bycatch and strandings data and concluded that although most gray whale catches over the past 400-500 years were in the Sea of Japan (including the Korean peninsula), recent sightings, entrapments and strandings have been mainly along the Pacific coast (although see Nambu, 2008). These data, together with the Korean whaling records (Mizue, 1951), have been interpreted as suggesting two or three 'substocks' of gray whales using different migration routes along either side of the Japanese archipelago and along the Korean Peninsula. There is also some evidence to suggest a wintering area in the Inland Sea of Japan, in addition to the presumed wintering area in southern China (around Hainan Island).

Reeves *et al.* (2008) plotted the approximate positions and dates (i.e. months) of 160 kills and sightings of gray whales by American whalers in the Sea of Okhotsk in the latter half of the 20th century. Gray whales were observed consistently in Shelikhov Bay (Zaliv Shelikhova) and Penzhinskaya Gulf (Penzhinskaya Guba) from early May to the end of August. They were also seen in Gizhiginskaya Bay (North-east Gulf) between mid-May and late August and near Magadan along the north central coast of the Sea of Okhotsk from at least early June to early July and from mid-August to mid or late September. The American whalers apparently did not visit the

coastal waters off north-eastern Sakhalin Island where gray whales now congregate to feed throughout the summer.

Brownell reported that the large catches (>1,750 gray whales) by Japanese modern whalers in the East Sea of Korea from 1890-1966, but mainly in the first third of the 20th century (Kato and Kasuya 2002), came at a time when the population of gray whales in the eastern Pacific was seriously depleted as a result of 19th century whaling. This mismatch in the timing of peak catches in the eastern and western North Pacific is consistent with the hypothesis of separate populations. The observation that not all eastern gray whales visit Mexico each year was also noted in this regard.

Whaling data from the eastern North Pacific are generally consistent with the well-known concept of a north-south coastal migration between summering grounds off Chukotka or Alaska and the Mexican wintering grounds. Some shore whaling stations in California operated seasonally in accord with the arrival of southbound migrating gray whales (relatively fat) in December or January and the departure of northbound migrants (relatively thin) from March to early May (Rice and Wolman, 1971; Reeves and Smith, 2010). At some stations, winter/early spring catches comprised mainly gray whales whereas at other seasons humpback whales were the main targets (Reeves and Smith, 2010).

3.2.6 Sightings data

NORTHERN BERING-SOUTHERN CHUKCHI SEAS (NBS/SCH), NORTHERN CHUKCHI SEA (NCH) AND CALIFORNIA (CA) REGIONS

Sue Moore summarised sightings data from aerial surveys in the northern Bering, north-eastern Chukchi and Alaskan Beaufort seas from 1982 to the present; noting a hiatus in broad-scale surveys in the region from 1992-2007 (Clarke *et al.*, 2013). Since 2008, surveys have been conducted from July-October by researchers at the National Marine Mammal Laboratory (NMML) as part of the Aerial Surveys of Arctic Marine Mammals (ASAMM) program². Gray whales are distributed predominantly along the Alaska coast in the north-eastern Chukchi Sea from roughly Point Lay to Barrow, and in the south-central Chukchi Sea southeast of Point Hope (Fig. 4). Many of the whales seen are associated with mud plumes and as a result are designated 'feeding whales'.

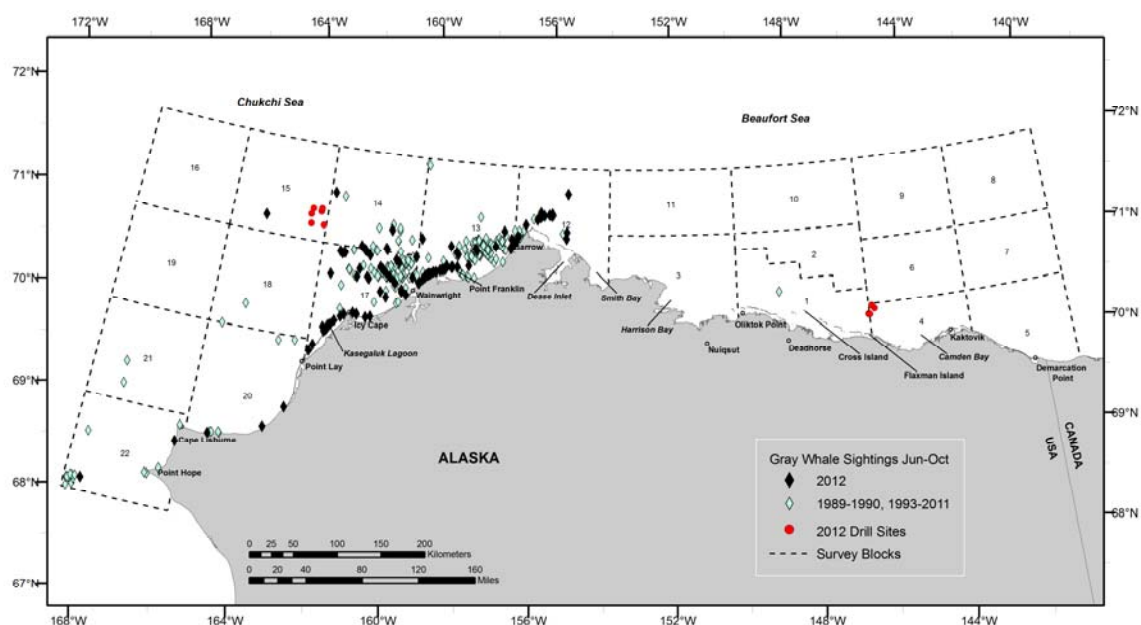

Fig. 4. Gray whale on-transect sightings in 2012, compared to years with light sea ice cover: 1989-1990, 1993-2011. Includes all on-transect sightings from primary and secondary observers. Reproduced with permission from Clarke *et al.*, 2013: fig. 24.

Recent surveys resulted in fewer observations of gray whales feeding near Hanna Shoal than was the case during the 1982-1991 period. Female-calf pairs are commonly observed along the Alaska coast with no noticeable change from the 1980s through 2013. In addition to ASAMM sightings, gray whales were routinely observed during

² <http://www.afsc.noaa.gov/nmml/cetacean/research/caepresearch.php?url=nmmlcaep1405>

summer oceanographic cruises that extended into Russian waters between 2009-2013, including two sightings of eleven whales in 2009, north of Wrangel Island (Moore *et al.*, 2014). Together, these sightings confirm the broad distribution of gray whales in the Chukchi Sea, as summarised by Berzin (1984).

In discussion it was noted that with so many calves seen along the Alaska coast, there might be opportunities for photo-identification and/or biopsy sampling there. In 2013, 36 gray whale photo ID's were obtained and 5 gray whales were tagged with satellite transmitters under the NMML-led ArcWEST program³; unfortunately, biopsy samples were not obtained. The ArcWEST program will continue for the next 2-3 years, and there may be opportunities to include biopsy sampling in future cruise plans. The Workshop **encourages** the ArcWEST program to collect biopsy samples if at all possible.

Female-calf sightings extend into September, beyond the time when females are generally thought to have weaned their calves. Moore noted that NMML staff had analysed calf sightings specifically, with results presented at the annual Alaska Marine Science Symposium each January. Moore noted that there might be sufficient sighting data from the 1980s to calculate relative abundance indices for comparison to sighting rates from recent (and ongoing) surveys in the 2000s, although the record is not continuous for gray whales in the Chukchi Sea. The Workshop **recommends** that such an analysis is undertaken if the data are found to be sufficient.

Shore-based sighting surveys of northbound gray whale cows with calves have been conducted annually from the Piedras Blancas Light Station, located near San Simeon, CA, since 1994 (Perryman *et al.* 2012). Weller reported that starting in 2012, photographs for identification of northbound mother-calf pairs passing the site have been collected and images forming this catalogue will be shared with other researchers for comparison to their catalogues. The primary goal of this effort is to identify migrating mother-calf pairs for comparison with gray whales known to be part of the PCFG. Annual additions of calves to the PCFG are thought to be underestimated because some calves are weaned before being photo-identified. This photographic effort may be expanded in 2015 to include the use of a small UAS (unmanned aircraft system) for photo-identification purposes.

MEXICO

Scott noted that records are available of gray whale sightings off Mexico (1970s to present) by tuna purse seine vessel observers of the US NMFS, Inter-American Tropical Tuna Commission and the Agreement for the International Dolphin Conservation Program. Additional sightings have likely been made during research cruises in the eastern tropical Pacific by the US NMFS.

RUSSIA

There have been local reports of distribution of gray whales around some of the whaling villages (e.g. Blokhin, 1986; 1987; 1989; 1990; 1998; Bogoslovskaya *et al.*, 1982; Melnikov, 2008; Melnikov and Bobkov, 1996; Melnikov *et al.*, 1997). Ilyashenko reported that V.V. Melnikov recently observed and filmed more than 20 gray whales near the Shantar Islands in the western Okhotsk Sea. Two gray whales were observed in September 2011 in the Laptev Sea in the central Russian Arctic (Shpak *et al.*, 2013). In addition, two gray whales were documented from a tourist ship near Frans Josef Land off north-western Russia in 2011.

3.2.7 Biological data (e.g. conception date)

Rice and Wolman (1971) provided the most detailed information available on gray whale life history, derived from 316 whales sampled off central California between 1959 and 1970. The authors reported that breeding and calving are seasonal and closely synchronized with timing of the migration. Non-pregnant mature females were found to ovulate regularly in late November and early December, which coincides with the initial phase of the southbound migration. Based on estimates of foetal growth rate, sampled females were determined to have conceived between late November and early January, with a mean conception date of 5 December. Rice and Wolman (1971) found that successive ovulations can occur, separated by a period of about 40 days, indicating that whales can enter oestrus while on the wintering ground. The gestation period is approximately 13 months, with calving occurring mainly from late December to early March on the wintering grounds, although some calves are born during the southbound migration (Shelden *et al.*, 2004 – cited in Moore, 2008).

There are no comparable reproductive data for gray whales in the western North Pacific. Andrews (1914) examined 23 gray whales taken during the southbound migration off Ulsan, Korea, and summarised observations made by the whalers working there. Adult females taken off Ulsan in December and January were carrying near-term foetuses, and one of the whales Andrews examined was a foetus measuring 4.76m. Rice and Wolman (1971) reported an average near-term foetus size of 4.62m from the eastern gray whales sampled off central California.

The coincidence in observed foetus size, season, and latitude between Korea and central California (mothers were moving past Korea and central California at the same time of year carrying same-sized fetuses) provides support

³ <http://www.afsc.noaa.gov/nmml/cetacean/research/caepresearch.php?url=nmmlcaep1407>

for the hypothesis that at least historically there were separate populations in the eastern and western North Pacific (Weller *et al.*, 2002).

The Workshop reviewed biological parameter data more fully under Item 6. It was noted that in the past, data on conception dates had proved useful in formulating stock structure hypotheses (e.g. WNP common minke whales). However, the Workshop **agrees** that there are insufficient such data for gray whales to be used in a stock structure context.

3.2.8 Ecology and behaviour

Sue Moore provided a brief summary of information related to gray whale feeding ecology in the northern Bering and southern Chukchi seas (NBS/SCh). A decline in sighting rate of feeding gray whales between the 1980s and 2002 in the NBS (Chirikov Basin) was demonstrated to coincide with a decline in amphipod-prey biomass there over that period (Moore *et al.* 2003). Gray whales are commonly seen feeding in the SCh and five whales tagged there during the 2013 ArcWEST program co-occurred with areas of high benthic-prey biomass. Additional lines of evidence that gray whales alter their behavioral ecology in response to variability in biophysical forcing (e.g. Pacific Decadal Oscillation, sea ice cover) are reviewed in Moore (2008).

There is some evidence that gray whale feeding ecology may vary considerably amongst region; e.g. the PCFG whales feed primarily on a different and larger variety of species than those in more northern seas (Darling *et al.*, 1998).

3.2.9 Other

Scordino suggested that future consideration be given to examining stable isotopes from bone artefacts. Stable isotope analysis could contribute to evaluations of stock structure and movements. Alter *et al.* (2012) evaluated the stable isotopes of bones found in Makah and Quilleute tribal middens from whales hunted 500 to 1,500 years before present compared to the isotopes from migrating whales hunted in the 1970s off California. Those authors assumed that the whales hunted in California during the migratory season represent whales that feed in the Bering, Chukchi and Beaufort seas. They found significant differences in Carbon-13 which suggests that the whales historically hunted by the Makah and Quilleute tribes fed further south than the whales hunted off California, although it was acknowledged that other factors could have caused the observed differences in Carbon-13 values.

Ilyashenko reported that Chukotka whalers (and scientists) have reported seeing more and more dark-skinned gray whales with no or few white marks from skin parasites, which they interpret to mean that these animals do not migrate far south but stay in cold water year-round. The numbers of such animals are not large but are increasing.

Finally, a recent paper by Tsai *et al.* (2014) reported on two specimens of fossil juvenile gray whale from the sea bottom between Taiwan and the Penghu Islands. These fossil specimens are Quaternary in age and of potential value to further assessments of gray whales in the western North Pacific.

3.3 Discussion of possible population structure hypotheses

As noted under Item 3.1, seven possible stock structure hypotheses were put forward at SC/65a (IWC, 2014). The original seven hypotheses focused primarily on evaluating stock structure relative to the whales feeding off Sakhalin, and thus additional variants needed to be added to address stock structure across the entire North Pacific. A small working group was formed to identify additional hypotheses that should be included, and the schematic for each hypothesis was drawn (or re-drawn in the case of the original seven) to incorporate a number of spatial regions⁴ (see Annex F) that were identified as areas where data were available that might be valuable in constructing and/or informing the hypotheses. The hypotheses identified at SC/65a retained their original numbering, and additional hypotheses were added as variants of the original seven hypotheses.

A number of key issues were identified during the initial discussion of hypothesis construction and these are considered below.

(1) Should each Mexican lagoon and the region offshore of Baja California be modelled as separate breeding sub-stocks?

Alter *et al.* (2009) compared mtDNA haplotype and microsatellite allele frequencies ($n=9$ loci) between the three major calving lagoons. Significant nuclear differences were found between Laguna San Ignacio and Bahía Magdalena, while the results of the remaining comparisons were not significant. While this finding provides an indication that structure among lagoons could exist, the evidence is equivocal given that most of the comparisons were not significant. Urbán noted that his group has collected approximately 450 samples from all three lagoons

⁴ The North Central Pacific was originally included as a region to allow for visualisation of an area on the western migratory route used primarily by Sakhalin whales before they reached the 'common' eastern part of the migratory route along the North American coast (and where they may mate). This region is not included in Annex F as it will not be modelled; trials are informed only by demographic data (e.g. only the demographic data are compared to the model output to determine plausibility).

over the past three seasons, and they are in the process of generating data on mtDNA control region haplotypes for 300 of these samples. The results are expected to be available by the end of the year. As noted earlier, there is evidence from photo-identification and telemetry of animals moving among lagoons and the offshore area within a season.

The Workshop **agrees** that at present, the Mexican wintering grounds will be treated as a single breeding area. However, the possibility that structure between lagoons exists will be reconsidered if needed based on the results of the Urbán study, which incorporates a much larger set of samples than previous studies. No schematic depicting this possibility was constructed.

(2) Should a hypothesis be included that considers the PCFG and feeding regions in the Gulf of Alaska, Bering and Chukchi Seas to represent a single feeding sub-stock?

While not completely ruling out the possibility of a single feeding stock, the Workshop **agrees** to follow the example of the AWMP trials and to include the PCFG as a separate feeding sub-stock. From a management perspective this is the most conservative in that it is more challenging from a conservation standpoint with respect to future hunting. Thus, although it may be plausible that the PCFG is part of the larger sub-stock that includes feeding areas north of the Aleutians, there is little value at this stage in running additional, less conservative variants. For this reason, no schematic depicting this possibility was constructed.

(3) Should a hypothesis that considers the PCFG to represent a breeding sub-stock be considered?

The results of previous analyses have not found significant nuclear differences when comparing samples collected from PCFG whales with samples collected on the feeding area(s) north of the Aleutians (Lang *et al.*, 2014) or with samples collected from whales in the Mexican lagoons (D'Intino *et al.*, 2012). These findings are consistent with interbreeding between PCFG whales and those from other feeding areas. However, as the Committee has noted many times in the past, the failure to detect significant differences does not necessarily mean that no differences exist.

There have been some observations of PCFG whales aggregating off northern California during late November to mid-December, which Rice and Wolman (1971) identified as the first breeding period. In principle, this could provide some limited support for a hypothesis that the PCFG may represent a separate breeding sub-stock. However, the Workshop **agrees** that this hypothesis should not be included at this time, recognising that in effect the existing hypothesis of PCFG as a separate feeding stock is sufficient. Analysis of relatedness patterns of PCFG whales by Lang and colleagues is underway, and the inclusion of this hypothesis will be reconsidered in the future if warranted by the results of this work. No schematic depicting this possibility was constructed.

(4) Should a hypothesis be included that considers the whales feeding in the northern Bering-southern Chukchi Seas to be a separate feeding sub-stock from those feeding in the northern Chukchi Sea?

Given that matrilineal fidelity of gray whales to feeding grounds on parts of their range is believed to occur (e.g., off Sakhalin and in the PCFG), it is possible that gray whales exhibit this behaviour throughout their range. However, little is known about whether this behaviour occurs in feeding areas north of the Aleutians. Six whales tagged in 2005 on the Mexican wintering grounds retained their tags through all or part of the subsequent feeding season in the Bering and Chukchi Seas. While some of these whales made wide-ranging movements (e.g., between Barrow and Wrangel Island, and between Barrow and the southern Chukchi Sea), others remained in smaller areas, particularly during the latter part (September and October) of the feeding season (Mate, 2006). Nine gray whales tagged off Chukotka and tracked for variable amounts of time between September and November remained in the western Bering Strait, largely staying within 5km of the Chukotka coast (Heide-Jorgensen *et al.*, 2012). Thus both wide-ranging and more localized movements have been documented in this area. Moore further noted that there are ecological differences between the two regions included in the existing models (NBS/SCH and NCH), which might result in the development of sub-structuring between these regions.

Given the limited data available, the Workshop **agrees** that while it is certainly possible that some sub-structure within the feeding area north of the Aleutians could exist, this hypothesis should not be evaluated as a priority at this time. However, that the Workshop also **recommends** that additional studies (photo-identification, genetics, tagging) should be conducted in these regions, as has been previously recommended by the Scientific Committee. In making this recommendation, the Workshop **recognises** the practical difficulties of working in these areas and also **recognises** the ongoing efforts off Chukotka referred to earlier in the report.

(5) Should the possibility that a Sakhalin whale might be killed in the Chukotka harvest be incorporated in the model(s)?

There is only limited information on this topic, but none of the three whales that were tagged off Sakhalin and migrated into the eastern North Pacific travelled through the area where the Chukotka harvest is conducted. It was also noted that the evidence from the Sakhalin feeding area is that abundance is increasing in the face of the >100 whales that are taken in that harvest each year. Given this the Workshop **agrees** that such a scenario does not

warrant inclusion as a full hypothesis. However, there is some merit in including some options in the context of a sensitivity test.

(6) Should multiple migratory pathways in the western North Pacific be incorporated into the model(s)?

Park (2001) suggested that up to three migratory routes (east coast of the Korean Peninsula, the Pacific coast of Japan, and the east coast of the Sea of Japan) were used by western North Pacific (WNP) gray whales in the past. However, no recent sightings of gray whales off the Korean Peninsula exist, despite shore-based and vessel-based sighting surveys conducted between 2003 and 2011 (Kim *et al.*, 2013). There are 14 records of gray whales from Japan since 1990; the majority of these ($n=12$) are from the Pacific coast of Japan (Weller and Brownell, 2012; Kato *et al.*, 2013). However, only limited genetic (Kanda *et al.*, 2010) and photo-identification (Weller *et al.*, 2008) data are available from these areas, and it is currently not possible to evaluate whether the use of multiple migratory routes led to sub-structuring of the Asian breeding stock in the past. This hypothesis is depicted and described in the schematic 5b (see Annex E). However, given the lack of available data from the Asian migratory routes, the Workshop **agrees** that this hypothesis should be given low priority.

3.4 Recommendations for hypotheses for inclusion in the modelling framework

The Workshop examined the hypotheses described in Annex F. It **agrees** that Hypotheses 1 and 2 (from SC65a) were not consistent with available data and should no longer be considered. It also **agrees** that hypotheses for which little or no data (other than catch records) are available to assess plausibility should be considered to be of low priority for inclusion in the modeling framework (Hypotheses 3b, 3d, 5b, 6a, 6c). Finally, it **agrees** that low priority should be assigned to hypotheses that would be represented in the modelling framework in the same way as other hypotheses (Hypotheses 4a, 4b, 6b, and 6c; see hypothesis 7 for details).

Following this evaluation, the Workshop **recommends** that the following three hypotheses be considered a high priority for inclusion in the initial modeling framework.

Hypothesis 3a

Two breeding stocks (Asia and Mexico) may exist, although the Asian stock may have been extirpated. Whales show matrilineal fidelity to feeding grounds, and the Mexico stock includes three feeding sub-stocks: PCFG, NBS/SCH-NCH-G of AK [hereafter, Northern], and Sakhalin.

Hypothesis 3e

Identical to hypothesis 3a except that the Asian breeding stock is extant and feeds off both coasts of Japan, Korea, and in the northern Okhotsk Sea west of the Kamchatka Peninsula. All whales off Sakhalin overwinter in the eastern North Pacific.

Hypothesis 5a

Identical to hypothesis 3a, except that the whales that feed off Sakhalin include both whales that are part of the Asian stock and remain in the WNP year-round, and whales that are part of the Mexican stock and migrate to the eastern North Pacific (ENP).

Hypothesis 3c should be included as a sensitivity test. This hypothesis incorporates the possibility that a Sakhalin whale may occasionally move through the NBS-SCHK region and thus will have a chance of being taken in the Chukotka harvest.

3.5 Recommendations for future data collection and/or analyses

The practicality and utility of the recommendations presented in SC/A14/NPGW01 were evaluated. One recommendation was to develop Single Nucleotide Polymorphisms (SNP) assays for use with gray whales. These assays would allow integration of genetic data between labs as well as over time, increasing the utility of such data for future analyses. In addition, this approach could be utilized with low-quality samples, such as bone and baleen, which could facilitate analysis of any historic samples identified. The Workshop **recommends** that a SNP panel be developed for use with gray whales and considers this task a high priority for future work. It was noted that while development of SNP assays would be valuable, some analyses, such as evaluating relatedness among sampled animals, would necessitate the identification of several hundred loci. Until such a SNP panel is developed, nuclear analyses of relatedness would likely require that SNP and microsatellite data be combined. Conducting a gray whale genome project, which was one of the recommendations of SC/A14/NPGW01, would allow SNP loci to be identified and would generate data that could be useful in addressing a wide range of questions. However, the cost and utility of such an approach is greater than that required by other methods used to identify SNPs (e.g., Next Generation Sequencing), and thus this approach is considered a lower priority in terms of evaluating stock structure.

Another high priority for future genetic studies of stock structure is to increase the sample numbers and sample coverage for the eastern North Pacific stock of gray whales. While a high proportion of the whales using the Sakhalin feeding ground have been sampled, the proportion of the eastern North Pacific stock that has been

sampled is low. In addition, few or no samples have been collected from some parts of the range of eastern North Pacific stock. The Workshop **recommends** additional sampling and photo-identification efforts be conducted in key areas, such as the northern Chukchi, with the goal of evaluating whether additional structure exists on feeding areas used by the ENP stock.

Genetic analyses of samples derived from the bones or baleen of pre-depletion western North Pacific gray whales was also recommended in SC/A14/NPGW01. Few known sources of such specimens have been identified, and finding additional samples would be difficult. It is unlikely that significant progress could be made in the near future. However, a smaller-scale project aimed at reviewing museum collections, archeological literature, and records of whaling station locations would be valuable in evaluating whether such samples exist. For such a project to be successful, it would be beneficial to identify scientists, ideally in countries bordering the range of gray whales in the western North Pacific, to conduct such work. This work should be considered a medium priority task for the future.

The Workshop noted the important contribution of the telemetry information provided and **recommends** further work in all areas, especially off Chukotka, Sakhalin and Kamchatka.

The Workshop **recommends** that existing acoustic data be analyzed for the presence of gray whale calls. Such an analysis would provide valuable information on gray whale distribution as well as on the presence of gray whales north of the Aleutians during winter months, and this work should be considered a medium priority task for the future.

4. REMOVAL DATA (TAKING INTO ACCOUNT DISCUSSIONS UNDER ITEM 2)

4.1 Commercial catches [post 1850]

4.1.1 Western North Pacific

Before the beginning of modern commercial whaling in this region, there was a long but poorly documented history of gray whale exploitation by hand harpoon and netting. In Japan, gray whales were probably hunted by hand harpoon from the late 16th century and they were definitely taken by net whaling beginning in the late 17th century (Omura, 1984). Net whalers took 50-60 gray whales annually from 1675-1890 (Omura, 1984) and between 1891-1899 they took at least 44 in Korea (16, 15 and 13 in 1890/91, 1891/92 and 1898/99 respectively; Park, 1987; Kato and Kasuya, 2002) and at least 29 in Japan (Omura, 1984). Japanese net whaling ended around 1900, at approximately the same time that modern whaling companies were being formed.

From the 1840s to mid-1880s, American sailing vessel whalers searched the Okhotsk Sea for bowhead whales and hunted gray whales as secondary targets, taking at least a few hundred in total in that region over an approximately 40-year period (Henderson, 1984; Reeves *et al.*, 2008).

A Russian company based in Haydamak (180km east of Vladivostok) initiated modern whaling in Asian waters. This company operated off the Korean Peninsula in some winters from 1890 until 1904 (Tønnessen, 1973; Kato and Kasuya, 2002). Gray whales that were killed in this operation were transported to Japan. Yablokov and Bogoslovskaya (1984) reported that gray whales were hunted sporadically by Russians near Peter the Great Bay, Russia, during World War II (WWII) but those authors provided no numbers or details on this operation.

The first catch numbers for gray whales by modern commercial whaling listed for Japan by Kato and Kasuya (2002) was of 23+ whales in 1900. However, catching must have started at least a few years earlier - Kato and Kasuya indicate '?' in their Japan catch column for 1898 and see Omura, 1984). Andrews (1914) reported

Captain Melson was the first whaler to learn to take 'Devilfish' in Korean waters and it was he who laid the foundation for the winter fishery which has been so successfully prosecuted there by the Japanese for the last fifteen years.

Brownell reported that Andrews visited the Toyo Hoge Ulsan whaling station in January-February 1912, so 15 years earlier would be 1897.

Japanese whaling operations in Korean waters started in 1898 but were limited. In 1909, Toyo Hoge opened a land station at Ulsan that operated for a number of years after Japan annexed Korea in 1910.

Modern whaling operations started in Japan in 1898, but only a few gray whales were taken there after the turn of the century (Kasahara, 1950; Omura, 1984). From at least 1909 onwards, several land stations on the central-eastern and south-eastern coasts of Korea were operated by Japan until 1945 at the end of WWII (Kasahara, 1950; Kato and Kasuya, 2002).

Kasahara (1950) reported that smaller catches were made in western Korea (Yellow Sea) and catches totalling at least 244 from 1911 to 1927 were made in north-eastern Korea (Broughton Bay, 40°N). The catch record is particularly poor and incomplete for the period 1898-1910, which is unfortunate since the available catch record

suggests that substantial numbers of gray whales were taken during those years. For example, at least 125 gray whales were taken in 1907 and 193 in 1912, which could mean that significant numbers were also taken in the years before 1907 and from 1907-1911. By the 1930s, total annual catches of western gray whales had declined to fewer than 50 (Kato and Kasuya, 2002).

The only known 'sizeable' catches of gray whales after WWII were by Korean whalers off southeastern Korea (Brownell and Chu, 1977). According to Brownell, post-WWII Records of bycatch and direct catches in Japanese waters probably total fewer than 20.

Twentieth century catch data compiled primarily by Bradford and Brownell from published sources are summarised in Table 4. The full Table is given as Annex F.

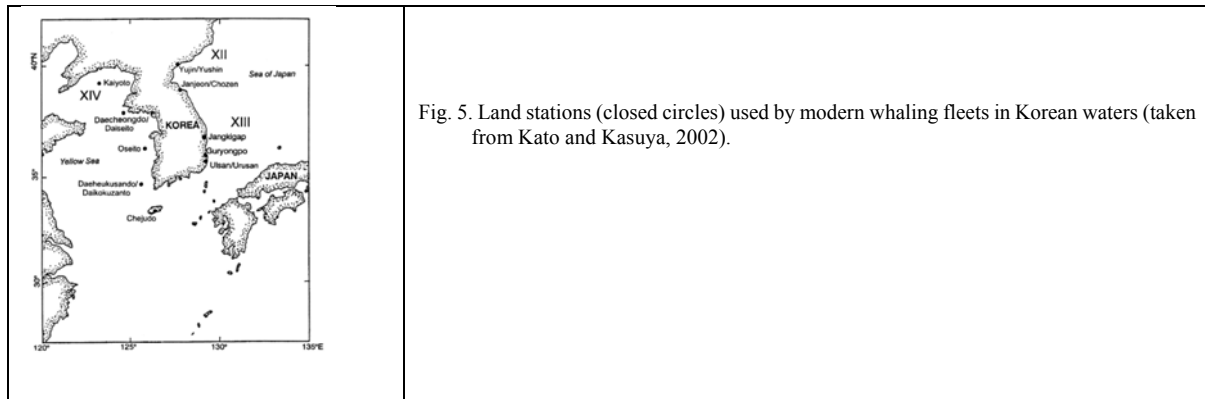

Table 4

Twentieth century catches for the western North Pacific by year based upon published sources. For details see Annex F.

Year	China	China?	Japan	Korea	Korea?	Russia	Unknown	Total
1900			2	23				25
1902				9			5	14

Total	5	2	49	1326	7	2	477
							1868

Although it is known that modern whaling for gray whales in the western North Pacific started in the 1890s and that some catches of gray whales were made in Korean waters, catch data are extremely sparse for years prior to 1904. Because of the likelihood (explained above) that substantial catches were made in at least some years between 1890 and 1910, the Workshop **recommends** that an investigation or investigations be carried out to obtain information on whaling effort (e.g. numbers of vessels, captains, stations) and other aspects (e.g. suspension of effort due to the Sino-Japanese War), by year, that could be used to estimate catches for these years by inference, interpolation or extrapolation using the known catches in 1907 and 1913 as a starting point (see Reeves and Smith, 2010). Such a study will require participation by researchers with appropriate language abilities – i.e. at least Japanese, Russian and Norwegian.

4.1.2 Eastern North Pacific

An agreed catch series for commercial catches and special permit catches of eastern North Pacific gray whales 1846-2009 is available from the IWC SC meeting in 2010 (IWC, 2011; JCRM 12, Suppl., p 145 and Appendix 3).

Ilyashenko reported that he had learned from a Russian fishery agency official in the Russia embassy in North Korea that the whaling catcher boat (as pictured on a postage stamp from 19xx – *fide* RLB) is no longer in operation. Only dolphins are hunted nowadays in North Korea and this hunting is done from military vessels.

4.1.3 Future

The Workshop **agrees** that modelling exercises will assume no commercial catches in the future.

4.2 Aboriginal subsistence catches

4.2.1 Past

WESTERN PACIFIC

There is little information on aboriginal subsistence whaling for western gray whales. Maritime Koryak people along the north-eastern Okhotsk Sea hunted whales, presumably including both bowhead and gray whales (Krupnik, 1984).

EASTERN PACIFIC

The aforementioned catch series agreed in 2010 for the eastern North Pacific (JCRM 12, Suppl., p 145 and Appendix 3) includes aboriginal catches, very crudely estimated from an unpublished compilation of literature by Mitchell and Reeves (in 1990) for 1600 to around the 1940s, and estimated with somewhat more precision thereafter through 2009 from a variety of sources. Reported catches since 2009 will need to be added to update that series.

4.2.2 Future

The current block quota for aboriginal subsistence whaling of gray whales is 744 for 2013-2018 (no more than 140 in any one year). No hunting of gray whales in Alaska is currently permitted and none is planned or foreseen. No hunting by the Makah in Washington State is currently permitted but the Tribe is continuing its efforts to obtain a quota for four removals per year. The Workshop **agrees** that modelling exercises should consider the range of catches used in the AWMP trials (IWC, 2011). Assumptions on allocations of removals will need to be made for the various stock structure hypotheses.

4.2 Incidental catches in fishing gear

4.2.1 Past

Like other cetaceans, gray whales are susceptible to entanglement or entrapment in various types of fishing gear. Several gray whales are known to have died in fishing gear (mainly set nets) in Japan – 1 in 1955, 1 in 1970, and 4 from 2005-2007 (Weller *et al.* 2008). Another died in 1996 from being harpooned and entangled in harpoon lines used to catch Dall's porpoises off Japan.

Based on a collection of digital and film images of gray whales off Sakhalin, Bradford *et al.* (2009) estimated that 20.0% (30 of 150) of whales identified from 1995-2004 had detectable anthropogenic scarring, with 18.7% ($n = 28$) determined to have been previously entangled in fishing gear at least once. However, Brownell noted that this rate is underestimated as photographs were not available for all areas of each whale.

In the eastern North Pacific, at least tens of gray whale deaths have been documented in gillnets (e.g. for salmon and herring), seine nets, net pens, longlines and pot or trap lines since the 1970s (Heyning and Lewis, 1990; Baird *et al.* 2002; Scordino and Mate, 2011). Carretta noted that about three fishery-related deaths or serious injuries to gray whales are reported in US waters each year. Most documentation is from opportunistic reports rather than systematic fishery observer programs. From 1990-2013 some 18,000 fishing sets were observed in the California offshore drift gillnet fishery (about 15% observer coverage) and inshore set gillnet fishery (5-10% coverage but not observed every year) but only four entanglements of gray whales were documented.

Carretta acknowledged that observed and reported bycatch represents only a fraction of the likely actual bycatch. Punt and Wade (2012), for example, estimated that only 3.9-13% of gray whales that die in a given year end up stranding and being reported. Carretta drew attention to SWFSC data suggesting that only about a quarter of the carcasses of common bottlenose dolphins that die in California each year are recovered, this despite the fact that these dolphins spend about 95% of their time in nearshore waters within 500m of land.

4.2.2 Future

As part of the *AWMP Implementation Review* for eastern gray whales, existing data were reviewed and scenarios of future removals determined (IWC, 2013). The Workshop **agrees** that this approach should be updated (see Item 4.5) for the whole North Pacific. Assumptions on allocations of removals will need to be made for the various stock structure hypotheses.

4.3 Ship strikes

4.3.1 Past

No records are available of ship strike mortality of gray whales in the western North Pacific. However, a small percentage of the whales photo-identified off Sakhalin ($n = 3$, or 2.0%) showed evidence of having survived at least one vessel strike (Bradford *et al.* 2009).

Laist *et al.* (2001) reported that of the various large whale species reported struck by ships, gray whales were one of the most frequently hit. Carretta reported that in addition to fishery-related deaths and serious injuries, approximately two gray whale deaths and/or serious injuries are attributed to ship strikes each year in US waters. These data reflect the most recent 5-year time period reported in US marine mammal stock assessment reports⁵.

4.3.2 Future

As part of the *AWMP Implementation Review* for eastern gray whales, existing data were reviewed and scenarios of future removals determined (IWC, 2013). The Workshop **agrees** that this approach should be updated (see Item 4.5) for the whole North Pacific. Assumptions on allocations of removals will need to be made for the various stock structure hypotheses.

4.5 Recommended time series for use in modelling framework

The Workshop **agrees** that the determination of time series of removals cannot be completed until the work outlined under Item 4 has been reported. For initial runs, this should be agreed at SC65b.

5. ABUNDANCE AND TRENDS

5.1 Review of available data and analyses

5.1.1 Western North Pacific

5.1.1.1 INDIVIDUAL IDENTIFICATION (PHOTO AND GENETIC)

The Russia-US team has been collecting gray whale photo-id data near Piltun lagoon from 1994 to the present. Since 2008, the project has been run solely by the Kamchatka Branch of the Pacific Institute of Geography (Burdin *et al.*, 2013). The IBM team (Institute of Marine Biology, Vladivostok) has been collecting photo-id data off Sakhalin since 2002 as part of the Sakhalin Energy/Exxon Neftegaz Limited (ENL) Joint Programme (Tyurneva *et al.*, 2013). Gray whale photo-id data have also been collected off south-eastern Kamchatka since 2006 (Tyurneva *et al.*, 2013).

The last time the catalogues were compared (using data through 2011), there was a total of 223 distinct whales in the Sakhalin catalogues, of which 187 were common to both catalogues (IUCN, 2013). Of the 150 distinct whales in the Kamchatka catalogue, 86 were found in at least one of the Sakhalin catalogues.

As of the 2013 season, the Russia-US Sakhalin catalogue contained 225 whales, which is probably more than the total number of whales currently alive in the Sakhalin population. Of these whales, 155 have been sexed genetically from biopsies.

⁵ <http://www.nmfs.noaa.gov/pr/sars/species.htm>

An assessment using the Russia-US data through 2011 was presented in SC/65a/BRG27. Cooke's model had been updated to allow:

- (i) individual heterogeneity in sampling probability;
- (ii) time lags in the effects of environmental variability on population parameters;
- (iii) immigration of 'foreign' whales (i.e. whales whose mothers were not in the Sakhalin population).

The standard AIC criterion for goodness of fit of the model to the data was used to determine which of those new factors were to be included in the final model choice. As in previous assessments, the sampling probability was found to be significantly stage-dependent: highest for mothers with calves and lowest for non-calf immature animals. Allowing, additionally, for individual heterogeneity in sampling probability resulted in a very substantial improvement in the fit of the model to the data, but it had only a small effect on estimates of population size and demographic parameters. Significant inter-annual fluctuations were found in both calving rates and calf survival rates, but no evidence was found of any net trend in these parameters over time. The best fit to the data was obtained by introducing a 2-year time lag into the correlation between calving rates and calf survival rates, i.e. a low (high) calf survival rate from year t to year $t+1$ tends to be associated with a low (high) calving rate in year $t+2$. There was little evidence for immigration: the level of immigration was estimated to be zero or negligible in recent years, but immigration earlier in the period could not be excluded.

As reported by IUCN (2013), the selected model was also fitted to: (a) the Russia-US data set, (b) the combined Russia-US and IBM Sakhalin data set and (c) all three data sets combined (Russia-US, IBM and Kamchatka, but only including whales seen at least once off Sakhalin). Estimates of key population parameters for each of the three data sets are listed in Table 5. The estimates of population size over time are shown in Fig. 6 for (i) the population aged 1+ (i.e. all animals except calves) and (ii) mature females only.

Table 5 – to come from Cooke

Fig. 6. Estimated population trends for the Sakhalin gray whale population for (i) aged 1+ animals (all animals except calves) and (ii) mature females only, for three data sets: (a) Russia-US(RUS) only; (b) RUS and IBM; (c) RUS, IBM and Kamchatka.

Combining the three data sets without considering potential differences between them may not be a valid approach. In particular, it is noted that relatively few subadult animals are included in the Sakhalin catalogues, and there is an indication that these may be better represented in the Kamchatka catalogue. Work is in progress to extend the model to allow for differences between data sets and locations, and to allow explicitly for the fact that

whales were selected on the basis of having been seen at least once off Sakhalin. In the meantime, the estimates of population growth rate ($3.4\% \pm 0.5\%$) and other demographic parameters obtained from fitting only to the Russia-US data set should be considered the best currently available for the Sakhalin feeding aggregation.

5.1.1.2 SIGHTINGS

The sightings work off Sakhalin Island undertaken as part of the Sakhalin Energy/ENL joint programme (e.g. see summaries in IUCN WGWAP reports) is not designed to estimate abundance but provides information on density and distribution for a portion of each summer season and can be used to examine changes in these by year.

5.1.1.3 PREVIOUS ANALYSES, MODELS AND ASSUMPTIONS (INCLUDING HISTORICAL CATCH SERIES)

An initial effort to model the population dynamics of gray whales in the WNP including historical catch was made by Bradford (2003). Mark-recapture survival estimates, in combination with other life history parameters, were used to calculate a current (1997-2002) population growth rate of gray whales feeding off Sakhalin Island, Russia, which were assumed to represent the western population of gray whales. This growth rate estimate and historical catch data were applied to a 20th century back calculation of the western gray whale population. Bayesian statistics were used to estimate model parameters and indices of population status. A mark-recapture estimate of current (2002) abundance off Sakhalin was treated as a model input to project the population using the backwards method described by Butterworth and Punt (1995). Back calculation results indicated that the western gray whale population should currently be growing at its maximum net recruitment rate, has an undefined carrying capacity, is currently at most between 8-9% of its original size, and has been highly depleted for over half of the 20th century. This assessment can be considered invalidated given the connection between at least some Sakhalin whales and the ENP.

5.1.3 Eastern North Pacific

5.1.3.1 INDIVIDUAL IDENTIFICATION (PHOTO AND GENETIC)

Individual photo-identification data have been collected from the Mexican lagoons and all the way to northern Alaska near Barrow, but mark-recapture abundance estimates have been produced only for the PCFG, defined spatially from 41° - 52° N and temporally from 1 June – 30 November. The data, estimation methods and results are described in SC/A14/NPGW03. A collaborative survey effort was conducted from 1998-2012 that covered survey regions between 41° N- 52° N (Northern California (NCA) to Northern British Columbia (NBC)). Additional data collected in 1996-1997 with less extensive effort was included to improve the earlier estimates in the time series. The current estimated abundance for 2012 excluding transient whales is 209 (SE=15.4). The annual survival estimate of adults was 0.963 (SE=0.0079) using whales first seen prior to 1999. For whales first seen after 1999, the post first-year survival estimate of adults was 0.905 – a relatively low value which reflects both mortality and permanent emigration from the PCFG by whales that initially entered this population in 1999 or later at the time of or after the 1999-2000 stranding event⁶. Calf survival estimates are first-year survival estimates which can include permanent emigration of calves associated with mothers that were transient and calf mortality within the photo-id season. The calf survival estimates ranged from 0.35 to 0.9 for calves with minimum tenure of 1 to 125 days. The average was 0.54 (SE=0.047).

5.1.3.2 SIGHTINGS

Counts of southbound migrating whales off California at Granite Canyon form the basis of abundance estimation for the eastern North Pacific stock of gray whales. Previous assessments (1967-2007) have estimated detection probability (p) from the detection/non-detection of pods by two independent observers (Laake *et al.*, 2012). However, tracking distinct pods in the field can be difficult for single observers, resulting in biased estimates of pod sizes that needed correcting, and matching observations of the same pod by both observers involved key assumptions. Due to these limitations, a new observation approach has been adopted wherein a paired team of observers work together and use a computerized mapping application to track and enumerate distinct pods and tally the number of whales passing during watch periods (Durban *et al.*, 2013). This approach has produced consistent counts over four recently monitored migrations (2006/7, 2007/8, 2009/10 and 2010/11), with an apparent increase in p compared to the previous method. To evaluate p and estimate abundance in these four years, counts from two independent stations of paired observers operating simultaneously were compared using a hierarchical Bayesian 'N-mixture' model to estimate p and abundance without the challenge of matching pods between stations. The overall average detectability $p_o = 0.80$ (95% Highest Posterior Density Intervals [HPDI] = 0.75-0.85) varied with observation conditions, observer effects and changes in whale abundance during the migration. Abundance changes were described using Bayesian model selection between a parametric model for a normally distributed common migration trend and a semi-parametric model that estimated the time trends independently for each year; the resultant migration curve was a weighted compromise between models, allowing for key departures from the common trend. The summed estimates of migration abundance ranged from 17,820

⁶ Darling commented that he was undertaking some analysis to examine the interpretation of the 1999-200 data.

(95% HPDI = 16,150-19,920) in 2007/8 to 21,210 (95% HPDI = 19,420-23,230) in 2009/10, consistent with previous estimates and indicative of a stable population.

5.1.3.3 PREVIOUS ANALYSES, MODELS AND ASSUMPTIONS (INCLUDING HISTORICAL CATCH SERIES)

Population models including historical catch have been constructed for the ENP as a single stock by Punt and Wade (2010) and for the PCFG as a plausible stock by Punt and Moore (2013). Punt and Wade (2010) constructed an age- and sex-structured population dynamics model which was fitted using Bayesian methods to data on the catches and abundance estimates for the ENP stock. They concluded that this stock was at its optimum sustainable population (OSP) level with probability 0.884. Punt and Moore (2013) constructed a deterministic, age- and sex-structured model that consisted of two groups (the 'north' group and the PCFG), which were assumed to be separate for purposes of the analysis, but with possible immigration (permanent movement) between them. With variants of the model, the probability that the PCFG was at OSP ranged from 0.35 on the low end (models F and G) to 0.88 on the high end. They concluded that additional data were needed to obtain better empirical estimates of bycatch mortality and net annual immigration rates, and to reduce uncertainty in Maximum Sustainable Yield Rate (MSYR) and Maximum Net Productivity Level (MNPL) that would potentially improve inferences about the likelihood of the PCFG being at OSP.

5.1.4 Consideration of integrated approach taking into account discussions under Item 2

The Workshop **agrees** that initially, a simple modelling approach will be used that will take into account the above information on abundance and trends (see Item 8). The Workshop also **recommends** that the existing ASAMM data should be analysed to examine trends in relative abundance over the longest period possible to assist in the modelling exercise.

6. POPULATION PARAMETERS

6.1 Review of available data and analyses

A number of biological parameters have been estimated for North Pacific gray whales or could be estimated from currently available data. These estimates are both model-derived and empirical and are summarised in Table 6. Abundance estimates from data collected off California have been used a number of times to model eastern gray whale population dynamics (Cooke, 1986; Lankester and Beddington, 1986; Punt and Butterworth, 2002; Reilly, 1981; Wade, 2002). The model-derived parameter estimates presented in Table 6 reflect the recent modelling effort by Punt and Wade (2012).

6.2 Consideration of integrated approach taking into account discussions under Item 2

The Workshop **agrees** that for the initial modelling purposes, the same values as used in the AWMP trials will be used for the eastern side of the North Pacific; for the western North Pacific, the values from Sakhalin can be used. This will need to be revisited by the Scientific Committee at a later stage.

7. HUMAN ACTIVITIES (OTHER THAN DIRECT REMOVALS) THAT MAY (OR MAY IN THE FUTURE) AFFECT STATUS

7.1 Habitat degradation and modification e.g. by climate change

Sue Moore briefly summarised the impact of climate change on gray whale Arctic habitats, especially the dramatic loss of volume and seasonal areal extent of sea ice Jeffries *et al.*, 2013. Compared to the 1980s, the Pacific Arctic sector (NBS/SCh) is now ice-free roughly 1-2 weeks earlier each spring, and sea ice forms there about 3-4 weeks later each autumn. So gray (and other baleen) whales have 1-1.5 months longer to feed in ice-free habitat. In addition, the loss of sea ice appears to be accompanied by an increase in primary production in the Pacific Arctic sector⁷, which may result in more prey for gray and other baleen whales. Finally, a step-change in inflow of Pacific water through the Bering Strait (50% increase in volume, 2001-2011) may be transporting prey (especially krill) into the SCh and NCh gray whale habitats.

Ilyashenko reported that hunters in Chukotka are having difficulty hunting gray whales because the whales stay farther offshore as ice cover declines (ice is now often >10km offshore in northern Chukotka).

7.2 Industrial activities

The dramatic reduction of sea ice in the Arctic has been accompanied by an upsurge in industrial activities in the Pacific Arctic sector (NBS/SCh), particularly with regard to commercial shipping and oil and gas exploration. Commercial ship passage between Europe and China can be roughly 12 days shorter along the Northern Sea Route (NSR) compared to a route through the Suez Canal. However, because great uncertainties remain regarding

⁷ http://www.arctic.noaa.gov/report12/primary_productivity.html

reliable transit along the NSR, it remains unclear whether the NSR is likely to develop into a major shipping artery. This matter was covered extensively at the IWC Arctic Impacts workshop (cite report). Oil and gas exploration, including seismic surveys and destination ship transits, will increase the risks of ship strikes (especially at narrow passages such as Bering Strait) and toxic spills (including oil) and bring more underwater noise to the region. These matters were also discussed at the Arctic Impacts workshop and are also discussed at annual meetings of the SC/E group (ref. SC 65a).

As in the case of Item 7.1, the Workshop recognised that this agenda item also applies to non-Arctic portions of the gray whale's range (certainly including Sakhalin Island and coastal regions of Korea, Japan and China). A number of anthropogenic threats to gray whales in the western North Pacific give cause for concern. For instance, incidental takes in fishing gear throughout the range may pose a threat to gray whales as discussed under Item 4.3. Near-shore industrialization and shipping congestion throughout the migratory corridor(s) represent additional risks by increasing the likelihood of exposure to pollutants and ship strikes as well as a general degradation of the habitat. Finally, the summer feeding area off Sakhalin Island is a region rich with offshore oil and gas reserves. Two major offshore oil and gas projects now directly overlap or are in near proximity to this important feeding area, and more development is planned there and in other parts of the Okhotsk Sea that include the migratory routes of these whales. Operations of this nature have introduced new sources of underwater noise, including seismic surveys, as well as increasing ship traffic and the risk of oil spills. Considerable information has been published in reports of the IWC SC, the report of the 2008 IUCN rangewide workshop, and various reports by the IUCN gray whale panels (see <http://www.iucn.org/wgwap/>).

7.3 Other

Military activities, research and tourism have also increased in the Arctic and elsewhere in the gray whale's range but no new information on these issues was presented at this Workshop.

7.4 Consideration of how these may be incorporated into a modelling framework

In an ecological context, the impacts of human activities on gray whales must be incorporated as an additional level of habitat variability coupled to that of climate change. The whales experience 'one habitat', which reflects the combined outcome of 'natural' variability and human activities. With regard to gray whale population structure and status, the potential for increased lethal takes (by ship strike) and habitat alteration and degradation (by increased offshore activities) in the Pacific Arctic sector is recognized, but for now impossible to quantify. The Workshop **agrees** that further consideration as to how to incorporate these factors into the modelling framework should take place after the initial simple modelling has been undertaken (see Item 8).

8. DEVELOP MODELLING APPROACH/SCENARIOS

The development of a population dynamics model for North Pacific gray whales will necessarily be an iterative process. The first step is to develop an age- and sex-aggregated model which includes multiple stocks (two or three depending on the hypothesis under consideration). The aim for developing this model will be primarily to understand whether sufficient data are available to justify the various stock structure hypotheses and whether parameterization of the model based on the associated hypotheses can provide reasonable fits to the data. The data included in the first step model will be the catches by area and month and the trends in 1+ abundance for the Sakhalin feeding area, the PCFG and the counts off southern California. The model will mimic the assumptions regarding how catches off North America and Chukotka are allocated to breeding stock.

The estimable parameters of the first step model will be the initial sizes of each breeding stock, the rate of increase of each stock in the limit of zero population size, and the levels of immigration and emigration into and out of the PCFG. The proportion of each stock which is found in each area will initially be pre-specified, but some of these parameters will be treated as estimable in the second and subsequent steps. The first step model should initially try to start the model projections for the system at unfished equilibrium. However, the fits to the data may be very poor unless allowance is made, for example, for changes in carrying capacity over time. Consequently, model runs should be produced when the model is initialized in a more recent year. The first step model should explore assumptions regarding the dynamics prior to the 1990s of the whales that feed off Sakhalin.

The results of the initial model fits will be reviewed by the Scientific Committee and this review may lead to refinement of the stock structure hypotheses, including rejection of some hypotheses which are clearly inconsistent with the available data.

The second step in the modelling process, assuming that the Scientific Committee considers the first phase a success, would be to extend the model to include age and sex structure and to include data on mixing proportions based on telemetry and genetics data. Subsequent steps may be required depending on how well it is possible to mimic the available data, and to explore the impact of future catches and other human activities.

The Workshop established an intersessional working group with members Punt (chair), Bradford, Cooke, Donovan, Lang, Mate and Weller to develop a set of model specifications for the first step in the modelling process.

9. WORKPLAN UP TO 2014 IWC ANNUAL MEETING AND BEYOND

9.1 Prior to SC65b

Develop the mathematical specifications for an age- and sex-structured model and identify data gaps (Punt, with help from the intersessional working group).

9.2 During SC65b

- (1) Implement the age- and sex-structured model for one hypothesis as a proof-of-concept (Punt).
- (2) Refine the specifications of the age- and sex-structured model.
- (3) Develop detailed terms of reference for the 2nd workshop.

9.3 After SC65b

Use the age- and sex-structured model to explore the remaining hypotheses.

10. RECOMMENDATIONS

10.1 Conduct a preliminary comparison of photographically and genetically identified gray whales in Mexico, off central California and in the PCFG with a focus on mothers and calves.

Objectives

- (1) Improve assessment of internal recruitment to the PCFG by identifying PCFG whales known to have given birth in Mexico (would increase the sample size of known PCFG mothers).
- (2) Improve estimates of calf survival for PCFG whales by identifying mothers with calves on wintering grounds and during migration and determining whether the calves were ever sighted again.
- (3) Improve determination of the number of known reproductive PCFG females that have been biopsied. This would come about two ways: 1) the comparison would reveal some biopsied PCFG whales that were not previously known to be reproductive females and 2) some PCFG whales that match to Mexico but have not been biopsied in the PCFG may prove to have been biopsied in Mexico.

Tasks

- (1) Conduct a rapid comparison of the approximately 1,500 photo-identified gray whale mothers known to have been accompanied by calves in Mexico from 2010-2014 and off central California from 2012-2014 to a subset of the catalogue (maintained by Cascadia Research Collective, CRC) consisting of known PCFG whales photo-identified in multiple years. This work would be carried out by the primary CRC photo-matcher who is familiar with PCFG whales and he/she would examine all Mexico/central California mothers for any that are recognized and then compare any familiar whales to the catalogue to verify the match. When a match is found, the calf of the mother will be compared to the full catalogue (all whales) maintained by CRC.
- (2) Conduct a simultaneous comparison by matchers at UABCS of the approximately 50 known PCFG mothers to the 1,500 Mexico mothers with calves. This will both provide an independent check on the comparison above and help explain some of the long gaps between calves observed with PCFG mothers – e.g. the female did have a calf in a given year but it was missed.

10.2 Develop Single Nucleotide Polymorphisms (SNP) assays for use with gray whales

Objectives

The development of a SNP panel be developed for use with gray whales would:

- (1) allow integration of genetic data between labs as well as over time, increasing the utility of such data for future analysis;
- (2) allow work with low-quality samples, such as bone and baleen, which could facilitate analysis of any historic samples identified.

10.3 Increase the sample numbers and sample coverage for the eastern North Pacific stock of gray whales

Objectives

While a high proportion of the whales using the Sakhalin feeding ground have been sampled, the proportion of the eastern North Pacific stock that has been sampled is low. In addition, few or no samples have been collected from some parts of the range of eastern North Pacific stock. Such studies are essential to improve comparisons amongst areas, better examine stock structure in the feeding grounds and improve stock structure hypotheses to allow for improved conservation and management via modelling.

Methods

Efforts should be made wherever practical to increase additional sampling and photo-identification efforts in key areas, such as the northern Chukchi, with the goal of evaluating whether additional structure exists on feeding areas used by the ENP stock.

10.4 Improve abundance and trend estimates for the PCFG by identifying and using additional photographic sources (Calambokidis, Darling and Laake)

Objectives

It is important to know the degree to which there was large-scale recruitment into the PCFG during the period prior to around 1998 (which would have to have been from an external source) to evaluate the status of the PCFG. The previous AWMP trials have made assumptions about a pulse increase in recruitment to PCFG. This was because broad-scale collaborative photo-ID sampling of a large portion of the PCFG began in 1998, shortly before the large-scale gray whale mortality event in 1999. Abundance trend models show a sharp increase at the beginning of the sampling that extends through the early 2000s. The addition of some of the partial data available from 1996 and 1997 did not allow for accurate abundance estimates in those years but it did cause the estimates for 1998 to increase somewhat.

Method

It is known that some additional identification photographs from 1996 and 1997 are available from other investigators, naturalists and opportunistic sources. These should be identified and investigated to see if they can inform the trend analysis of the PCFG and thereby improve understanding of recruitment for this population.

10.5 Compare photographs of gray whales from areas of the Okhotsk Sea and elsewhere in Asia with the Sakhalin and Kamchatka catalogues (e.g Weller, Bradford, Tyurneva...)

Objectives

To better understand the stock structure and movements of gray whales on the western side of the North Pacific.

Method

Photographs have been taken of gray whales encountered in other parts of the Okhotsk Sea aside from Sakhalin Island (e.g. Shantar Archipelago, Kuril Islands, Magadan) and have been archived by both the Russia-U.S. western gray whale research program and the Institute of Marine Biology (IBM), Vladivostok. Subsets of these photographs have been compared previously by both teams to individuals photographed off Sakhalin Island (e.g. Weller *et al.* 2002, 2003), but a combined matching effort has not been attempted. The Workshop **recommends** that all available photographs of gray whales outside of Sakhalin in the Okhotsk Sea (and potentially other parts of the western Pacific) be catalogued and matched against the two Sakhalin catalogues.

10.6 Putting bounds on the proportion of Sakhalin whales that migrate to the eastern North Pacific in winter (Cooke)

Objective

In order to further questions of stock structure and whether ‘true’ western gray whales regularly feed off Sakhalin, it is of great interest to determine what proportion of Sakhalin gray whales migrate to the eastern North Pacific. In statistical terms, the question is what bounds, or confidence limits, can be placed on the proportion that migrates to the eastern North Pacific.

Data sources

The three sources of data are: telemetry, photo-id and genetic. The provisional results obtained so far include:

Data source	Matches	Comparison
Telemetry	3	Sakhalin whales tracked to E. Pacific (out of 3 tagged for which transmissions lasted sufficiently long)
Photo-identification of individuals	5	Sakhalin whales matched to PNW catalogue
	17	Sakhalin whales matched to Mexican catalogue
	3	Sakhalin whales matched to other ENP catalogues
Genetic identification of individuals	3	Sakhalin whales matched to ENP samples

The interpretation of the genetic and photo-id data requires specifying the sizes of the samples in which the matches were found. Because this varies over the years, the sample sizes by year are needed.

Data required for analysis

For each year of each catalogue (at least the Sakhalin, Mexican and Pacific Northwest):

- (1) number of distinct whales photo-identified that year;
- (2) number of new whales photo-identified that year; and

- (3) for each match between Sakhalin and another catalogue, years for each catalogue in which that whale was photo-identified.

In the case of the Pacific Northwest (PNW) catalogue, whales deemed to belong to PCFG should be omitted. Other catalogues can be included where practicable.

Genetic identification data should be summarized in a similar way to the photo-id data, but the sample sizes are generally lower.

Proposed analysis

The proposed analysis is to apply a capture-recapture model to each source of data to yield a combined likelihood for the proportion p of Sakhalin whales that migrate to the eastern North Pacific in winter. Two models will be considered:

- (1) each Sakhalin whale migrates to the eastern North Pacific with a probability p each year
- (2) a fraction p of Sakhalin whales migrates to the eastern North Pacific each winter; the rest do not.

Other models can be considered if the data warrant this. The results will be expressed in terms of confidence intervals for p .

10.7 Continued development of the population model for the Sakhalin feeding area

The Workshop **strongly encourages** the continued development and publication of the Cooke approach. It **reiterates** the importance of careful incorporation of all relevant data from Sakhalin and Kamchatka into the model (e.g. see IWC, 2013).

10.8 Continued telemetry studies

The IWC Scientific Committee has several times reiterated the great importance of further telemetry studies, particularly off Sakhalin, Kamchatka and in the northern areas such as Chukotka. This work not only can inform on migration routes and usage but also on determining the likelihood of whales from various areas being taken in hunts, fishing gear or ship strikes. The Workshop **reiterates** this and **recommends** that such work be undertaken.

10.9 Improved estimates of western North Pacific catches 1890-1910 (to come from Brownell and Reeves)

Objective

To determine whether it is possible, and if so to estimate, the likely large catches for the years 1890-1910 in the western North Pacific around the Korean Peninsula.

Method

Carry out a literature/museum/logbook investigation to obtain information on whaling effort (e.g. numbers of vessels, captains, stations) and other aspects (e.g. suspension of effort due to the Sino-Japanese War), by year, that could be used to estimate catches for these years by inference, interpolation or extrapolation using the known catches in 1907 and 1913 as a starting point (see Reeves and Smith, 2010). Such a study will require participation by researchers with appropriate language abilities – i.e. at least Japanese, Russian and Norwegian.

10.10 Improved estimates for future ship strikes and bycatches throughout the whole North Pacific (Scordino and Carreta)

Objective

To develop future removal series to be used in modelling for the entire North Pacific.

Approach

To extend the approach to determine future non-deliberate removals used for the AWMP trials (e.g. see Scordino and Mate, 2011; IWC 2013) and update this for the whole North Pacific. Assumptions on allocations of removals will need to be made for the various stock structure hypotheses.

10.11 Develop plans for a second workshop to review the results of the initial modelling exercise

The Workshop **recommends** that the Scientific Committee begins to plan for a second workshop to review the modelling results recommended from the present workshop as part of the process towards meeting the long term objective of improving conservation and management of this species.

11. ADOPTION OF REPORT

Most of the report text and the recommendations were agreed and adopted on the last day of the Workshop. Additional drafting and editing work was conducted after the Workshop and all participants were given the opportunity to review and comment by e-mail before the report was finalised. This version was completed on 13

May 2014 although some participants had yet to comment. The Chair thanked the participants for their enthusiasm to participate in all aspects of this wide-ranging workshop, whatever their primary disciplines. He noted that this was an important step to understanding the status of gray whales throughout the North Pacific and for determining management and conservation priorities. He also re-iterated thanks for the wonderful facilities provided by the SWFSC. The Workshop participants thanked the Chair for steering them through a long and complex agenda, with good humour and fairness.

Annex A

List of Participants*

Scott Baker

Oregon State University, USA.

John Bickham

Department of Forestry and Natural Resources and
Center for the Environment, Purdue University.

Amanda Bradford

NOAA, Hawaii.

Robert Brownell Jr.

Southwest Fisheries Science Center, La Jolla, CA
USA.

John Calambokidis

Cascadia Research, California.

Jim Carretta

Southwest Fisheries Science Center, La Jolla, CA
USA.

Justin Cooke

IUCN Cetacean Specialist Group.

Jim Darling

Whale Trust, Canada.

Donna Darm

NOAA fisheries

Greg Donovan

IWC Secretariat

Valentin Ilyashenko

Russian Federation.

Jeff Jacobsen

Humboldt State University, Arcata, CA USA.

Jeff Laake

The National Marine Mammal Laboratory
(NMML).

Aimee Lang

Southwest Fisheries Science Center, La Jolla, CA
USA.

Karen Martien

Southwest Fisheries Science Center, La Jolla, CA
USA.

Bruce Mate

Marine Mammal Institute, Oregon State University,
OR USA.

Jeff Moore

Southwest Fisheries Science Center, La Jolla.

Sue Moore

NOAA Fisheries, WA, USA.

Wayne Perryman

Southwest Fisheries Science Center, La Jolla.

Andre Punt

University of Washington, Seattle, WA USA

Randy Reeves

Okapi Research, Canada

Lorenzo Rojas-Bracho

National Institute of Ecology, Mexico

Jon Scordino

Makah Fisheries Management, Neah Bay, USA.

Michael Scott

Inter-American Tropical Tuna Commission, La
Jolla, CA USA.

Barbara Taylor

Southwest Fisheries Center, La Jolla, USA.

Jorge Urbán

Universidad Autónoma de Baja California Sur
(UABCS), Mexico.

Dave Weller

Southwest Fisheries Science Center, La Jolla, CA
USA.

*Full addresses to be added later

Annex B

Agenda

1. INTRODUCTORY ITEMS

- 1.1 Convenor's opening remarks
- 1.2 Election of Chair
- 1.3 Appointment of rapporteurs
- 1.4 Adoption of Agenda
- 1.5 Documents and data available

2. SUMMARY OF POPULATION MODELLING APPROACHES THAT HAVE BEEN OR MAY BE RELEVANT FOR NORTH PACIFIC GRAY WHALES

- 2.1 AWMP (including Pacific Coast Feeding Group)
- 2.2 Western North Pacific (Cooke model)

3. STOCK STRUCTURE AND MOVEMENTS

- 3.1 Summary of existing hypotheses
- 3.2 Review of available data and analyses
 - 3.2.1 Genetic data on population structure
 - 3.2.2 Osteological data comparing populations
 - 3.2.3 Individual identification data (photo and genetic)
 - 3.2.4 Telemetry data
 - 3.2.5 Removals data
 - 3.2.6 Sightings data
 - 3.2.7 Biological data
 - 3.2.8 Ecology and behaviour
 - 3.2.9 Other
- 3.3 Discussion of possible population structure hypotheses
- 3.4 Recommendations for hypotheses for inclusion in the modelling framework
- 3.5 Recommendations for future data collection and/or analyses

4. REMOVAL DATA

- 4.1 Commercial catches [post 1850]
 - 4.1.1 Western North Pacific
 - 4.1.2 Eastern North Pacific
 - 4.1.3 Future
- 4.2 Aboriginal subsistence catches
 - 4.2.1 Past
 - 4.2.2 Future
- 4.3 Incidental catches in fishing gear
 - 4.2.1 Past
 - 4.2.2 Future
- 4.4 Ship strikes

4.3.1 Past

4.3.2 Future

4.5 Recommended time series for use in modelling framework

5. ABUNDANCE AND TRENDS

5.1 Review of available data and analyses

5.1.1 Western North Pacific

- 5.1.1.1 Individual identification (photo and genetic)
- 5.1.1.2 Sightings
- 5.1.1.3 Previous analyses, models and assumptions (including historical catch series)

5.1.3 Eastern North Pacific

- 5.1.3.1 Individual identification (photo and genetic)
- 5.1.3.2 Sightings
- 5.1.3.3 Previous analyses, models and assumptions (including historical catch series)

5.1.4 Consideration of integrated approach taking into account discussions under Item 2

6. POPULATION PARAMETERS

- 6.1 Review of available data and analyses
- 6.2 Consideration of integrated approach taking into account discussions under Item 2

7. HUMAN ACTIVITIES (OTHER THAN DIRECT REMOVALS) THAT MAY (OR MAY IN THE FUTURE) AFFECT STATUS

- 7.1 Habitat degradation and modification e.g. by climate change
- 7.2 Industrial activities
- 7.3 Other
- 7.4 Consideration of how these may be incorporated into a modelling framework

8. DEVELOP MODELLING APPROACH/SCENARIOS

9. WORKPLAN UP TO 2014 IWC ANNUAL MEETING AND BEYOND

- 9.1 Prior to SC65b
- 9.2 During SC65b
- 9.3 After SC65b

10. RECOMMENDATIONS

11. ADOPTION OF REPORT

Annex C

List of Documents

SC/A14/NPGW01. Bickham, J., Dupont, J., Broker, K. Status of the western North Pacific gray whale: review of stock structure hypotheses and genetic approaches. 17pp.

SC/A14/NPGW02. Bickham, W. J. The challenge of identifying management units in large, vagile marine animals: meta-analysis reveals why conservation geneticists should think smart not big. 34pp.

SC/A14/NPGW03. Calambokidis, J., Laake, J., and Perez, A. Updated analysis of abundance and population structure of seasonal gray whales in the Pacific Northwest, 1996-2012. 76pp.

Annex D

Summary of genetic data and analyses

Table 1
Available samples by study

Region	Reference	Samples*	Time Period	Type of samples	Month												Utilized mtDNA?	mtDNA bps sequenced	Utilized microsatellites?	# of microsatellite loci	Comments
					1	2	3	4	5	6	7	8	9	10	11	12					
Baja Mexico, all three lagoons	Urban in process	450	2013-2014	Biopsies		x	x										Y (In progress)		N		Approximately 50% of samples processed Urban confirmed that this is a different sample set from Alter et al. 2009
Baja Mexico, Bahia Balenas	Goerlitz et al. 2003	2	1996	Biopsies				x									Y	302	N		
Baja Mexico, Bahia Magdalena lagoon	Alter et al. 2009	32	2001-02, 2005-2006	Biopsies		x	x										Y	442	Y	9	
Baja Mexico, Offshore, San Jose del Cabo	Goerlitz et al. 2009	1	1996	Biopsies				x									Y	302			Urban confirmed that this is a different sample set from Alter et al. 2009
Baja Mexico, Ojo de Liebre lagoon	Alter et al. 2009	24	2001-02, 2005-2006	Biopsies		x	x										Y	442	Y	9	
Baja Mexico, Ojo de Liebre lagoon	Goerlitz et al. 2009	14	1997	Biopsies		x	x										Y	302	N		Urban confirmed that this is a different sample set from Alter et al. 2009
Baja Mexico, San Ignacio lagoon	Alter et al. 2009	56	2001-02, 2005-2006	Biopsies		x	x										Y	442	Y	9	
Baja Mexico, San Ignacio lagoon	Goerlitz et al. 2009	66	1996, 1997	Most biopsies, 4 strandings		x	x										Y	302	N		Urban confirmed that this is a different sample set from Alter et al. 2009
ENP (not specified)	Alter et al. 2007	42															N		N		Incl. sequences from mtDNA cyt B, seven nuclear introns, and one X-linked region.
Migratory, CA/OR/WA (89), AK (9), Chukotka (5)	LeDuc et al. 2002	104	1979-2000	Strandings (91), harvest (6), bycatch (2), biopsies (21)	x	x	x	x	x	x	x	x	x	x	x	x	Y	523	N		Analysis also included n=16 Steeves et al samples, grouped with ENP stratum
Pacific Northwest, 41-52 (not ided as PCFG)	Lang et al. 2011, Pers. Comm.	33	1996-2012	Biopsies					x	x	x	x	x	x	x		Y	523	Y	12	
Pacific Northwest, 41-52	Alter et al. 2012	16	150-2690 ybp	Bones from middens													Y	383	N		

Region	Reference	Samples*	Time Period	Type of samples	Month												Utilized mtDNA?	mtDNA bps sequenced	Utilized microsatellites?	# of microsatellite loci	Comments
					1	2	3	4	5	6	7	8	9	10	11	12					
Pacific Northwest, 41-52	Ramakrishnan et al. 2001	45		Biopsies													Y	523	N		Includes Steeves et al. samples from Pacific Northwest; not all samples correlated with photoid (i.e. may not be PCFG)
Pacific Northwest, 41-52, PCFG	Lang et al. 2014, Lang pers comm. D'Intino et al. 2012	134	1996-2012	Biopsies	x	x		x	x	x	x	x	x	x	x	x	Y	523	Y	23	Likely overlap with Frasier et al., which provides mtDNA data.
Pacific Northwest, 41-52, PCFG	Frasier et al. 2011	82		Biopsies							x	x	x	x	x		N		Y	15	
Pacific Northwest, 41-52, PCFG		40	1995-2006	Biopsies							x	x	x	x	x		Y	345	N		
Pacific Northwest, 41-52, PCFG	Steeves et al. 2001	16	1995-1996	Biopsies						x	x	x	x	x	x		Y	311	N		These samples likely used in Frasier et al. and D'Intino et al.
Alaska, Kodiak	Lang pers com	6	2001, 2005	Biopsies							x	x					Y	523	N		
Alaska, Barrow	Lang et al. 2014, Lang pers comm.	23	1997-1998, 2000, 2002, 2010-2011	Biopsies, Tagging, Strandings							x	x	x				Y	523	Y	12	Only Lang et al. 2014 samples processed for 12 loci.
Russia, Chukotka	Kanda et al. 2010	7	2008	Harvest						x	x	x	x	x			Y	486	N		Also 1137 bp of cyt B sequence
Russia, Chukotka	Meschersky et al. 2012	84		Harvest													Y	555	N		
Russia, Chukotka	Ilyashenko pers comm.	~150		Harvest													N		N		
Russia, Chukotka	Lang et al. 2014	75	1994, 2001, 2003-2005	Harvest							x	x	x	x	x		Y	523	Y	12	Also 1137 bp of cyt B sequence Likely same samples as Meschersky et al. 2011
Russia, Koryak coast	Meschersky et al. 2012	16	2010-2011	Biopsies													Y	555	N		
Russia, Koryak coast	Lang et al. 2014	17	2010	Biopsies						x							Y	523	Y	12	
Russia, Sakhalin Island	Meschersky et al. 2012	14	2010-2011	Biopsies													Y	555	N		Also 1137 bp of cyt B sequence
Russia, Sakhalin Island	Lang reported	155	1995-2007, 2010-2011	Biopsies							x	x	x				Y	523	Y	23	These samples also included in Lang et al. studies Cytochrome B sequences also generated; these individuals also sampled as part of LeDuc et al. 2002 and Lang et al. studies
Russia, Sakhalin Island	LeDuc et al. 2002	45	1995-1999	Biopsies						x	x	x	x	x			Y	523	N		
Russia, Sakhalin Island	Bickham et al. 2013	6	2011	Biopsies						x	x	x	x	x			Y		N		

Region	Reference	Samples*	Time Period	Type of samples	Month												Utilized mtDNA?	mtDNA bps sequenced	Utilized microsatellites?	# of microsatellite loci	Comments
					1	2	3	4	5	6	7	8	9	10	11	12					
Russia, SE Kamchatka	Meschersky et al. 2012	17	2010-2011	Biopsies													Y	555	N		Also 1137 bp of cyt B sequence
Russia, SE Kamchatka	Lang pers comm.	16	2004, 2010-2011	Biopsies						x	x	x					Y	523	Y	12-23	
Japan, Pacific coast	Kanda et al. 2010	5	1995-2007	Strandings, Bycatch	x			x	x		x	x					Y	486	N		
Japan, Sea of Japan coast	Kanda et al. 2010	1	1996	Strandings Bycatch					x								Y	486	N		
China	Lang Pers. Comm.	2*	1996, 2011	Strandings, Bycatch											x	x	Y*	523	Y*	23	The 1996 sample failed to produce useable DNA when extracted.

Table 2

Summary of genetic analyses, including regions compared, sample sizes (n), number of mtDNA haplotypes (Nb haps), mtDNA haplotype diversity (h), number of mtDNA haplotypes shared between areas (Nb shared), and results of comparisons between strata for both mtDNA (p-values in parentheses for F_{ST} and Φ_{ST}) and microsatellites (p-values in parentheses for F_{ST}).

Reference	Stratum 1					Stratum 2						mtDNA						Microsatellites		
	Region	n		Nb haps	h		Region		n	Nb haps	h		Nb shared		F_{ST}	Φ_{ST}	Exact Test		F_{ST}	Exact Test/Chi-square

* "South" refers to samples collected within the season (June – November) and range (41-52° N) of the PCFG but not necessarily linked to a whale photographically identified as being part of the PCFG.

Annex E

Summary of catch data for the western North Pacific

Minimum numbers and details of western gray whales caught during the 20th century (from Bradford, 2003). Years are displayed continuously until 1966, the reported end of modern whaling for western gray whales. Highlighted rows represent total yearly minimum catches.

Year	Month	Location	Water Body	Country	Whalers	Method	Catch	Source
1900	?	Jangjeon	Sea of Japan	Korea	Japanese?	Modern	23	Kato and Kasuya (2002) from Park (1987)
1900	?	Kawajiri, Yamaguchi	Sea of Japan	Japan	Japanese	?	2	Omura (1984) from Tada (1978)
1900							25	
1901							?	Kato and Kasuya (2002) from Park (1987)
1902	?	Jangjeon	Sea of Japan	Korea	Russian	Modern	9	Kato and Kasuya (2002) from Park (1987)
1902	?	Unknown	Unknown	Unknown	Unknown	Modern	5	Kato and Kasuya (2002) from Park (1987)
1902							14	
1903							?	Kato and Kasuya (2002)

Annex F

Stock structure hypotheses

MOVEMENTS:

AREAS:

Wintering Regions:

- (1) MEX: wintering area(s) in the Mexican lagoons and offshore waters of Baja California
- (2) ?AS: wintering area(s) in the western North Pacific; the location is unknown but suspected to be near the South China Sea

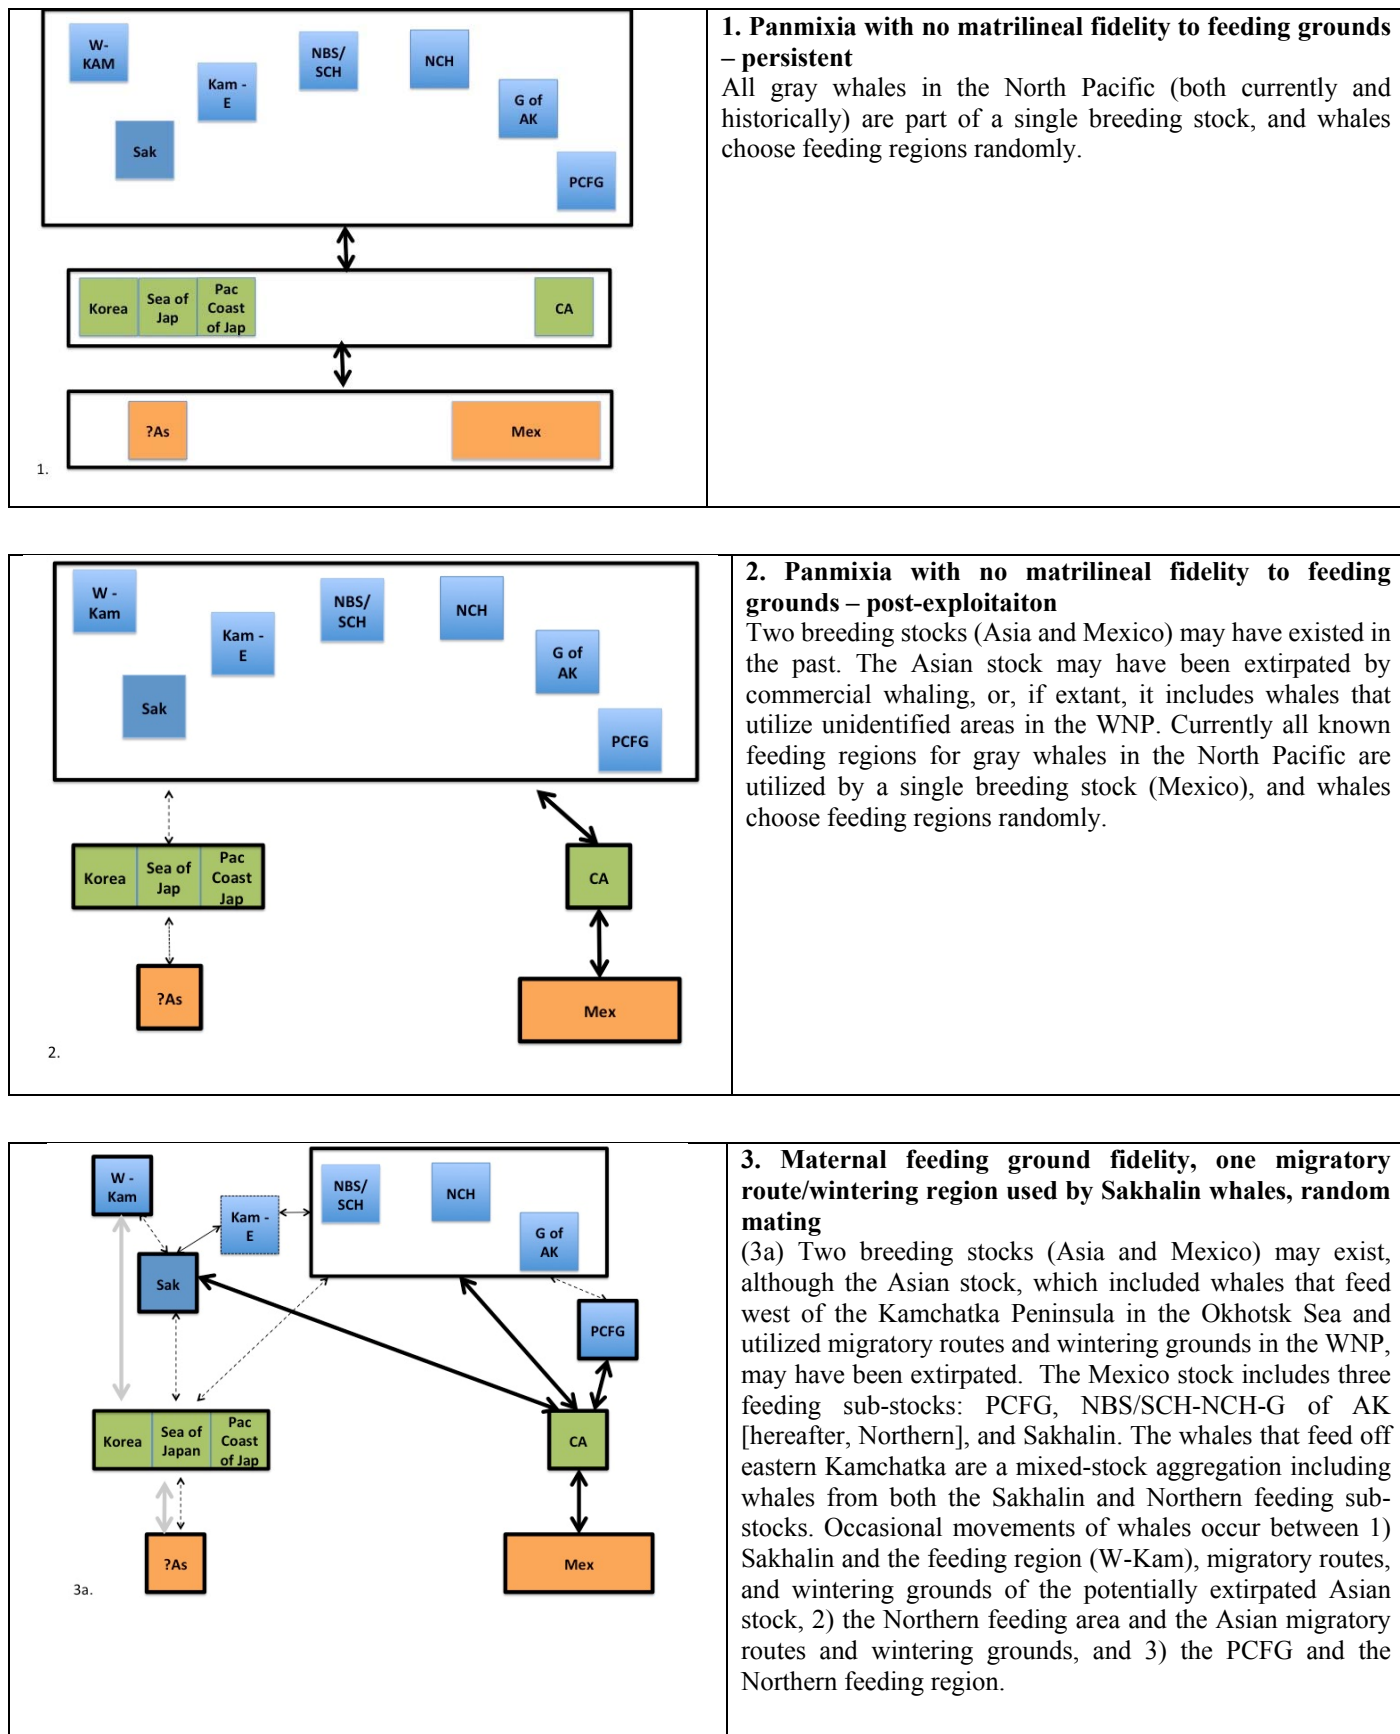

Migratory Routes:

- CA: the migratory route that extends from the feeding area north of the Aleutians to the Mexican wintering area(s). This route is also referred to as the ENP migratory route. Of note, this migratory route passes through the PCFG feeding region, although it is not depicted as such in the schematic to avoid confusion about where whales are feeding versus migrating.
- KOREA, SEA OF JAP, PAC COAST OF JAP: These are potential migratory routes in the WNP. Although it is possible that all three of these routes (mainland coast of Korea, Sea of Japan coast of Japan, and the Pacific coast of Japan) were utilized in the past, it is not possible to identify which routes connected with specific feeding regions; therefore these routes are grouped together in most schematics.
- NCP: this region was designated to identify an area to the west of the CA route that might be used by whales largely by whales migrating from Sakhalin. This region was removed from the schematics following the discussion.

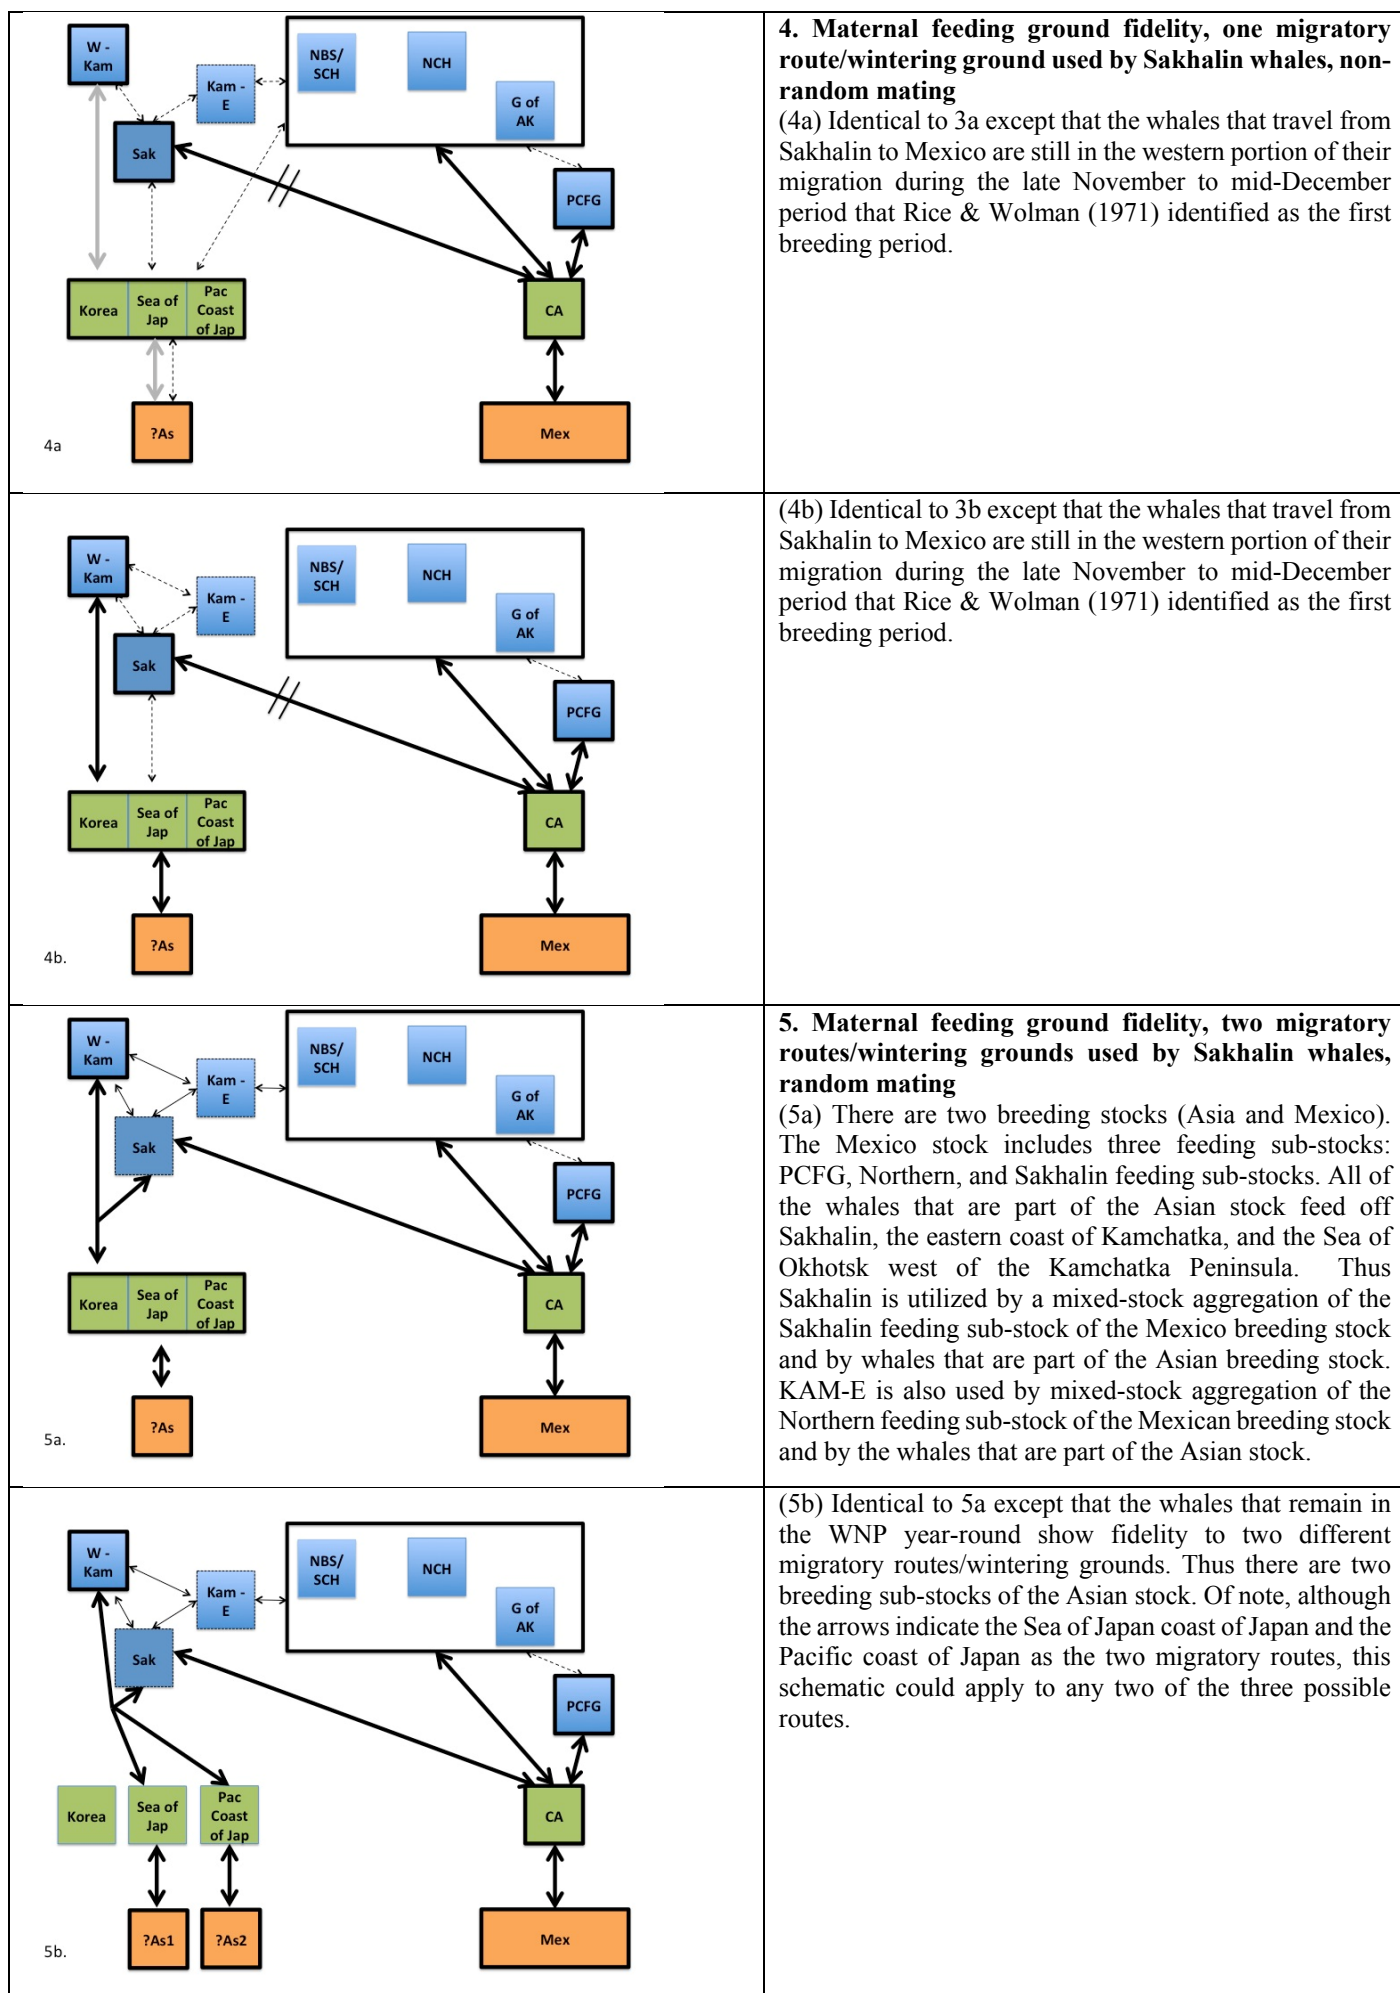

Feeding regions:

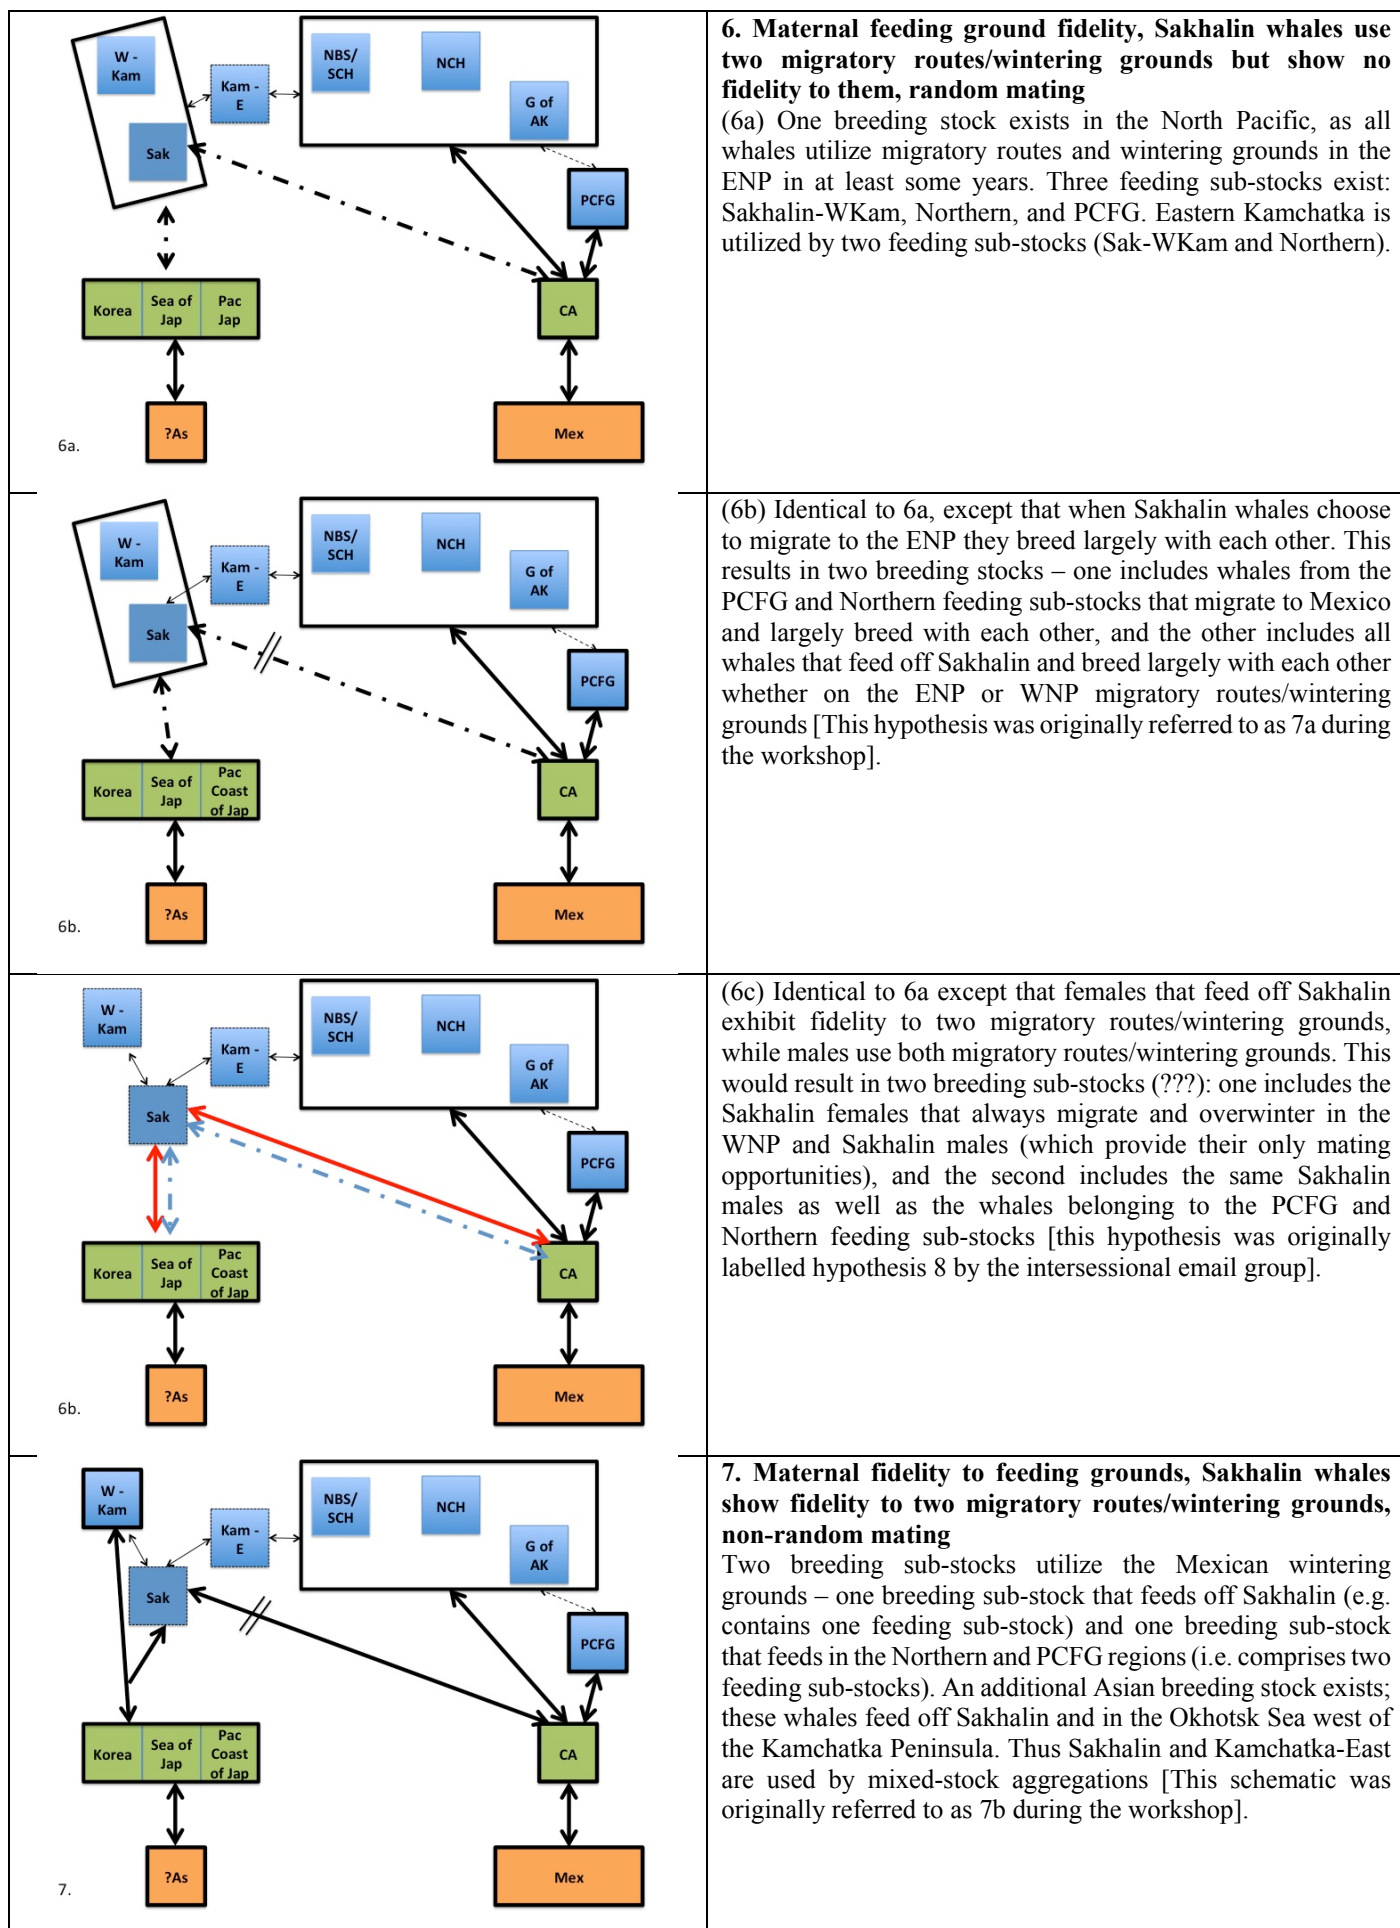

- PCFG: feeding range used by the Pacific Coast Feeding Group. This area extends from the coast of northern CA (41° N) to western Vancouver Island (52° N).
- G of AK: the Gulf of Alaska region
- NCH: the northern portion of the Chukchi Sea, including Wrangel Island in the west to Barrow, AK in the east.
- NBS/SCH: the northern Bering and southern Chukchi Seas, including the Chukotka Peninsula and St. Lawrence Island
- KAM-E: includes the coastal regions of southeastern Kamchatka, Russia, including Vestnik Bay and Olga Bay
- KAM-W: includes waters to the west of Kamchatka in the Sea of Okhotsk, incorporating Shelikof Gulf, Taiu Bay (Magadan area), and the Shantar Islands region. Excludes the northeastern coast of Sakhalin Island, which is considered separately.
- SAK: waters off the northeastern coast of Sakhalin Island.

HYPOTHESES CONSIDERED

<p>3b.</p>	<p>(3b) Identical to 3a, except that the Asian stock is considered to be extant and to feed in the Okhotsk Sea west of the Kamchatka Peninsula as well as off the coast of eastern Kamchatka. Thus the eastern coast of Kamchatka is used by a mixed-stock aggregation of the Sakhalin feeding sub-stock (part of the Mexican breeding stock) and the W-Kam feeding stock (of the Asian breeding stock).</p>
<p>3c.</p>	<p>(3c) Identical to 3a except that on occasion whales migrating between the Sakhalin feeding region and Mexico travel through the NBS/SCHK region.</p>
<p>3d.</p>	<p>(3d) Identical to 3a except that the Gulf of Alaska region is considered a separate feeding sub-stock of the Mexico breeding stock.</p>
<p>3e.</p>	<p>(3e) Identical to 3a except that the Asian breeding stock is extant and feeds off both coasts of Japan, Korea, and in the northern Okhotsk Sea west of the Kamchatka Peninsula. This scenario is also similar to 3b, with two exceptions: 1) that the coast of Korea and both coasts of Japan are used as feeding areas rather than migratory routes, and 2) that the KAM-E region is not used by whales that are part of the Asian stock.</p>

Report of the Third Workshop on the Rangewide Review of the Population Structure and Status of North Pacific Gray Whales

Report of the Third Workshop on the Rangewide Review of the Population Structure and Status of North Pacific Gray Whales¹

The Workshop was held at the Southwest Fisheries Science Center (SWFSC), La Jolla, California from 18-20 April 2016. The list of participants is given as Annex A.

1. INTRODUCTORY ITEMS

1.1 Convenors' opening remarks

Donovan and Punt (co-Convenors) welcomed the participants to the Workshop. They thanked Weller and the SWFSC for yet again hosting this meeting, the third in a series of workshops examining the rangewide status of North Pacific gray whales (and see IWC, 2015b; 2016). The output from this process is intended to assist in the updating of the IUCN/IWC western gray whale Conservation Management Plan² and the general provision of conservation and management advice for North Pacific gray whales.

1.2 Election of Chair

Donovan was elected Chair.

1.3 Appointment of rapporteurs

Weller, Lang and Punt were appointed rapporteurs with assistance from the Chair and others as appropriate.

1.4 Adoption of Agenda

The adopted agenda is given as Annex B.

1.5 Documents and data available

The list of documents is given as Annex C. Annex G provides an updated schematic of present knowledge of North Pacific gray whale distribution and migration.

2. PROGRESS ON 'NON-MODELLING' RECOMMENDATIONS AND NEW DATA

2.1 Update on comparison of identified gray whales in Mexico, off central California and in the PCFG with a focus on mothers and calves

Weller presented an update of information on photo-identification and related research that has been conducted since the two previous Workshops (IWC, 2015b; 2016). The comparison of gray whales identified off Mexico to those identified off Sakhalin and Kamchatka is unchanged from the earlier paper (Urbán R. *et al.*, 2013). A new research undertaking involves comparing gray whale photo-identification images collected opportunistically mostly by commercial whale watching boats off the US west coast to existing catalogues from Sakhalin Island and the PCFG (Weller, pers. comm.).

Table 1 provides an update of the information on available photo-identification data for the North Pacific from that developed at the first Workshop (IWC, 2015b).

Continued efforts to collect shore-based photo-identification images of mother-calf pairs passing by central California concurrent to the annual NOAA calf count continued in 2015, resulting in a catalogue that now spans the period 2012-15 (Weller, pers. comm.) Finally, in 2015

and 2016 a remotely operated hexacopter was used during the NOAA calf count to obtain aerial images of mother-calf pairs to examine length, girth and body condition (Perryman, pers. comm.).

2.2 Comparison of photographs (and genetic material) of gray whales from areas of the Okhotsk Sea and elsewhere in Asia with the Sakhalin and Kamchatka catalogues

Annex D provides a summary of gray whale photo-identification and genetic matching within the western North Pacific. Based on the reported results, two sets of mixing proportions were generated and used in the age structured model described in table 3 of SC/A16/GW02. Table 3a of that paper lists data for the eastern Sea of Japan/Pacific coast of Japan that are based on 'definite' matches/non-matches and table 3b includes the 'likely' matches/nonmatches.

2.3 Development of Single Nucleotide Polymorphisms (SNP) assays for use with gray whales

Table 2 summarises the available samples available for genetic analyses – this is an update to the table presented in the first rangewide Workshop (IWC, 2015b).

Bickham noted that whole genome sequencing of two whales sampled off Sakhalin Island and one whale sampled off Barrow, Alaska, had been completed. These sequences were used to identify 96 SNP loci linked to genes with known functions. Using primers designed from the sequence surrounding these SNPs, 36 biopsies representing 29 gray whales sampled off Sakhalin between 2011 and 2013 were successfully genotyped at 88 of these gene-associated markers, 2 molecular sexing markers and 2 mitochondrial markers. A report detailing these results will be provided for review at SC/66b, and both the genome and primer sequences will be made publicly available through the National Center for Biotechnology Information, allowing researchers in other labs to use this SNP panel in future gray whale studies. Genotyping of samples collected from Sakhalin whales in 2014 and 2015 is planned, and Bickham and his team are trying to identify additional samples from the eastern North Pacific to facilitate a comparative analysis in the future. Such an analysis has the potential to identify differences between Sakhalin whales that overwinter in the eastern North Pacific and any that remain in the western North Pacific year-round.

The Workshop thanked Bickham for this information and looked forward to the full paper that would be presented at SC/66b. In discussion, it was noted that environmental changes have probably resulted in several cycles of splitting and merging between eastern and western North Pacific gray whales over the past 100,000 years, which could affect the magnitude of any such differences, and thus the likelihood that they would be detected.

Lang reported that additional efforts to identify SNP loci in gray whales were underway at SWFSC. Genotyping by-sequencing (GBS) is being conducted on samples ($n=190$) collected from PCFG whales, whales feeding off Sakhalin Island, and whales feeding north of the Aleutians. GBS utilises a highly multiplexed approach that includes the use of restriction enzymes to reduce genome complexity and is

¹Presented to the Scientific Committee meeting as SC/66b/Rep07.

Table 1
Photo-identification data for North Pacific gray whales.

Location	Photos	Catalogue size	Years	Season(s)
Mexico lagoons	Yes	7,000+ IDs	2006-present*;	Primarily Jan.-Apr.
Mexico offshore	Yes	No catalogue; <100 IDs	2007-13	Primarily Jan.-Apr.
California (31-41°N)	Yes	No catalogue; opportunistic/whalewatchers	-	South/northbound migration
Central California	Yes	<150 IDs; shore-based mother/calves	2012-present	North migration Apr.-May
PCFG (41°-52°N)	Yes	>1,500 IDs	Primarily 1980s-2000s*	Primarily Jun.-Nov. opportunistic year round
Aleutians (52°N)	?	N/A	N/A	N/A
Kodiak	Yes	<250 IDs	2002-12 some annual gaps; 2015	Primarily Aug.-Sep.
US Bering Sea	Yes	<10 IDs; opportunistic (St Lawrence Island)	2012	Aug.
Chukchi-Beaufort Sea	Yes	<40 IDs	2013	Aug.-Sep.
Chukotka	No	A catalogue is being developed	N/A	N/A
East Kamchatka	Yes	<160 IDs	2004-12	Primarily Jul.-Aug.
Okhotsk Sea, west of Kamchatka	Yes	No catalogue; opportunistic	1990s-2000s	N/A
Sakhalin	Yes	<250 IDs	1994-present (no data in 1996)	Primarily Jul.-Oct.
Korea	No	N/A	N/A	N/A
Japan: Pacific	Yes	No catalogue; <10 IDs	1990s-2000s	N/A
Japan: Sea of Japan	Yes	No catalogue; 1 ID	2014	Mar.-Apr.
China	Yes	No catalogue; 1 ID	2011	Nov.

*Some data to 1970s.

predicted to result in hundreds to thousands of genotyped SNP markers. These samples have been submitted for sequencing and the resulting data are expected to be available in the next month. Although SNPs identified using this approach are intended to be a random subset from the genome, it was noted that comparison of these sequence data with the genome data generated in Bickham's study could provide information on whether these SNPs are associated with identified genes.

The Workshop thanked Lang for this information. There was some discussion of what might be learned by comparing samples collected during the early field efforts off Sakhalin Island, when photo-identification studies indicated that the feeding ground was used by 100 or fewer whales, to samples collected more recently when the abundance was higher (*ca* 170). It was noted that at least for the Russia-US research programme, efforts were made to avoid sampling individuals more than once, such that samples collected in later years of the study, when many of the individuals had already been biopsied, were not necessarily representative of the whales using the Sakhalin feeding ground during those years. However, it was noted that it would be worthwhile to explore other approaches (e.g. using close kin approaches to estimating abundance) to augment mark-recapture estimates of abundance as well as the use of effective population size estimators, to explore whether changes in abundance over time based on photo-identification data were also reflected in the genetic data.

2.4 Updated information from the eastern North Pacific

Weller provided an update on a recent survey, the Collaborative Large Whale Survey (CLaWS), conducted jointly by the SWFSC and the Alaska Fisheries Science Center. This survey, which took place between 9 July and 9 November 2015, was devoted to the assessment of several large whale species off the US and Canadian west coast between northern California and Kodiak, Alaska. A major component of this effort was the completion of the first range-wide assessment of gray whale feeding grounds south of the Aleutians. Photo-identification images of ~140 individuals were obtained, and 92 biopsies were collected. The majority of photo-identifications and biopsies were obtained off the coast of British Columbia, with a smaller proportion collected off Kodiak, Alaska. Although the coastal

waters between the US-Canadian border and Kodiak, Alaska were covered twice during the survey, no gray whales were sighted within this area.

Processing of the gray whale photo-identification data collected on CLaWS is near completion, and the resulting catalogue will be sent to Cascadia for comparison with their catalogue of whales sighted within the PCFG range. In discussion, it was noted that B. Gisborne, who typically surveys the southern and western portion of Vancouver Island, reduced his survey effort during the 2015 season; as such, the data from CLaWS from that area will be particularly valuable in filling in this gap in survey effort.

A recent analysis shows that a high number of calves (36 of 56) born to known PCFG mothers seen prior to 2013 have been documented returning to the PCFG area (Perez *et al.*, 2015).

Counts of southbound migrating whales off California form the basis of abundance estimation for the eastern North Pacific stock of gray whales. Previous assessments span the period 1967-2011. The summed estimate of migration abundance in 2011 was 20,990 (95% HPDI=19,230-22,900). Two new field counts, for the 2014/15 and 2015/16 migrations respectively, have been completed and will serve as the basis for updated estimates of abundance to be presented at the 2017 Scientific Committee meeting (Weller, pers. comm.).

The Workshop thanked Weller for this important new information and looked forward to receiving the full report of the CLaWS cruise in due course. It emphasised the value of conducting photographic comparisons with all catalogues in the North Pacific in addition to the catalogue of animals from the PCFG range.

2.5 Updated abundance and trend estimates for the PCFG by identifying and using additional photographic sources

Laake reported that an updated abundance estimate for the PCFG, incorporating data from 2013 and 2014, is in preparation. This will add to the previously reported time-series of estimates between 1996 and 2012.

The Workshop welcomed this news, but agreed that for the purposes of the present work, the previous estimates would be used (and see Item 4).

Table 2

Summary of available samples of gray whales (not all have been analysed and there may be some overlap between studies included here).
When known, the number of individuals (*I*) sampled is included in parentheses after the total number of whales sampled.

2.6 Updated estimates for past and future ship strikes and bycatches throughout the North Pacific

In discussion of the bycatch time-series (hereafter used to include ship strikes, entrapments and entanglements) for the western North Pacific (WNP), it was agreed that only records from 1990 through 2014 would be included given that effort to detect stranded whales was lower prior to that time period. Upon review of the available records, it was agreed to include the four whales entangled off Japan between 2005 and 2007 (Kato *et al.*, 2013) in the time series, as well as the whale bycaught in the Taiwan Strait off China in 2011 (Wang *et al.*, 2015). Details of the WNP bycatch time series are included in Table 3.

Fisheries interactions off Sakhalin Island were also discussed. The histories of fisheries, primarily for salmon, in proximity to the Sakhalin feeding ground are unclear. In recent years, however, there has been a notable increase in set nets in the inshore feeding area and pot gear in the offshore fishing area. No direct observations of bycatch have been recorded off Sakhalin since research efforts began in 1997 but the following cases were noted:

- (1) a photo-documented entanglement of a whale in 2012 that was subsequently sighted in 2013 free of the entangling line (Weller *et al.*, 2014);
- (2) a dead stranded whale near Chayvo in 2009 (WGWP-7 2009);

Table 3
Records of gray whales in the WNP that are included in the WNP bycatch time-series.

Date (mm/dd/yy)	Location	Length (m)	Sex	Comment	Reference
5/11/2005	Tomiyama (Tokyo Bay), Chiba, Pacific coast of Japan (35°04'N-139°49'E)	7.81	F	Juvenile	Kato <i>et al.</i> (2014)
7/15/2005	Enoshima, Onagawa, Miyagi, Pacific coast of Japan (38°23'N-141°37'E)	12.79	F	-	Kato <i>et al.</i> (2014)
7/15/2005	Enoshima, Onagawa, Miyagi, Pacific coast of Japan (38°23'N-141°37'E)	7.75	F	Calf of the adult female from same date	Kato <i>et al.</i> (2014)
1/18/2007	Sanriku, Ofunato, Iwate, Pacific coast of Japan (39°09'N-141°54'E)	9.19	F	-	Kato <i>et al.</i> (2014)
11/5/2011	Fujian Province, Taiwan Strait, China	13.1	F	-	Wang <i>et al.</i> (2015)

- (3) a weathered whale carcass found by a hunter on 10 October 2010 on the southeastern coast of Sakhalin (WGWAP-14 2014); and
- (4) a verbal report from fisherman working off northeastern Sakhalin of a bycaught whale suspected, but not confirmed, to be a gray whale (WGWAP-14 2014).

With respect to case (3), the hunter who photographed the carcass estimated that it was 8m long. Line associated with the carcass, as shown in photographs, led experts to conclude that entanglement could not be ruled out as the cause of death (37 entanglement experts were contacted via the IWC's entanglement experts' network). Features of the carcass shown in photographs were used by Brownell (pers. comm.) to identify the animal as a gray whale.

The Workshop concluded that although these several cases suggest that fisheries interactions are occurring off Sakhalin, the paucity of available information makes further assessments of this issue difficult. It is clear, however, that in recent years the presence of salmon and pot gear has increased on and near the feeding areas off Sakhalin and therefore is of elevated concern.

The Workshop understood that there was a possibility of a more detailed study of fisheries off Sakhalin being undertaken in the context of the IUCN Western Gray Whale Advisory Panel (WGWAP). The Workshop **encourages** such a study.

3. PROGRESS REPORT ON MODELLING-RELATED ISSUES

The Workshop used the terminology and associated assumptions as agreed during the 2nd Workshop on the Rangewide Review of the Population Structure and Status of North Pacific Gray Whales (IWC, 2016).

- (1) *Breeding stocks*. There are up to two extant breeding stocks (Western and Eastern).
- (2) *Feeding aggregations*. The eastern breeding stock consists of up to three feeding aggregations depending on hypotheses: Western Feeding Group (WFG), Pacific Coast Feeding Group (PCFG) and 'North'. There is dispersal between the PCFG and North feeding aggregations, but the WFG is demographically independent of the other two feeding aggregations (i.e. there is no permanent movement of animals from the North or PCFG to the WFG).
- (3) *Sub-areas*. The model includes 11 geographic sub-areas to explain the movements of gray whales in the North Pacific:
 - (a) Vietnam-South China Sea [VSC];
 - (b) Korea and western side of the Sea of Japan [KWJ];
 - (c) eastern side of the Sea of Japan and the Pacific coast of Japan [EJPJ];

- (d) off northeastern Sakhalin Island [SI];
- (e) areas of the Okhotsk Sea not otherwise specified [OS];
- (f) East Kamchatka and the Kuril Islands [EKK];
- (g) the Northern Bering and Chukchi Sea [BSCS];
- (h) Southeast Alaska [SEA];
- (i) British Columbia to Northern California [BCNC];
- (j) California [CA]; and
- (k) Mexico [M].

The model also includes two 'latent' sub-areas used to link model predictions to observed indices of abundance. These are denoted Calif-3 and BC-BCA-3.

The Workshop focussed on the three priority stock structure hypotheses selected by the Scientific Committee at the 2014 Annual Meeting (IWC, 2015a). These can be summarised (and see Fig. 1) as follows.

- (1) *Hypothesis 3a*. Although two breeding stocks (Western and Eastern) may once have existed, the Western stock is assumed to have been extirpated. Whales show matrilineal fidelity to feeding grounds, and the Eastern stock includes three feeding sub-stocks or feeding aggregations: PCFG, Northern Bering Sea (NBS)/Southern Chukchi (SCH)-Northern Chukchi-Gulf of Alaska ('Northern') and WFG.
- (2) *Hypothesis 3e*. Identical to hypothesis 3a except that the Western breeding stock is extant and feeds off both coasts of Japan and Korea and in the northern Okhotsk Sea west of the Kamchatka Peninsula. All of the whales feeding off Sakhalin overwinter in the eastern North Pacific.
- (3) *Hypothesis 5a*. Identical to hypothesis 3a except that the whales feeding off Sakhalin include both whales that are part of the Western stock and remain in the western North Pacific year-round, and whales that are part of the Eastern stock and migrate to the eastern North Pacific.

3.1 Updated bounds on the proportion of Sakhalin whales that migrate to the eastern North Pacific

Comparisons of photo-identification catalogues collected in Mexico and off Sakhalin, supplemented by results of whales tagged in Sakhalin, have previously been used to estimate confidence bounds on the proportion of adult Sakhalin whales that do not migrate to breeding grounds in Mexico (Cooke, 2015). The earlier results showed that inferences could be sensitive to assumptions about the extent to which immature animals join the migration. This was because the matching rate between animals observed in the WNP and the ENP was significantly lower for immature gray whales than for adult gray whales.

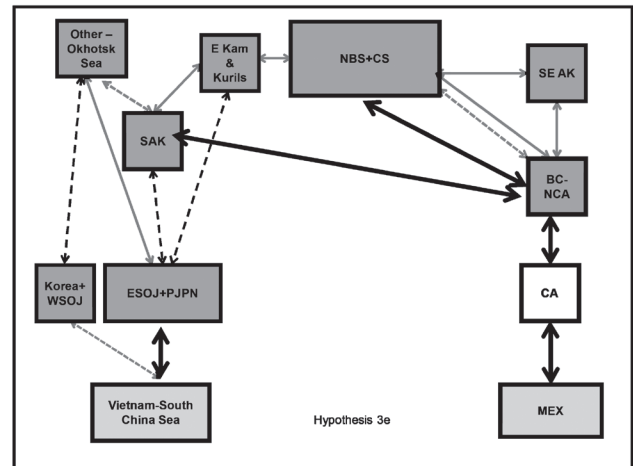

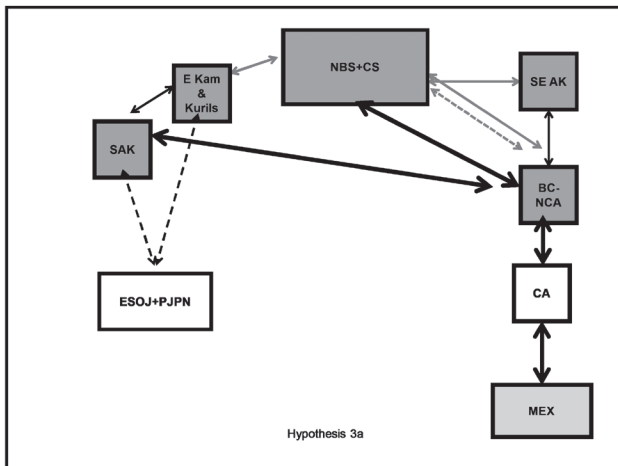

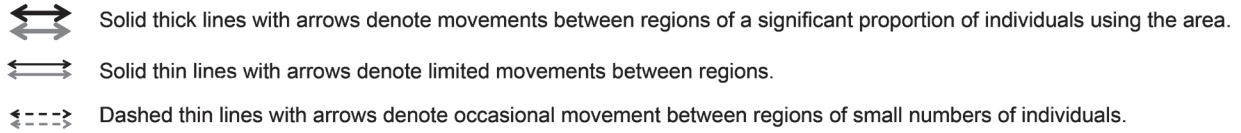

SC/A16/GW06 used data on the reproductive status of migrating gray whales collected off California by Rice and Wolman (1971) to refine the bounds on the proportion of

Revised Geographic Diagrams - April 2015 v3

Geographic areas utilised by gray whales are illustrated with shaded boxes:

Arrows represent movements between geographic areas, with grey representing movements between feeding regions and black representing migratory movements:

Geographic diagrams X feeding aggregation/stock - April 2015 v3

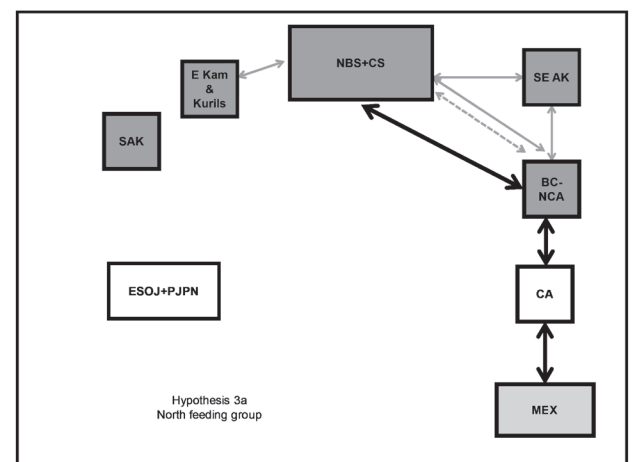

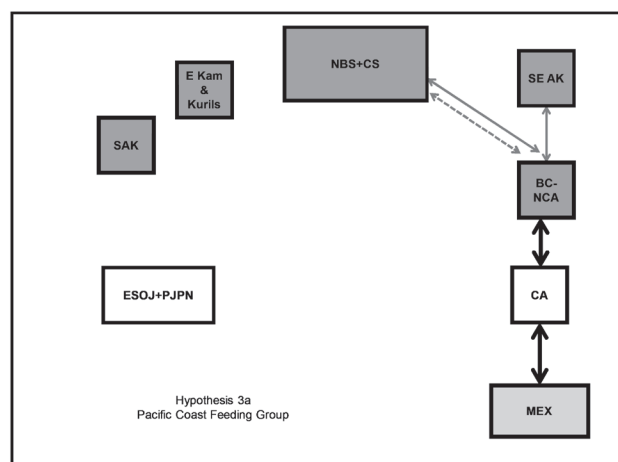

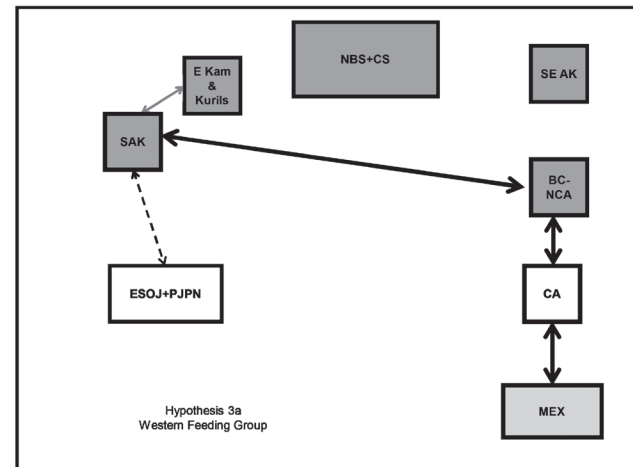

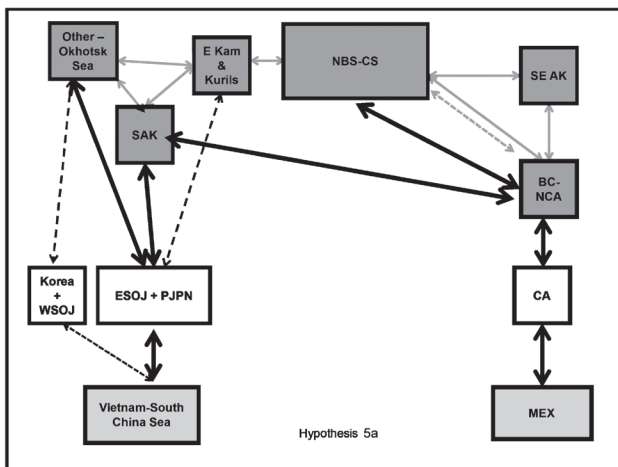

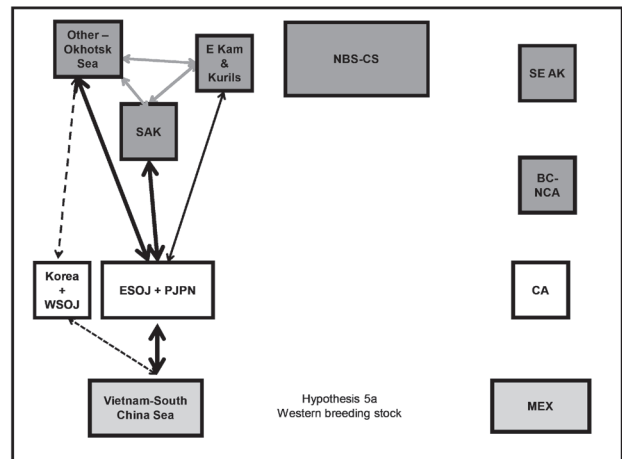

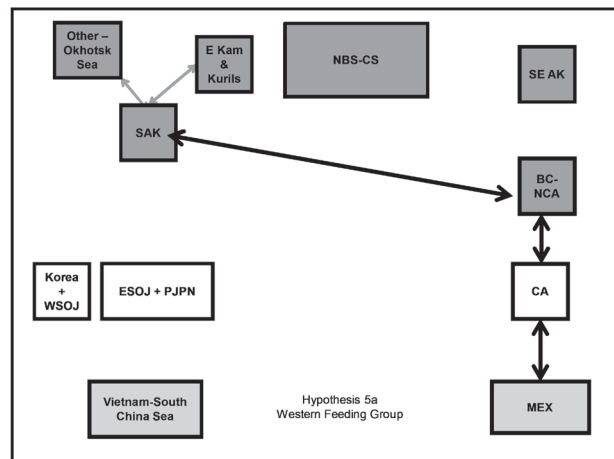

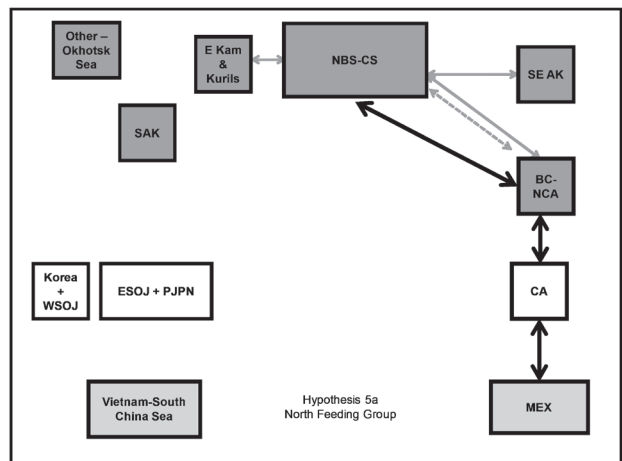

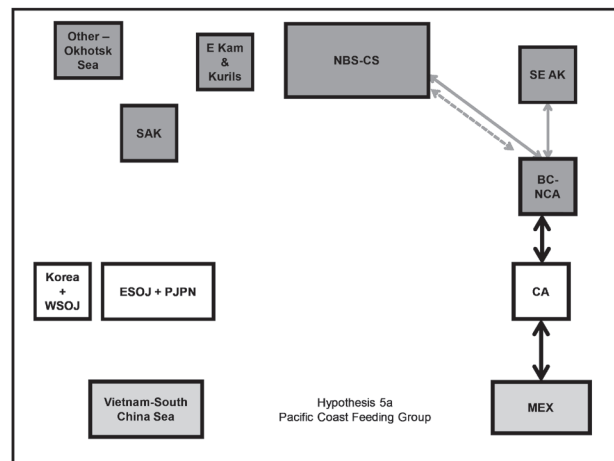

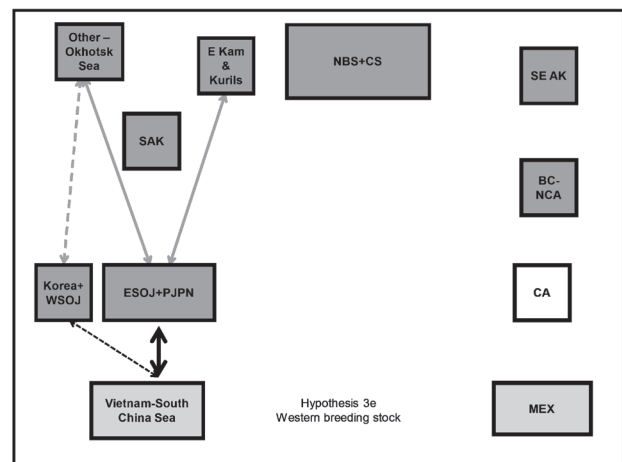

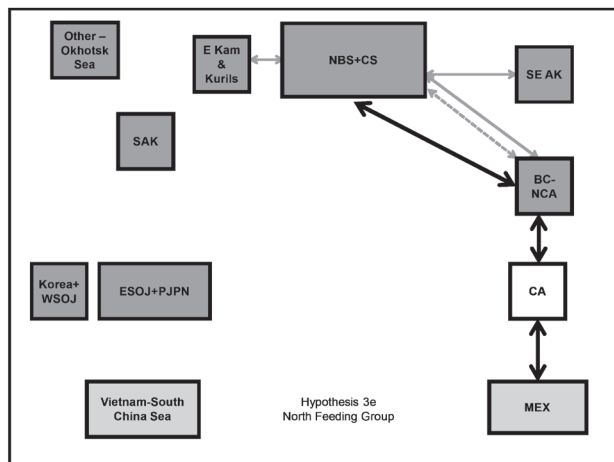

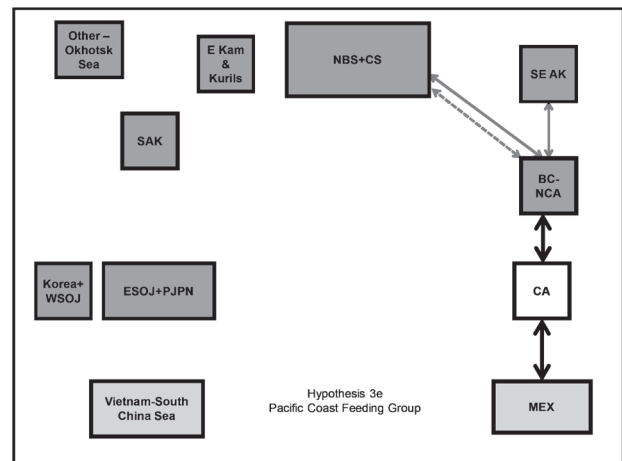

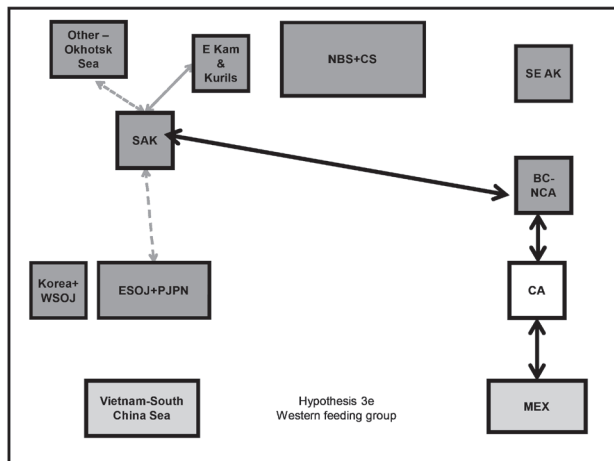

Fig.1. Stock structure hypotheses.

Sakhalin whales that undertake the migration. The revised bounds are not appreciably narrower: between 30% and 100% of mature (aged 7+) Sakhalin whales are estimated to migrate to the ENP. The proportion of immature whales undertaking the migration may be somewhat less. The existence of a breeding ground outside the ENP is thus neither confirmed nor excluded by this new analysis.

The Workshop thanked Cooke for his work in updating the analysis as requested by the previous Workshop. It looks forward to further updates to the estimated bounds when analyses of data on additional confirmed matches and non-matches become available. The Workshop **agreed** that further consideration should be given at SC/66b to whether the analyses should continue to be limited to only those animals included in the Mexican catalogue.

3.2 Development of an age- and sex-structured model

SC/A16/GW02 outlined a sex- and age-structured population dynamics model that can represent the stock hypotheses developed during the previous Workshops (IWC, 2015b; 2016). The model allows for multiple breeding stocks, each of which may consist of several feeding aggregations, multiple feeding and wintering grounds, as well as migratory corridors. Animals can move permanently between feeding aggregations in a pulse or diffusively. The values for the parameters of the model can be estimated by fitting it to data on trends in relative and absolute abundance, in addition

to mixing proportions based on mark-resight data, bycatch rates, and estimates of numbers immigrating into the PCFG.

4. UPDATE ON MODELLING FRAMEWORK AND INITIAL RUNS

4.1 Progress on modelling

The modelling framework (SC/A16/GW02) was modified from that presented to the 2015 meeting of the Scientific Committee in that allowance was made for the dispersal rate between the 'north' and 'PCFG' feeding aggregations to be density dependent. Assuming that the dispersal rate is constant over time leads to poor fits to the abundance estimates for the PCFG feeding aggregation (models 12A, 12B and 12C in SC/A16/GW02) and this change was made to address this. In addition, uncertainty was quantified using a bootstrap procedure. SC/A16/GW02 provided example applications of the model based on the three priority stock structure hypotheses (see above). It also provided results for model variants that could be considered further to capture uncertainty regarding the assumptions of the model. SC/A16/GW02 also provided examples of projections in which the subsistence catches for the BSCS subarea (the Chukotka hunt) and the BCNC sub-area (the Makah hunt) are based respectively on the *Gray Whale* and *PCFG SLAs (Strike Limit Algorithms)* and where fishing effort (and hence bycatch rate by area) were constant into the future.

Fig. 2. (a) The plot for the areas with abundance data showing the abundance estimates and their 90% confidence intervals, the fit of the model to the actual data ('deterministic'; solid black lines), and the median and 90% intervals from the 100 replicates (solid grey line and shaded area respectively). The results in this figure pertain to the reference case model. Results are shown for stock hypotheses 3a, 3b and 5a on the upper, middle and lower panels respectively.

Fig. 2. (b) Summary of the fits to the data on mixing proportions (left column), immigration rate (centre column), and bycatch rates (right panel) for the reference case model. The grey dot and intervals show the median and 90% intervals for the bootstrap data sets, the stars are the fit of the model to the actual data ('deterministic'), and the black dots and lines are median and 90% intervals from the 100 replicates. The histogram in the centre plot show the bootstrap distribution for the immigration rates in the model (the black line is the median of the target values and the grey line the result of the fit to the actual data). The results in this figure pertain to the reference case model. Results are shown for stock hypotheses 3a, 3b and 5a on the upper, middle and lower panels respectively.

SC/A16/GW02 provided three diagnostics plots to assist with the evaluation of the conditioning of the models (see Fig. 2a-c for examples).

- (1) The abundance estimates and their 90% confidence intervals, with the fit of the model to the actual data ('deterministic'; solid black lines), and the median and 90% intervals from the 100 replicates (solid grey line and shaded area respectively).
- (2) Fits to the data on mixing proportions, immigration rate, and bycatch rates. The grey dot and intervals show the median and 90% intervals for the bootstrap data sets, the stars are the fits of the model to the actual data ('deterministic'), and the black dots and lines are median and 90% intervals from the 100 replicates. The histogram in the centre plot shows the bootstrap distribution for the immigration rates in the model (the black line is the median of the target values and the grey line the result of the fit to the actual data).
- (3) Time-trajectories of numbers of mature females by breeding stock/feeding aggregation. The black line is the fit of the model to the actual data ('deterministic'; solid black lines), and the solid grey line and shaded area respectively are the median and 90% intervals from the 100 replicates.

The Workshop noted that the model was generally able to mimic the time-series of abundance estimates and the bycatch rates well. One exception was that the model failed to capture the decline in abundance from 1998 to 2000, even though the model includes a parameter to account for additional mortality. It also failed to mimic well the change in abundance estimates from 1987/88 to 1992/93. The Workshop noted several hypotheses for the latter result, including that migratory behaviour may have changed between 1987/88 and 1992/93 (e.g. differing proportions migrating past the central California census depending upon body condition), but agreed not to change the model without independent data to corroborate this (e.g. data on body condition are available for the years 1997-2003 and 2012 and there are ongoing (since 2015) efforts to collect such data).

The 'deterministic' fit to the immigration rate was close to the pre-specified value. The model predictions of mixing rates for the EJPJ sub-area suggested that 2/3 of the animals in this area were from the Western Feeding Ground (WFG), which is expected given that two of the three identified animals were WFG animals. In general, the model mimics the mixing proportions but some of the fits were poor.

The Workshop requested additional diagnostic plots be developed to show the model predictions of immigration over time as well as the time-trajectories of bycatch. Examples of these figures are shown in Fig. 3.

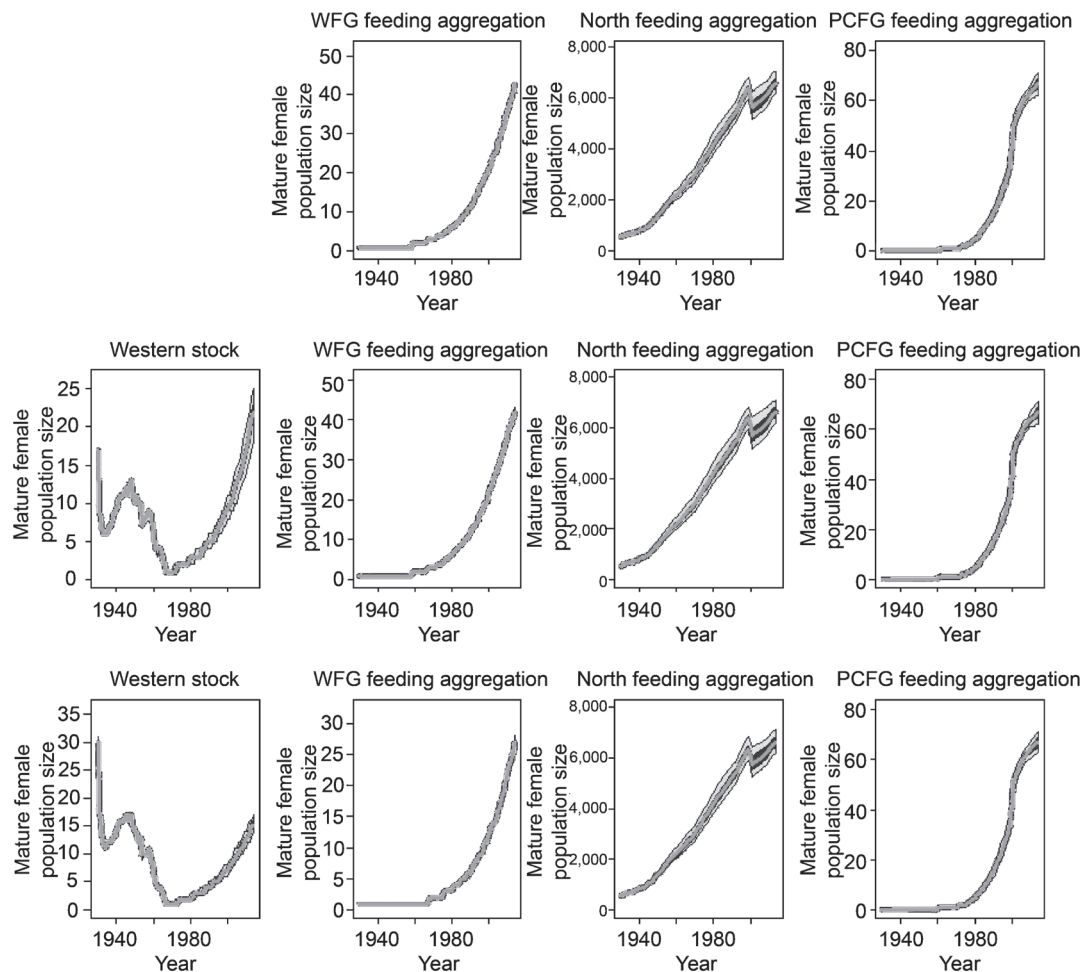

Fig. 2. (c) Time-trajectories of numbers of mature females by stock/feeding aggregation and stock hypothesis (3a, 3b and 5a on the upper, middle and lower panels respectively) for the reference case model. The black line is the fit of the model to the actual data ('deterministic'; solid black lines), and the solid grey line and shaded area respectively are the median and 90% intervals from the 100 replicates.

In conclusion, the Workshop thanked Punt for his thorough work and agreed that these plots provided an appropriate basis for evaluating model performance. It **agreed** that the plot showing the fit to the mixing proportions should be modified to include all the mixing proportions (so the sum of the observed mixing proportions adds to 1 across stocks for each sub-area). The Workshop **encouraged** SWFSC to examine the body condition data mentioned above in relation to the annual ice condition data.

4.2 Finalise data sets by stock structure hypothesis

4.2.1 Removals and abundance estimates

The Workshop agreed to make two changes the time-series of historical removals:

- (1) the catches for 2014 in the BSCS sub-area should be 43 males and 81 females (C. Allison, pers. comm.); and
- (2) the catch series for EJPJ sub-area should include the catch of 1 (unknown sex) as discussed in Brownell and Kasuya (1999).

Most of the analyses in SC/A16/GW02 were based on annual estimates of the number of dead animals due to bycatch and ship strikes (sensitivity to this was explored to five times this number). As in previous Workshops, the Workshop **reiterated** that the number of dead animals would underestimate, probably considerably, the actual number of animals killed due to bycatch and ship strikes. The Workshop therefore **agreed** to four scenarios regarding based on:

- (a) the numbers reported as dead;
- (b) the numbers reported as dead or 'seriously injured' *sensu* Carretta *et al.* (base-case); and
- (c) four times the numbers reported as dead;
- (d) ten times the numbers reported as dead.

The value of four was based on Carretta *et al.* (2016) estimate of the fraction of carcasses recovered of coastal common bottlenose dolphins (0.25, 95% CI=0.20 -0.33), while the value of ten was based on the results of Punt and Wade (2012), who estimated that between 3% and 14% of gray whales that died during the 1999-2000 mortality event were reported.

The bycatches used in the modelling were extended to include bycatch for the BCSC sub-area and were separated between the feeding (June-November) and migratory (December-May) periods for the SEA sub-area (Table 1). Annex D documents the basis for the estimates of bycatch for the VSC and EJPJ sub-areas while Annex E documents the basis for the bycatch/ship strike estimates for the eastern sub-areas. The estimates of bycatch for the VSC and EJPJ sub-areas are assumed to pertain to years 1990-2014, as the reporting of strandings, ship strikes and bycatches off Japan is likely to have been more consistent since 1990.

4.2.2 Abundance estimates

The analyses in SC/A16/GW02 were based on updated abundance estimates and their associated variance covariance matrix for the Sakhalin sub-area based on the

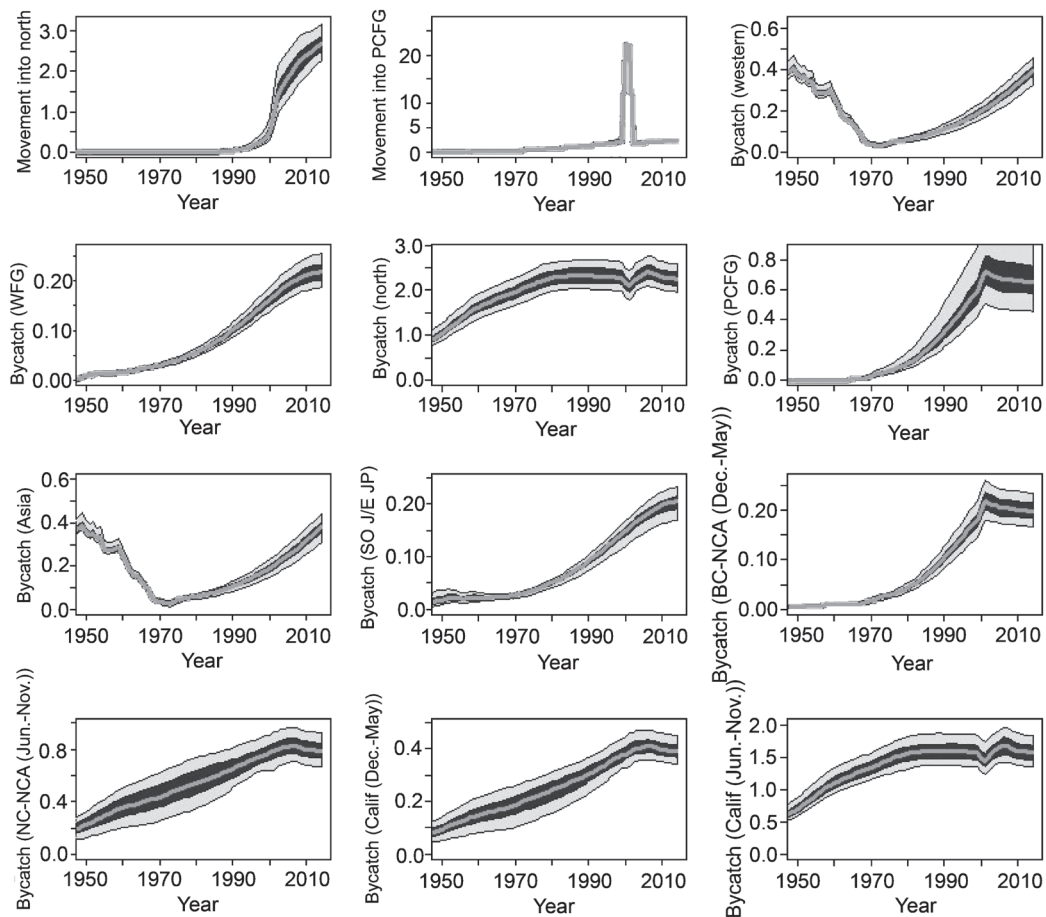

Fig. 3. Time-trajectories of: (a) number dispersing between the ‘north’ and PCFG’ feeding aggregations; (b) bycatch by stock/feeding aggregation; and (c) bycatch by sub-area. The black line is the fit of the model to the actual data (‘deterministic’; solid black lines), and the solid grey line and shaded area respectively are the median and 90% intervals from the 100 replicates. The results here pertain to stock structure hypothesis 3e.

Table 4
Scenarios regarding bycatch.

Sub-area	Years	Numbers dead	Dead and serious injury	Numbers dead x 4	Numbers dead x 8
VSC	1990-2014	1/25	??	4/25	8/25
EJPJ	1990-2014	4/25	??	16/25	32/25
SI	1997-2014	1.5/18	??	6/18	12/18
BSCS					
SEA (Jun.-Nov.)					
SEA (Dec.-May)					
BCNC (Jun.-Nov.)					
BCNC (Dec.-May)					
CA (Jun.-Nov.)					
CA (Dec.-May)					

Bayesian version of the model developed by Cooke (e.g. see the report of WGAP-16). The Workshop **endorsed** use of these abundance estimates as provided in Annex F. Other abundance estimates agreed in IWC (2016) are also provided in Annex F.

4.2.3 Mixing proportions

SC/A16/GW05 provided an update for the availability of PCFG whales by region and season using the database of whale sightings maintained by the Cascadia Research Collective for sightings through 2014. Availability was calculated as the number of observations of whales meeting the IWC definition for PCFG whales (IWC, 2015b) divided by the total number of gray whale observations. Observations were defined as a uniquely identified whale photographically identified by day. Small changes in availability were

calculated for PCFG whales in the summer feeding season and migratory season in the northern California to British Columbia region and central and southern California in the feeding season as compared to the values reported in Scordino *et al.* (2014).

The Workshop reviewed the data on the stock identity of animals caught off Japan and **agreed** with the two scenarios (base-case: definite matches/non-matches; sensitivity: definite and likely matches non-matches; table 2a in SC/A16/GW02).

The Workshop thanked Scordino for the updated analyses in SC/A16/GW02, and **agreed** to modify the mixing rates to the values suggested in SC/A16/GW05. Given that the collection of photographs in the CA sub-area during the migration season (December-May) is not random but targeted towards PCFG whales, the Workshop **agreed**

Table 5
Data on mixing proportions (definite and likely matches/non-matches only) to be used when conditioning the models.

Sub-area	Year	Stock concerned	Estimate (assumed SD)
EJPJ	2007 ^d	WFG	1 (0.1)
EJPJ	2012 ^d	Western	1 (0.1)
EJPJ	2015 ^d	WFG	1 (0.1)
EJPJ	2005 ^l	Western	1 (0.1)
EJPJ	2007 ^l	Western	1 (0.1)
SI	2012	Western	0.40 ^a (0.1)
SEA (Jun.-Nov.)	2012	PCFG	0.559 (0.15)
BCNC (Jun.-Nov.)	2012	PCFG	0.951 (0.05)
BCNC (Dec.-May)	2012	WFG	0.002 (0.05)
BCNC (Dec.-May)	2012	PCFG	0.339 (0.15)
CA (Jun.-Nov.)	2012	PCFG	0.472 (0.15)

^aStock structure hypothesis 5a only (changed in sensitivity analysis).

^dDefinite; ^lLikely.

Table 6
Factors considered in the model scenarios. The bolded values are the base-levels.

Factor	Levels
Model fitting related	
Stock hypothesis	3a, 3e, 5a
Proportion of 'Western' stock in Sakhalin sub-area	0 (stock hypotheses 3a, 3e), 0.33 (stock hypothesis 5a), 0.70
MSYR ₁₊ (western)	As for WFG
MSYR ₁₊ (north)	4.5% , 5.5%, Estimated (common); estimate (separately)
MSYR ₁₊ (WFG)	4.5% , 5.5%, Estimated (common); estimate (separately)
MSYR ₁₊ (PCFG)	2%, 4.5% , Estimated (common); estimate (separately)
Matches	Definite; Definite+Likely (Table 2)
Immigration into the PCFG	0, 2, 4
Bycatches and ship strikes	Numbers dead, M/SI, numbers dead x 4; x numbers dead x 10
Pulse migrations into the PCFG	10, 20 , 30
Bycatch off Sakhalin	1.5 , 3
Projection-related	
Northern need in final year (from 150 in 2014)	340 , 530
Struck and lost rate	25% 50% , 75%
Future effort	Constant , Increase by 100% over 100 years
Probability of mismatching a north whale, p_1	0.01
Probability of mismatching a PCFG, p_2	0.05 (trials)
PCFG harvest month	Migratory

to modify the catch mixing matrix for this combination of sub-area and season so that it is assumed that all animals are equally vulnerable to capture. It also **agreed** that all animals should be assumed to be equally vulnerable to capture, or proportionately to abundance for all areas noted in Table 5 (and see Annex E).

The final mixing proportions are given in Table 5.

4.3 Further development of trials to reflect uncertainty and anthropogenic removals

4.3.1 Base-case models and sensitivity tests

The Workshop **agreed** to the following changes to specifications the base-case model:

- the SEA sub-area should be divided into feeding and movement seasons given different bycatch rates in this sub-area seasonally (Table 5); and
- the proportion of animals in Sakhalin that are Western stock animals should be set to 0.33 (table 3 of SC/A16/GW06).

The Workshop reviewed the set of factors on which trials could be based suggested in SC/A16/GW06 and made the following changes (see Table 6):

- the alternative value for the proportion of Western stock animals in the SI sub-area was changed to 0.33 based on table 3 of SC/A16/GW06;

- scenarios in which MSYR₁₊ is estimated should be considered for two cases, one in which MSYR₁₊ is assumed to be the same for all feeding aggregations and the other in which MSYR₁₊ differs among feeding aggregations;
- the higher alternative number of 'north' animals immigrating into the PCFG feeding aggregation was reduced from 8 to 4 based upon information provided by Laake, and the fact that the value of 8 provided a poor fit³ - the case of 8 was retained for the trial involving estimated MSYR to examine whether this might improve the fit;
- the scenarios regarding bycatches and ship strikes was updated (see Item 4.2.2);
- the assumption that dispersal is not density-dependent was dropped as this assumption leads to poor fits to the available data (SC/A16/GW02); and
- two scenarios regarding the bycatch off Sakhalin were added (see Annex F).

Table 7 lists the trials. The bulk of the trials involve one change from the base-case models. Trials 16-20 involve two changes to the base-case trials. Trial 16 involves two changes that should make achieving conservation objectives

³The immigration rate of 0 is consistent with observations that internal recruitment into the PCFG has been high in recent years (Perez *et al.*, 2015).

Table 7
The trial specifications.

Trial	Description/stock hypothesis	PCFG in BSCS	MSYR ₁₊ North	MSYR ₁₊ PCFG	MSYR ₁₊ WFG	% Western in Sakhalin	PCFG immigration	PCFG pulse	Bycatch multiplier
1A	Reference 3a	No	4.5%	4.5%	4.5%	0	2	20	1

20C	MSYR estimated and much higher immigration 5a	No	Est	Est	Est	0.33	8	20	1

for the PCFG feeding aggregation more difficult while all but one set of the remaining multi-factor trials combine estimates of feeding-aggregation-specific MSY rates with different assumptions regarding immigration into the PCFG feeding aggregation. Trial 20 explores whether it is possible to mimic the data when the immigration into the PCFG feeding aggregation is 8 and MSYR₁₊ is estimated by feeding aggregation.

The Workshop examined the stock structure hypotheses developed by IWC (2015b; 2016). Most of these hypotheses are either equivalent to stock structure hypotheses 3a, 3e and

5a or there are insufficient data to parameterise them. In review, however, the Workshop decided that hypothesis 6b⁴, which was initially assigned low priority because it would be represented in the same way as hypothesis 5a in the modelling framework, should be reconsidered. This hypothesis assumes that the WFG feeding aggregation, *per se*, does not exist, but that

⁴Two breeding stocks – one includes whales from the PCFG and Northern feeding sub-stocks that migrate to Mexico and largely breed with each other, and the other includes all whales that feed off Sakhalin and breed largely with each other whether on the ENP or WNP migratory routes/wintering grounds.

whales feeding in the SI sub-area represent an extant Western breeding stock that utilises two wintering grounds (VSC and M). In discussion, it was noted that modelling this hypothesis does differ from that of hypothesis 5a, in that: (1) all catches off Japan are assumed to be Western stock animals; and (2) the abundance estimates off Sakhalin are assumed to relate only to the Western stock. Thus the Workshop **agreed** that an attempt should be made to implement this stock structure hypothesis and evaluate the conservation implications.

4.3.2 Projections

The aim of the projections is to explore the population consequences of various scenarios regarding anthropogenic removals of gray whales, with a view to informing future conservation and management. Table 6 lists the factors to be considered in the projections. The Workshop **agreed** that the projections would assumed that future subsistence whaling in the BCNC sub-area would occur during the migratory period and would be based on 'the SLA variant with research' (IWC, 2015b) recommended by the Scientific Committee.

It was **agreed** that the results of the projections should be summarised by:

- (a) time-trajectories of mature female numbers relative to carrying capacity, catches by stock due to aboriginal whaling, and incidental catches by stock;
- (b) the conservation-related metrics used for the implementation for the PCFG SLA; and
- (c) a table for the proportion of catch of WFG whales by sub-area (20 and 100 years).

5. WORK PLAN

The following work plan was **agreed** by the Workshop, recognising that this was ambitious and would depend upon the availability of individuals.

- (1) Scordino and Reeves to update and circulate to the Steering Group the bycatch values for the BCNC subarea by 25 April.
- (2) Punt to distribute the diagnostic plots for the base-case trials by 30 April.
- (3) Punt to fit all of models in Table 4 as well as a base-case model based on the new stock structure hypothesis and distribute the results to the Steering Group by mid-May (Punt, Donovan, Wade, Cooke, Reeves).
- (4) Steering Group to provide comments on the model fits and guidance on projection runs to Punt by 20 May.
- (5) Punt to conduct the projections in accordance with guidance from the Steering Group and present results to SC/66b.

6. ADOPTION OF REPORT

The report was adopted at 11:44 on 21 April 2016, subject to final editorial corrections. Donovan thanked Weller for his hard work in organising the excellent facilities and assisting with the hotel. He thanked all participants and especially the rapporteurs for their co-operative spirit. Most of all he thanked Punt for his dedicated, innovative and tireless work during both the intersessional period and the meeting itself.

Annex B

Agenda

1. Introductory items
 - 1.1 Convenor's opening remarks
 - 1.2 Election of Chair
 - 1.3 Appointment of rapporteurs
 - 1.4 Adoption of Agenda
 - 1.5 Documents and data available
2. Short report on progress on 'non-modelling' recommendations and new data since SC66a
 - 2.1 Update on comparison of identified gray whales in Mexico, off central California and in the PCFG with a focus on mothers and calves
 - 2.2 Comparison of photographs (and genetic material) of gray whales from areas of the Okhotsk Sea and elsewhere in Asia with the Sakhalin and Kamchatka catalogues
 - 2.3 Development of Single Nucleotide Polymorphisms (SNP) assays for use with gray whales
 - 2.4 Updated information from the eastern North Pacific
 - 2.5 Updated abundance and trend estimates for the PCFG by identifying and using additional photographic sources
 - 2.6 Updated estimates for past and future ship strikes and bycatches throughout the North Pacific
3. Progress report on modelling-related issues
 - 3.1 Updated bounds on the proportion of Sakhalin whales that migrate to the eastern North Pacific
 - 3.2 Development of an age- and sex-structured model
4. Update on modelling framework and initial runs
 - 4.1 Progress on modelling since SC/66a
 - 4.2 Finalise datasets by stock structure hypothesis
 - 4.2.1 Removals and abundance estimates
 - 4.2.2 Abundance estimates
 - 4.2.3 Mixing proportions
 - 4.3 Further development of trials to reflect uncertainty and anthropogenic removals
5. Work plan
6. Adoption of Report

Annex C

List of Documents

SC/A16/GW

1. Punt, A.E. Progress report on rangewide gray whale modelling.
2. Punt, A.E. A revised age-structured model for exploring the conceptual models developed for gray whales in the North Pacific.
3. Agenda for Workshop.
4. Weller, D.W., Lang, A.R. and Brownell, R.L., Jr. Gray whale photo/genetic match-no match summary in Western North Pacific: data for April 2016 IWC rangewide Workshop.
5. Scordino, J. and Calambokidis, J. Availability of PCFG whales by region during the migratory and feeding season: update with data through 2014.

Annex D

Gray Whale Photo/Genetic Match-No Match Summary in Western North Pacific

D.W. Weller, A.R. Lang and R.L. Brownell, Jr.

Table 1

Summary of information available regarding matches and non-matches (genetic or photographic) for gray whales from the western North Pacific.

Due to the tsunami in 2011, it is assumed that DNA or tissue is no longer available for the genetic records marked with an asterisk.

Information from: Kato *et al.*, 2015; Lang *et al.*, 2011; Weller *et al.*, 2002; 2003; 2008; 2012; 2015.

No.	Type	Date	Country	Sample	Comments
1	Genetic*	07/04/1995	Japan	Stranding Female 9.5m	Hokkaido (Pacific). Haplotype identified as G or O in Kanda <i>et al.</i> (2010). Haplotype G is found in low frequencies among both sampled Eastern North Pacific (ENP) whales and sampled Sakhalin whales (found in two individuals off Sakhalin). Haplotype O has not been found among biopsied Sakhalin individuals and is found in low frequencies among sampled ENP animals.
2	Genetic*	16/05/1996	Japan	Killed	Hokkaido (Sea of Japan). Haplotype identified as A in Kanda <i>et al.</i> (2010). Haplotype A is common in both sampled ENP and sampled Sakhalin whales (and is one of the two most commonly identified haplotypes in whales biopsied off Sakhalin).
3	Photo-ID	22/07/1997	Japan	Sighting	Kochi (Pacific). Photos unusable for matching (Kato and Tokuhiro, 1997).
4	Photo-ID	06/05/2003	Japan	Sighting	Shizuoka (Pacific). Photos unusable for matching. Two animals present.
5	Photo-ID Genetic*	11/05/2005	Japan	Entangled Female 7.81m	Chiba (Pacific). Marginal quality photo – no match to Sakhalin Russia-US catalogue. Haplotype identified as L or U in Kanda <i>et al.</i> (2010). Based on mtDNA and microsatellite data produced at SWFSC obtained from whole genome amplification products brought from Japan for analysis, this whale has haplotype U and is not a genetic match (based on microsatellites) for any of the whales the Russia-US team sampled off Sakhalin. Haplotype U has not been found in any biopsied Sakhalin whales but has been found in one individual biopsied off SE Kamchatka. This haplotype is not common among sampled ENP whales. Note that this whale and the whale entangled off Japan on 01 August 2007 (see note in record 8 below) share the same haplotype, although the microsatellite data indicates that they are not a mother-offspring pair. The possibility that these whales share an alternate relationship (e.g. maternal half-sibs) has not yet been assessed.
6	Photo-ID Genetic*	15/07/2005	Japan	Entangled Mother 12.8m	Miyagi (Pacific). Was with a calf. Photos unusable for matching. Haplotype of the adult female identified as Z in Kanda <i>et al.</i> (2010) ² . Haplotype Z is found in only a few whales sampled in the ENP and among one individual sampled off Sakhalin
7	Photo-ID Genetic*	18/01/2007	Japan	Bycatch stranding Female 9.19m	Iwate (Pacific). Useable quality photo, match to Sakhalin Russia-US catalogue. Haplotype identified as Haplotype B in Kanda <i>et al.</i> (2010), which is consistent with haplotype data we have for this same whale when sampled off Sakhalin in 2006. Haplotype B is found in moderate frequencies in sampled ENP whales and in high frequencies among biopsied Sakhalin animals.
8	Genetic*	01/08/2007	Japan	Entangled Female 12.33m	Hokkaido (Pacific). Identified as Haplotype L or U in Kanda <i>et al.</i> (2010). Based on mtDNA and microsatellite data produced at SWFSC obtained from whole genome amplification products brought from Japan for analysis, this whale has haplotype U and is not a genetic match (based on microsatellites) for any whales sampled off Sakhalin by the Russia-US team. Haplotype U has not been found in any biopsied Sakhalin whales but has been found in one individual biopsied off SE Kamchatka. It is uncommon among sampled ENP whales. See note above in record 5 regarding this whale.

Cont.

No.	Type	Date	Country	Sample	Comments
9	Photo-ID	??/11/2011	China	Bycatch	Taiwan Strait (Pacific). Useable quality photo (left side only) – no match to Sakhalin Russia-US catalogue.
No.	Type Genetic	Date	Country	Sample	Comments
					Identified as haplotype R in Wang <i>et al.</i> (2015) and confirmed by SWFSC. Based on SWFSC microsatellite genotypes, not a genetic match to any whale sampled off Sakhalin by the Russia-US team. This haplotype has not been identified among Sakhalin whales and is relatively uncommon among sampled ENP whales.
10	Photo-ID	12/03/2012	Japan	Sighting	Irako port, Tawara-city. Excellent quality photos – no match to Sakhalin RussiaUS catalogue.
11	Photo-ID	06/04/2014	Japan	Sighting	Teradomari. Excellent quality photos – no match to Sakhalin Russia-US catalogue. Inter-Japan match shows same whale as record 14 (Aoyagi <i>et al.</i> , 2016).
12	Photo-ID	03/2015	Japan	Sighting	Kozu Shima. Useable quality photo, match to Sakhalin Russia-US catalogue. Same whale as record 13.
13	Photo-ID	04-05/2015	Japan	Sighting	Suruga Bay. Marginal quality photos, match to Sakhalin Russia-US catalogue. Same whale as record 12.
14	Photo-ID	03/2015	Japan	Sighting	Teradomari. Fair quality photos – no match to Sakhalin Russia-US catalogue. InterJapan match shows same whale as record 11 (Aoyagi <i>et al.</i> , 2016).
15	Genetic	7/12/1996	China	Stranding	Yellow Sea. Baleen is archived at SWFSC but thus far, efforts to extract DNA from this baleen sample have failed and no genetic data has been obtained. See details in Zhao (1997).
16	Photo-ID	07/2000	Russia	Sighting	Paramushir Island, Kuril Islands (Okhotsk Sea). Good quality photos, match to Sakhalin Russia-US catalogue. Same whale as record 17.
17	Photo-ID	09/2000	Russia	Sighting	Shantar Island (Okhotsk Sea). Good quality photos, match to Sakhalin Russia-US catalogue. Same whale as record 16.
18	Photo-ID	06/2000	Russia	Sighting	Bering Island (Bering Sea). Good quality photos, match to Sakhalin Russia-US catalogue.
19	Photo-ID	01/2016	Japan	Sighting	Sagami Bay (Pacific). Fair quality photos, match to Sakhalin Russia-US catalogue. Same whale as records 12 and 13.
20	Photo-ID	02/2016	Japan	Sighting	Miyake-Jima (Pacific). Fair quality photos, match to Sakhalin Russia-US catalogue. Same whale as records 12, 13 and 19.
21	Photo-ID	03/2016	Japan	Stranding	Chiba (Pacific). Photos unusable for matching.

Annex E

Non-whaling Anthropogenic Mortality of Gray Whales: 2016 Update

J. Scordino and R.R. Reeves

Scordino and Mate (2012) summarised bycatch and ship strike mortality from stranding databases, human-whale interaction databases and ship strike databases maintained by NOAA's Northwest Region and Southwest Region (databases did not include events in Alaska). Their summary also included bycatches and ship strikes reported by Baird *et al.* (2002) for 1990-95 in British Columbia and all reported ship strikes and bycatch events from 1978-2010 in the USA. Scordino and Mate (2012) chose to calculate annual human-caused mortality rates based on data from 1990-2010 for the USA and 1990-95 for Canada because fishing effort in the two jurisdictions was more similar in those years than earlier in the time-series and because stranding networks in the USA were well established by 1990, giving more confidence that animals stranded in the USA with signs of human-caused mortality would have been reported.

In 2014, Scordino *et al.* (2014) presented new estimates of annual bycatch and ship strike rates for the time period of 2008-12 using a classification procedure developed by NOAA (2012) to account for the uncertainty in outcome of injuries to large whales due to entanglements and ship strikes. This procedure makes it possible to prorate mortality values for injuries based on the known fates of individual whales observed with similar injuries in the past. Gray whale deaths and injuries were documented through fisheries observer programmes, self-reporting by fishermen and sailing captains, reporting by the public and examinations of dead whales on the beach in the USA and Canada. Every report was documented in a Canadian or US government database. Based on descriptions in the databases, each event was determined to have been either a death, a serious

injury, or a non-serious injury, based on NOAA (2012). All US events were assessed for serious vs non-serious injury by a NOAA working group (Carretta *et al.*, 2014) and that group's results were used as the basis for scoring the events reported by Scordino *et al.* (2014) and summarised by Scordino *et al.* (2016).

Here we use data for 2007-14 from NOAA serious injury reports (Carretta *et al.*, 2013; 2014; 2015; 2016) received from James Carretta (NOAA, SWFSC, La Jolla, pers. comm.) for the US and from Paul Cottrell (Department of Fisheries and Oceans, Sydney, BC, pers. comm.) for Canada to update the input data on incidental mortality given in IWC (2016). The previous tables of ship strike and bycatch mortality in IWC (2016) incorrectly classified two observations at Valdez-Cordova as being from Southeast Alaska instead of from the Far North region; these have been rectified in the new tables provided here (Tables 1 and 2).

Annex F

Specifications of the Population Model

A. BASIC CONCEPTS AND STOCK STRUCTURE

The aim of the projections is to explore the population consequences of various scenarios regarding anthropogenic removals of gray whales, with a view to informing future conservation and management. The model distinguishes ‘breeding stocks’ and ‘feeding aggregations’. Breeding stocks are demographically and genetically independent whereas feeding aggregations may be linked through dispersal of individuals¹, though perhaps at very low rates for some combinations of feeding aggregations. Each breeding stock/feeding aggregation is found in a set of sub-areas, each of which may have catches (commercial, aboriginal or incidental), proportions of breeding stock/feeding aggregation mixing² in those sub-areas, observed bycatch rates³, and indices of relative or absolute abundance. Removals may be specified to sets of months during the year for some sub-areas if the various feeding aggregations are not equally vulnerable to catches throughout the year for those sub-areas. The trials capture uncertainty regarding stock structure and MSYR, as well as uncertainty regarding bycatch and immigration.

The region concerned, the North Pacific, is divided into 11 sub-areas. The model also includes two ‘latent’ sub-areas used to link model predictions to observed indices of abundance. These are denoted CA-3 and BCNC3. There are up to two extant *breeding stocks* (Western and Eastern). The Eastern breeding stock consists of up to three *feeding aggregations* depending on the stock structure hypothesis: Western Feeding Group (WFG), Pacific Coast Feeding Group (PCFG) and ‘North’. There is dispersal between the PCFG and North feeding aggregations, but the WFG is demographically independent of the other two feeding aggregations (i.e. there is no *permanent* movement of animals from the North or PCFG to the WFG or vice-versa).

The trials consider four stock structure hypotheses.

- (1) *Hypothesis 3a*. Although two breeding stocks (Western and Eastern) may once have existed, the Western stock is assumed to have been extirpated. Whales show matrilineal fidelity to feeding grounds, and the Eastern stock includes three feeding aggregations: PCFG, Northern Bering Sea (NBS)/Southern Chukchi (SCH)-Northern Chukchi-Gulf of Alaska (‘Northern’) and WFG.
- (2) *Hypothesis 3e*. Identical to hypothesis 3a except that the Western breeding stock is extant and migrates off both coasts of Japan and Korea and in the northern Okhotsk Sea west of the Kamchatka Peninsula. All of the whales feeding off Sakhalin overwinter in the eastern North Pacific.
- (3) *Hypothesis 5a*. Identical to hypothesis 3a except that the whales feeding off Sakhalin include both whales that are part of the extant Western stock and remain in the western North Pacific year-round, and whales that are part of the Eastern stock and migrate between Sakhalin and the eastern North Pacific.
- (4) *Hypothesis 6b*. This hypothesis assumes that the WFG feeding aggregation does not exist, but that whales feeding in the SI sub-area represent an extant Western breeding stock that utilises two wintering grounds (VSC and M). This hypothesis differs from hypothesis 5a, in that: (1) all removals off China and Japan are assumed to be Western breeding stock animals; and (2) the abundance estimates for Sakhalin are assumed to relate only to the Western breeding stock.

B. BASIC DYNAMICS

The population dynamics are based on the standard age- and sex-structured model, which has formed the basis for the evaluation of *Strike Limit Algorithms* for eastern North Pacific gray whales, i.e.:

$$\begin{aligned}
 N_{t+1,0}^{m/f,i,j} &= 0.5B_{t+1}^{i,j} & a=0 \\
 N_{t+1,a}^{m/f,i,j} &= ((N_{t,a-1}^{m/f,i,j} - C_{t,a-1}^{m/f,i,j})S_{a-1} + I_{t,a-1}^{m/f,i,j})\tilde{S}_t^{i,j} & 1 \leq a \leq x-1 \\
 N_{t+1,x}^{m/f,i,j} &= ((N_{t,x}^{m/f,i,j} - C_{t,x}^{m/f,i,j})S_x + (N_{t,x-1}^{m/f,i,j} - C_{t,x-1}^{m/f,i,j})S_{x-1} + I_{t,x}^{m/f,i,j} + I_{t,x-1}^{m/f,i,j})\tilde{S}_t^{i,j} & a=x
 \end{aligned} \tag{B.1}$$

where:

$N_{t,a}^{m/f,i,j}$ is the number of males/females of age a in feeding aggregation j of breeding stock i at the start of year t ;

$C_{t,a}^{m/f,i,j}$ is the number of anthropogenic removals of males/females of age a in feeding aggregation j of breeding stock i during year t (whaling is assumed to take place in a pulse at the start of each year);

¹The term ‘dispersal’ is used here in the sense of ‘effective dispersal’, and refers to permanent movement of individuals among feeding aggregations. Such individuals become part of the feeding aggregation to which they move and contribute to future reproduction.

²Mixing is defined here as two feeding aggregations that overlap at some time on the feeding grounds, but do not interbreed.

³Bycatch is understood to include mortality or ‘serious’ injury from entanglement or entrapment in fishing gear (or debris) and ship strikes.

S_a is the annual survival rate of animals of age a in the absence of catastrophic mortality events (assumed to be the same for males and females):

$$S_a = \begin{cases} S_0 & \text{if } a = 0 \\ S_{1+} & \text{if } 1 \leq a \end{cases} \quad (\text{B.2})$$

S_0 is the calf survival rate;

S_{1+} is the survival rate for animals aged 1 and older;

$\tilde{S}_t^{i,j}$ is the amount of catastrophic mortality (represented in the form of a survival rate) for feeding aggregation j of breeding stock i during year t (catastrophic events are assumed to occur at the end of the year after mortality due to anthropogenic removals and non-catastrophic natural causes, and dispersal; in general $\tilde{S}_t^{i,j} = 1$, i.e. there is no catastrophic mortality);

$B_{t+1}^{i,j}$ is the number of births to feeding aggregation j of breeding stock i during year $t+1$;

$I_{t,a}^{s,m/f}$ is the net dispersal of female/male animals of age a into feeding aggregation j of breeding stock i during year t ; and

x is the maximum (lumped) age-class (all animals in this and the $x-1$ class are assumed to be recruited and to have reached the age of first parturition). x is taken to be 15.

C. DENSITY-DEPENDENCE

Density-dependence is assumed to be a function of numbers of animals aged 1 and older by feeding ground relative to the carrying capacity by feeding ground. The density-dependence component for feeding aggregation j of breeding stock i is the sum of the density-dependence components by feeding aggregation weighted by the proportion of animals from feeding aggregation j of breeding stock i that are found on each feeding ground, i.e.:

$$F(i, j, t) = \sum_A \psi^{A,i,j} \left(X^{A,i,j} (N_t^{1+,A} / K^{1+,A})^z \right) / \sum_A \psi^{A,i,j} X^{A,i,j} \quad (\text{C.1})$$

where

z is the degree of compensation;

$\psi^{A,i,j}$ indicates whether sub-area A impacts density-dependence for feeding aggregation j of breeding stock i ;

$N_t^{1+,A}$ is the number of 1+ animals on feeding ground A at the start of year t :

$$N_t^{1+,A} = \sum_i \sum_j X^{A,i,j} \sum_{a=1}^x (N_{t,a}^{m,i,j} + N_{t,a}^{f,i,j}) \quad (\text{C.2})$$

$K_t^{1+,A}$ is the carrying capacity for feeding ground A :

$$K^{1+,A} = \sum_i \sum_j X^{A,i,j} \sum_{a=1}^x (N_{-\infty,a}^{m,i,j} + N_{-\infty,a}^{f,i,j}) \quad (\text{C.3})$$

$X^{A,i,j}$ is the proportion of animals in feeding aggregation j of breeding stock i that are found in feeding ground A ⁴ (see Table 1).

The number of births at the start of year t for feeding aggregation j of breeding stock i , $B_t^{i,j}$, is given by:

$$B_t^{i,j} = b_t^{i,j} N_t^{f,i,j} \quad (\text{C.4})$$

where $N_t^{f,i,j}$ is the number of mature females in feeding aggregation j of breeding stock i at the start of year t :

$$N_t^{f,i,j} = \sum_{a=a_m}^x N_{t,a}^{f,i,j} \quad (\text{C.5})$$

a_m is the age-at-maturity (the convention of referring to the mature population is used here, although this actually refers to females that have reached the age of first parturition);

$b_t^{i,j}$ is the probability of birth/calf survival for mature females in feeding aggregation j of breeding stock i during year t :

$$b_t^{i,j} = \max(0, b_K \{1 + A^{i,j} (1 - F(I, j, t))\}) \quad (\text{C.6})$$

b_K is the average number of live births per year per mature female at carrying capacity; and

$A^{i,j}$ is the resilience parameter for feeding aggregation j of breeding stock i .

⁴It is usually the case that $\sum X^{A,i,j} = 1$. However, for gray whales, this is not necessarily the case because removals can take place in the various feeding grounds at different times. What is then important is the relative values of the $X^{A,i,j}$ among feeding aggregations for a given feeding ground.

Table 1

The mixing matrices for stock structure hypotheses 3a, 3e, 5a and 6b. The γ s denote the estimable parameters of the catch mixing matrix and the χ s denote values that are varied in the tests of sensitivity. Note that the 'CA-3' sub-area is included so that the surveys (= encompasses all methods for obtaining abundance estimates) cover all of the PCFG, Sakhalin and north feeding aggregations while the BCNC-3 sub-area is included so that the surveys for the BCNC sub-area pertain only to the PCFG feeding aggregation.

Breeding stock	Sub-area															
Feeding aggregation	VSC	KWJ	EJPJ	OS	SI	EKK	BSCS	SEA (J-N)	SEA(D-M)	BCNC (J-N)	BCNC (D-M)	BCNC-3	CA (J-N)	CA (D-M)	CA-3	M
(a) Hypothesis 3a (no extant Western breeding stock)																
Eastern WFG	-	-	1	1	1	1	-	-	1	-	γ_4	-	-	1	1	1
North	-	-	γ_1	-	-	-	1	1	1	1	1	-	1	1	1	1
PCFG	-	-	-	-	-	-	χ_1	γ_2	1	γ_3	γ_5	1	γ_6	1	1	1
(b) Hypothesis 3e (extant Western breeding stock)																
Western	1	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
Eastern WFG	-	-	γ_7	1	1	1	-	-	1	-	γ_4	-	-	1	1	1
North	-	-	-	-	-	-	1	1	1	1	1	-	1	1	1	1
PCFG	-	-	-	-	-	-	χ_1	γ_2	1	γ_3	γ_6	1	γ_6	1	1	1
(c) Hypothesis 5a (with Western breeding stock in SI)																
Western	1	1	1	1	γ_8	-	-	-	-	-	-	-	-	-	-	-

PCFG	-	-	-	-	-	-	χ_1	γ_2	1	γ_3	γ_5	1	γ_6	1	1	1
(d) Hypothesis 6b (no WFG feeding aggregation)																
Western	1	1	1	1	1	1	-	-	1	-	γ_4	-	-	1	1	1
Eastern North	-	-	-	-	-	-	1	1	1	1	1	-	1	1	1	1
PCFG	-	-	-	-	-	-	χ_1	γ_2	1	γ_3	γ_5	1	γ_6	1	1	1

D. IMMIGRATION (DISPERSAL)

The numbers dispersing into feeding aggregation j of breeding stock i , include contributions from pulse migration as well as diffusive dispersal:

$$I_{t,a}^{s,j,i} = \sum_k \delta^{k,j,i} \tilde{N}_{t,a}^{s,i,k} \left(\frac{N_{t,a}^{f,j,k}}{N_{t,a}^{f,i,k}} \right)^\lambda - \sum_k \delta^{j,k,i} \tilde{N}_{t,a}^{s,i,j} \left(\frac{N_{t,a}^{f,i,j}}{N_{t,a}^{f,i,j}} \right)^\lambda + \sum_{k \neq j} \Omega_y^{k,j,i} \frac{\tilde{N}_{t,a}^{s,i,k}}{\sum_{a=1}^x (\tilde{N}_{t,a}^{m,i,k} + \tilde{N}_{t,a}^{f,i,k})} - \sum_{k \neq j} \Omega_y^{j,k,i} \frac{\tilde{N}_{t,a}^{s,i,j}}{\sum_{a=1}^x (\tilde{N}_{t,a}^{m,i,j} + \tilde{N}_{t,a}^{f,i,j})} \quad (D.1)$$

where

$\delta^{k,j,i}$ is the rate of dispersal from feeding aggregation k to feeding aggregation j of breeding stock i ;

λ is a factor to allow for density-dependence in the dispersal rate (set to 2);

$\Omega_y^{k,j,i}$ is the number of animals that disperse during year y from feeding aggregation k to feeding aggregation j of breeding stock in a pulse; and

$$\tilde{N}_{t,a}^{s,i,k} = (N_{t,a}^{s,i,k} - C_{t,a}^{s,i,k}) S_a$$

E. ANTHROPOGENIC REMOVALS

The catch by feeding aggregation is generally determined by apportioning the catches by fleet⁵, taking account of mixing (i.e. exposure to harvesting) matrices, according to:

$$C_{t,a}^{m/f,i,j} = \sum_k C_t^{m/f,k} \frac{\alpha_a^k X_{A_k,i,j} N_{t,a}^{m/f,i,j}}{\sum_{i,j,a} \alpha_a^k X_{A_k,i,j} N_{t,a}^{m/f,i,j}} \quad (E.1)$$

where

$C_t^{m/f,k}$ is the catch of males/females caught by fleet k during year t ;

A_k is the sub-area in which fleet k operates; and

α_a^k is the relative vulnerability of animals of age a to harvest by the fleets that operate in sub-area k .

The incidental catches (bycatch as defined above) by feeding ground are computed using the equation:

⁵A fleet is the combination of a fishery sector (commercial/aboriginal) and the feeding ground in which the catch is taken.

$$C_t^{1,A} = \lambda^A E_t^A \sum_{i,j,a,m/f} \tilde{\alpha}_a X^{A,i,j} N_{t,a}^{m/f,i,j} \quad (\text{E.2})$$

where

$C_t^{1,s,A}$ is the incidental catch of animals of sex s in feeding ground A during year t ;

E_t^A is a measure of the effort in feeding ground A during year t ;

λ^A is the catchability coefficient for bycatch; and

$\tilde{\alpha}_a$ is 1 for ages 0 to 5 and 0 for all other ages (IWC, 2016).

The incidental catches are allocated to feeding aggregation, sex and age using the formula:

$$C_{t,a}^{1,m/f,i,j} = \sum_A C_t^{1,A} \frac{\tilde{\alpha}_a X^{A,i,j} N_{t,a}^{m/f,i,j}}{\sum_{i,j,m/f,a} \tilde{\alpha}_a X^{A,i,j} N_{t,a}^{m/f,i,j}} \quad (\text{E.3})$$

F. INITIALISING THE PARAMETER VECTOR

The numbers at age in the pristine population are given by:

$$\begin{aligned} N_{-\infty,a}^{m/f,i,j} &= 0.5 N_{-\infty,0}^{i,j} \prod_{a'=0}^{a-1} S_{a'} & \text{if } a < x \\ N_{-\infty,x}^{m/f,i,j} &= 0.5 N_{-\infty,0}^{i,j} \prod_{a'=0}^{x-1} S_{a'} / (1 - S_x) & \text{if } a = x \end{aligned} \quad (\text{F.1})$$

The value for $N_{-\infty,0}^{i,j}$ is determined from the value for the pre-exploitation size of the 1+ component of feeding aggregation j of breeding stock i using the equation:

$$N_{-\infty,0}^{m,i,j} = K^{1+,i,j} / \left(\sum_{a=1}^{x-1} \left(\prod_{a'=0}^{a-1} S_{a'} \right) + \frac{1}{1 - S_x} \prod_{a'=0}^{x-1} S_{a'} \right) \quad (\text{F.2})$$

where $K^{1+,i,j}$ is the carrying capacity (in terms of the 1+ population size) for feeding aggregation j of breeding stock i :

$$K^{1+,i,j} = \sum_{a=1}^x (N_{-\infty,a}^{m,i,j} + N_{-\infty,a}^{f,i,j}) \quad (\text{F.3})$$

$N_{-\infty,a}^{m/f,i,j}$ is the number of animals of age a that would be in feeding aggregation j of breeding stock i in the pristine population.

The model is based on the assumption that the age-structure at the start of year τ is stable rather than that the population was at its pre-exploitation equilibrium size at some much earlier year. The determination of the age-structure at the start of year τ involves specifying the effective 'rate of increase', γ , that applies to each age-class. There are two components contributing to γ , one relating to the overall population rate of increase (γ^+) and the other to the exploitation rate due to all forms of anthropogenic removal. Under the assumption of knife-edge recruitment to the fishery at age a_r , only the γ^+ component (assumed to be zero following Punt and Butterworth, 2002) applies to ages a of a_r or less. The number of animals of age a at the start of year τ relative to the number of calves at that time, $N_{\tau,a}^*$, is therefore given by the equation:

$$N_{\tau,a}^* = \begin{cases} 1 & \text{if } a = 0 \\ N_{\tau,a-1}^* S_{a-1} & \text{if } a \leq a_r \\ N_{\tau,a-1}^* S_{a-1} (1 - \gamma) & \text{if } a_r < a < x \\ N_{\tau,x-1}^* S_{x-1} (1 - \gamma) / (1 - S_x (1 - \gamma)) & \text{if } a = x \end{cases} \quad (\text{F.4})$$

where B_τ is the number of calves in year τ and is derived directly from equations C.1 and C.6.

$$B_\tau = \left(1 - \left[1 / (N_\tau^f b_K) - 1 \right] / A \right)^{1/z} \frac{K^{1+}}{N_\tau^{1+,*}} \quad (\text{F.5})$$

The effective rate of increase, γ , is selected so that if the population dynamics model is projected from year τ to a year Ψ , the size of the 1+ component of the population in a reference year Ψ equals a value, P_Ψ .

G. CONDITIONING

The parameters of the model are: (a) the carrying capacity of each stock; (b) the population (expressed relative to carrying capacity) for each stock at the start of 1930; (c) MSYR by stock; (d) annual survival under ‘normal’ conditions; (e) maturity as a function of age; (f) the impact of the mortality event in the eastern Pacific in 1999 and 2000; (g) selectivity; (h) the rate of dispersal between the North and PCFG feeding aggregations; (i) the parameters of the mixing matrices; (j) the catchability coefficients that determine bycatch by sub-area; and (k) the extent of additional variation for each abundance index. Some of these parameters are pre-specified:

- (1) MSYR (except for trials 14-20);
- (2) annual survival under ‘normal’ conditions ($=e^{-0.05}$);
- (3) maturity as a function of age (a logistic function of age, with an age-at-50%-first-parturition of 8 years and a minimum age-at-first parturition of 3 years); and
- (4) selectivity (knife-edged at age 1).

Under the assumption that the estimates of abundance for a feeding ground (see Table 2) are log-normally distributed, the negative of the logarithm of the likelihood function is given by:

$$-\ln L = \ln \sqrt{\text{Det}[V]} + 0.5 \sum_k (\ell \ln \underline{N}^{A,obs} - \ell \ln \underline{N}^A) [V^{-1}] (\ell \ln \underline{N}^{A,obs} - \ell \ln \underline{N}^A)^T \quad (\text{G.1})$$

where

$\underline{N}_t^{A,obs}$ is the survey estimate of abundance for sub-area A during year t ; and

V is the sum of the variance-covariance matrix for the abundance estimates plus an additional variance term (assumed to be independent of year).

The data on the proportion of each stock (see Table 3) in each feeding ground is modelled under the assumption that the proportions are normally distributed, i.e.:

$$-\ln L = \sum_i \sum_A \sum_t \frac{1}{2(\tau_t^{i,A})^2} (p_t^{i,A} - p_t^{i,A,obs})^2 \quad (\text{G.2})$$

where

$p_t^{i,A}$ is the model-estimate of the proportion of the animals in feeding ground A that are from feeding aggregation i of the Eastern breeding stock;

$p_t^{i,A,obs}$ is the observed proportion of animals in feeding ground A that are from feeding aggregation i of the Eastern breeding stock; and

$\tau_t^{i,A}$ is the standard error of $p_t^{i,A,obs}$.

The (non-zero) bycatches by sub-area (see Table 4) are assumed to be log-normally distributed, and the model is fitted to the average bycatch by sub-area over a pre-specified set of years, i.e.:

$$-\ln L = \sum_A \frac{1}{2\sigma_{BC}^2} \left(\ln C^{I,A,obs} - \ln \hat{C}^{I,A} \right)^2 \quad (\text{G.3})$$

where

$C^{I,A,obs}$ is the observed average annual bycatch from feeding ground A over the pre-specified period;

$\hat{C}^{I,A}$ is the average over this period of the model-estimate of the bycatch from feeding ground A ; and

σ_{BC} is the standard error of the logarithms of the observed bycatches.

A penalty is imposed on the average number of animals moving permanently from the ‘north’ feeding aggregation into the ‘PCFG’ feeding aggregation between 2001 and 2008, i.e.:

$$-\ln L = \frac{1}{2\sigma_I^2} \left(\tilde{I} - \frac{\delta^{m/f,north,West}}{8} \sum_{t=2001}^{2008} \sum_{s=m/f}^x \sum_{a=1}^x \tilde{N}_{t,a}^{s,East,north} \right)^2 \quad (\text{G.4})$$

where

\tilde{I} is the pre-specified average number of immigrants into the PCFG feeding aggregation from the ‘North’ feeding aggregation; and

σ_I is a weighting factor.

H. QUANTIFYING UNCERTAINTY USING BOOTSTRAP

A bootstrap procedure is used to quantify uncertainty for a given model specification. Each bootstrap replicate involves:

- (1) generating pseudo time-series of abundance estimates based on the assumption that the abundance estimates are log-normally distributed with means and variance-covariance matrices given by the observed abundance estimates and the reported variance-covariance matrices;
- (2) generating pseudo mixing proportions from beta distributions with means and CVs given by the observed means and CVs;
- (3) generating pseudo bycatch rates by feeding ground from log-normal distributions with means of $C^{I,A,obs}$ and a log standard error of σ_{BC} ; and
- (4) generating a pseudo immigration rate from the 'North' into the PCFG feeding aggregation based on a normal distribution (truncated at zero) with mean \bar{l} and standard error σ_l .

I. GENERATION OF DATA

The actual historical estimates of absolute abundance (and their associated CVs) provided to the *Strike Limit Algorithms* are listed in Table 2. The future estimates of abundance for sub-areas BCNC-3 and CA-3 (say sub-area K) are generated using the formula:

$$\hat{P} = PY_w / P^* \beta^2 Y_w \quad (F.1)$$

where:

Y is a lognormal random variable $Y=e^\varepsilon$ where $\varepsilon \sim N(0; \sigma_\varepsilon^2)$ and $\sigma_\varepsilon^2 = \ln(1 + \alpha^2)$;

w is a Poisson random variable with $E(w) = \text{var}(w) = \mu = (P / P^*) / \beta^2$, Y and w are independent;

P is the current total (1+) population size in survey area K :

$$P = P_t^K = \sum_i \sum_j \sum_g \sum_{a \geq 1} N_{t,a}^{g,i,j} \quad (F.2)$$

P^* is the reference population level, and is equal to the total (1+) population size in the survey area prior to the commencement of exploitation in the feeding ground for which an abundance estimate is to be generated. For consistency with the first-stage screening trials for a single stock (IWC, 1991; 1993), the ratio $\alpha^2 : \beta^2 = 0.12 : 0.025$, so that $CV^2(\hat{P}) = \tau(0.12 + 0.025 P^*/P)$. If \overline{CV} is the target CV then $\tau = \overline{CV}^2 / (0.12 + 0.025 P_{\text{ref}}/P^*)$ where P_{ref} is the population size in a reference year.

An estimate of the CV is generated for each estimate of abundance:

$$CV(\hat{P})_{\text{est}}^2 = \sigma^2 \chi^2 / n \quad (F.3)$$

where $\sigma^2 = \ln(1 + \alpha^2 + \beta^2 P^* / \hat{P})$, and χ is a random number from a Chi-square distribution with n degrees of freedom (where $n=10$ as used for NP minke trials; IWC, 2004).

J. TRIALS

The factors included in the trials are listed in Table 5 and the trials in Table 6.

Table 5
Factors considered in the model scenarios. The **bolded** values are the base-levels.

Factor	Levels
Model fitting related	
Stock hypothesis	3a, 3e, 5a
Proportion of 'Western' stock in Sakhalin sub-area	0 (stock hypotheses 3a, 3e), 0.33 (stock hypothesis 5a), 0.70
MSYR ₁₊ (western)	As for WFG
MSYR ₁₊ (north)	4.5% , 5.5%, Estimated (common); estimate (separately)
MSYR ₁₊ (WFG)	4.5% , 5.5%, Estimated (common); estimate (separately)
MSYR ₁₊ (PCFG)	2%, 4.5% , Estimated (common); estimate (separately)
Matches	Definite; Definite+Likely (Table 2)
Immigration into the PCFG	0, 2, 4
Bycatches and ship strikes	Numbers dead, M/SI, numbers dead x 4; x numbers dead x 10
Pulse migrations into the PCFG	10, 20, 30
Bycatch off Sakhalin	1.5, 3
Projection-related	
Northern need in final year (from 150 in 2014)	340, 530
Struck and lost rate	25%, 50% , 75%
Future effort	Constant , Increase by 100% over 100 years
Probability of mismatching a north whale, p_1	0.01
Probability of mismatching a PCFG, p_2	0.05 (trials)
PCFG harvest month	Migratory

K. MANAGEMENT OPTIONS

The strike limits for the BSCS feeding ground are based on the *Gray Whale SLA* (IWC, 2005), while the strike limits for the BCNC feeding ground are based on 'research with variant' (*SLA* variant 1) option (IWC, 2013). The steps below show how the proposed Makah Management plan operates. Variant 1 would have steps (1), (3), and (4) but not (2). Variant 2 would have (2) (3) and (4). Furthermore, variant 1 has hunting from December-May.

- (1) Compute the ABL (Allowable Bycatch Limit of PCFG whales)
 - (a) Strike an animal.
 - (b) If the animal is struck-and lost in December-April⁶:
 - (c) if the total number of struck and lost animals is 3, stop the hunt.
 - (d) if the total number of struck animals equals the need of 7 stop the hunt.
 - (e) go to step (2).
- (2) If the animal is struck-and lost in May:
 - (a) add one to the number of whales counted towards the ABL.
 - (b) if the ABL is reached; stop the hunt.
 - (c) if the total number of struck and lost animals is 3, stop the hunt.
 - (d) if the total number of struck animals equals the need of 7; stop the hunt.
 - (e) go to step (2).
- (3) If the animal is landed and is matched against the catalogue⁷:
 - (a) add one to the number of whales counted towards the ABL.
 - (b) if the ABL is reached; stop the hunt.
 - (c) if the total number of landed whales equals 5; stop the hunt.
 - (d) if the total number of struck animals equals the need of 7; stop the hunt.
 - (e) if the number of landed whales for the current five-year block equals 20; stop the hunt.
 - (f) go to step (2).
- (4) If the animal is landed and does not match any whale in the catalogue:
 - (a) if the total number of landed whales equals 5; stop the hunt.
 - (b) if the total number of struck animals equals the need of 7; stop the hunt.
 - (c) if the number of landed whales for the current five-year block equals 20; stop the hunt.
 - (d) go to step (2).

Removals due to bycatch are based on the scenarios regarding future trends in effort. Table 5 lists the factors considered in the projections.

⁶Whether a whale is struck and lost is determined from a Bernoulli trial with probability 0.5 (base-case).

⁷PCFG whales are mismatched as north stock whales with probability p_2 while north stock whales are matched to the catalogue with probability p_1 .

L. OUTPUT STATISTICS

The population-size statistics are produced for each breeding stock/feeding aggregation, while the removal-related statistics are for each sub-area.

L.1 Risk

D1. Final depletion: P_T/K .

D2. Lowest depletion: $\min (P_t) : t=0,1,\dots,T$.

D3. Plots of $\{P_{t[x]} : t=0,1,\dots,T$ where $P_{t[x]}$ is the x th percentile of the distribution of P_t . Results are presented for $x=5$ and $x=50$.

L.2 Removal-related

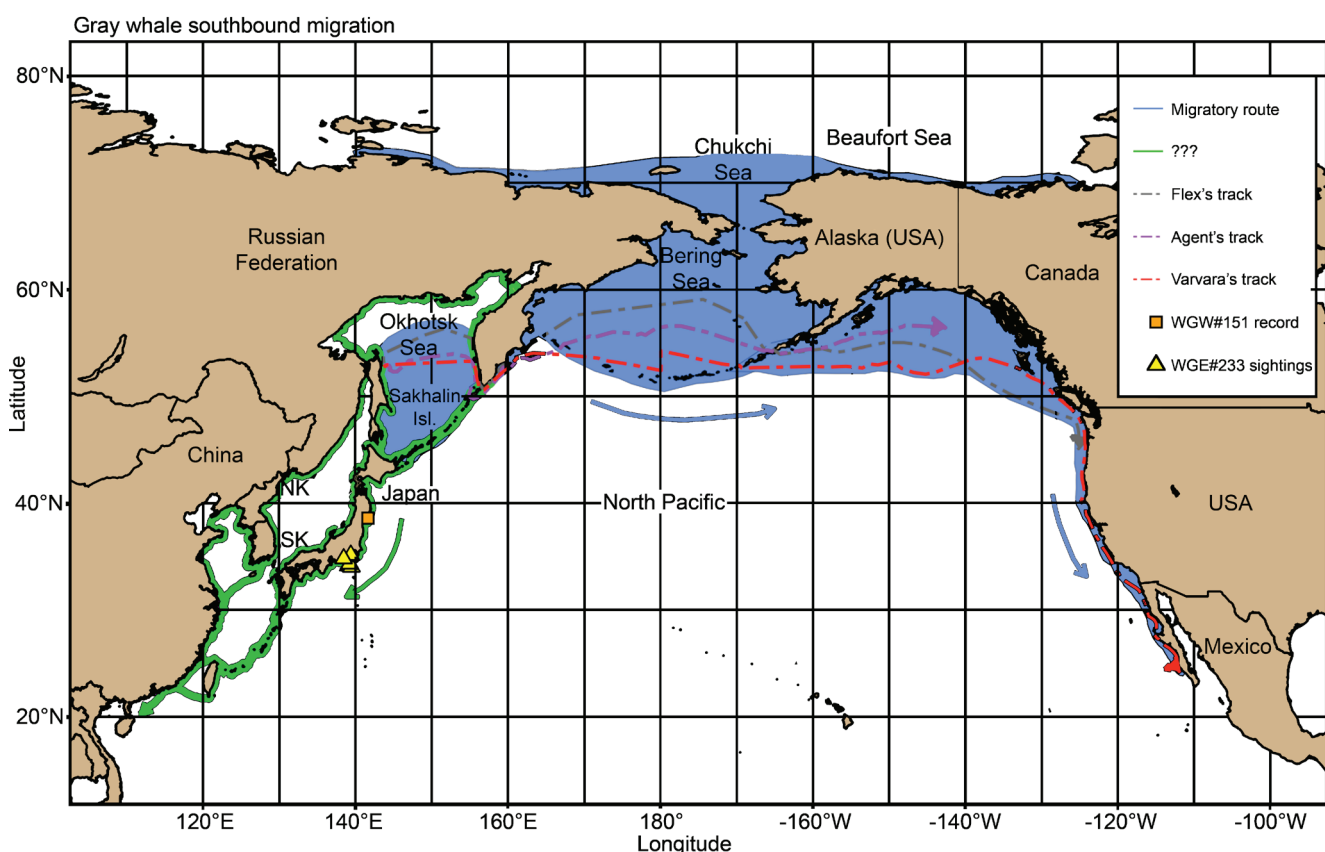

- R1.** Plots of strikes by year for simulations 1-100.
- R2.** Plots of landed whales by year for simulations 1-100.
- R3.** Plots of incidental catches by year for simulations 1-100.
- R4.** A table for the proportion of catch of WFG whales by sub-area (20 and 100 years).

Annex G

Schematic Summarising Present Knowledge of the Distribution of Gray Whales in the North Pacific on a Seasonal Basis

This four-panel map is a schematic summarising present knowledge of the distribution of gray whales in the North Pacific on a seasonal basis: the summer feeding period (a), the period of southward migration (and breeding) in late autumn (b), the winter calving, early calf rearing and fasting season (c), and the period of northward migration in spring (d). The maps also include all known reports of gray whales in the western North Pacific since 1995 (for details see Annex E).

Report of the Scientific Committee

Bled, Slovenia, 24 April-6 May 2018

The meeting (SC/67b) was held at the Rikli Balance Hotel, Bled, Slovenia, from 24 April-06 May 2018 and was chaired by Caterina Fortuna. The next meeting of the Commission (IWC/67) will take place 4-14 September 2018. The list of participants is given as Annex A (about one-third of the Contracting Governments were represented by delegates).

1. INTRODUCTORY ITEMS

1.1 Chair's welcome and opening remarks

Fortuna welcomed the participants to the meeting. Although the meeting was not officially hosted by the Slovenian Government, she thanked it for welcoming them back and noted how pleased the Scientific Committee was to be once again in such a beautiful place. She thanked the IWC Secretariat staff for their hard work during the intersessional period, particularly Mark Tandy for organising the meeting under time pressure Stella Duff and Andrea Cooke for their assistance with meeting documents and Greg Donovan for all his support intersessionally. She thanked Sava Hotels for providing the meeting facilities and her Slovenian colleagues for helping meeting arrangements run smoothly. Fortuna also thanked the vice-Chair Robert Suydam, the Convenors (including those of intersessional groups) and Committee members for all their hard work since the last meeting.

Rebecca Lent, the new IWC Executive Secretary, welcomed participants to the meeting. She noted this was her first IWC meeting, but already knew of its excellent global reputation and looked forward to attending many sessions. She noted her pleasure at joining the IWC at such an exciting time, with a busy year of meetings and several new initiatives. Two new coordinators have joined the Secretariat as part of the IWC work programmes endorsed by the Commission in 2016: Marguerite Tarzia as bycatch coordinator; and Karen Stockin as strandings coordinator. They will lead the Commission's work in these areas and will provide valuable input into the Scientific Committee's work.

Lent noted that the external "The IWC review – final report" (<https://archive.iwc.int/?r=6890>) undertaken as part of the IWC's Governance Review has recently become available and she noted that the Commission would welcome comments on it from the Scientific Committee, and that in particular, the Commission's Operational Effectiveness Working Group will take into consideration the comments from the Scientific Committee in making its recommendations to the Finance and Administration Committee; that Committee will then make recommendations to the Commission, which will determine the next steps in the governance review. Budget Management has become more challenging in recent years and there is much work to do to make sure the workplan of the Commission and all its subsidiary bodies is affordable going forward and into the long term. Finally, she thanked Scientific Committee members for their scientific input over the next two weeks and wished everyone a successful meeting.

The Committee was saddened to learn of the death of four scientists connected with the Scientific Committee:

- (1) Greg Kaufman, a member of the Committee since 2006 and an active member of the sub-committee on whale watching and the Whale watching Working Group of the Conservation Committee;
- (2) Doug Coughran, who although he did not attend Scientific Committee meetings, was a participant in numerous IWC workshops on entanglement and stranding response and was a charter member of both the IWC's entanglement and stranding expert (advisory) groups;
- (3) Dale Rice, who although he has not attended IWC meetings in recent years, first represented the USA on the Scientific Committee as far back as 1960; and
- (4) John Reynolds, who although not a member of the Scientific Committee, was a mentor to many Committee members.

The Committee paused in silence and respect for these scientists who had contributed directly and indirectly to the Committee's work and to whale conservation and management. Short obituaries can be found in Annex AA.

1.2 Appointment of rapporteurs

Donovan was appointed rapporteur with assistance from various members of the Committee as appropriate. Chairs of sub-committees and Working Groups appointed rapporteurs for their individual meetings.

1.3 Meeting procedures and time schedule

The Committee agreed to the meeting procedures and time schedule outlined by the Chair.

1.4 Establishment of sub-committees and Working Groups

The following pre-meetings were held:

- (1) the Standing Working Group on Environmental Concerns held a pre-meeting on 'Cumulative Effects' from 22-23 April; and
- (2) the sub-committee on Whale Watching held a pre-meeting on the IWC's 'Five Year Strategic Plan for Whale Watching' from 22-23 April.

Several sub-committees and Working Groups were established. Their reports were either made Annexes (see below) or subsumed into this report.

Annex D – Sub-Committee on the Revised Management Procedure;
 Annex E – Standing Working Group on an Aboriginal Whaling Management Procedure;
 Annex F – Sub-Committee on In-Depth Assessments;
 Annex G – Sub-Committee on Other Northern Hemisphere Whale Stocks
 Annex H – Sub-Committee on Other Southern Hemisphere Whale Stocks;
 Annex I – Working Group on Stock Definition and DNA testing;
 Annex J – Sub-Committee on Non-Deliberate Human-Induced Mortality of Cetaceans;
 Annex K – Sub-Committee on Environmental Concerns;
 Annex L – Standing Working Group on Ecosystem Modelling;
 Annex M – Sub-Committee on Small Cetaceans;
 Annex N – Sub-Committee on Whale Watching;
 Annex O – Sub-Committee on Conservation Management Plans;
 Annex P – Revised ‘Annex P’;
 Annex Q – Standing Working Group on Abundance Estimates, Stock Status and International Cruises;
 Annex R – *Ad hoc* working Group on Sanctuaries;
 Annex S – *Ad hoc* Working Group on Photo-ID;
 Annex T – *Ad hoc* Group on Global databases and repositories
 Annex U – Statements on Special Permit discussions
 Annex V – IWC-SORP – Southern Ocean Research Partnership
 Annex W – Updated Rules of Procedure
 Annex X – Comments on the ‘Governance Review’
 Annex Y – Intersessional groups
 Annex Z – Minority Statements on the Agenda

1.5 Computing arrangements

Donovan outlined the computing and printing facilities available for delegate use.

2. ADOPTION OF AGENDA

The adopted Agenda is given as Annex B. Statements on the Agenda are given as Annex Z.

3. REVIEW OF AVAILABLE DATA, DOCUMENTS AND REPORTS

3.1 Documents submitted

The documents available are listed in Annex C. As agreed at the 2012 Annual Meeting, primary papers were only available at the meeting in electronic format (IWC, 2013a, pp 78-79).

3.2 National Progress Reports on research

The National Progress Reports have their origin in Article VIII, Paragraph 3 of the Convention. All member nations are urged by the Commission to provide Progress Reports to the Scientific Committee following the most recent guidelines developed by the Scientific Committee and adopted by the Commission. The report is intended to provide (1) a concise summary of information available in member countries and (2) advice on where to find more detailed information if required. In addition, the IWC holds several specialist databases (including, catches, sightings, ship strikes, images – see Item 23).

As agreed at the 2013 Annual Meeting (IWC, 2014), all National Progress Reports were submitted electronically through the IWC National Progress Reports data portal. Encouragingly, 18 countries (Argentina, Australia, Brazil, Croatia, Denmark, France, Germany, Iceland, Italy, Japan, Korea, Mexico, New Zealand, Netherlands, Norway, Spain, UK and USA) submitted reports this year compared to 12 last year. Information was provided on bycatch, entanglement, ship strikes, direct and indirect takes, sampling, sightings and tracking studies.

Nearly all the recommendations identified by the Committee in 2017 (IWC, 2018c) have been implemented although further guidance is required on the appropriate level of aggregation for some records (e.g. strandings) to simplify and accelerate data entry without losing valuable resolution.

Although data entry this year was hampered due to problems with the IWC server, this generic issue has already been resolved by the IWC Secretariat. Several suggestions for improvements, including the removal of default values, can be See Annex T for full details.

Attention: C, CG, S, SC

*Despite the technical issues of the portal, the eighteen Progress Reports submitted to SC67b was an improvement on the twelve submitted to SC67a. Nevertheless, this represents a small proportion of IWC member nations. The Committee **reiterates** that National Progress Reports are required under the Convention and they represent a useful tool and **recommends** that Contracting Governments to submit them annually through the IWC data portal (<http://portal.iwc.int>).*

*National Progress Reports include records of reported bycatch and ship strikes. The Committee **agrees** that the data collected in these reports are not intended to replace in-depth studies and they should be considered and used with great caution. However, it also **agrees** the reports have value because much of these data would not otherwise be available and the reporting process can assist in supporting national compilation of cetacean data.*

*To address in part several of the issues and challenges described above the Committee **agrees** to:*

- (1) develop a strategy with the Scientific Committee Chair and Secretariat to raise awareness of National Progress Reports and promote reporting by member nations;*
 - (2) produce a short summary explaining the utility of National Progress Reports and suggest including this text in the circular to member nations calling for data submission;*
 - (3) request the Secretariat to issue the first call for data submission in February and repeat the call a few weeks prior to the start of the SC meeting;*
 - (4) develop text acknowledging the likely limitations of the reported data (subsequently this text will be included in all reports and data downloads;*
 - (5) further explore approaches (using R markdown) to produce PDF- formatted national reports.*
- This work will be conducted by the GDR Steering Group intersessionally (see Annex Y).*

3.3 Data collection, storage and manipulation

3.3.1 Catch data and other statistical material

Table 1 lists data received by the Secretariat since the 2017 meeting.

Table 1
List of data and programs received by the IWC Secretariat since the 2017 meeting.

Date	From	IWC ref.	Details
18/05/2017	St Vincent&G: J. Cruickshank-Howard	E128 Cat2016	Information from St Vincent and the Grenadines aboriginal hunt 2016-17
3-10 7/2017	S. Kromann and Y. Ivashchenko	E127 C	Individual catch data for Taiyo Gyogyo, Japan in 1943-44. Copy of data held at NMML Seattle
16/08/2017	Y. Ivashchenko	E127	Extra details of N. Pacific sei whale catches by the USSR 1963-71
16/02/2018	Japan: K. Matsuoka	CD103	2017 POWER sightings cruise data (except photographs)
16/02/2018	Japan: K. Matsuoka	CD104	2017 ICR North Pacific dedicated sighting survey data.
04/04/2018	Canada: S. Reinhart	E130 Cat2017	Details of the Canadian bowhead harvest for the 2015-7 seasons and some information on the 2018 quota
11/04/2018	Japan: K. Matsuoka	E131	Data from the 2017-18 NEWREP-A dedicated sighting survey
18/04/2018	Iceland: G. Vikingsson	E130 Cat2017	Individual records of minke whales caught by Iceland 2017 [there was no fin whale catch]
18/04/2018	Norway: N. Øien	E130 Cat2017	Individual minke records from the Norwegian 2017 commercial catch. Access restricted (specified 14-11-00).
19/04/2018	USA: R. Suydam	E130 Cat2017	Individual records from USA Alaska aboriginal bowhead hunt 2017
20/04/2018	Japan: H.Morita	E130 Cat2017	Individual data for Japan's catch in 2017 in the N. Pacific (JARPN II) & 2017/8 in the Antarctic. (pdf format)

3.3.2 Progress of data coding projects and computing tasks

On behalf of Allison, Donovan reported that the 2017 catches and Japan coastal records in 1943-44 (data from NMML Seattle) have been added to the database. The changes agreed at the 2017 meeting, in particular to split out the catches taken *en route* to and from the Antarctic whaling grounds, have been implemented. Work on computing tasks with respect to work on the AWMP, RMP and in-depth assessments is reported under the relevant agenda items.

4. COOPERATION WITH OTHER ORGANISATIONS

Attention: C-A

*The Committee **stresses** the value of cooperation with other organisations when addressing the range of issues affecting cetacean conservation and management. In addition to the summaries below, co-operation is also discussed where relevant elsewhere in the agenda.*

4.1 African States Bordering the Atlantic Ocean (ATLAFCO)

There was no meeting of the Ministerial Conference of ATLAFCO during the intersessional period.

4.2 Arctic Council

4.2.1 PAME (Protection of the Arctic Marine Environment)

The PAME II-2017 meeting was held in Helsinki, Finland from 18-20 September 2017. No IWC observer attended the meeting. The Committee agrees that if possible an IWC observer should attend the next meeting of PAME.

4.3 Convention on Biological Diversity (CBD)

There was no meeting of the Conference of Parties during the intersessional period. The next meeting will take place 10-22 November 2018. The Committee agrees that if possible an IWC observer should attend the next meeting of CBD.

4.4 Convention for the Conservation of Antarctic Marine Living Resources (CCAMLR)

The 36th Meeting of the CCAMLR Scientific Committee was held 16 - 20 Oct 2017 October 2016 in Hobart, Australia. Although no IWC observer attended the meeting, co-operation with CCAMLR remains an important component of the IWC's work and is discussed further under Item 16.1.

4.5 Convention on the Conservation of Migratory Species (CMS)

4.5.1 Scientific Council

The Second Meeting of the Sessional Committee of the Scientific Council was held 10- 13 July 2017 in Bonn, Germany. No IWC observer attended the meeting.

4.5.2 Conference of Parties

The Conference of Parties met 23-28 October 2017 in Manila, Philippines. No IWC observer attended the meeting.

4.5.3 Agreement on Small Cetaceans of the Baltic and North Seas (ASCOBANS)

The report of the observer to ASCOBANS is given as SC/67b/COMM01E. The following key activities have occurred since the last IWC Scientific Committee meeting:

- (1) first Joint Meeting of the 13th Meeting of the Jastarnia Group (Baltic Sea harbour porpoises) and the 6th Meeting of the North Sea Group;
- (2) best-practice workshop on 'Fostering Inter-regional Cooperation on Underwater Noise Monitoring and Impact Assessments in waters around Europe, within the context of the European Marine Strategy Framework Directive';
- (3) 23rd Meeting of the Advisory Committee; and
- (4) 14th Meeting of the Jastarnia Group.

The key ongoing ASCOBANS activities are:

- (1) work on the three harbour porpoise Action Plans (Baltic, Belt and North Seas)- in place since February 2018;
- (2) web-accessed database on marine mammal stranding and necropsy in preparation (ZSL/IOZ leading), 2018-2020;
- (3) preparation of an action plan for common dolphins; and
- (4) implementing a change in the national reporting cycle from annual (on all topics) to a four-year cycle (selected topics each year) - the intention is that all the key ASCOBANS working groups and meetings align their agendas to home in on these issues in the respective years of reporting (e.g. covering 2017 in 2018).

The Action Points at the last Advisory Committee meeting included:

- (1) preparing a discussion on prey depletion and changes in prey quality on the agenda of the 24th Meeting of the Advisory Committee;
- (2) co-organisation of a workshop with ACCOBAMS on strandings and marine debris (the report has been made to the Scientific Committee);
- (3) future focuses will include the white-beaked dolphin and the white-sided dolphin.
- (4) a draft Action Plan for the Common Dolphin is due to be presented at the 24th Advisory Committee Meeting.

The Committee thanked Simmonds for his report and **agrees** that he should represent the Committee as an observer at the next ASCOBANS meeting.

4.5.4 Agreement on the Conservation of Cetaceans of the Black Sea, Mediterranean Sea and Contiguous Atlantic Area (ACCOBAMS)

MEETING OF PARTIES

There was no Meeting of the Parties (MoP) to ACCOBAMS during the intersessional period. Donovan will represent the Committee as an observer at the next ACCOBAMS MoP.

SCIENTIFIC COMMITTEE

There was no meeting of the ACCOBAMS Scientific Committee during the intersessional period. Donovan will represent the Committee at the next ACCOBAMS Scientific Committee meeting.

4.6 Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES)

No relevant meetings of CITES have taken place during the intersessional period.

4.7 Food and Agriculture Organisation of the United Nations (FAO)

There was no meeting of The Committee on Fisheries (COFI) during the intersessional period. The next meeting will take place in Rome, Italy 9-13 July 2018.

4.8 Inter-American Tropical Tuna Commission (IATTC)

The 92nd meeting of the Inter-American Tropical Tuna Commission (IATTC) was held in Mexico City, Mexico 24-28 July 2017. No observer attended IATTC meetings in the intersessional period.

4.8.1 Agreement on the International Dolphin Conservation Program (AIDCP)

No observer attended IADCP meetings in the intersessional period.

4.9 International Committee on Marine Mammal Protected Areas (ICMMPA)

There was no meeting of ICMMPA task force during the intersessional period. The 5th International Conference will be held from 8- 12 April 2019 in Greece. It will evaluate progress in meeting the ICMMPA's long-standing goal of bringing the MMPA community closer together. A primary goal is to focus on the challenges ahead towards achieving effective place-based protection and management for marine mammals. It will build on previous initiatives to advance our understanding of science, management, and effective biodiversity conservation in protected areas. It will also provide updates on plans for the worldwide Important Marine Mammal Area (IMMA) initiative (marinemammalhabitat.org). Rojas-Bracho will represent the Committee at this meeting.

4.10 International Council for the Exploration of the Sea (ICES)

The report of the IWC observer documenting the 2017 activities of ICES is given as SC/67b/COMM01A. The ICES Working Group on Marine Mammal Ecology (WGMME) reported on recent information on status of, and threats to, marine mammal populations and briefly reviewed current knowledge of effects of plastics and underwater noise. Criteria for assessment of abundance trends in offshore cetaceans in the context of the Marine Strategy Framework Directive (MSFD) were reviewed, modifying the proposed indicator (previously based solely on the rate of decline) to make specific reference to baseline values. The group also considered the outcomes of the 2016 SCANS III survey¹. All three SCANS surveys have arisen from individual projects. WGMME recommended that the surveys be co-organised and coordinated by Member States as part of their routine monitoring and that the frequency is increased to once every six years to match the MSFD reporting cycle.

A Workshop on Predator-prey Interactions between Grey Seals and other marine mammals (WKPIGS) focused on predatory behaviour of grey seals towards other grey seals, harbour seals and harbour porpoises in European waters. The workshop aimed to consolidate pathological indicators of grey seal predation events, collate data on the prevalence and distribution and discuss methods to aid in detection of predation events and potential population level consequences of reported incidences. Cases of predation on harbour porpoises peaked in spring months. Reported incidence has increased over the last decade although it is not known if this represents a true increase in prevalence, an increase in seal numbers or an increase in effort/reporting.

Highlights from the 2017 ICES Working Group on Bycatch of Protected Species (WGBYC) included: review of ongoing bycatch mitigation research projects; presentations on interdisciplinary bycatch monitoring programs in the US Northwest Atlantic northeast region; collaborations with other ICES working groups; positive advancements on WGBYC database development working jointly with the ICES Data Centre; and progress on summarising bycatch for the Baltic Sea and Bay of Biscay/Iberia fisheries overviews.

Four cetacean species were reported as bycatch from the 2015 member state reports (common dolphins, white-beaked dolphin, bottlenose dolphin, and harbour porpoise). The WGBYC continues to highlight the inconsistent submission and content of annual reports provided by some member states and the shortcomings to accurately reflect the full magnitude of cetacean bycatch in European fisheries. WGBYC is preparing for the transition away from regular member state reports as the primary source of data on bycatch of cetaceans over to data coming through the ICES regional database.

¹ <https://synergy.st-andrews.ac.uk/scans3/>

The 2017 ICES Annual Science Conference (ASC) had no sessions devoted entirely to marine mammals. Nevertheless, some sessions had marine mammals included as an integral part - the most relevant sessions were: ‘microbes to mammals: metabarcoding of the marine pelagic assemblage’ and ‘from iconic to overlooked species: how (electronic) tags improve our understanding of marine ecosystems and their inhabitants’.

More information is available from the ICES website www.ices.dk.

The Committee thanked Haug for his report and **agrees** that he should represent the Committee as an observer at the next ICES meeting.

4.11 International Maritime Organisation (IMO)

The report of the observer is given as SC/67b/COMM01D. At IWC66, the Commission endorsed recommendations of the IWC Conservation and Scientific Committees for continued engagement with the IMO, including submission of a paper to the IMO Marine Environment Protection Committee (MEPC) providing an update of recent information related to the extent and impacts of underwater noise from shipping. This paper was written by an intersessional group appointed at SC67a and submitted to the IMO MEPC 72 meeting 9-13 April 2018 (MEPC 72/Inf.9).

The ship strike section of the IWC website now contains a list of the measures that have been put in place globally through IMO or national regulations, to reduce ship strike risks to whales. These include Traffic Separation Schemes, Areas to be Avoided, Recommended Routes, voluntary and mandatory speed restrictions. New measures relevant to ship strikes include three recommendatory areas to be avoided (ATBA) encompassing King Island, Nunivak Island, and St. Lawrence Island in the Bering Sea proposed by the United States (NCSR 5/3/8). The proposal noted that King Island is a biologically important site to the gray whale, while St. Lawrence Island’s ATBA would provide protection to bowhead whales, gray whales, and humpback whales. These areas were recommended for adoption (with a reduced size for the St. Lawrence ATBA) by the IMO Navigation, Communications and Search and Rescue sub-committee NCSR 5 in February 2018.

Members of the IWC Scientific Committee have attended IMO meetings in order to discuss how best to provide information on populations of marine mammals relevant to the marine mammal avoidance provisions of the IMO Polar Code. This is discussed further under Item 14.3.

The Committee thanked Ferris and Leaper for their report and **agrees** that they should represent the Committee at the next IMO meeting.

4.12 International Union for the Conservation of Nature (IUCN)

The report of the observers to IUCN is given as SC/67b/COMM01G. The IUCN Marine Mammal Protected Areas Task Force (<https://www.marinemammalhabitat.org>) held its 3rd regional workshop in Malaysia in March 2018 to identify, describe and map candidate areas for inclusion in the Important Marine Mammal Area (IMMA) e-Atlas (marinemammalhabitat.org/imma-eatlas). The 46 candidate IMMAs proposed by the workshop are currently undergoing independent review.

Cetaceans entries on the Red List are in the process of being updated. The first batch of updates covering 19 taxa was published on redlist.org in December 2017 and is summarised at iucn-csg.org/index.php/page/3. Most of the remaining mysticete species assessments and some subpopulation assessments, as well as around 10 more new assessments of small and medium-sized odontocetes, have been submitted for publication in the next Red List update in June 2018. Most of the remaining taxa are in the pipeline for publication in late 2018.

IUCN continues to convene the Western Gray Whale Advisory Panel (WGWAP), which provides advice to Sakhalin Energy Investment Company (SEIC) and other parties, especially on the mitigation of industrial and other impacts on the gray whales that feed each summer off Sakhalin Island, Russia. Details of the Panel’s recent work are given in Annex O, Appendix 3.

Regular news items on activities by members of the IUCN SSC Cetacean Specialist Group are posted on the CSG website, www.iucn-csg.org.

4.13 North Atlantic Marine Mammal Commission (NAMMCO)

Scientific Committee

The report of the IWC observer at the 24th meeting of the NAMMCO Scientific Committee (NAMMCO-SC) is given as SC/67b/COMM01B. The NAMMCO-SC discussed a current joint project, ‘Exploring marine mammal consumption relative to fisheries removal in the Nordic and the Barents Seas’. Preliminary results suggest that marine mammal consume around 15 million tons \pm 50% of prey per year, predominantly targeting low and mid trophic level species (zooplankton and small pelagic fish). Fisheries remove around 4.3 million tons per year, targeting mid and top trophic levels (small pelagic fish and larger demersal and pelagic fish).

The NAMMCO By-Catch Working Group (BYCWG) met in May 2017. Methods used for collection of data and by-catch estimation were reviewed, and both the WG and the SC recommended methodological improvements to be implemented both in the data collection and the analysis before the bycatch estimates could be endorsed. Greenland is an atypical case because marine mammals that are caught, either directly or indirectly, are assumed to be reported as direct

catch (with large whales being the exception where bycatch is reported as such). The primary concern is to ensure that any bycatch is included in the total number of removals to be used in population assessments.

The NAMMCO SC noted and appreciated that the IWC *Implementation Reviews* for North Atlantic fin whales and North Atlantic common minke whales are completed. The NAMMCO SC provided advice on sustainable catch levels for these species in Icelandic waters (from 2018-2025) based upon application of the RMP. The NAMMCO SC also recommended that the *SLAs* that are developed in the IWC SC be used for advice for large whales in Greenland and provided advice on strike limits for West Greenland humpback whales for the 2019-24.

The NAMMCO SC received the results from an updated global review of monodontids and provided updated assessments and advice for white whales and narwhals in Greenland and Canada. It also received a new abundance estimate for bottlenose whales from the Faroese component of the 2007 T-NASS survey that was analysed together with data on deep diving species from the SCANS-II and CODA surveys. Sightings were mainly from the Faroese survey block.

Increased research on harbour porpoises in Norway is being driven by the concerns regarding bycatch. Bycaught harbour porpoises were collected in 2016 and 2017 by Norway for biological sampling, and a food-web model is being developed for the Vestfjord area close to Lofoten to study the role of the species in this area. An abundance estimate is now available from the SCANS-III survey which was extended from 62°N to include Vestfjorden, an area with high bycatch. Preliminary investigations using this new abundance estimate suggest that bycatch levels are within PBR.

NAMMCO's whale sighting surveys in the Northeast Atlantic in 2015 (NASS2015) included an intensive survey with the purpose of estimating the abundance of pilot whales around the Faroe Isles, an aerial survey of the coastal waters in East Greenland and a ship-based survey around Jan Mayen following methods developed for the Norwegian minke whale surveys. The next NASS survey should be in 2022-23. The NAMMCO SC strongly recommended that an attempt be made to conduct again a trans-Atlantic coordinated survey and charged the NAMMCO Secretariat to explore what are the present plans and how much flexibility they encompass.

Council

The report of the IWC observer at the 26th Annual Council meeting of NAMMCO held in Tromsø, Norway 7-8 March 2018 is given as SC/67b/COMM01C. Relevant items discussed at the Council meeting include the following:

- (1) A newly established working group on bycatch, entanglements and live strandings has started its work and will gather information on the matter from other organisations and develop recommendations for NAMMCO. The focus is animal welfare associated to non-hunting related activities, and how NAMMCO can best contribute to addressing significant adverse impacts of by-catch, entanglement and live strandings on marine mammals; and
- (2) The report of the Global Review of Monodontids (white whales and narwhals) reviewed the conservation status, threats, and data gaps for all stocks globally. The last review was in 1999.

The Committee thanked Moronuki for his report.

4.14 North Pacific Marine Science Organisation (PICES)

The report of the IWC observer at 2017 annual meeting of PICES is given as SC/67b/COMM01F.

The marine birds and mammals section (S-MBM) focussed on 'seasonal and climatic influences on prey consumption by marine birds, mammals and predatory fishes'. Presentations were made on (1) significance of seasonal changes in prey consumption on energy budgets and ecosystem dynamics; (2) effects of changes in water temperature and other climatic variables on food requirements; (3) relationships between dietary shifts and population trends; (4) limits of plasticity in prey selection; and (5) how prey consumption of birds, mammals and predatory fishes is affected by the recent extreme climatic events. Overall, the collection of presented studies in this session contributed to the efforts of the S-MBM to estimate prey consumption of birds and mammals. They provided new methods to estimate prey consumption of marine mammals and gave insights into the existing databases of diets and population estimates that can be used to further this effort.

For 2018, the S-MBM will focus on 'diets, consumption and abundance of marine birds and mammals in the North Pacific'. Since the 2016 workshop, work on the agreed upon databases to estimate prey consumption has been initiated and will continue to be added to over the coming 12 months in anticipation of the 2018 workshop, when invited experts will review the compiled information. This process should result in near-complete databases of diets, abundances and energy requirements of marine birds and mammals in the North Pacific.

The 2018 annual meeting of the PICES will be held in Yokohama, Japan 25 October-4 November 2018. The Committee thanked Tamura for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next PICES meeting.

4.15 Protocol on Specially Protected Areas and Wildlife (SPA) of the Cartagena Convention for the Wider Caribbean

No observer attended SPAW meetings in the intersessional period.

4.16 Pacific Region Environment Programme (SPREP)

No observer attended SPREP meetings in the intersessional period.

5. GENERAL ASSESSMENT ISSUES WITH A FOCUS ON THOSE RELATED TO THE REVISED MANAGEMENT PROCEDURE (RMP)

Several assessment topics apply not only to the Revised Management Procedure (RMP), but to the work of the Scientific Committee as whole. This item focuses on general assessment issues, such as: (1) the relationship between $MSYR_{mat}$ and $MSYR_{1+}$; (2) implications of RMP and AWMP simulation trials for consideration of ‘status’; and (3) matters of relevance to special permits that involve RMP considerations including effects of catches upon stocks.

5.1 Evaluate the energetics-based model and the relationship between $MSYR_{1+}$ and $MSYR_{mat}$

$MSYR$ is a key parameter in the *Implementation Simulation Trials* used to evaluate the conservation and catch performance of alternative RMP variants for specific species and regions. In recent years, the Committee has been reviewing progress on an individual based energetics model (IBEM) to provide insights into the relationship between $MSYR_{1+}$ and $MSYR_{mat}$. Two papers on the IBEM were reviewed by the Committee in SC/67b.

SC/67b/EM07 outlined enhancements to the IBEM since the last meeting. This included the ability to explicitly model the effects of feeding while on migration, which can have effects on the yield curve as well as $MSYR$ and $MSYL$. The Committee discussed (Annex D, Item 2.1) several ways in which this model can potentially enhance understanding of the relationship between biological processes and $MSYR$.

SC/67/RMP01 reported on trials using the IBEM within the standard RMP testing framework. The results were consistent with the behaviour of the RMP *CLA* observed in less complex population models and will also provide a point of comparison for the emulator model for the IBEM currently under development. The Committee has previously agreed that a fully-developed emulator model could form the basis for future *Implementation Simulation Trials*.

Attention: SC

*The Committee **agrees** that work continue to develop an emulator model; assess whether it is possible to represent the trajectories from the IBEM using an emulator model; compare the yield curves from the IBEM with those from the emulator model; and develop guidelines for how to use an emulator model as the basis for a multi-stock, multi-area population dynamics model and how such a model could be conditioned given available data.*

5.2 Implications of ISTs for consideration of species’ and populations’ status

Last year, the Committee recommended that a set of *Implementation Simulation Trials* should be summarised using three statistics to provide information on status (IWC, 2018d). The Committee was advised that intersessional tasks toward that goal could not be completed prior to SC/67b due to computing workloads.

Attention: SC

*The Committee **agrees** that Allison should modify the control programs used for Implementation Simulation Trials to report the three measures of status agreed last year (IWC, 2018d). The RMP sub-committee, in conjunction with the Working Group on ASI, will review outcomes of the analyses at SC/68a. Punt and Donovan will develop draft updates to the Guidelines for Implementations and Implementation Reviews to reflect decisions on evaluation status of stocks for consideration at SC68a.*

5.3 General consideration of how to evaluate the effect of special permit catches on stocks and levels of information needed to show improved management performance

5.3.1 General issues

The Committee developed general guidelines on the levels of information needed to show improved management improvement, for proposals that identify this as an objective (Annex D; appendix 2). The guidelines are intended to assist proponents in proposal preparation and to facilitate the review process. It was stressed that these were guidelines not requirements. Proponents might request the establishment of an Advisory Group to provide comment on intersessional work, but this is not mandatory. An Advisory Group may most benefit nations which have not previously developed proposals or may be lacking analysts familiar with the modelling approaches commonly applied at the IWC.

Attention: SC

*The Committee **agrees** that the general guidelines on the levels of information needed to show improved management improvement, for proposals that identify this as an objective (Annex D; appendix 2), should be included as an Appendix to the Scientific Committee handbook.*

5.3.2 Specific issues

SC/67b/RMP03 provided draft specifications for RMP/IST type simulations to evaluate management procedures based on modified *CLAs* that use information on recruitment inferred from age data from Antarctic minke whales. This work originally arose from discussions of NEWREP-A and Recommendation 1 of the Panel Review of that proposal (and see Item 19). The Committee noted that SC/67b/RMP03 was a work-in-progress, and that several features of the operating models would need to be extended before final conclusions could be drawn. The author of SC/67b/RMP03 plans to continue this work and received several suggestions from the Committee to carry those efforts forward (Annex D, Item 2.3).

5.4 Work plan 2019-20

Details of work to be undertaken both before and during the 2019 Annual Meeting are given in Table 2.

Table 2

Work plan for general assessment matters with a focus on the RMP

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Item 5.1: Conduct work to evaluate the energetics-based model and hence the relationship between MSYR ₁₊ and MSYR _{mat}	(a) Continue to assess whether it is possible to represent the trajectories from the IBEM using the emulator model (Annex Y); (b) Compare the yield curves from the IBEM with those from the emulator model (Annex Y); and (c) Develop guidelines for how to use an emulator model as the basis for a multi-stock, multi-area population dynamics model and how such a model could be conditioned given available data (Annex Y).	Continue to work to evaluate the energetics-based model and hence the relationship between MSYR ₁₊ and MSYR _{mat}	Conduct follow-up analyses	Continue to work to evaluate the energetics-based model and hence the relationship between MSYR ₁₊ and MSYR _{mat}
Item 5.2: Implications of ISTs, for consideration of status	(a) Modify the control programs used for <i>Implementation Simulation Trials</i> to report the three measures of status (Allison) (b) Draft updates to the Guidelines for <i>Implementations</i> and <i>Implementation Reviews</i> to reflect decisions on evaluation status of stocks (Punt and Donovan)	Review the results of the projections Review the draft guidelines		
Item 5.3: levels of information needed to show improved management performance		Review progress implementing the suggested changes to the specifications of the model in SC/67b/RMP03 and any results.		

6. RMP – IMPLEMENTATION-RELATED MATTERS (RMP)

This agenda item includes the details of ongoing *Implementation Reviews* and preparation for new *Implementation Reviews*. For discussions related to the stock structure and abundance of these stocks, see also Items 11 and 12.

6.1 Completion of the *Implementation Review* of western North Pacific Bryde's whales

6.1.1 Report of the intersessional Workshop

The second intersessional Workshop on western North Pacific Bryde's whales was held in Tokyo from 14-16 February 2018 (SC/67b/Rep02). The objective was to facilitate completion of the *Implementation Review*. Much of the Workshop focussed on completing the final trial specifications, especially confirming the mixing matrices, updating the abundance estimates for the new sub-areas and confirming future sighting survey plans and whaling options. The Workshop reviewed preliminary conditioning results and agreed that they were satisfactory. It developed a workplan to try to ensure completion of the *Review* at SC/67b.

The Committee noted that the intersessional workshop had led to considerable progress towards completing the *Implementation Review*. It thanked Donovan for chairing the meeting, the Government of Japan for providing excellent facilities and all the participants for their contributions to the development of trial specifications and workplan.

The code and specifications for *Implementation Simulation Trials* were updated following the intersessional Workshop.

Attention: SC

*The Committee **agrees** to the updated trial specifications for the Implementation Review of western North Pacific Bryde's whales. These specifications are provided in Annex D, Appendix 3. It also **agrees** that conditioning has been achieved satisfactorily.*

6.1.2 Conclusions and recommendations

Once the trial specifications and conditioning had been agreed, the next step was to conduct projections under alternative RMP variants and survey plans. There was insufficient time during the meeting to complete all of the required projections and to check the associated calculations. Consequently, the remaining work will be completed intersessionally and reviewed and summarised by a Steering Group (Annex Y). This will occur well before SC/68a so that Japan has sufficient time to consider the results (e.g. with regard to its preferred survey options), prior to final conclusions being drawn. The Committee expects that this work can be completed before the end of 2018, but if complications arise conducting the projections, an extra day should be added to the 'First Intersessional Workshop for the western North Pacific minke whales' (see Item 6.2) to address outstanding issues.

Attention: SC

*The Committee **agrees** that the Implementation Review of western North Pacific Bryde's whales will be completed at SC/68a. Outstanding tasks will be completed intersessionally and the results reviewed and summarised by a Steering Group (Annex Y). This will occur well prior to SC/68a, and if complications arise then an extra day should be added to the First Intersessional Workshop for the western North Pacific minke whales (see Item 6.2) to address those issues.*

6.2 Start of the *Implementation Review* of western North Pacific common minke whales

6.2.1 Report of the intersessional Workshop

Donovan summarised the report of the preparatory Workshop for the Western North Pacific common minke whale *Implementation Review* (SC/67b/Rep05). Last year, the Committee recognised that the most difficult aspect of the last *Implementation Review* had been selecting, modelling and assigning plausibility to stock structure hypotheses. The objective of this Workshop was to begin to review work undertaken since the last *Implementation Review* and to develop, if necessary and possible, consensus advice on further analyses that will assist in the forthcoming *Implementation Review*. Stock structure discussions on common minke whales are detailed in Annex I, item 4.2.

This past lack of agreement with respect to the plausibility of existing stock structure hypotheses has, in part, revolved around how genetic analyses can be used to assign whales as part of the 'J' versus 'O' stocks. While some whales assign strongly to one of the two groups based on genetic data, the assignment of others is dependent on the assignment probability deemed sufficient to assign stock affinity. At the intersessional workshop (SC/67b/Rep05), the results of new stock structure-related analyses were reviewed by an advisory panel, and two recommendations were made with regard to additional genetic analyses needed to better understand stock structure. One of the recommended analyses involved evaluating the consistency of individual assignment probabilities when additional loci were genotyped. Progress with respect to that recommendation is discussed below.

The Workshop was also provided with an update to SC/67a/SCSP/13 that used information on the trend over time in the J:O stock ratio for common minke whale bycatches around Japan to draw various inferences, in particular about the value of the MSYR. The Workshop agreed that J:O stock ratios in bycatch will require attention when formulating stock distribution assumptions for the process of conditioning *ISTs* in the coming *Implementation Review* and made some recommendations on how this could be achieved.

The Committee noted that the intersessional Workshop was held in an excellent spirit of co-operation among the participants and led to identification of additional data sets and analyses that should be taken forward. The Committee thanked Donovan for chairing the meeting, the Government of Japan for providing excellent facilities and all the participants for their contributions to progress the *Implementation Review*.

6.2.2 Progress since the intersessional Workshop

SC67b/SDDNA06 presented the results of the recommended analysis from the Workshop (see Item 6.2.1) and the Committee confirmed that the workshop's recommendation for this analysis had been properly completed.

Attention: SC

The Committee reviewed new results of genetic analyses that were recommended at the intersessional workshop (SC/67b/Rep05) to better evaluate the use of genetic data to assign stock affinity in North Pacific common minke whales. The Committee:

- (1) **agrees** that future analyses should incorporate a range of assignment thresholds to encompass uncertainty;
- (2) **supports** the additional genetic analyses described in Annex I Appendix 5 relating to the second recommendation of the intersessional workshop and agrees that they should be performed prior to the next intersessional workshop; and
- (3) **encourages** the inclusion of non-genetic biological data to inform stock structure where possible.

SC/67b/RMP/02 aimed at suggesting a plausible range for $MSYR_{1+}$ for the western North Pacific common minke whales, and the relative plausibility of two stock structure hypotheses. The Committee thanked Kitakado for the updated analysis, which implemented some of the recommendations from the intersessional Workshop. Details of this paper and associated discussion can be found in Appendix D, Item 3.2.2. The Committee also discussed the analysis of genetic data conducted since the intersessional workshop (Annex I, Item 4.5).

Attention: SC, CG-A

The Committee **agrees** that:

- (a) it is necessary to update the mixing matrices in the trial specifications to be more consistent with observed genetic and bycatch data, also taking into account sensitivity to alternative methods of genetic assignment to stock;
- (b) whether it is possible to use the bycatch data to assign plausibility ranks to $MSYR_{1+}$ values and stock structure hypotheses depends on assumptions regarding trends in fishing effort spatially and temporally; and
- (c) trials would need to consider different assumptions regarding the use of J:O bycatch ratios, including that these data do not provide information on $MSYR_{1+}$ and the plausibility of stock structure hypotheses because of possible differential distributional changes by stock.

The Committee therefore **agrees** that scientists from Japan and Korea should provide data on the amount, location and timing (seasonal and annual) of fishing effort and bycatch to the First Intersessional Workshop (see item 6.2.3).

6.2.3 Preparation for the First Intersessional Workshop

The Committee began preparations for the First Intersessional Workshop on the *Implementation Review* of western North Pacific common minke whales. It re-established the Steering Group (Annex Y) to organise this Workshop.

In accordance with the Committee's 'Requirements and Guidelines for Implementations and Implementation Reviews' (IWC, 2012b), the primary objectives of the First Intersessional Workshop will be to: (a) consider plausible hypotheses and eliminate any hypotheses that are inconsistent with the data; (b) examine more detailed information in expected whaling operations, including options or suggested modifications to the pattern of those operations; (c) review the small geographical areas ('sub-areas') that will be used in specifying the stock structure hypotheses and operational pattern; and (d) specify the data and methods for conditioning the trials that will be carried out before the next annual meeting. An initial annotated agenda for the Workshop, highlighting the associated data and analysis requirements can be found in Annex D, appendix 5.

6.3 Workplan 2019-20

Details of work to be undertaken both before and during the 2019 Annual Meeting are given in Table 3.

Table 3

Work plan for RMP (*Implementation-related matters*)

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Item 6.1: Western North Pacific Bryde's whales	Finalise the projections and the application of the criteria for evaluating which RMP variants are acceptable, borderline, and unacceptable	Complete the <i>Implementation Review</i>		
Item 6.2: Western North Pacific minke whales	(a) conduct the First Intersessional Workshop; (b) code the resulting trials and condition the trials	Conduct the work required for the First Annual Meeting	Conduct the Second Intersessional Workshop	Conduct the work required for the Second Annual Meeting

7. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT PROCEDURE (AWMP)

This item continues to be discussed as a result of Resolution 1994-4 of the Commission (IWC, 1995), which has been strengthened by Resolution 2014-1 (IWC, 2016a). The report of the Standing Working Group (SWG) on the development of an aboriginal whaling management procedure (AWMP) is given as Annex E. The Committee's deliberations, as reported below, are largely a summary of that Annex, and the interested reader is referred to it for a more detailed discussion. The primary issues at this year's meeting comprised: (1) finalising the development of *SLAs (Strike Limit Algorithms)* for Greenlandic hunts, with a focus on fin and common minke whales; (2) finalising the work on the scientific components of the AWS (Aboriginal Subsistence Whaling Management Scheme); (4) completion of the *Implementation Review* for Bering-Chukchi-Beaufort Seas stock of bowhead whales; and (3) providing management advice for aboriginal hunts (see Item 8).

Considerable progress on items (1) and (2) was made because of intense intersessional work including two workshops in Copenhagen in October 2017 and March 2018, as well as a small technical meeting in December 2018 at OSPAR headquarters in London.

7.1. SLA development for the Greenland hunts

7.1.1 Fin whales

SC/67b/Rep06 incorporated the discussions of the two intersessional Workshops and the small working group meeting. Considerable progress was made in relation to (a) updated abundance estimates; (b) finalisation of the trial structure; (c) review and approval of conditioning; and (d) initial consideration of new *Strike Limit Algorithms (SLAs)* and results.

The Committee thanked Donovan, the Workshop chair and the participants for the excellent progress made.

The final trial specifications for the West Greenland fin whales are provided in Annex E (Appendix 2).

Table 4 below summarises the main factors considered in the *Evaluation Trials*. The most influential involve different stock structure hypotheses, different productivity rates (MSYR) and different 'need' envelopes (need envelopes incorporate scenarios where need remains constant at the present level for 100 years (termed A), where it increases linearly to twice the present level over the 100-year simulation period (termed B) and where it increases linearly to three times the present level over the 100-year period (termed C).

Table 4
Summary of the key factors considered in the fin whale trials

Factor
Stock structure hypotheses
Mixing matrices
MSYR rate
Survey bias
Need envelope

7.1.1.1 CANDIDATE SLAS

The Committee received two papers with candidate *SLAs*, SC/67b/AWMP13 and SC/67b/AWMP15. The general properties of the three *SLAs* presented in SC/67b/AWMP13 involve taking an inverse variance weighted average of the last three estimates as an estimate of abundance and calculating the strike limit as a growth rate fraction of a lower percentile of the abundance (conditional on a trend modifier), a snap to need feature and a protection level. The three variants relate to how they are 'tuned' (the trade-off balance between conservation and need).

The three *SLAs* presented in SC/67b/AWMP15 are based on a weighted-average interim *SLA* which uses all abundance estimates, but where the earlier ones are down-weighted. An adjustment to the multiplier of the abundance estimate in the interim *SLA* is applied which depends on the trend of the abundance indices. The three variants relate to how they are 'tuned' (the trade-off balance between conservation and need).

7.1.1.2 REVIEW FINAL RESULTS AND PERFORMANCE

In total, seven potential *SLAs* (which include the 'Interim' *SLA* – a modified version of the *Interim SLA* used to provide advice previously by the Committee until the final *SLAs* had been developed) were considered. The full range of conservation and need statistics were reviewed for the *Evaluation Trials*², noting that the initial focus is on meeting the Commission's conservation objectives. Those candidate *SLAs* that meet these are then evaluated on their ability to meet need satisfaction. In summary, conservation performance is deemed satisfactory if either the population is not at MSYL but it is increasing towards it or the population is above MSYL (in which case it may be increasing or decreasing towards MSYL). These concepts are captured in the 'D1' and 'D10' statistics (defined fully in Annex E, table 2) and can be visualised in bivariate plots given in Annex E.

The Committee agreed that the proposed *SLAs* had performed satisfactorily on the joint conservation statistics for the A and B (but not for the C) need envelopes for all trials. The focus was then to evaluate the need satisfaction performance over 20 and 100 years and consider stability in catch levels. This performance was captured by examining three statistics:

² The Committee also examines the results of *Robustness Trials* to ensure that the *SLA* does not exhibit unusual behaviour in more extreme trials.

N9(20) the average need satisfaction over the first 20 years, N9(100) the average need satisfaction over the 100 years and N12 the mean down step statistic (these are also defined fully in Annex E, table 2). They can be visualised in ‘Zeh’ plots (e.g. see Annex E).

Given the present incorporation into the trial structure of two widely different stock structure hypotheses (‘influx’ and ‘partial’ - see Annex E, appendix 2) to explain the variability of the abundance estimates, the need satisfaction over 20 years was given more weight in the evaluation as it is likely that future *Implementation Reviews* may be able to remove one or other scenario.

After an examination of the full range of results, there was no obvious ‘winner’ between two of the *SLAs* (one from each developer). Depending on the trials considered, and which statistic was examined, they performed slightly differently but their performance overall was equivalent.

Following an approach originally adopted during the development of the *Bowhead SLA*, it was decided that an *SLA* which sets the strike limit to the average of the values obtained by the two *SLAs*³ would be preferable, providing performance was as good or better than either individual *SLA*; no ‘snap to need’ for the averaged *SLA* has been applied. The results of the ‘combined *SLA*’ are summarised in Annex E, appendix 3⁴.

7.1.1.3 CONCLUSIONS AND RECOMMENDATIONS

The management advice developed using this *SLA* is given under Item 8. 6.

Attention: C-A, SC

*The Committee **draws attention** to the extensive work undertaken over recent years to develop an *SLA* for the West Greenland hunt for fin whales. In concluding this work, the Committee:*

- (1) **agrees** that the combined *SLA* (which sets the strike limit to the average of the values obtained by the two best *SLAs* considered) performed satisfactorily in terms of conservation performance and was to be preferred over the individual *SLAs* in terms of need satisfaction;*
- (2) **recommends** that this ‘WG-Fin *SLA*’ be used to provide management advice to the Commission on the subsistence hunt for West Greenland fin whales (provided the need request falls within need scenarios A and B);*
- (3) **expresses** its great thanks to the developers, Brandão and Witting for the vast amount of work put into the development process and to Allison and Punt for their extensive work developing the operating models and running the trials; and*
- (4) **agrees** that one focus of the next *Implementation Review* will be to examine further stock structure in relation to the two hypotheses being considered at present, and especially the ‘influx’ model which was developed in the context of low abundance estimates in some years, rather than being based upon genetic information.*

7.1.2 Common minke whales (Greenland)

SC/67b/Rep06 incorporated the discussions of the two intersessional Workshops and a small working group meeting. Considerable progress was made in relation to (a) updated abundance estimates; (b) finalisation of the trial structure; (c) conditioning; and (d) initial consideration of new *Strike Limit Algorithms (SLAs)* and results.

The Committee thanked Donovan, the Workshop chair and the participants for the excellent progress made.

The final trial specifications for the West Greenland common minke whales are provided in Annex E (appendix 4).

Table 5 below summarises the main factors considered in the *Evaluation Trials* for common minke whales. The most influential involve different stock structure hypotheses, different productivity rates (MSYR) and different ‘need’ envelopes (see discussion under Item 7.1.1), where it increases linearly to twice the present level over the 100-year simulation period (termed B) and where it increases linearly to three times the present level over the 100-year period (termed C).

Considerable work was undertaken to finalise the list of trials, to ensure that the mixing matrices were correctly specified and to complete and agree conditioning. The final trial specifications are provided in Annex E, Appendix 4.

⁴ Final validation and archiving of results will be undertaken by Allison in Cambridge.

7.1.2.1 CANDIDATE SLAS

SC/67b/AWMP14 developed a candidate *SLA* for common minke whales off West Greenland similar to that used for fin whales in SC/67b/AWMP13. It operates on an inverse variance weighed average of the last three abundance estimates. The strike limit is calculated as a growth rate fraction of a lower percentile of the abundance measure, conditional on a ‘snap to need’ feature, and a protection level. It does not include a trend modifier.

It was tuned to have a 5th percentile of D10 of 0.80 for need envelope A for the most difficult *Evaluation Trial* (trial M04-1A – see Annex E, appendix 4), where there are two sub-stocks in the western North Atlantic in which the mixing between the Central and the Western stock, and mixing between the putative western sub-stocks, is minimal, and where the MSYR is 1%).

7.1.2.2 CONSIDERATION OF RESULTS

Conditioning of the *Evaluation Trials* was completed satisfactorily and a summary of the results of the is provided in Annex E (appendix 5⁵). Annex E, fig. 3 provides the bivariate plot.

In determining satisfactory conservation and need performance when evaluating *SLAs*, the Committee considers the full range of results across all the *Evaluation Trials*, not simply the worst-case scenarios. Conservation performance was satisfactory for all but the most extreme trial (trial M04-1A) where it was slightly below for the lower 5th percentile. This trial had low MSYR and two W-stocks; it had been originally considered in the context of investigating potential problems for the hunt to simulate possible local depletion in the hunting area rather than for conservation reasons. Genetic stock structure in the entire North Atlantic is subtle such that even an hypothesis of almost complete panmixia is not rejected by most of the analyses and thus differentiation among ‘C’ and ‘W’ is very low. This is even more true for substructure within the W stock (if, indeed, there is any). Given that trials are conservative in so far as they overrate isolation among stocks, and the very subtle differentiation among stocks and sub-stocks in the North Atlantic, a single trial (which implements two fully separate W sub-stocks, for which there is little evidence) not meeting the D1/D10 criteria is not of conservation concern.

The SWG (Annex E, item 2.2.3) had noted that given the unforeseen situation with Secretariat computing, there had been insufficient time for it to consider the results of the *Robustness Trials* during its meeting. Such trials are not needed to determine an *SLA* but are examined to ensure that the selected *SLA* has no unforeseen properties in extreme trials. These were subsequently run prior to the plenary discussions and the results showed no unexpected properties.

7.1.2.3 CONCLUSIONS AND RECOMMENDATIONS

The management advice developed using the *WG-common minke SLA* is provided under Item 8.5.

Attention: C-A, SC

*The Committee **draws attention** to the extensive work undertaken over recent years to develop an SLA for the West Greenland hunt for common minke whales. In concluding this work, the Committee:*

- (1) **agrees** that the tested SLA which performed satisfactorily in terms of conservation performance;*
- (2) **agrees** that this ‘WG-Common minke SLA’ be used to provide management advice to the Commission on the subsistence hunt for West Greenland common minke whales provided the need request falls within need scenario A (i.e. does not exceed 164 annually);*
- (3) **expresses** its great thanks to the developers, Brandão and Witting for the vast amount of work put into the development process and to Allison and Punt for their extensive work developing the operating models and running the trials; and*
- (4) **agrees** that one focus of the next Implementation Review will be to examine further stock structure in relation to the two hypotheses being considered at present, should be consideration of the results of analyses of genetic data using additional samples from Canada (as well as the additional samples that will become available from West Greenland and Iceland); and*
- (5) **agrees** to establish an intersessional advisory group (Annex Y) to facilitate issues relating to samples.*

7.1.3 North Pacific gray whales (Makah whaling)

7.1.3.1 MANAGEMENT PLAN PROPOSED BY THE U.S. FOR MAKAH WHALING

The Makah Indian Tribe has requested that the U.S. National Marine Fisheries Service (NMFS) authorise a tribal hunt for Eastern North Pacific (ENP) gray whales in the coastal portion of its ‘usual and accustomed fishing area’ in Washington State. The Tribe intends to hunt gray whales from the ENP population, which currently numbers approximately 27,000 animals (Durban *et al.*, 2017). However, at certain times of the year there is a possibility that the hunt may take animals from the PCFG (Pacific Coast Feeding Group) and/or the WNFG (Western North Pacific Feeding Group). In an updated management plan – known as the Makah Management Plan (the Committee had approved an earlier plan for this hunt in 2012 (IWC, 2013), NMFS has taken measures to restrict the number of PCFG whales that are struck or landed in a given 10-year period and to avoid, to the extent possible, striking or killing a WNFG gray whale. The Government of the USA requested the Committee to test this plan to ensure that it meets IWC conservation objectives.

⁵ Final validation and archiving of results will be undertaken by Allison in Cambridge.

This task was begun at the Fifth Rangewide Workshop on the Status of North Pacific Gray Whales (SC/67b/Rep07) from 28-31 March 2018. The major focus of the Workshop related to finalising the specifications for modelling, to enable results to be available for SC67b including incorporation of the Makah Management Plan (SC/67b/Rep07, Annex E, appendix 1) into the modelling framework. The factors taken into account in the trials are given in Table 6.

Table 6

Summary of the main factors considered in the Makah gray whale trials

Factor	
Model fitting related	Projection-related
Stock hypothesis	Additional catch off Sakhalin
MSYR	Catastrophic events
Mixing rate	Northern need in final year
Immigration into the PCFG	Struck and lost rate
Bycatches and ship strikes	Future effort
Pulse migrations into the PCFG	Factors related to obtaining and matching photographs

At the present meeting, the focus was on the conservation performance of the Makah Management Plan. Performance was evaluated in the same manner as described for the evaluation of the *SLAs* for West Greenland fin and common minke whales (see Items 6.1 and 6.2). The results can be found in Annex E (appendix 6). The only scenarios under which the plan might not perform adequately were considered to have low plausibility (e.g. a bycatch mortality of ~ 20 PCFG whales per year). Annex E, fig. 4 shows the bivariate plot.

7.1.3.2 CONCLUSIONS AND RECOMMENDATIONS

The management advice relating to the Makah Management Plan is provided under Item 8.2.

Attention: C-A, SC

The Committee reviewed a US Management Plan for a Makah hunt of gray whales off Washington State (the Committee had evaluated a previous plan in 2011 - IWC, 2011; 2012), using the modelling framework developed for its rangewide review of gray whales (SC/67b/Rep07). In conclusion, the Committee:

- (1) **agrees** that the performance of the Management Plan was adequate to meet the Commission's conservation objectives for the Pacific Coast Feeding Group, Western Feeding Group and Northern Feeding Group gray whales;*
- (2) **notes** that the proposed management plan is dependent on photo-identification studies to estimate PCFG abundance and the mixing proportions of PCFG whales available to the hunt (and to bycatch in its range);*
- (3) **stresses** that its conclusions are dependent on the assumption that these studies will continue in the future; and*
- (4) **expresses its great thanks** to Punt, Brandon and Allison for their excellent work in developing and validating the testing framework and running the trials.*

7.1.4 Conclusions on AWMP work

The Chair of the SWG on the AWMP, Donovan, noted that this meeting represented the end of a long journey – with the adoption of the two new *SLAs*, the SWG and the Committee has completed the development tasks it had been assigned by the Commission, originally in Resolution 1994-1. It was an immense task but a great pleasure to work with such dedicated and talented people. He thanked all of the scientists who have made such a wonderful contribution to this work over the years and especially Geof Givens, Kjartan Magnússon (sadly no longer with us), Eva Dereksdóttir, Lars Witting, Anabela Brandão, Doug Butterworth, Cherry Allison and André Punt – the SWG has, in his view, achieved ground-breaking work over the last two decades in a spirit of great collaboration and co-operation, even when there were disagreements, as inevitably there were. He also thanked the hunters and their representatives who had made major contributions in terms of not only data provision but also advice on the AWS (see Item 7.2). The Committee **concurred** that this was an excellent example of what the Scientific Committee could achieve with international collaboration. Finally, they **thanked** Donovan for his dedicated, good humoured and impartial leading of such a major piece of complex work over such a long period - this work has been central to the Committee's role in providing the best scientific advice to the Commission on aboriginal subsistence whaling hunts, bringing together conservation needs and the needs of the hunters.

7.2 Aboriginal Whaling Scheme (AWS)

7.2.1 Introduction

The Scientific Committee's Aboriginal Whaling Management Procedure (AWMP) applies stock-specific *Strike Limit Algorithms* (*SLAs*) to provide advice on aboriginal subsistence whaling (ASW) strike/catch limits.

ASW management (as part of an AWS, the aboriginal whaling scheme) incorporates several components, several of which have a scientific component:

- (1) *Strike Limit Algorithms* (case-specific) used to provide advice on safe catch/strike limits;

- (2) operational rules (generic to the extent possible) including carryover provisions, block quotas and interim relief allocations;
- (3) Guidelines for *Implementation Reviews*; and
- (4) Guidelines for data and analysis (e.g. guidelines for surveys, other data needs).

Considerable work on updating the AWS since the version presented (but not accepted by) to the Commission in 2002 (IWC, 2003) was undertaken by an intersessional correspondence group (SC/67b/AWMP 21) and at the intersessional workshops (SC/67b/Rep04).

7.2.2 Carryover request from the Governments of USA and Denmark/Greenland

The Governments of USA and Denmark/Greenland (SC/67b/Rep06, Annex F, appendix) had requested advice at the March intersessional Workshop on the conservation implications of carryover provisions allowed for a carryover provision that allowed use of unused strikes from the previous three blocks, provided that the number used in any year did not exceed 50% of the annual strike limit.

This request was tested on the two SLAs available for stocks hunted by the USA and Greenland at the time of the Workshop i.e. the *Bowhead SLA* (applicable to the Bering-Chukchi-Beaufort Seas stock) and the *WG-Humpback SLA* (applicable to West Greenland).

Three types of options were examined:

- (1) baseline case - all strikes taken annually (i.e. no need for carryover);
- (2) 'frontload' case - strikes taken as quickly as possible within block (+50% limit annually until the block limit is reached); and
- (3) Two alternative scenarios where carryover strikes are accrued for one or three blocks, followed by a period of carryover usage subject to the +50% limit.

The three-block scenario considered in (3) served as a direct test of the provision described in the request of USA and Denmark/Greenland.

Attention: CG-A

The Committee received a request from the USA and Denmark/Greenland (SC/67b/Rep06, Annex F, appendix) on the conservation implications of carryover provisions that

'...allow for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit'.

The Committee reviewed the request using its simulation frameworks and the two SLAs available for stocks hunted by the USA and Greenland available at the time of the Workshop i.e. the Bowhead SLA (applicable to the Bering-Chukchi-Beaufort Seas stock) and the WG-Humpback SLA (applicable to West Greenland) and

- (1) agrees that a carryover provision for up to 3-blocks meets Commission's conservation objectives; and*
- (2) reiterates its previous advice, applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable; and*
- (3) agrees to evaluate the above request for the other Greenland SLAs at the 2019 Committee meeting.*

7.2.3 Review proposed updates to the AWS

The proposed update to the previous AWS is provided in Annex E, appendix 8. It has sections on carryover, block quotas, interim relief allocation (and see Annex E, appendix 7), *Implementation Reviews* and guidelines for surveys and data.

7.2.4 Conclusions and recommendations

Attention: C-R

The Committee has been working for some years to update the scientific components of an Aboriginal Whaling Scheme. It has completed this work and recommends the AWS provided in Annex E, appendix 8 to the Commission. It has sections on carryover, block quotas, interim relief allocation (and see Annex E, appendix 7), Implementation Reviews and guidelines for surveys and data. It notes that the Commission's AWS may include additional, non-scientific provisions.

7.3 Implementation Review of BCB bowhead whales

According to the Committee's guidelines, the primary objectives of an *Implementation Review* are to:

- (1) review the available information (including biological data, abundance estimates and data relevant to stock structure issues) to ascertain whether the present situation is as expected (i.e. within the space tested during the development of a *Strike Limit Algorithm (SLA)*) and determine whether new simulation trials are required to ensure that the SLA still meets the Commission's objectives; and
- (2) to review information required for the SLA, i.e. catch data and, when available at the time of the *Review*, new abundance estimates (note that this can also occur outside an *Implementation Review* at an Annual Meeting).

The *Bowhead SLA* was adopted in 2002 (IWC, 2003, p.158) and there was an extensive *Implementation Review* completed in 2007 (IWC, 2008a, p.124) with a major focus on stock structure including three intersessional workshops. That included consideration of additional trials investigating management implications of assuming additional population structure even though these were considered of low plausibility. The Committee concluded that the *Bowhead SLA* remained the best tool to provide management advice. The next *Implementation Review* was completed in 2012 (IWC, 2013b, p.147); that concluded that there was no need to develop additional trials to those evaluated during the previous *Implementation Review* (IWC, 2008c).

The primary review was undertaken by the SWG on the AWMP (Annex E, Item 4) but the review benefitted from discussions within two other groups, SD-DNA (Annex I, Item X) and ASI (Annex Q, Item Y).

7.3.1 Stock structure: review new information

A full discussion of the work on stock structure can be found in Annex E (item 4.1) and Annex I. New information considered included genetic analyses (SC/67b/SDDNA 01) and telemetry results (SC/67b/AWMP04). SC/67b/SDDNA01 provided information on genetic analyses using samples from the BCB, Canadian and Okhotsk Sea stocks of bowhead whales. Within the BCB stock, no significant differences were identified in temporal or spatial comparisons, and age-related structure was not detected in comparisons between groups of large (old) versus small (young) whales. While comparisons of the BCB stock with the Okhotsk Sea stock revealed significant differences, there were only small, and in most cases statistically insignificant, differences between BCB and Canadian stocks. While this pattern could be related to historical connectivity between the two stocks, it could also, or additionally, be driven by some degree of contemporary gene flow.

Attention: SC

With respect to stock structure, considering the multiple lines of evidence, the Committee:

- (1) **agrees** that BCB bowheads comprise a single population, with no signs of substructure;
- (2) **agrees** that there was no need to consider any new SLA trials regarding stock structure, since the trials conducted in 2002 and 2007 already covered all plausible stock structure hypotheses;
- (3) **welcomes** the telemetry information provided, thanks the hunters involved for their skill and assistance;
- (4) **encourages** additional telemetry efforts; and
- (5) **agrees** with the suggestions for future genetic studies in the Arctic provided under Item 11.

7.3.2 Abundance estimates: review new information

A new abundance estimate (SC/67b/AWMP) has been accepted for the year 2011 from a long-term photo-id capture-recapture study (27,133, CV=0.217; 95% CI from 17,809 to 41,337) that it has been agreed is suitable for providing management advice and for use in the *SLA* (Annex Q). The previously accepted, completely independent, 2011 abundance estimate from the ice-based survey (Givens *et al.*, 2016) is also acceptable for use in the *SLA* and has already been used in that regard (16,820, CV=0.052; 95% CI 15,176 to 18,643).

There are thus two independent estimates for the same year considered suitable for use in the *SLA* and this is considered under Item 8.3.

The Committee also discussed plans for future surveys (SC/67b/AWMP 12 and AWMP 16) in Annex Q (item 3.1.1.1). These plans are in accord with the AWS Guidelines that 'plans for undertaking a survey/census should be submitted to the Scientific Committee in advance of their being carried out, although prior approval by the Committee is not required.

7.3.3 Biological parameters: review new information

New and extensive information on biological parameters was received as discussed Annex E (item 4.3). These covered such matters: length at sexual maturity and pregnancy rate from hunted animals (SC/67b/AWMP 07); the potential use of samples from baleen plates to examine hormone cycles and pregnancy; and information on calves from aerial surveys (SC/67b/AWMP03).

Attention: SC

With respect to biological parameter information, the Committee:

- (1) **welcomes** the extensive information presented;
- (2) **encourages** the continued collection of such data from the hunt;
- (3) **encourages** the work on the baleen plate analyses to examine hormone levels and pregnancy;
- (4) **encourages** continued aerial surveys under the ASAMM surveys and any future collaboration involving life history data from the harvest; and
- (5) **agrees** that the information presented does not suggest the need to consider any new SLA trials regarding stock structure.

7.3.4 Removals: review new information

The Committee received updated information about the 2017 harvest (SC/67b/AWMP 05) and long-term removals (SC/67b/AWMP 06). In 2017, 57 bowhead whales were struck resulting in 50 animals landed. The total landed for the hunt in 2017 was higher than the average over the past 10 years (2007-2016 mean of landed =41.7; SD=6.7). Efficiency (number landed / number struck) in 2017 was 88%, which was also higher than the average for the past 10 years (mean of efficiency=75.2%; SD=6.5%).

The Committee also received SC/67b/AWMP06 that provided a summary of bowhead whale catches in Alaska between 1974 and 2016. The authors pointed to the excellent cooperation and contribution of the whale hunters from the 11 villages that are members of the Alaska Eskimo Whaling Commission (AEWC). This information is discussed in Annex E (item 4.4).

From 2013 to 2017, four bowhead whales (2 females and 2 males) were harvested near Chukotka, mainly in Anadyr Bay (SC/67b/AWMP20). The average length was 14.5m (minimum 13.0m, maximum 17.0m). Although the portion of the annual strike limit allocated to Russia under their bilateral agreement with the USA is 5 animals, the actual annual take is usually only 1-2 whales per year, and this has been the case since at least 2004.

The Committee thanked the authors of the provision of this information, noting that catch and strike data are used in the SLA calculations (see Item 8.3).

7.3.5 Other anthropogenic threats and health: review new information

The Committee received extensive information related to threats and health ranging from entanglement, predation and health (body condition, pathology and parasite loads). The discussion of this can be found in Annex E (item 4.5).

Attention: SC

With respect to threats and health to the BCB bowhead whales, the Committee:

- (1) welcomes the extensive information presented;*
- (2) agrees that whilst the present level of unintentional human induced mortality is too low to require new Implementation trials or incorporation into the SLA calculations, the situation should continue to be monitored and evaluated at the next Implementation Review;*
- (3) agrees that the health analyses give no cause for concern with respect to the continued application of the Bowhead SLA; and*
- (4) encourages that the excellent work on health-related issues continues.*

7.3.6 Conclusions and recommendations (and, if needed, workplan to complete Review)

Attention: SC

With respect to the Implementation review of BCB bowhead whales, the Committee concludes that:

- (1) the Implementation Review has been satisfactorily completed; and*
 - (2) the range of hypotheses and parameter space already tested in Bowhead SLA trials was sufficient and therefore the Bowhead SLA remains the best way to provide management advice for this stock;*
- In addition, it thanks the US scientists for the extremely hard work that they have put into providing comprehensive papers to facilitate this review.*

8. STOCKS SUBJECT TO ABORIGINAL SUBSISTENCE WHALING (NEW INFORMATION AND MANAGEMENT ADVICE)

The Committee noted that the Commission will be setting new catch/strike limits for at its 2018 biennial meeting in Brazil. It had received written or verbal requests for limits to be considered for each hunt as discussed below.

Attention: C-A

A general request had been received from the USA and Denmark (SC/67b/Rep06, annex F, appendix) for advice on whether there would be a conservation issue if there was a one-time 7-year block followed by a return to 6-year blocks to address logistical issues related to the Commission.

The Committee agrees there are no conservation issues associated with this suggestion (and see the block quota section of the ASW in Annex E, appendix 8).

8.1 Eastern Canada/West Greenland bowhead whales

8.1.1 New abundance information

Last year, the Committee had recommended that Canadian scientists attend the Committee to present the results of their work on abundance. It was very pleased that Doniol-Valcroze from Department of Fisheries and Oceans Canada, and the primary author of the paper on the 2013 aerial survey abundance estimate, was present at the meeting.

The Committee accepted, for the provision of management advice and use in an *SLA* (see Annex Q for details), the fully corrected abundance estimate (Doniol-Valcroze *et al.*, 2015) from a 2013 aerial survey of 6,446 bowheads (CV=0.26, 95% CI 3,722-11,200). The survey covered the major summering area for the Eastern Canada/West Greenland (EC/WG) stock.

The Committee recalled that the *WG-Bowhead SLA* had been developed on the conservative assumption that the abundance estimates for the West Greenland area alone (1,274 whales in 2012 (CV=0.12)) represented the abundance of the whole stock, as it believed that it was not possible to assume that a non-member country would continue with regular surveys. Doniol-Valcroze advised the Committee that the present management strategy of Canada does involve obtaining regular abundance estimates. The Committee noted it would be pleased to receive such estimates from Canada being presented to the Committee in the future.

Attention: SC

The Committee greatly appreciated the presence of a Canadian scientist at its meeting. The Committee:

- (1) welcomes the provision of the abundance estimate for the Eastern Canada/West Greenland stock and (see Item 8.1.2) the regular provision of information on catch data by Canada;*
- (2) welcomes the attendance of Canadian scientists at its meetings;*
- (3) agrees that consideration of how to incorporate abundance estimates from Canada should be one focus of the next Implementation Review for this stock;*
- (4) notes the regular collaboration of Canadian and Greenlandic scientists on other matters such as genetic sampling (inter alia for mark-recapture abundance estimation); and*
- (5) encourages further collaboration between Canada, Greenland and the USA for the study of bowhead whales across their range and the presentation of these results at future Committee meetings.*

8.1.2 New catch information

SC/67B/AWMP/10 provided an update of recent Canadian takes made in the Inuit subsistence harvest of the EC-WG bowhead whale stock. In the eastern Canadian Arctic, the maximum allowed take is 7 bowhead whales per year according to domestic policy, with no carry-over of unused takes between years. Since 2015, 5 strikes were taken and 4 bowhead whales were successfully landed (1 in 2015, 2 in 2016 and 1 in 2017). Witting reported that West Greenland hunters struck no bowheads in 2017. There was one 14.7m whale that died from entanglement in crab gear.

The Committee notes that the reported number of strikes was within the parameter space that was tested for the *WG-Bowhead SLA*, and encourages the continued collection of genetic samples from harvested whales.

8.1.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67 and no changes were requested for bowhead whales. The Committee therefore:

- (1) agrees that the WG-Bowhead SLA remains the best available way to provide management advice for the Greenland hunt;*
- (2) notes that this SLA had been developed under the conservative assumption that the number of bowhead whales estimated off West Greenland represented the total abundance between West Greenland and Eastern Canada;*
- (3) based on the agreed 2012 estimate of abundance for West Greenland (1,274, CV=0.12), the catch of one whale in Canada in 2017, and using the agreed WG-Bowhead SLA, agrees that an annual strike limit of two whales will not harm the stock and meets the Commissions conservation objectives; and*
- (4) although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for the WG-Bowhead SLA, reiterates its advice, applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next, is acceptable.*

8.2 North Pacific gray whales

8.2.1 New information (including catch data)

The Committee received considerable new information on the hunt off Chukotka as discussed in Annex E (item 5.2). In 2017, a total of 119 gray whales were struck in 2017 (37 males and 82 females). No whales were struck and lost, and no stinky (inedible) gray whales were taken. Similar whaling methods were employed as in recent years and the overall efficiency of the hunt was almost same as in 2016.

In advance of the gray whale *Implementation Review* that is scheduled to begin in 2019, the Committee reviewed new information regarding the stock structure of gray whales in the North Pacific (SC67b/SDDNA02 and SC67b/SDDNA03) – for details see Annex I. The results were based on whole genome sequence data from three individuals (one sampled off Barrow, Alaska and two sampled off Sakhalin Island, Russia) and SNP genotype data generated from larger sample sets representing whales sampled off Sakhalin and in the Mexican lagoons.

Attention: SC

*In reviewing the results of new genetic analyses of gray whales in the North Pacific, the Committee **agrees** that the genetic and photographic data for this species be combined to better assess stock structure-related questions. Given the potential for genomic data to aid in better evaluating the stock structure hypotheses currently under consideration for North Pacific gray whales, the Committee **encourages** the continuation of work to produce additional genomic data from sampled gray whales.*

8.2.2 Management advice

Attention: C-A

The Russian Federation (SC/67b/AWMP/17) had requested advice on the following provision:

‘For the seven years 2019, 2020, 2021, 2022, 2023, 2024 and 2025, the number of gray whales taken in accordance with this subparagraph shall not exceed 980 (i.e. 140 per annum on average) provided that the number of gray whales taken in any one of the years 2019, 2020, 2021, 2022, 2023, 2024 and 2025 shall not exceed 140.’

The Committee therefore:

- (1) **agrees** that the Gray Whale SLA remains the best available way to provide management advice for the gray whale hunts;*
- (2) **advises** that an average annual strike limit of 140 whales will not harm the stock and meets the Commission’s conservation objectives;*
- (3) **notes** that its previous advice that the interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next remains acceptable;*
- (4) **advises** that the Makah Management Plan (see Item 2.3) also is in accord with the Commission’s management objectives.*

8.3 Bering-Chukchi-Beaufort Seas bowhead whales

8.3.1 New information

New information (on abundance and catches) was considered as part of the *Implementation Review* discussed under Item 7.3.

The USA had indicated that it was proposing no changes to the present catch/strike limits although it may suggest changes to its carryover request in light of the advice received by the Committee as discussed at the intersessional workshop (SC/67b/Rep06).

The Committee noted that there are now two independent estimates of abundance for this stock in 2011 (see Item 7.3.1). Recognising the need to formally consider the general question of how best to combine estimates in such cases as part of the workplan in the next biennium, the Committee noted that if they are combined as a weighted average by the inverse of their variances, there is little difference (it is slightly higher) between the combined estimate and that from the ice-based census estimate; the ice-based approach has been the method used for the other estimates used in the *SLA*. Therefore, the ice-based census estimate for 2011 (16,820, CV=0.052; 95% CI 15,176 to 18,643) is considered the most recent estimate of abundance for use in the *Bowhead SLA* this year.

8.3.2 Management advice

Attention: C-A

The USA indicated that it requested advice on the existing catch/strike limits. The Committee therefore:

- (1) **agrees** that the Bowhead Whale SLA remains the best available way to provide management advice for this stock;*
- (2) **advises** that a continuation of the present average annual strike limit of 67 whales will not harm the stock and meets the Commission’s conservation objectives; and*
- (3) **advises** that provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit, has no conservation implications (see SC/67b/Rep04).*

8.4 Common minke whales off East Greenland

8.4.1 New information on catches

In the 2017 season, nine common minke whales (3 males and 6 females) were landed in East Greenland, and one was struck and lost. Genetic samples were obtained from 8 of the landed whales. One common minke whale died from entanglement in fishing gear.

8.4.1 New information on abundance

The Committee endorsed the 2015 aerial survey abundance estimate of 2,762 (CV=0.47; 95%CI 1,160-6,574). This is only a small part of the wider Western and Central stocks from which catches may occur.

8.4.2 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on an annual take of 20 animals (it had previously been 12). It had also requested advice on any conservation implications of a 12-month hunting season for common minke whales.

The Committee therefore:

- (1) **notes** that in the past its advice for the East Greenland hunt had been based upon the fact that the catch was a small proportion of the number of animals in the Central Stock;
- (2) **notes** the process to develop an SLA for common minke whales off West Greenland resulted in a simulation framework that produces a considerably more rigorous way to provide advice for this hunt than before, by taking into account stock structure issues;
- (3) **notes** that the results of the simulation trials that incorporated a continuing catch of 20 whales from East Greenland gave rise to no conservation concerns;
- (4) **notes** that the 2015 aerial survey abundance estimate of 2,762 (CV=0.47; 95%CI 1,160-6,574) is only a small part of the wider western and central stocks;
- (5) **advises** that a continuation of the present average annual strike limit of 20 whales will not harm the stock and meets the Commission's conservation objectives;
- (6) **advises** that changing the length of the season to 12 months had no conservation implications; and
- (7) **agrees** that an SLA should be developed for this hunt in the future; and
- (8) **encourages** the continued collection of samples for collaborative genetic analyses (and see Item 7.1.2.3).

8.5 Common minke whales off West Greenland

8.5.1 New information on catches

In the 2017 season, 129 common minke whales were landed in West Greenland and four were struck and lost. Of the landed whales, there were 95 females, 33 males and one of unknown sex. Genetic samples were obtained from 104 whales, and the Committee was pleased to note that samples were already part of the data used in the genetic analyses of common minke whales in the North Atlantic. The Committee **encourages** the continued collection of samples and the collaborative approach of the genetic analysis.

8.5.2 New information on abundance

The Committee endorsed the 2015 aerial survey abundance estimate of 5,095 (CV0.46; 95%CI 2,171-11,961) as discussed in Annex Q.

8.5.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 164 animals (i.e. no change). It had also requested advice on any conservation implications of a 12-month hunting season for common minke whales.

The Committee therefore:

- (1) **agrees** that the WG-Common minke SLA is the best available way to provide management advice for this stock under need scenario A;
- (2) **advises** that a continuation of the present average annual strike limit of 164 whales will not harm the stock and meets the Commission's conservation objectives;
- (3) although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for this SLA, **reiterates** its previous advice, applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable;
- (4) **advises** that changing the length of the season to 12 months had no conservation implications; and
- (5) **encourages** the continued collection of samples for collaborative genetic analyses (and see Item 7.1.2.3).

8.6 Fin whales off West Greenland

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 19 animals (i.e. no change).

8.6.1 New information on the catch

A total of seven fin whales (5 females and 2 males) was landed, and one was struck and lost, off West Greenland during 2017. The Committee was pleased to note that genetic samples were obtained from five of these, and that the genetic samples are analysed together with the genetic samples from the hunt in Iceland.

8.6.2 New information on abundance

The Committee endorsed the 2015 aerial survey abundance estimate of 2,215 (CV=0.41; 95%CI 1,017-4,823) for use in providing management advice and in the SLA as discussed in Annex Q (Item Y).

8.6.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 19 animals (i.e. no change). It also requested advice on whether there were any conservation implications of removing length limits (while retaining the prohibitions relating to calves).

The Committee therefore:

- (1) **agrees** that the WG-Fin SLA is the best available way to provide management advice for this stock;
- (2) **advises** that a continuation of the present average annual strike limit of 19 whales will not harm the stock and meets the Commission's conservation objectives; and
- (3) although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for this SLA, **reiterates** its advice, applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable;
- (4) **advises** that removing the length limits had no conservation implications; and
- (5) **encourages** the continued collection of samples for collaborative genetic analyses (and see Item 7.1.1.3).

8.7 Humpback whales off West Greenland

8.7.1 New information on catches

A total of two (both female) humpback whales were landed and none were struck and lost in West Greenland during 2017. Genetic samples were obtained from all the landed whales. The importance of collecting genetic samples and photographs of the flukes from these whales is emphasised.

Five humpback whales were observed entangled in fishing gear in West Greenland in 2017. Of these, one died, two became free and one was successfully disentangled by a disentanglement team. The remaining animal was alive and still entangled when it was last sighted.

Inclusion of bycaught whales had been incorporated into the scenarios for the development of the *Humpback SLA*. If high levels continued, then this will need to be taken into account in any *Implementation Review*. The Committee noted the IWC efforts with respect to disentanglement and prevention and welcomed the news that the Greenland authorities requested IWC disentanglement training that took place in 2016 and that they successfully disentangled one humpback whale.

8.7.2 New information on abundance

The Committee endorsed the 2015 aerial survey abundance estimate of 993 (CV=0.46; 95%CI 434-2,272) as discussed in Annex Q (Item Y) for use in the provision of management advice and in the SLA.

8.7.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 10 animals (i.e. no change).

The Committee therefore:

- (1) **agrees** that the WG-Humpback SLA is the best available way to provide management advice for this stock;
- (2) **advises** that a continuation of the present average annual strike limit of 10 whales will not harm the stock and meets the Commission's conservation objectives;
- (3) **advises** that that provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit' has no conservation implications (see SC/67b/Rep04); and
- (4) **encourages** the continued collection of samples and photographs for collaborative analyses.

8.8 Humpback whales off St. Vincent and The Grenadines

The alternate Commissioner for St Vincent and the Grenadines advised that no change to the present limits were envisaged.

8.8.1 New information on catch

It was reported that one humpback whale was struck and landed in 2017 by St. Vincent and The Grenadines.

8.8.2 New information on abundance

Last year, the Committee had requested that the USA provide a new abundance estimate for the western North Atlantic based upon the available NOAA data. A progress report on this work was provided with a focus on information on abundance estimates generated by the MONAH study, conducted in 2004 and 2005 on Silver Bank (a breeding ground in the West Indies) and in the Gulf of Maine feeding ground. The best estimate around 12,300, similar to the Committee endorsed best estimate from the YONAH project from 1992/93, which was 10,400 (8,000, 13,600). The lack of strong population growth was unexpected given information on rates of increase from some other areas of the North Atlantic, and may reflect either a true rate of increase, unidentified sampling bias, and/or the idea that Silver Bank as a habitat has reached maximum capacity. It is not clear whether the MONAH estimate is representative of the entire population, nor the extent to which the full estimate can be applied to the southeastern Caribbean in the context of the St Vincent hunt. However, four animals from the Gulf of Maine have been linked to animals seen in the southeastern Caribbean (including one that was caught in the hunt).

The Committee also noted several endorsed recent abundance estimates of humpback whales in parts of the North Atlantic including: 993 (95% CI: 434-2,272) in West Greenland in 2015; 4,223 (95% CI: 1,845-9,666) in East Greenland in 2015; and 12,879 (95% CI 5,074; 26,455) in the Iceland-Faroes region in 2007.

It has now been nearly two decades since the IWC has done an In-Depth Assessment on North Atlantic humpback whales. The Committee **agrees** that it would be a valuable exercise to perform a North Atlantic Rangewide review of humpback whales, similar in scope to the Rangewide Review for North Pacific gray whales and taking into account recent work on stock structure including that of Stevick *et al.* (2018).

8.8.3 Management advice

Attention: C-A

The alternate Commissioner for St Vincent and the Grenadines advised that no change to the present limits were envisaged. The Committee therefore:

- (1) **notes** that it does not have an approved abundance estimate for western North Atlantic since that in 1992;*
- (2) **notes** that in accord with the advice provided in the AWS (see Annex E, Appendix 8), it therefore considered the available evidence to see if was sufficient to provide safe management advice;*
- (3) **advises** that, given the information above on recent abundance in the North Atlantic combined with the size of the requested catch/strikes (an average of four annually), continuation of the present limits will not harm the stock;*

*The Committee also **reiterates** its previous advice that:*

- (1) the status and disposition of genetic samples collected from past harvested whales be determined and reported next year;*
- (2) photographs for photo-id (where possible) and genetic samples are collected from all whales landed in future hunts; and that*
- (3) the USA (NOAA, NMFS) provides an abundance estimate from the MONAH data as soon as possible for the Committee.*

8.9 Workplan 2019-20

Table 7 summarises the work plan for work related to aboriginal subsistence whaling. The Committee also established an Intersessional Correspondence Group to work on ASW related issues (Annex Y).

Table 7

Work plan for matters related to aboriginal subsistence whaling

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
(1) Annual review of catch/strike limits		Carry out		Carry out
(2) Implementation Review		Gray whales based upon rangewide review		West Greenland humpback whales
(3) SLAs		Consider development of an SLA for the hunt of common minke whales off East Greenland based on operational models developed for the West Greenland hunt		Adopt SLA if it is decided one is necessary
(5) Interim relief allowance testing	Run trials for gray whale hunts	Review results	Run trials for West Greenland common minke whales and fin whales	Review results
(6) Carryover (US/Denmark request)	Run trials for remaining Greenland hunts (West Greenland common minke whales, bowhead whales and fin whales)	Review results		

9. WHALE STOCKS NOT SUBJECT TO DIRECTED TAKES

9.1 In-depth Assessments

Donovan gave a presentation explaining a streamlined procedure whereby the Committee, via its sub-groups, can undertake Comprehensive Assessment (traditionally the first time an assessment is undertaken for a particular species/ocean basin) or an in-depth assessment (assessments subsequent to a comprehensive assessment). This can be found as SC/67B/GEN04 and is summarised in Fig. 1. The objective is to provide a consistent approach (including methods) that initially focusses on ensuring that sufficient data are available to undertake an assessment (the pre-assessment approach that will normally be undertaken at annual meetings) and then follows this with a concentrated effort (ideally two workshops and two annual meetings, with no new data) to complete the assessment. The objective is to provide Commission with robust information on present status. This involves identifying:

- (1) if populations are recovering, recovered or if there is cause for concern;
- (2) factors that may be or are affecting status so that conservation and management needs can be determined; and
- (3) information gaps and ways to address these in order to reduce uncertainty at the next assessment.

9.1.1 Comprehensive Assessment of North Pacific humpback whales

Work towards a Comprehensive Assessment of North Pacific humpback whales began in 2016, and included an intersessional workshop held in April 2017 (IWC, 2018b). After the 2017 Committee meeting, an intersessional steering group continued preparing the input data and assessment model (IA/67b/IA03). The assessment model is a simplified age-aggregated model of the breeding and feeding grounds. The development of the input data (stock structure, abundance, catches, and life history parameters) continued during the year but given the slower than initially expected progress, particularly with respect to narrowing down the number of stock structure hypotheses, the steering group had agreed that it was premature to hold the anticipated workshop prior to SC67b.

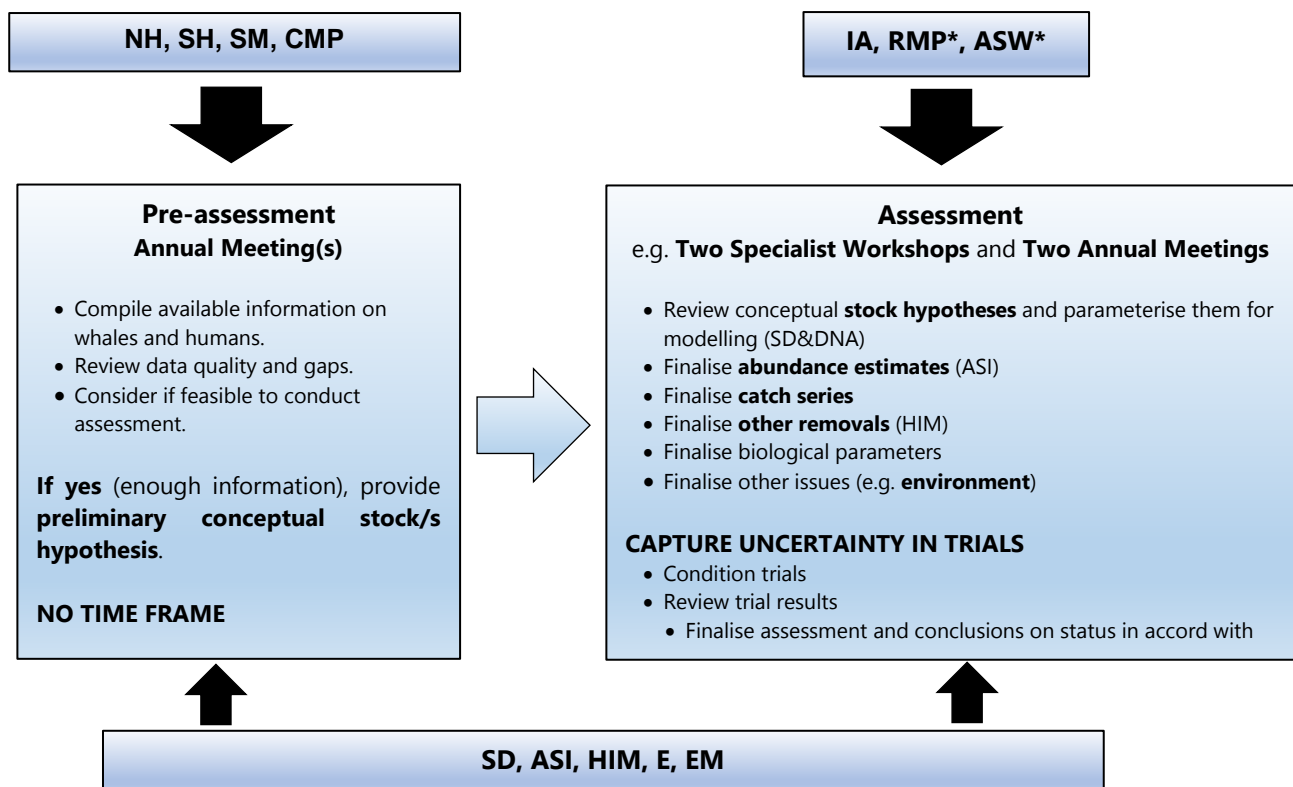

Fig. 1. Schematic of the approach to conduct assessments within the Scientific Committee. Acronyms refer to sub-groups. Normally the final assessment will take place in the sub-committee on in-depth assessments but for stocks subject to direct catches it may occur in the context of the RMP or AWMP sub-groups as appropriate.

Work continued at this meeting and the detailed discussions can be found in Annex F (item 4). The subdivisions of the North Pacific humpback whale feeding and breeding grounds in Annex F (fig. 1) are broadly consistent with existing data; identified uncertainties will be addressed in the assessment by evaluating four scenarios with different numbers of feeding and breeding grounds. This work will be greatly assisted by undertaking comparisons of humpback whale photographs from the Pacific obtained after the conclusion of the photographic component of the SPLASH (Structure of Populations, Levels of Abundance and Status of Humpback Whales) programme in 2005 (e.g. see Calambokidis *et al.*, 2008).

The general underlying structure of the assessment model has been developed but before the model can be run the input data (e.g. catches and abundance estimates) need to be updated and allocated for each stock structure hypotheses and mixing matrices developed and parameterised.

Attention: SC, G

*The Committee is undertaking a Comprehensive Assessment of North Pacific humpback whales. To complete this assessment the Committee **agrees** that:*

(1) a large-scale matching effort of post-2005 photo-identifications should be undertaken (see Annex F, item 4 for methods); and

(2) this matching effort will (a) help clarify the connections among the feeding/breeding areas within the North Pacific; and (b) assist in developing updated abundance estimates where appropriate.

*The Committee **stresses** that to obtain the most robust assessment and thus conservation advice, all available data should be included in the matching effort. Therefore, the Committee **strongly encourages** all catalogue holders to participate in this exercise, after the appropriate data sharing agreements are made.*

*The Committee also **welcomes** the provision of new abundance estimates (e.g. those from the IWC-POWER surveys and from local areas in Japan), noting that they will also need to be adjusted for the various stock structure hypotheses.*

*The Committee **agrees** that the next assessment workshop should take place at a time prior to SC68b when the intersessional Steering Group (Annex Y) decides sufficient progress has been made.*

9.1.2 Comprehensive Assessment of North Pacific sei whales

The Committee began what was called an in-depth assessment of North Pacific sei whales in 2015 (IWC, 2016c) but, in keeping with the discussion under Item 9.1 will now be termed a Comprehensive Assessment for consistency. Work has focussed since then on finalising the stock structure hypotheses (two have been agreed for use in the assessment - a single-stock hypothesis and a five-stock hypothesis), developing an appropriate population model and finalising the model inputs in accordance with these hypotheses (including catches, mark-recovery locations, abundance estimates, estimates of mixing between sub-areas, and life history parameters).

Considerable progress was made with this work intersessionally and at this meeting as discussed in Annex H, item 3.

Attention SC, G

*The Scientific Committee intends to complete the Comprehensive Assessment of North Pacific sei whales within the next biennial period. It notes the progress made at this meeting with respect to stock structure, abundance estimates, marking data, catch history, life history parameters and the assessment model. To complete this work, the Committee **agrees** to:*

(a) the work undertaken to finalise input data for the assessment (Annex F, appendices 2-7);

(b) support the modelling work identified in Annex F; and

(c) re-establish the intersessional steering group to oversee the assessment.

*In addition, the Committee **encourages** telemetry work in waters outside the 'pelagic' sub-area to assist in quantifying the movement patterns of animals.*

9.1.3 In-depth Assessment of Indo-Pacific Antarctic minke whales

An intersessional correspondence group under Murase completed its task to finalise a document synthesising the results of the 2001 - 2014 in-depth assessment of an eastern Indian stock (I-stock) and a western South Pacific stock (P-stock) of Antarctic minke whales distributed between 35°E and 145°W.

The Committee **commends** the authors for completing this paper and submitting it to the *Journal of Cetacean Research and Management*. As the paper has just entered the review process, the intersessional correspondence group (Annex X) has been re-established to see the paper through to publication.

9.1.4 Workplan 2019-20

The work plan for Comprehensive and in-depth assessments for the next biennium is provided in Table 8.

Table 8
Work plan for in-depth assessments

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting (SC/68b)
In-depth Assessment of Indo-Pacific Antarctic minke whales	Complete review of paper submitted for publication	-	-	-
Comprehensive Assessment of North Pacific sei whales	Re-establish the ISG (Annex Y) to further data preparation and development of the assessment model	Review progress of intersessional work and continue the assessment	Finalise preparation of assessment	Review progress of intersessional work and finalise the assessment
Comprehensive Assessment of North Pacific humpback whales	Re-establish the ISG (Annex Y) to further data preparation, development of the assessment model and hold a Workshop	Review progress of intersessional work and continue the assessment	Finalise /continue preparation of assessment	Review progress of intersessional work and continue/finalise the assessment

9.2 Evaluation for potential new Comprehensive or In-Depth Assessments

9.2.1 North Pacific blue whales

The Committee welcomed the report of an intersessional group that had been determining the data that are available on items required to carry out a Comprehensive Assessment of blue whales in the North Pacific. The status of the eastern North Pacific population is well known and a stock assessment was reviewed and accepted by the Committee in 2016 (Monnahan and Branch, 2015). However, information from the central and western North Pacific is sparser. Information presented at this meeting concerned stock structure, catch history, biological parameters, photo-identification, Discovery marks and sighting surveys. Details can be found in Annex G (item 6.1).

Several papers and datasets were discussed including: the use of blue whale sounds to identify stocks; morphological data; genetic data; sightings data (SC/67b/IA02; SC/67b/SCSP06; SC/67b/SCSP07; SC/67b/NH08).

Attention: SC

*The Committee **agrees** the following priorities to progress the pre-assessment:*

- (1) obtain abundance estimates from the IWC-POWER surveys;*
- (2) obtain abundance estimates from the JARPN and JARPNII surveys;*
- (3) analyse and compare genetic samples from ENP, IWC-POWER and ICR biopsy samples to determine stock structure throughout the North Pacific;*
- (4) compare photo-identification data from POWER, JARPN/JARPNII and other ENP catalogues;*
- (5) Review new acoustic locations and information and conduct fine-scale analysis of song features for central Pacific blue whale calls, with particular focus on calls around Japan;*
- (6) Obtain better life history parameters (especially age at sexual maturity and calving interval) from the Cascadia Research Collective, the Mingan Island Cetacean Study Research Station and the CICIMAR-IPN photo-ID dataset;*

*With respect to (3), the Committee **requests** the collection of about 20 biopsy samples if possible during the NEWREP-NP surveys in the western North Pacific to improve the power to evaluate stock structure and **encourages** genetic analysis of the existing Japanese samples.*

*With respect to (5), the Committee **requests** a reanalysis of recordings from the Northern Mariana Islands (Saipan and Tinian) collected by the Pacific Islands Fisheries Science Center to look for the presence or absence of the new song type recorded from Japan. It also **encourages** passive acoustic data collection during surveys (e.g. IWC-POWER, university/training cruises) from the region of high blue whale density southeast of the Kamchatka Peninsula to determine the song type produced by animals in that region.*

*The Committee **agrees** that the intersessional correspondence group continue to review data needed for an assessment of North Pacific blue whales be reappointed under Branch (Annex Y).*

9.2.2 Non-Antarctic Southern Hemisphere blue whales

9.2.2.1 SOUTHERN HEMISPHERE POPULATION STRUCTURE

The Committee is currently preparing for a Comprehensive Assessment of pygmy blue whales. For this reason, it continues to gather information on population structure (see Item 3.1, IWC, 2018a). This year, the web-based pygmy blue whale song library funded by the IWC will be launched (SC/67b/SH12). This will enable researchers to compare their acoustic recordings with validated song archetypes and greatly assist the determination of Southern Hemisphere blue whale distribution patterns and stock structure. Photo-ID and genetic evidence support the idea that each distinct pygmy blue whale song represents a geographically and genetically distinct population of pygmy blue whales around the Southern Hemisphere. A full description of the discussion of the use of songs in this pre-assessment is given in Annex H (item 3.1), including comparison with genetic and photo-identification data. The Committee also received information

from whale bones and notes that further analysis of blue whale bones from old whaling land stations will be helpful to establish the past distribution of these stocks.

Assessments require catches to be allocated to populations and in 2016 the Committee funded an examination of regional catches to assign them to each putative population (Item 5.1, IWC, 2017a). The results of this work are provided in SC/67b/SH23 and discussed in Annex H (item 3.1). Total pygmy blue whale catches were estimated at 12,184 with totals for each population of 1,228 (Northern Indian Ocean), 6,889 (South West Indian Ocean), 3,646 (South East Indian Ocean) and 421 (South West Pacific Ocean).

The Committee also discussed an intersessional effort to identify and standardise genetic markers used in Southern Hemisphere blue whale research (only four loci were common across all research laboratories) and received a progress report (SC/67b/PH04) on matching within the Southern Hemisphere Blue Whale Catalogue, which has been supported by funding from the Committee (Item 10.2.2, IWC, 2017a). This helps understanding of blue whale movements between regions, and allows estimation of regional abundance. The catalogue is currently being migrated to IWC servers (and see Item 23.2.3.2).

Attention: SC, G

In order to progress its work towards an assessment of pygmy blue whales, the Committee:

- (1) **agrees** that further work is needed to identify high and base case catch scenarios for pygmy blue whales;*
- (2) **encourages** deployment of more acoustic recorders in the southern Indian Ocean;*
- (3) **agrees** that further population modelling is needed to assess pygmy blue whale populations;*
- (4) **strongly encourages** blue whale research groups to publish the metadata associated with their sequences in order that levels of sample overlap can be established and datasets compared;*
- (5) **agrees** that the Southern Hemisphere Blue Whale Catalogue should be continued to help understand blue whale movements, with a priority focus on matching photographs within regions to measure regional abundance of pygmy blue whales.*

9.2.2.2 INDONESIA/AUSTRALIA BLUE WHALES

The Australian blue whale photo-ID catalogue data have now nearly all been uploaded and matched within the Southern Hemisphere Blue Whale Catalogue, at which point quality control analysis can begin. This will allow the potential for using these data for mark recapture abundance estimation to be assessed. The Scientific Committee was informed that mark-resighting data from the Perth Canyon (Australia) will be analysed intersessionally, to provide a new estimate of Australian blue whale abundance which assist in a future assessment of this population.

Attention: SC, G

*The Committee **encourages** analysis to provide an estimate of Australian blue whale abundance using mark-resighting data.*

9.2.2.3 MADAGASCAR BLUE WHALES

The Committee was informed that passive acoustic monitoring of blue whales in the Mozambique Channel detected both South West Indian Ocean (SWIO) and Antarctic blue whale song types, as well as fin and Antarctic minke whales (SC/67b/SH14). In addition, SC/67b/SH24 reported an unidentified blue whale song off Oman. A full discussion of the results of these papers can be found in Annex I (item 3.3.2).

This new information means that the blue whale catch allocations for the Indian Ocean, currently only ascribed to a single 'NIO' population in the Northern Indian Ocean, will need revision to take this new acoustic pattern into account.

Attention: SC, G

The Committee notes that the distribution and population isolation of blue whales is poorly understood in the northern and western Indian Ocean. The Committee therefore:

- (1) **strongly encourages** further acoustic work in the western Indian Ocean and Arabian sea to better understand the distribution, seasonality and overlap of blue whale calls;*
- (2) **strongly encourages** the collection and analysis of available tissue samples for analysis of genetic population structure in this region to assist with characterising these populations; and*
- (3) **agrees** that catch allocations of blue whales be revised to include the new blue whale song in the northwest Indian Ocean as a potential distinct 'stock'.*

9.2.2.4 NEW ZEALAND BLUE WHALES

Three papers were presented on blue whales off New Zealand (see Annex H, item 3.3.4 for a full discussion).

SC/67b/SH09 reported a recent study of blue whale movement and habitat use in the Taranaki region of New Zealand in which two animals were tagged. However, due to the small sample size and La Niña conditions, it is uncertain how representative these movements are for blue whales in New Zealand waters.

SC/67b/SH05 summarised a multi-disciplinary study included acoustics, genetics and photo-identification in the same area, and provided a conservative estimate of blue whale population abundance (see Annex Q, item 3.1.1.9), to consider if this estimate can be used in the upcoming regional assessments of pygmy blue whales. SC/67b/SH04 reported projects underway to assist regional conservation management, including a description of fine-scale habitat use during summer months in the South Taranaki Bight, and response to local acoustic disturbance.

Attention: SC, G

With respect to information on blue whales off New Zealand, the Committee:

- (1) welcomes the work being undertaken to understand abundance and connectivity, which will contribute towards the pygmy blue whale population assessments; and*
- (2) agrees that New Zealand photo-identifications should be combined with others within the Southern Hemisphere Blue Whale Catalogue to provide the fullest possible assessment of regional abundance and connectivity*

9.2.2.5 SOUTHEAST PACIFIC BLUE WHALES

The Committee received two papers relevant to blue whales off Chile and the full discussion can be found in Annex H (item 3.3.1). SC/67b/SH03 presented a morphometric analysis of Chilean blue whales which reinforces the argument that Chilean blue whales should be considered a separate sub-species from the Antarctic and pygmy forms. (Bedrinana-Romano *et al.*, 2018) reported distribution modelling of blue whales using Chilean Northern Patagonia waters. Preliminary delimitations of possible blue whale conservation areas in this region overlap with highly used vessel navigation routes and areas allocated for aquaculture. The Committee was also informed that predictions of southeast Pacific blue whale habitat following Redfern *et al.*, (2017) will be completed intersessionally.

Attention: SC, G

In view of the recent identification of movements of Chilean blue whales into the South Atlantic and ongoing questions about the distribution of this population, the Committee:

- (1) encourages further satellite tracking and surveys (including collection of photo-ID and genetic data) to assess the population limits, habitat use and abundance and sub-species identity of blue whales in Chile;*
- (2) encourages compilation of morphometric data available for northeast Pacific blue whales and comparison with Chilean data, to assess morphological differentiation of these whales in the eastern Pacific and evaluate sub-species identity; and*
- (3) welcomes plans for further photo-ID catalogue matching within this region to assist with regional abundance estimation.*

9.2.2.6 WORK PLAN

The work plan for all Southern Hemisphere blue whales is given in Table 9.

9.2.3 Antarctic blue whales (Areas III and IV)

Undertaking a regional population assessment of Antarctic blue whales is challenging due to the scarcity of whales and logistical challenges. The Committee received new information this year on sightings, abundance and genetic studies.

SC/67b/SH08 presents a preliminary estimate of abundance (the first using photo-ID data) and this is discussed in Annex Q (see item 3.1.19) where suggestions were made to refine the analyses. Reports from two 2017/18 NEWREP-A summer cruises included sightings of blue whales and information on biopsy sampling (SC/67b/SP08 and SC/67b/ASI07). An IWC-SORP Southern Ocean blue whale-focussed cruise is planned for January to March 2019 (140°E-175°W), which intends to describe krill swarms in relation to blue whale density and distribution (SC/67b/SH07).

With respect to genetic work, IWC-SORP funded work on blue whale bones to compare past and current genetic diversity levels is reported in SC/67b/SH02 and discussed in Annex I (item 4.4.2). The Committee was also updated about ongoing work to analyse a collection of 1,626 baleen plates (roughly 50:50 blue and fin whales) from the Japanese whaling in the 1940s and held at the Smithsonian Natural History Museum, USA. A pilot study has established that mitochondrial DNA can be sequenced from these plates. Further analyses including of stable isotope and hormone levels are planned for these samples.

Attention: SC, G

The Committee welcomes the progress being made towards being able to undertake an in-depth assessment of Antarctic blue whales. The Committee:

- (1) encourages further work to update the abundance estimate for Antarctic blue whales following Committee recommendations;*

(2) **strongly encourages** continued opportunistic photo-ID data collection in the Antarctic to assist with developing estimates of population abundance for this subspecies; and
 (3) **encourages** continued collection and analysis of bone and baleen from historical Antarctic commercial whaling samples and sites to evaluate loss of genetic diversity and shifts in population structure.

9.2.3.1 WORK PLAN

The work plan for all Southern Hemisphere blue whales is given in Table 9.

Table 9.

Workplan for Southern Hemisphere Antarctic and pygmy blue whales

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Antarctic blue whales				
Catalogue matching	Catalogue matching of photo-IDs (Annex Y)	Report	Catalogue matching (opportunistic collected photos)	Report
Abundance estimation	Mark recapture modelling work to update SC/67b/SH08 Annex Y	Report		
Photo-ID outreach material	Create photo-ID information booklets for distribution via IAATO operators	Report		
SH non-Antarctic blue whales				
Population assessment	Improve catch separation model, explore alternative catch allocation models (Annex Y)	Report	Population assessment. Analyse minimum and extrapolated recovery status of all populations for which abundance is available	Report
Catalogue matching	Catalogue matching of photo-IDs within southeast and central east Pacific (Annex Y)	Report	Catalogue matching (opportunistic photos from citizen scientists and collaborators) if funds are available	Report
Blue whale song library	Finish implementation of blue whale song library (Annex Y)	Report		
Australian abundance estimate	Analyse Perth Canyon abundance using mark recapture data (Annex Y)	Report		

9.2.4 Southern Hemisphere fin whales

9.2.4.1 POPULATION STRUCTURE

As part of its pre-assessment work, the Committee is gathering information on Southern Hemisphere fin whales in order to: (1) clarify the subspecies status of these whales (currently two Southern Hemisphere subspecies are recognized, Committee on Taxonomy, 2017); and (2) measure population differentiation around the Southern Hemisphere to establish whether any distinct populations exist.

A summary of available data on Southern Hemisphere fin whale structure was presented in SC/67b/SH15 and is discussed in detail in Annex H (item 4.1). The only evidence for any structure comes from acoustics. A genetic study from the southeast Pacific (SC/67b/SH13) found high local diversity in Chile, with no significant differentiation from the other Southern Hemisphere datasets. The Committee noted however that genetic differentiation can be difficult to detect when diversity levels are high and genetic differentiation is low (see Annex H, item 4.1).

Attention: SC, G, S

Knowledge of population structure is essential to future efforts to assess Southern Hemisphere fin whales. To determine the differentiation and potential sub-species structure among fin whales the Committee:

- (1) **agrees** that analysis of concurrently collected acoustic recordings of fin whales, to assess song variation around the Southern Hemisphere, is a priority;
- (2) **agrees** that a review of all Discovery mark data published on fin whales to assess population connectivity patterns should be carried out; and

- (3) **requests** that the Secretariat provide a letter of support for a study examining the evidence for *B. physalus patachonica*, which requires access to the holotype for this species from the Bernardino Rivadavia Natural Sciences Museum in Buenos Aires.

The Committee also **encourages**:

- (1) analysis of fin whale distribution and geographic aggregations using all available catches;
- (2) strategic biopsy sampling and analysis to measure the genetic differentiation of fin whales around the Southern Hemisphere;
- (3) further biopsy sampling and sequencing of multiple nuclear loci to establish Chilean fin whale differentiation patterns, with co-collection of photo-IDs and body length measurements to establish population identity;
- (4) satellite telemetry to discern seasonal movements; and
- (5) photo-identification to understand site fidelity and residency patterns and linkages between high- and low-latitude grounds.

9.2.4.2 DISTRIBUTION AND ABUNDANCE

The Committee welcomed a review of the available metadata on Southern Hemisphere fin whales (SC/67b/SH19), compiling data from dedicated and opportunistic surveys, moored acoustic recorders, sonobuoy surveys, photo-identifications, satellite tagging and biopsy sampling. The Committee also welcomed a summary of recent work by the Brazilian Antarctic Program to conduct dedicated fin whale research using sighting surveys, photo-ID, biopsy sampling and telemetry.

Reports from two 2017/18 NEWREP-A summer cruises included sightings of fin whales and information on biopsy sampling (SC/67b/SP08 and SC/67b/ASI07). A new abundance estimate for fin whales using sightings data from the third IDCR-SOWER circumpolar survey is expected to be available for review at next year's meeting.

SC/67b/14 provided information on the presence of fin whales in the Mozambique Channel and a new lower-latitude song. Details of the discussions can be found in Annex H (item 4.2).

The Committee was also informed that an analysis has suggested that Antarctic fin whales are sufficiently well marked to enable to use in photo-ID projects (SC/67b/PH01) and this is discussed in Annex S (item 4.1).

Attention: SC, G, CG-A

With respect to obtaining information on the distribution, movements and abundance of Southern Hemisphere fin whales for use in a future assessment, the Committee:

- (1) **encourages** a meta-analysis of the Antarctic Peninsula and Scotia Sea sightings data, to measure recent fin whale distribution, density and habitat use;
- (2) **strongly encourages** continued work by the Brazilian Antarctic Program towards the understanding of fin whale population structure, movements and habitat use
- (3) **agrees** that a new abundance estimate for fin whales from the IWC IDCR/SOWER programme should be presented for review at next year's meeting,
- (4) **welcomes** news that fin whales can be used in photo-ID studies, and **encourages** further photo-ID data collection at high latitudes.

9.2.4.3 WORK PLAN

The work plan for Southern Hemisphere fin whales is given in Table 10.

Table 10

Work plan for Southern Hemisphere fin whales

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Fin whale acoustic structure	Review fin whale call patterns across Southern Hemisphere, investigate call variation (Annex Y)	Report	Complete review of fin whale call patterns (Annex Y)	Report
Discovery marks	Review available Discovery mark data on fin whales (Pastene and Jackson)	Report		
Catch maps	Update fin whale catch model to include Soviet catch data (de la Mare)	Report		

9.2.5 North Atlantic sei whales

The Committee welcomed information on two separate habitat-based density modelling efforts, using visual survey data to produce seasonal abundance estimates for sei whales from the purported ‘Nova Scotia’ stock, ranging from Nova Scotia to the southeastern USA (SC/67b/NH07). There was also some consideration of passive acoustic and strandings data from the US eastern seaboard. No new data are available from around Iceland or Norway, partially due to difference in timing between surveys and species’ arrival in regional waters. This information was discussed in Annex G (item 6.2). An intersessional correspondence group (Annex Y) will compile additional information this species in the North Atlantic and the Committee looks forward to a further update on reanalysis of historical data, particularly related to stock structure and strandings, next year.

9.2.6 North Atlantic right whales

Since 2016, the Committee has recommended a comprehensive update on North Atlantic right whales. SC/67b/NH05 summarised the information on the status of the North Atlantic right whale. This population has been slowly declining since 2010 and the abundance at the end of 2015 was estimated to be around 460 individuals (Pace *et al.*, 2017⁶). Of particular concern is the lower annual survival rate of females than males and poor recent calving (five in 2016/17 and none so far in the 2017/18 calving season). The observed number of dead whales in 2017 was 17 whales, several showing signs of death from fishing gear or blunt force trauma. These clearly represent minimum numbers and there was some discussion as to whether it was possible to scale minimum observed mortalities to an overall estimate but several confounding factors preventing this were identified (see Annex F, item 6.3 and Annex J, item 2.1.2).

Due to the increased 2017 Canadian interactions in the Gulf of St. Lawrence, on 19 April 2018 the Government of Canada implemented mitigation measures to reduce future interactions (DFO, 2018), including: closing a large part of the Gulf of St. Lawrence snow crab fishery on 30 June; creating a dynamic 15-day fishing closure; introducing a 10 knot speed restriction when any single right whale sighting in any area is detected; putting in place mandatory gear marking and reporting of any lost gear; minimising the allowable amount of floating line at surface; and using vessel monitoring systems that reports the boats position every 5 minutes.

A substantial increase in collaboration and data sharing between the US and Canada has occurred as a result of these mortalities.

Attention: C-A, CC

The Committee reiterates its serious concern over the status of the western North Atlantic stock of right whales as it is probably the only viable population of this species, for which entanglements and ship strikes have long been identified as key threats.

This year, the Committee:

- (1) **recognises** that entanglements have now replaced ship strikes as the primary cause of deaths (Kraus et al. 2016);*
- (2) **reiterates** its recommendation for the USA to submit a comprehensive update on the status of North Atlantic right whales (IWC, 2017:40) including an update of the Pace et al. abundance estimate, prior to the 2019 meeting;*
- (3) **stresses** that this update will allow time for explanations or additional analyses to be undertaken before the proposed 2019 Workshop on the Comparative Biology, Health, Status and Future of North Atlantic Right Whales: Insights from Comparative with other Balaenid Populations (including bowheads);*
- (4) **encourages** updates from the US Large Whale Take Reduction Team (ALWTRT) on progress of the Whale Safe Rope and Gear Marking Feasibility Subgroups; and*
- (5) **requests** that the Commission asks the IWC Executive Secretary to write to the U.S. National Marine Fisheries Service (NMFS) and the Canadian Department of Fisheries and Oceans, informing them of the Committee’s serious concerns over the declining population trend of this species, and stressing that, **as a matter of absolute urgency**, every effort be made to reduce human induced mortality in the population to zero.*

9.2.7 North Pacific right whales

The Committee received a report of a dead right whale caught in a set net off Izu, Japan in 2018 (SC/67b/NH06) – the first in a set net since one in Korea in 2015 (Kim *et al.*, 2015).

The Committee welcomed information on a single sighting off Hokkaido (and a biopsy sample) from a Japanese national cruise (SC/67b/ASI10). It also welcomed information on North Pacific right whales from the visual, acoustic and biopsy sampling components of the 2017 IWC-POWER cruise in the eastern part of the Bering Sea. A total of 9 schools and 18 individuals (including 2 duplicate schools of 3 individuals) of right whales were sighted with photo-identification of 12 individuals and biopsy samples from 3 individuals. Discussion of these sightings can be found in Annex G (item 6.4).

In response to a recommendation made last year (IWC, 2018c), US and Japanese scientists presented the results of new genetic analyses of right whales in the North Pacific. Comparison of whales sampled in the eastern and western North Pacific revealed statistically significant differentiation based on mtDNA data, supporting presumed separation of the two stocks based on gaps in the spatial distribution of sightings (and also see discussion in Annex I, item 4.3).

⁶ Any revised estimate from the Pace *et al.* 2017 paper will be reviewed by the ASI sub-committee during SC68a.

Attention: SC

*The results of new genetic analyses support the recognition of separate stocks of right whales in the eastern and western North Pacific. Given the importance of this work and the precarious situation of this species, especially in the eastern North Pacific, the Committee **encourages** the publication of this information as soon as possible.*

9.2.8 Workplan 2019-20

The Committee agreed to the two-year workplan in Table 11.

9.3 New information and workplan for other northern stocks (NH)

9.3.1 North Pacific fin whales

The Committee received new information on studies of North Pacific fin whales. New sightings of fin whales were reported in the papers (SC/67b/ASI12, SC/67b/ASI10, SC/67b/SCSP06) during the POWER cruise in the Bering Sea and the two surveys in the western North Pacific (Areas 7, 8 & 9). Over 260 schools found, many individuals were photo-identified and biopsy samples were obtained from 28 whales.

9.3.2 Omura's whale

The Committee welcomed the new information on this species (SC/67b/NH09) from the west coast of Madagascar, supporting the current understanding that the population is resident and non-migratory with strong site fidelity. Likely threats to the Madagascar population include entanglement in local fisheries, impacts from oil and gas exploration, and most imminent the risk of coastal water contamination from a recently initiated mining operation for Rare Earth Elements. Future work should include a long-term latitudinal study that incorporates multiple methodologies to investigate all aspects of the species biology and conservation threats to the population.

Kim and colleagues reported on the first confirmed documentation of Omura's whale in the waters of South Korea. Two of six large baleen whales bycaught were confirmed by genetic analysis to be Omura's whale. This bycatch reinforces the concept that this coastal species is vulnerable to anthropogenic impacts, especially entanglement in fishing gear.

Attention: SC, G

The Committee notes that little information is available to assess the status of Omura's whale. The Committee:

- (1) **recognises** the significant contribution the research efforts off Madagascar have made to the understanding of this species and **encourages** this work to be continued and expanded into the future; and*
- (2) **encourages** identification of study sites that are suitable for long-term comparative study on Omura's whales in other parts of its range (e.g. New Caledonia, Komodo Islands, Indonesia, and the Bohol Sea, Philippines).*

Table 11

Workplan for other Northern Hemisphere stocks

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
North Pacific blue whales	Data collection and review with focus on catches and stock structure	Review especially stock structure	Develop proposal for stock structure	Agree stock structure hypotheses
North Atlantic sei whales	Review distribution, strandings, sightings and stock structure	Review new information for assessment	Develop proposal for stock structure	Agree stock structure hypotheses
North Atlantic right whales		Review status and mortality data		Review status and mortality data
North Pacific right whales		Review new information for assessment		Review new information for assessment
North Atlantic humpback whales		Consider information for new assessment		Develop plans for new assessment
Gulf of Mexico Bryde's whale		Review new information on mortality		Review new information on mortality
All other stocks		Review new information		

9.3.3 North Atlantic Bryde's whales

SC/67b/ASI01 presented sightings collected during recent coastal surveys off Guinea, Sierra Leone and Liberia in March 2018. During this survey, two groups of five individual Bryde's whales were observed.

The Committee welcomed this information and **encourages** future surveys in this region.

9.3.4 North Atlantic blue whales

The Committee welcomed new information from the USA on blue whales in the North Atlantic including recent sightings, serious injuries or mortalities, seasonal occurrence based on acoustics. Lesage *et al.* (2018) provides an extensive summary of recent data collected in Canadian waters. This is discussed in Annex G (item 7.6) where it was noted that multiple new datasets (including from passive acoustic monitoring) have been recently collected and may provide more information on blue whale distribution in North Atlantic waters

Attention: SC, G

The Committee notes that there has been a recent increase in information available on North Atlantic blue whales. The Committee:

- (1) **draws attention to** the lack of data on interchange between blue whales in the eastern and western North Atlantic and **recommends** that U.S., Canadian and Icelandic colleagues conduct a new comparison of blue whale photo-identification catalogues and present this information at SC/68a; and
- (2) **encourages** Canadian colleagues to generate a new population abundance estimate as soon as feasible, and looks forward to updates on new passive acoustic and visual sightings data SC/68a.

9.3.5 North Atlantic humpback whales

The Committee received new information (NOAA, 2018b) on humpback mortalities along the US coast (vessel strikes and entanglements were noted as the primary causes of anthropogenic mortality). An 'Unusual Mortality Event' was declared by the USA for humpback whales in April 2017. This is discussed further in Annex G (item 7.7). New abundance estimates for parts of the North Atlantic are discussed in Annex Q (item 3.1.1.3) and presented in Item 12.1. Consideration of the need for a new in-depth assessment of North Pacific humpback whales is given in Annex E (item 5.8.2) and Item 8.7.3.

9.3.6 North Atlantic bowhead whales not subject to aboriginal subsistence whaling

No new information was available to the Committee.

9.3.7 North Pacific bowhead whales not subject to aboriginal subsistence whaling

No new information was available to the Committee.

9.3.8 North Pacific sperm whales

Three papers (SC/67b/ASI10,12 and SC/67b/SCSP06) provided new information of sperm whale occurrence and distribution was collected during 2017 in the western North Pacific, eastern Bering Sea. An intersessional correspondence group to examine possible ways to assess sperm whales has been reappointed (Annex Y)

9.3.9 Gulf of Mexico Bryde's whales

9.3.9.1 NEW INFORMATION

The Committee received an update on activities related to monitoring and new research plans for the critically endangered Gulf of Mexico sub-species of Bryde's whale. The Southeast Fisheries Science Center undertook a shipboard survey in the northern Gulf of Mexico in 2017, including known habitat of the Gulf of Mexico Bryde's whale. Passive acoustic data were collected in historic habitat of the central and western Gulf from June 2016 to June 2017. The In the USA, there is legislation that provides funds to restore and protect ecosystems of the Gulf of Mexico following the Deepwater Horizon oil spill (2010); this work will include research on the Gulf of Mexico Bryde's whale.

Attention: SC, G

*The Committee **agrees** that the NOAA scientists working with this sub-species should present results from shipboard and acoustic data analyses to the IWC at the 2019 Scientific Committee meeting and looks forward to receiving a report from the Workshop held in conjunction with the initiation of research associated with funds to restore and protect ecosystems of the Gulf of Mexico following the Deepwater Horizon oil spill.*

*The Committee also **encourages** U.S. and Mexican scientists to collaborate in efforts to determine whether any of these whales occur in Mexican waters (e.g. Bay of Campeche) where a major oil spill of three million barrels occurred in 1979. This should include consideration of the use of passive acoustics as well as visual surveys focusing on areas of habitat similar to that found in the core known range in the north-eastern Gulf. It was further noted that passive acoustic data or specimen records from the northern coast of Cuba would be useful to determine potential occurrence of this subspecies in that region.*

9.3.9.2 CONSERVATION ADVICE

Attention: CG-R, S

*The small population size, known human related mortality, restricted range and low genetic diversity place the Gulf of Mexico sub-species of Bryde's whale (added to the Critically Endangered category of the IUCN Red List in 2017) at significant risk of extinction. The Committee **reiterates** its previous **recommendations** that US authorities:*

(1) make full and immediate use of available legal and regulatory instruments to provide the greatest possible level of protection to these whales and their habitat;
 ensure that seismic surveys and associated activities that degrade acoustic habitat are excluded from the region of the eastern Gulf of Mexico inhabited by these whales, including an appropriate geographic buffer against acoustic impacts from activities in the Central Planning Area and active leases in the Eastern Planning Area;
 (2) characterise the degree of overlap between the whales' currently known preferred habitat and ship traffic, and immediately implement appropriate measures to reduce the risk of ship strikes (e.g. re-routing, speed restrictions);
 (3) based on the known distribution of these whales and overlap with certain fisheries, improve understanding of potential for interaction with fishing gear, and expand and implement appropriate measures, such as area closures, to reduce the risk of entanglement throughout their range;
 (4) develop and implement restoration projects (with funds from the Deepwater Horizon oil spill settlement) for these whales and their habitat as a priority and ensure that a robust monitoring and adaptive management plan is in place to evaluate the effectiveness of all restoration efforts;
 (5) design and conduct research programmes (sighting surveys, acoustic monitoring, genetic mark-recapture, photoidentification if feasible, satellite tagging if feasible, health studies if feasible) to further investigate these whales' distribution, movements, habitat use, health, survival and fecundity - this should include efforts to better document the whales' total geographic range and to document causes of mortality through necropsies when carcasses are reported; and
 (6) ensure that information about core known habitat and movements in the Gulf of Mexico is transmitted to the U.S. Coast Guard, shipping industry trade organizations, and Gulf of Mexico port authorities (e.g. in Tampa, Florida) for their consideration to mitigate ship-strike risk.

In addition, the Committee **reiterates** its recommendation that the IWC Secretariat (i) communicate the above concerns and recommendations to range state authorities and (b) specifically explore in collaboration with the International Maritime Organization the feasibility of providing internationally recognized forms of protection to these whales (e.g. designation of an Area to be Avoided) that would reduce the risk of ship strike and help mitigate degradation of acoustic habitat by ship noise.

9.3.10 Other stocks - Northern Indian Ocean sperm whales

No new information was available to the Committee.

9.3.11 Workplan 2019-20

The Committee agreed to the two-year workplan in Table 11.

9.4 New information and workplan for other Southern stocks

9.4.1 Southern Hemisphere humpback whales

9.4.2.1 BREEDING STOCK D

The assessment of the Breeding Stocks D (West Australia), E1 (East Australia) and Oceania was completed in 2014 (IWC, 2015a), but there were substantial associated problems in obtaining a reliable estimate of absolute abundance for Breeding Stock D. See Annex H (IWC, 2017a; 2018a) for a detailed discussion of these issues. Last year (IWC, 2018c), the Committee had agreed that efforts should focus on designing and implementing a new 'survey' (perhaps using new approaches such as drones), and recommended that prior to implementation, an assessment of the feasibility of such a 'survey', focusing in particular on the study conducted by du Fresne *et al.*, (2014), is conducted.

Attention: SC, G, CG-R

The Committee **agrees** that obtaining a reliable estimate of absolute abundance for humpback whale Breeding Stock D (west Australia) is a priority for any future in-depth assessment. The Committee **reiterates** its recommendation that an evaluation of abundance survey feasibility be carried out for this population, focusing in particular on the study conducted by du Fresne *et al.* (2014), with a view to implementing a new survey of this population in the future.

9.4.2.2 WORK PLAN

The work plan for Southern Hemisphere humpback whales is given in Table 12.

Table 12.
Work plan for Southern Hemisphere humpback whales

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Survey feasibility	Reanalyse pilot study to assess feasibility of future West Australia surveys (Kelly)	Receive report		

9.4.3 Southern Hemisphere right whales not the subject of CMPs

The Committee would like to progress regional population assessments for southern right whales (Item 10.8.1.5, IWC, 2017b) This requires a good understanding of population structure, abundance, trend and past exploitation levels. It was agreed that Australia should be the highest priority region for the next assessment (Item 9, IWC, 2018a).

9.4.3.1 SOUTH AFRICA

SC/67a/SH01 provided the results of the 2017 survey of southern right whales flown along the coast of South Africa, part of a long-term monitoring programme since 1979. Since 2015 there has been a marked decline in the presence of unaccompanied adults and cow-calf pairs for unknown reasons (see discussion in Annex S, item 5.1.3). Photo-ID analyses indicated an increasing occurrence of apparent 4- and 5-year calving intervals since 2014. SC/67b/SH22 applied a life history model to photo-ID data collected from 1979 to 2017. They showed that a model variant which allows the probability of a resting female remaining in the resting phase (rather than having a calf) to vary through time provided a better fit to the data than a time-invariant model. They calculate an annual population growth rate of 6.5% and measure first year survival at 0.852, with subsequent annual survival of 0.988.

Attention: SC, G, C-A, CG-A

*The Committee is **concerned** that the future of the exemplary long-term monitoring programme of right whales in South African waters remains uncertain. The Committee therefore **reiterates** that it:*

- (1) **strongly recommends** continuation of the survey;*
- (2) **requests** the Commission to urge South Africa to do all it can to ensure the long-term future of this vital monitoring programme; and*
- (3) **encourages** South African scientists to investigate the offshore movements and locations of southern right whales with future surveys.*

9.4.3.2 AUSTRALIA

The Committee was informed about the latest of a series of aerial surveys conducted in South and West Australia in 2017. The 2017 counts were the highest yet in the series and an exponential increase of ~6% per year remains a good description of the data. Funding has been obtained for the next three years of surveys. The Committee was also informed about: (a) a 26-year cliff-top study conducted at the Head of the Great Australian Bight (south Australia) on right whale population trends and identifications (Charlton *et al.*, In prep); and (b) an aerial survey in southeast Australia where small numbers of whales have been sighted (Watson *et al.*, 2015). Right whales in southeast Australia are genetically and geographically distinct from the large population in south/southwest Australia (e.g., Carroll *et al.*, In press).

The Committee was advised that the Australian Government has recently allocated funds towards a two-year project that will provide an abundance estimate for Australia's two southern right whale populations. It will investigate life history characteristics as well as connectivity between breeding areas on the eastern, southern and western coasts of Australia.

Attention: SC, G, CC, CG-A

*The Committee **recognises** the value of the Australian long-term right whale monitoring programmes to understand right whale population trends and dynamics, and **recommends** that this monitoring continues.*

*In regard to right whales in southeast Australia, the Committee **reiterates** concerns expressed in 2017 that abundance remains low despite this area having been a significant historic calving ground. The Committee therefore:*

- (1) **recommends** an assessment of the likely effects of fish farms and other developments in hindering population recovery in this region; and*
- (2) **encourages** further work to estimate the abundance of the southeast Australia population.*

9.4.3.3 NEW ZEALAND

The Committee welcomed information that surveys will be conducted in the Auckland Islands in 2020/21 to estimate abundance (updating the last estimate from 2009), to assess trend and population age structure, as well as changes in genetic diversity of right whales using this calving ground.

9.4.3.4 FEEDING GROUNDS

The Committee welcomed the results of a visual and acoustic survey of southern right whales off South Georgia/Islands (SC/67b/SH20). SC/67b/SH06 used genotypic markers to assess re-sight rates and sex ratios from biopsy samples ($n=157$) collected during 14 summer surveys in Antarctic Area IV. A preliminary abundance estimate was calculated using these data and further mark recapture analyses will be conducted intersessionally to provide an abundance estimate for review at next year's meeting. To further investigate linkages it was suggested that these high latitude data be compared the western Australia stock to investigate what population component is using this high latitude area.

Attention: SC

The Committee **encourages** further mark recapture analysis of the genotype data of the 14-year dataset collected in the high latitudes of Area IV, to estimate the abundance of southern right whales in this feeding area and **agrees** that this will be considered at next year's meeting.

9.4.3.5 PROGRESS TOWARDS POPULATION ASSESSMENT

This year, the Committee reviewed newly available information on population structuring of southern right whales around the Southern Hemisphere (Carroll *et al.*, In press) which further confirms the genetic differentiation of regional calving grounds off Argentina, South Africa, New Zealand and Australia, showing limited migratory movements between these areas (see Annex H, item 5.1.).

The Committee was provided with updates on trends and distribution for calving grounds off South Africa and off south and southwest Australia. Recent published data on population size and trend for calving grounds across the Southern Hemisphere were summarised in Annex H (table 2); this will be reviewed at next year's meeting. Given the trends in abundance and calving rates reported this year (Items 9.4.3.1 and 9.4.3.2), integration of these analyses in a common modelling framework was suggested as a useful way to evaluate common patterns and changes in demography and investigate the relative importance of environmental drivers in determining these patterns.

Another important aspect of population assessment is to update the pre-modern catch series for southern right whales, to better reflect patterns of regional exploitation. The Committee was informed that substantial new data are available on offshore whaling patterns and extent, particularly from American and British voyage logbooks (see Annex H, item 5.2.), which are likely to increase regional catch estimates and provide revised estimates of the numbers of whales struck but lost at sea by the different fisheries.

Attention: SC, G

To better understand patterns of right whale population dynamics around the Southern Hemisphere, and further the work on updated assessments, the Committee:

- (1) **agrees** that analysis of three southern right whale calving grounds (Head of the Bight and southwest Australia, southwest Atlantic and south Africa) should be undertaken using the same life-history model, to estimate regional demographic parameters and investigate commonalities in the population dynamics of these populations; and
- (2) **supports** the compilation of new data on pre-modern right whale catches, and the organisation of a workshop to investigate regional right whale catches and rates of whales struck but lost by fisheries, in order to proceed toward regional population assessments.

9.4.3.6 WORK PLAN AND BUDGET REQUESTS FOR 2019-2020

The work plan for southern right whales not the subject of a CMP is given in Table 13.

Table 13.

Workplan for southern right whales that are not the subject of a CMP

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Southern right whales	Examine southern right whale demographic parameters across multiple calving grounds using a common modelling framework	Review progress		Complete comparison
Southern right whales	Plan right whale catch series workshop	Progress update	Organise catch series workshop	Workshop report

10. STOCKS THAT ARE OR HAVE BEEN SUGGESTED TO BE THE SUBJECT OF CONSERVATION MANAGEMENT PLANS (CMPs)

10.1 Stocks with existing CMPs

This item covers stocks (with a focus on progress with scientific work and information) that are either: (1) the subject of existing CMPs; or (2) are high priority candidates for a CMP. It also considers stocks that have previously been considered as potential CMPs, recognising that the Commission has stressed the need for Range States to support any IWC CMPs.

10.1.1 SE Pacific southern right whales

10.1.1.1 NEW INFORMATION

The Committee received information on advances with respect to sightings (SC/67b/CMP20) and acoustic monitoring (SC/67b/CMP08; SC/67b/CMP18) of the critically endangered population of SE Pacific southern right whales. This information is discussed in detail in Annex O (item 2.1.1). Four confirmed observations were made off Chile in 2017

(three opportunistic sightings and one entangled carcass) and there was another, as yet unconfirmed sighting involving adults and calves. Analysis to date of acoustic data collected off the southwestern tip of Isla de Chiloe in 2012 has provided valuable new information about call parameters and patterns.

10.1.1.2 PROGRESS WITH THE CMP

The Committee received information on progress in implementing priority actions of the CMP (SC/67b/CMP20) as discussed in Annex O (item 2.1.1.2).

This progress includes:

- (1) deployment of Passive Acoustic Monitoring (PAM) devices along the coast of Chile and Peru (SC/67b/CMP18) in two locations that will also be used as the focus of educational and capacity-building activities in communities near the monitoring sites;
- (2) additional capacity-building and awareness efforts (including posters, press releases and social media) including advice on how fishermen and the public can provide information to the national sighting network; and
- (3) additional training towards increasing the capacity of range states to respond to entanglements.

Attention: SC, CC

*The Committee **reiterates** the importance of the CMP for the conservation of this critically endangered population of southern right whales in the southeastern Pacific, **welcomes** the progress being made in its implementation by Chile and Peru. It therefore:*

*(1) **commends** the scientific work and international co-operation being undertaken for the PAM project and looks forward to receiving the results of the acoustic studies such that future sighting surveys will be more informed and baseline information on the location of breeding grounds will be available; and*

*(2) **advises** that satellite imagery be explored as an additional means to inform the design of sighting surveys because it is likely that line-transect surveys would not successfully identify whales in some areas even if they were present.*

10.1.2 Southwestern Atlantic southern right whales

10.1.2.1 NEW INFORMATION

The Committee was pleased to receive a considerable amount of new information on the southwest Atlantic population of southern right whales; this is fully discussed in Annex O (item 2.1.2.1).

With respect to abundance, SC/67b/CMP/05 suggested that although the population has continued to increase, the rate may have been slowing, perhaps as a consequence of changes in distribution due to density-dependence processes (SC/67b/CMP02).

The Committee has for some time been focussing on the die off at Peninsula Valdes (e.g. IWC, 2011; 2015) and the excellent work of the Southern Right Whale Health Monitoring Program. New and updated information was presented this year on strandings and investigations related to health including examination of levels of stress hormones in baleen and kelp gull attacks (SC/67b/CMP04) and nutritional condition (SC/67b/CMP03). This work is ongoing.

Information was received on telemetry studies (one animal in 2016 and 8 in 2017) as part of an ongoing long-term study to understand the migratory routes and destinations of southern right whales wintering off the coast of Argentina (SC/67b/CMP17). Tracks reveal that these animals are found across a vast extent of the South Atlantic and each season visit multiple potential feeding areas.

The Committee also received the report of a land-based survey of whales near Miramar on the southwest coast of the Buenos Aires Province, Argentina, where there has been a recent expansion of right whales into the region where they have been seen from May to October with peaks in August and September (SC/67b/CMP21).

Attention: SC, G

*The Committee **reiterates** the importance of continued monitoring of the southwestern Atlantic population of southern right whales and research into threats that it may face. The Committee therefore:*

*(1) **commends** the work being undertaken on understanding the mortality events and **encourages** its continuation;*

*(2) **encourages** the researchers working on stress hormones in baleen to increase their sample size, consider suggestions for additional studies provided in Annex O (item 2.1.2.1) and present a full report to the Committee when it becomes available;*

*(3) **commends** the telemetry work, **encourages** its expansion and draws attention to additional analyses that could be addressed using the telemetry data suggested in Annex O (item 2.1.2.1).*

10.1.2.2 PROGRESS WITH THE CMP

The overall objective of the southern right whale CMP is to protect their habitat and minimise anthropogenic threats to maximise the likelihood that the population will recover to healthy levels and recolonise its historical range. The Committee was pleased to receive information on progress with the actions of the CMP from Argentina (SC/67b/CMP14),

including the work described under Item 10.1.2.2, and Brazil (Annex O, appendix 2). Work in Brazil includes long-term monitoring via sightings and strandings networks, mitigation of entanglements and the development of a management plan for whalewatching (see Annex O, item 2.1.2.2).

Attention: SC, CC

The Committee reiterates the importance of the CMP for the conservation of the southwestern Atlantic population of southern right whales. The Committee therefore:

- (1) welcomes the progress being made in the implementation of the CMP reported by Argentina and Brazil and supports its continuation;*
- (2) encourages the continued co-operation and collaboration amongst range states towards implementing the CMP and addressing mortality events in this population; and*
- (3) recognising the report of a ship-struck southwestern Atlantic southern right whale in the range of the southeastern Pacific (Estrecho de Magallanes), encourages co-operation with those involved in the southeastern Pacific CMP to facilitate a regional assessment; and*
- (4) encourages the research work identified under Item 10.1.2.1.*

10.1.3 North Pacific gray whales

10.1.3.1 RANGEWIDE ASSESSMENT

Donovan summarised the report of the Fifth Rangewide Workshop on the Status of North Pacific Gray Whales (SC/67b/Rep07) held at the Granite Canyon Laboratory, California of the Southwest Fisheries Science Center from 28-31 March 2018. The primary tasks of the workshop were to (a) review the results of the modelling work identified at the fourth rangewide workshop (IWC, 2018a) and the 2017 Scientific Committee meeting (IWC, 2018b), (b) examine the new proposed Makah Management Plan (submitted by the USA – given as Annex E, Appendix 1) for gray whaling off Washington state and (c) to update as possible, and develop a workplan for, updating the scientific components of the Conservation Management Plan (CMP) for western gray whales.

A full discussion of the workshop can be found in Annex O (item 2.1.3.1). The Workshop finalised its work on (a) prioritising stock structure hypotheses, (b) finalising inputs for the modelling work especially related to bycatch; and (c) incorporating the Makah Management Plan (SC/67b/Rep07, Annex E, Appendix 1) into the modelling framework.

Two stock structure hypotheses (3a and 5a) were given priority whilst others were used in sensitivity tests. In summary, Hypothesis 3a assumes that whilst two breeding stocks (Western and Eastern) may once have existed, the Western breeding stock is extirpated. Whales show matrilineal fidelity to feeding grounds, and the Eastern breeding stock includes three feeding aggregations: Pacific Coast Feeding Group (PCFG), Northern Feeding Group (NFG), and the Western Feeding Group. Hypothesis 5a assumes that both breeding stocks are extant and that the Western breeding stock feeds off both coasts of Japan and Korea and in the northern Okhotsk Sea west of the Kamchatka Peninsula. Whales feeding off Sakhalin include both whales that are part of the extant Western breeding stock and remain in the western North Pacific year-round, and whales that are part of the Eastern breeding stock and migrate between Sakhalin and the eastern North Pacific.

In discussion of the report and intersessional progress, the Committee thanked Donovan, Punt and the participants for the progress made, approved the conditioning results developed after the workshop, noted the preliminary results from the modelling and agreed a strategy for obtaining conservation advice (see recommendation below under Item 10.3). The management implications of the results for the Makah Management Plan are found under Item 7.1.3.

10.1.3.2 REGIONAL STUDIES

The Committee was pleased to receive recent information from long-term studies in the breeding lagoons of Mexico (SC/67b/CMP09) as discussed in Annex O (item 2.1.3.1.1).

The Committee received several updates on work undertaken in the Russian Federation (see Annex O, item 2.1.3.2). It welcomed the annual update of activities from the IUCN Western Gray Whale Advisory Panel (see Annex O, appendix 3) which highlighted work to develop a monitoring and mitigation plan for a 2018 seismic survey being undertaken near the feeding grounds off Sakhalin Island, Russia and issues related to fishing gear. SC/67b/CMP07 updated findings from the long-term monitoring programme carried out by the Russian Gray Whale Project off Sakhalin Island, Russia. The research programme run in the same area by two oil companies was presented in SC/67b/ASI04 and discussed in Annex S (item 4.2).

The recent status of conservation and research on gray whales in Japan was reported in SC/67b/CMP12. During May 2017–April 2018, no anthropogenic mortalities were reported from the adjacent waters off Japan, while two opportunistic sightings of gray whales were made near Aogashima Island in May 2017 and February 2018.

Finally, SC/67b/CMP11 reported on the possible occurrence of a gray whale off the east coast of Korea; work is continuing to try to confirm the species identification; if confirmed it will be the first record in these waters in over 40 years.

Attention: CG-R, SC, G

The Committee **reiterates** the importance of long-term monitoring of gray whales, **recommends** that range states support such work and **welcomes** the information provided this year. In particular, the Committee:

- (1) **commends** the work in the breeding lagoons and urges its continuation;
- (2) **encourages** an additional calf-count survey for Punta Banda to address apparent differences in numbers of calves observed in the lagoons with counts from California;
- (3) **reiterates its concern** at the risk of whales becoming entangled in gear placed by the salmon trap-net fishery off Sakhalin Island, recognises that disentanglement training has occurred but **recommends** that measures to be taken to reduce risk;
- (4) **encourages** continued genetic analyses to assist in stock structure discussions especially related to a western breeding stock;
- (5) **welcomes** the continued provision of information from Japan and **encourages** researchers to continue to collect as much information on sightings as possible, including, if feasible, attempting to obtain biopsy samples; and
- (6) **welcomes** the information from Korea and the willingness of researchers to investigate sightings from social media as a form of 'citizen science', which can be especially valuable for areas where occurrence is very rare animals in areas with little to no information on critically endangered species.

10.1.3.3 PROGRESS WITH THE CMP

As noted above, one of the objectives of the fifth rangewide workshop was to progress work with updating the scientific components of the original IWC/IUCN CMP in the light of the results of the rangewide review. Although some work was undertaken, there was insufficient time at the workshop to complete this although a workplan to achieve it was suggested (see SC/67b/Rep07). The Committee concurred with this view and this is incorporated into the workplan below.

Another important component of the CMP effort is the need for a stakeholder workshop (tentatively forecast to occur in 2019) to finalise the CMP and develop a strategy for its implementation. The plan is for a workshop, co-sponsored by IWC, IUCN and the signatories to the Memorandum of Cooperation, to: (1) review and updating of the CMP; (2) establishing a stakeholder Steering Group to monitor CMP implementation, (3) arrange for a coordinator of the CMP and (4) establish a work plan and consider funding mechanisms to implement the actions of the plan.

Attention: C-A, CG-R, CC, SC

The Committee **reiterates** the importance of the CMP for the conservation of western gray whales. The Committee therefore:

- (1) **recognises** the tremendous work undertaken in the rangewide assessment and the value of the modelling framework developed;
- (2) **agrees** that the next part of the process is to develop conservation-related questions and to use the framework to address these with a view to examining results at SC68a;
- (3) **agrees** that a small group meeting (see Item 27) attended by at least the national co-ordinators of the Memorandum of Co-operation on gray whales, Reeves, Punt and Donovan be held to: (a) draft an update to the CMP; and (b) identify conservation-related questions to be addressed by the modelling framework and to present results at SC68a;
- (4) **requests** those signatories to the Memorandum of Co-operation on western gray whales who have not yet named a national co-ordinator to do so promptly; and
- (5) **supports** the holding of a stakeholder workshop in 2019 co-sponsored by the IWC, IUCN and the states that have signed the Memorandum of Co-operation and **welcomes** the valuable assistance of IUCN in organising the workshop.

10.1.4 Franciscana

10.1.4.1 NEW INFORMATION

The Committee received valuable new information on franciscana at this meeting related to fisheries and bycatch from five localities in North Espírito Santo State, Brazil (SC/67b/SM30) – bycatches of Guiana dolphins was also reported. Additional information was presented assessing fisheries that operate in Fisheries Management Area (FMA) Ib for their compliance with Brazilian ordinance (IN) 12 (e.g. with respect to gill-net regulations and no-take zones) and risk of bycatch (SC/67b/SM05) – compliance was limited and enforcement poor. Both projects were funded by the IWC Small Cetacean Fund and the Government of Italy. This information is discussed in Annex O (item 2.1.4.1) and a related recommendation is given under Item 10.4.2.2.

10.1.4.2 PROGRESS WITH THE CMP

The overall objective of the CMP, submitted by Argentina, Brazil and Uruguay (IWC/66/CC11) and adopted in 2016, is to protect franciscana habitat and minimise anthropogenic threats, especially bycatch. It includes seven high priority actions, ranging from public awareness and capacity building through research to mitigation. Coordination with Uruguay to implement the CMP in this area will be initiated during a workshop that will take place in May 2018 with the main stakeholders (SC/67b/CMP16). The CMP is funded by the IWC CMP Voluntary Funds and the World Wildlife Fund.

Attention: CG-R

The Committee **emphasises** the importance of the CMP for the conservation of franciscana in the waters of Argentina, Uruguay and Brazil. The Committee therefore:

- (1) **stresses** the value of the actions included in the CMP towards future assessments of the status of franciscana, which is imperative for determining the effectiveness of conservation efforts;
- (2) **recommends** that research be undertaken to estimate the abundance of franciscana dolphin off Buenos Aires province, Argentina; and
- (3) **recommends** that additional research be undertaken to determine the effectiveness of management measures, such as that described in SC/67b/SM05 for other ports (e.g. Macaé, Tamoios (Cabo Frio) and Armação dos Búzios – the fishery in Tamoios coincides with a high diversity of marine megafauna).

The Committee established an intersessional correspondence group that will help co-ordinate the presentation of CMP projects for this species across sub-committees at SC/68a (Annex Y).

10.2 Progress with identified priorities

10.2.1 Humpback whales in the northern Indian Ocean including the Arabian Sea

10.2.1.1 NEW INFORMATION

The Committee received several papers that improved knowledge of Arabian Sea humpback whales and a full discussion can be found in Annex O (item 2.2.1). It welcomed the information on the progress of work being undertaken by the Arabian Sea Whale Network (ASWN) formed in 2015 (SC/67b/CMP10). The ASWN is an informal collaboration of researchers, consultants and conservation and governmental organisations interested in the conservation of whales in the Northern Indian Ocean. A primary goal of the ASWN is to promote and foster research and collaboration in previously unsurveyed parts of the Arabian Sea humpback whales' suspected range, as well as in Oman where surveys have been conducted since 2000. Work has focused on collecting data on whale distribution and status (including through increased awareness and an observer programme – described in SC/67b/CMP15)), the introduction and implementation of a regional online data platform (SC/67b/PH03) and providing updates on research activities in Oman, India, Pakistan and Sri Lanka (SC/67b/INFO07). Two marine protected areas have been established in Pakistan (Astola Island and Indus Canyon).

Madhusudhana *et al.* (2018) reported on and compared humpback whale songs recorded off India, Oman, Reunion Island and Comoros Islands in the southwest Indian Ocean. The results highlighted (a) the distinct nature of the Arabian Sea population and (b) that SW Indian Ocean whales may move into the Arabian Sea more commonly than previously thought.

SC/67b/CMP13 reported on a humpback whale tagged off Oman that moved to the southern tip of India and back again - the first recorded movement of a whale across the Arabian Sea. Four additional satellite tags were deployed where the whales remained over the continental shelf of central and southern Oman.

Attention: G, SC

The Committee **welcomes** the new information from the region on this critically endangered population and **commends** the researchers for their initiatives and collaborative efforts. In light of the information presented, the Committee:

- (1) **encourages** the collection of genetic information which would be helpful for identifying stock structures within the area;
- (2) **recommends** future use of unoccupied aerial systems to (i) measure whale health, (ii) develop long-term health metrics, (iii) compare body condition to stock C in the Southern Hemisphere, which is the presumed 'source' population for whales in the Arabian Sea and (iv) assess for evidence of anthropogenic threats;
- (3) **commends** the use of fishing crew as observers and **advises** that the crew-based observer programme continue, recognising that it is not clear if the timing of the sightings reflects the seasonal distribution of whales or the seasonal nature of fishing effort and **encourages** future research to tease apart timing of the distributions using targeted surveys;
- (4) **advises** that capacity building for local scientists be continued such that surveys can be deployed in suspected areas of humpback whale distribution and data can be gathered for future assessments;
- (5) **advises** the continuation of monitoring songs of Arabian Sea humpback whales and that additional data sets be acquired comparison purposes, particularly from the southwest Indian Ocean, if they exist, to further (i) detect the movement of southwestern Indian Ocean animals in Boreal winter, (ii) document potential diffusion of southwestern Indian Ocean song, (iii) provide a long-term data set for the comparison of songs across Oman, Pakistan and India to assess continuity of whales in the Arabian Sea and (iv) evaluate the unprecedented temporal stasis of song in the Arabian Sea; and
- (6) **agrees** that an intersessional correspondence group (Annex Y) be formed to review the methods used for the preliminary estimates of abundance, in order to increase their robustness by taking into account the non-random survey approach that violates some key assumptions of mark-recapture models.

10.2.1.2 PROGRESS WITH INTERNATIONAL CO-OPERATION AND REGIONAL MEASURES SUCH AS CMPS

A Concerted Action for Arabian Sea humpback whales under the Convention on Migratory Species (CMS; SC/67b/INFO06) was drafted and passed with wide support from Arabian Sea range states at the CMS COP in October 2017. It is hoped that this Concerted Action can be implemented in conjunction with a CMP as a means to translate current research and conservation efforts and plans into concrete, government-supported conservation measures in Arabian Sea humpback whale range states.

Attention: C-A, S

*The Committee **reiterates** its serious concern about the status of the endangered Arabian Sea humpback whale population and the anthropogenic threats it faces. It therefore:*

- (1) **commends** efforts to develop the Concerted Action under the CMS, noting that it covers many of the elements required for a CMP;*
- (2) **stresses** the value of regional initiatives and **encourages** range states to explore future sources of collaboration; and*
- (3) **encourages** continued efforts between range states and Secretariats to work toward a joint CMS-IWC CMP.*

10.2.2 Mediterranean fin whales

The ACCOBAMS Meeting of Parties has endorsed the development of a CMP, ideally jointly with the IWC, for fin whales in the Mediterranean Sea. A small group will meet in the summer of 2018 to draft an outline for a CMP that can be presented at SC/68a. ACCOBAMS is also considering the development of CMPs for other species in the region.

10.2.3 South American River Dolphins

Advice was sought regarding the development of a CMP for South American river dolphins, which currently have several actions plans endorsed by various range states.

Attention: CG-A

*The Committee **advises** that the applicable range states work towards developing a draft CMP for presentation at SC/68a.*

10.3 Workplan 2019-20

The workplan on matters related to stocks that are or might be the subject of CMPs is given as Table 14.

Table 14
Summary of the work plan on conservation management plans.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Southeast Pacific right whales		Review progress with scientific aspects of the CMP		Review progress with scientific aspects of the CMP
Southwestern Atlantic right whales		Review progress with scientific aspects of the CMP		Review progress with scientific aspects of the CMP
Gray whales	Hold workshop on scientific aspects of CMP and use of modelling framework.	Review results and provide advice on scientific aspects of CMP	Stakeholder workshop	Review scientific aspects of results of stakeholder workshop
Franciscana		Pre-assessment for in-depth review		Continue pre-assessment and develop plan for in-depth assessment
Humpback whales in Northern Indian Ocean	Intersessional email group (Annex Y) on abundance estimates	Review new information and progress towards CMP		Review new information and progress towards CMP
Mediterranean fin whales	Develop outline draft	Review draft and progress towards CMP		Review progress towards CMP
South American river dolphins		Review new information and progress towards CMP		Review new information and progress towards CMP

11. STOCK DEFINITION AND DNA TESTING

This agenda item merges two previously separate sub-groups, the Working Group on Stock Definition and the Working Group on DNA. During SC67b, the Stock Definition and DNA Testing Working Group assessed genetic methods used for species, stock and individual identification, including matters associated with the maintenance of DNA registers (see 11.1); continued to develop and update guidelines for preparation and analysis of genetic data within the IWC context (see 11.2); and provided the Committee with feedback and recommendations concerning stock structure related methods

and analyses (see 11.4), including those relevant to other sub-committees (see 11.3). The Report of the Working Group is given as Annex I.

11.1 DNA testing

This item has been considered since 2000 in response to a Commission Resolution (IWC, 2000).

11.1.1 Genetic methods for species, stocks and individual identification

The Committee received two papers relating to the use of genetic methods for species, stock and individual identification. The first paper (Carroll *et al.*, 2018) provided a review of how technological advances, particularly those associated with the development of high throughput sequencing (HTS) technology, can aid in genetic monitoring. Of particular interest to the Committee was discussion of targeted capture approaches that allow for microsatellite genotyping via HTS (e.g. De Barba *et al.*, 2017). Much of the past genetic work has relied on generating microsatellite datasets, including the work to maintain DNA registries of bycaught or direct catches (see Items 11.1.2 and 11.1.3). These ‘legacy’ datasets may include microsatellite genotypes for thousands of individuals. While technical challenges exist, microsatellite genotyping via HTS could ‘bridge the gap’ by maintaining the utility of these legacy datasets while also taking advantage of the newer HTS approaches.

The second paper (Baker *et al.*, In press) presented the results of a study confirming the potential to detect environmental DNA (eDNA) in seawater collected from the wake of killer whales. This is a new approach for detecting and identifying cetacean species, including those that may be elusive to study using other methods. Although eDNA has been more broadly used to detect the occurrence of species in an area (i.e. DNA barcoding), it could provide sequence data useful for stock-level identifications of cetaceans under certain circumstances (e.g., when a single animal is present). It was noted, however, that its utility in addressing questions requiring individual identification via multi-locus genotyping is, at least currently, limited for scenarios in which the water sample could contain DNA from multiple individuals.

Attention: SC

*The Committee **welcomes** the opportunity to review papers that take advantage of technological advances to improve the ability to detect and identify species, stocks, and individual cetaceans. It **encourages** the submission of similar papers in the future and recognises the relevance of these techniques to the Committee’s work.*

11.1.2 ‘Amendments’ of sequences deposited in GenBank

While *GenBank*⁷ is an important scientific resource, it is an uncurated database of DNA sequences and thus contains sequences that are misidentified or have other annotation problems. While retaining the ‘raw data’ represented in *GenBank* is valuable, less-experienced users may be unaware that additional sequence validation may be needed when incorporating *GenBank* sequences into a study. The Committee has agreed (IWC, 2018c, p. 228) that its revised DNA quality guidelines will contain a section discussing the precautions that should be taken when including *GenBank* sequences in a study. This text has been drafted and will be incorporated into the revised guidelines (see Item 11.2).

11.1.3 Collection and archiving of tissue samples from catches and bycatches and

11.1.4 Reference databases and standards for diagnostic DNA registries

The Committee previously endorsed a new standard format for the updates of national DNA registers to assist with the review of such updates (IWC, 2012a, p. 53), and the new format has worked well in recent years. This year, the update of the DNA registers by Japan, Norway and Iceland were based again on this new format. Details are given in Annex I (appendices 2-4) for each country, covering the period up to and including 2017. Almost all samples in the three registries have been analysed for microsatellites, and work on unanalysed samples is continuing. Almost all samples in the registries of Japan and Iceland have also been analysed for mtDNA.

During last year’s discussion of the Norwegian minke whale DNA register (IWC, 2018c, p. 228-229), the Committee was informed that mtDNA analysis on Norwegian samples had been discontinued and that microsatellite typing would eventually be replaced by SNP analysis. The Committee had expressed concern regarding the comparability of the DNA registers in the future. This year, the Committee noted that Norway had discontinued mtDNA typing of samples and substituted it with SNP genotyping.

Attention: CG-A

*The Committee **expresses appreciation** to Japan, Norway and Iceland for providing updates to their DNA registries using the standard format agreed in 2011 and providing the detailed information contained in their DNA registries.*

11.2 Guidelines and methods for genetic studies and DNA data quality

Two sets of guidelines have been developed for reference in the Committee’s discussions of stock structure. The most recent version of the guidelines for genetic data analyses are in press with the Commission’s *Journal of Cetacean*

⁷ <https://www.ncbi.nlm.nih.gov/genbank/>

Research & Management. The DNA data quality guidelines address DNA validation and systematic quality control in genetic studies, and are currently available as a ‘living document’ on the IWC website⁸. In recent years, it has become common for the Committee to review papers using data derived from Next Generation Sequencing (NGS) approaches, including SNPs, to address stock structure questions (see Item 11.3).

Attention: SC

*The Committee **emphasises** the importance of keeping its guidelines related to genetic data quality and analyses up to date. It therefore:*

- (1) **reiterates** the need to update these guidelines to incorporate the discussion of data quality measures used for Next Generation Sequencing data; and*
- (2) **agrees** to continue the intersessional correspondence group (Annex Y) to review revised sections of the DNA data quality guidelines that apply to data generated from next generation sequencing platforms, including SNPs and whole genome sequencing, with the goal of posting an updated version of the guidelines on the website next year.*

11.3 Provide advice on stock structure to other sub-groups

The Working Group on Stock Definition and DNA also has the task of discussing high-priority stock related papers from other sub-committees and working groups to provide them with stock structure related feedback and recommendations. These discussions often refer to the genetic analysis guidelines and genetic data quality documents.

The discussions (see Annex I for details) are summarised under the relevant stock agenda items in this report. Two, more general issues arose from discussions of Southern Hemisphere stocks and North Atlantic common minke whales. These are considered below.

11.3.1. Southern Hemisphere whale stocks and use of samples

The Committee reviewed the results of genetic analyses of Southern Hemisphere whale stocks, including Southern Hemisphere blue, fin, right and sei whales. These results highlighted the value of existing collections of tissue samples to address stock structure questions.

Attention: SC

*In reviewing the results of stock structure analyses of Southern Hemisphere whale stocks, the Committee expresses **concern** regarding the depletion of tissue samples in existing collections (including those collected during the IWC SOWER surveys, although the Steering Group does take this into account when reviewing requests). Given recent advances in high throughput sequencing technology, the Committee **agrees** that an intersessional correspondence group (Annex Y) should be formed to provide recommendations on genomic approaches to maximise the utility of these samples for future studies.*

11.3.2. North Atlantic common minke whales

The Committee reviewed the results of genetic analyses pertaining to the stock structure of North Atlantic minke whales (SC/67b/Rep06). The analyses presented involved the use of a new approach to evaluate stock mixing proportions by (1) identifying a ‘reference’ year in which mixing of stocks was considered low based on a lack of heterogeneity in genetic characteristics estimated for each area, and (2) using principal component analysis of the genetic data to assign stock affinities in the non-reference years based on proximity to mean values in the reference year.

Attention: SC, C-A

The Committee reviewed the use of a new approach that used ordination analyses of genetic data to assign stock mixing proportions. Recognising that this new approach requires making certain assumptions about the data, the Committee:

- (1) **agrees** that the inference of mixing rates was informative for AWMP/RMP simulation trials in the absence of empirical data; and*
- (2) **encourages** the attempt to use genetic data to estimate mixing rates in the context of other IWC-related tasks.*

11.4 New statistical and genetic issues relating to stock definition

11.4.1. Simulation tools for spatial structuring

TOSSM was developed with the intent of testing the performance of genetic analytical methods in a management context using simulated genetic datasets (Martien *et al.*, 2009), and more recently the TOSSM dataset generation model has been used to create simulated datasets to allow the plausibility of different stock structure hypotheses to be tested (Archer *et al.*, 2010; Lang and Martien, 2012). The Working Group noted that while TOSSM has been particularly valuable in

⁸ <http://iwc.int/scientific-committee-handbook#ten>

informing the interpretation of results of stock structure related analyses, it has not been broadly used within the IWC Scientific Committee for this purpose.

In recent years, a wide-range of software packages have become available for producing simulated datasets that can be used for statistical inference and/or validating statistical methods (Hoban, 2014, and see ; IWC, 2017c p.44), and in 2016 the Committee agreed to expand this item (formerly specific to TOSSM) to include a broader range of tools (IWC, 2016c p.44).

Attention: SC

*The Committee noted that while simulation-based approaches have been particularly valuable in informing the interpretation of results of stock structure-related analyses, they have not been broadly utilized within the Committee for this purpose. The Committee **agrees**:*

- (1) to continue an intersessional review via an email correspondence group (Annex Y) of the available simulation tools and their potential utility to the Committee; and*
- (2) to consider bringing in invited expertise to present an overview of the applicability of such approaches in order to expedite progress on this agenda item.*

11.4.2. Terminology

Defining and standardising the terminology used to discuss ‘stock issues’ remains a long-standing objective of the Working Group, in order to help the Committee report on these issues according to a common reference of terms (IWC, 2014 p.287-8). At SC67b, the status of the existing draft glossary on key terms related to stock definition was revisited.

Attention: SC

*The Committee **agrees** to establish an intersessional correspondence group (Annex Y) to revisit terminology with specific reference to the implications of inferred stock structure in other sub-committees, particularly those that deal with large whale assessments, and suggest revisions where appropriate for consideration at SC68a.*

11.4.3. Close-kin mark-recapture

An overview of the close-kin mark-recapture (CKMR) approach (Bravington *et al.*, 2016) was presented to the Committee last year (IWC, 2018c p.40). CKMR uses multi-locus genotyping to find close relatives among tissue samples from dead and/or live animals; the number of kin-pairs found, and their pattern in time and space, can be embedded in a statistical mark-recapture framework to infer absolute abundance, parameters like survival rate, and stock structure. No papers applying the CKMR approach were reviewed by Committee this year, although the value of integrating data from epigenetic aging (see 11.4.4) into CKMR was noted.

Attention: SC, G

*Given that close-kin mark-recapture has multiple applications that fall within the Committee’s scope of work, the Committee **encourages** the submission of papers using this approach in the future.*

11.4.4. Epigenetic ageing

Information on estimated age of individuals can be used in many aspects of the Committee’s work, including (1) discriminating between the parent and offspring among genetically identified parent-offspring pairs, which can inform both assessment of stock structure as well as genetic mark-recapture estimates of abundance (e.g. CKMR); and (2) integrating age information into the population modelling exercises integral to assessment work (e.g. on RMP implementation). Recently, epigenetic (DNA-methylation) ageing has been successfully used to estimate age in humpback whales (Polanowski *et al.*, 2014). This year, the Committee invited Jarman, the lead scientist on the humpback whale work, to give an overview presentation to the Committee. This session was organised as a special evening session in order to enable participation across sub-committees and Working Groups. He covered issues specific to age estimation in cetaceans, including how DNA methylation-based age estimation are likely to perform in cetaceans and what current and near-future prospects there are for this class of methods (see Annex I, item 5.5).

The Committee also reviewed the results of a study to evaluate the feasibility of using the DNA-methylation technique to estimate age in Antarctic minke whales (SC/67b/SDDNA04). This study was initiated in response to a recommendation made during the Expert Panel review of the NEWREP-A proposal (SC66A/REP06, p17). DNA-methylation rates were examined for seven methylation sites (CpG sites) within three genes, and regressions of each CpG methylation site against age determined by earplug were conducted. When all sites were incorporated, the assay predicted age from skin samples with a standard deviation of about 8.9 years. While some sites showed age-related effects, others did not show such correlation. Thus, using only those loci that appear to have an age-related effect might reveal a stronger relationship between methylation rates and age.

During the discussion (Annex I, item 5.5) it was noted that the humpback whale age assay, which used the same sites, reports a precision of 2.99 years, measured as the average of the absolute values of the differences between known and estimated ages (Polanowski *et al.*, 2014). During the presentation, the precision as measured by the standard deviation for absolute age prediction was reported as 4.8 years. That was a preliminary study demonstrating the fundamental feasibility of this approach, and is not as accurate or precise as tests developed for humans and mice based on analysis of many more CpG sites. While precision is expected to improve with the inclusion of more CpG sites, the maximum precision possible for any DNA methylation-based age estimator is likely limited by the imperfect relationship between chronological age and biological age. To date, that precision has ranged from 3.9% in humpback whales (Polanowski *et al.*, 2014 assuming a 95-year lifespan), to 3.2% of lifespan in humans (e.g. Horvath, 2013) and 1.7% of lifespan in mice (Stubbs *et al.*, 2017). These observations indicate that the SD and 95% CI for age estimation described in Polanowski *et al.* (2014) and in SC67b/SDDNA04 could be substantially improved before an inherent limit is reached. These precision estimates adhere to age determination in individual specimens. Hence, averaged age estimates over cohort will improve over larger sample sizes and may be more precise.

The Committee noted that the implications of this upper limit on precision in estimating age for individuals would need to be evaluated in the context of the specific application for which the age data were being used. For example, although additional precision is helpful, CKMR studies may be informed by relatively crude estimates of age allowing the parent to be discriminated from the offspring (i.e. ordinal age).

Attention: SC

The Committee welcomed the results of the study to evaluate the feasibility of using epigenetic techniques to estimate age in Antarctic minke whales and agrees:

- (1) that the current set of loci did not provide sufficient precision for use in the population dynamics modelling exercise recommended for NEWREP-A; and*
- (2) that identification of additional sites with an age-related DNA-methylation pattern is encouraged, as it would likely allow more precise estimates of age to be made in the future; and*
- (3) given that there is an upper limit to the degree of precision that can be achieved using this technique, the utility of epigenetic age estimation to the Committee should be further evaluated by the sub-committees concerned with regard to the degree of precision needed for the specific application of interest.*

11.5 Workplan 2019-20

The details of the workplan are given in Table 15.

Table 15

Workplan on topics related to genetics.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
3.1 DNA quality guidelines	Intersessional group (Annex Y) to review recent revisions to the DNA quality guidelines that pertain to data produced using NGS approaches.	Report and finalise updated guidelines		
4.4.2 Recommendations to avoid sample depletion	Intersessional email group to provide recommendations on genomic approaches to maximize the utility of tissue samples that are in danger of becoming depleted in the future.	Report and provide advice		
4.5 North Pacific minke whale stock structure	Perform genetic analyses detailed in Appendix 5; report results at intersessional workshop on the North Pacific minke whale IR.	Review results and provide advice		
5.1 Simulations	Intersessional email group to review software packages and evaluate utility to the Committee.	Report	Continue as needed	Report (if needed)
5.3 Terminology	Intersessional email group to continue discussions of the use of stock structure-related terms within the Committee.	Report	Continue as needed	Report (if needed)

12. CETACEAN ABUNDANCE ESTIMATES, STOCK STATUS

The Committee received new information from the Standing Working Group on Abundance Estimates, Status and International Cruises (ASI) that had been established (IWC, 2017c, p. 94) to formally review and agree on the status of the abundance estimates submitted to the Scientific Committee across all of the Committee's sub-committees and working groups. It also assists the Committee and the Secretariat in developing a biennial document reporting to the Commission on the abundance and status of whale stocks.

12.1 Summary of abundance estimates and update of IWC consolidated table

Appendix 3 of Annex Q provides detailed information about abundance estimates agreed by the Committee, including estimates received prior to and during 2017, as well as ones evaluated this year. The Secretariat maintains a consolidated table.

Broadly, cetacean abundance estimates are usually obtained in one of three ways. Line transect surveys require observers on ships or aircraft to detect animals while the observers are traveling on paths traversing the survey area. Statistical methods are used to estimate how many animals were not seen, usually by evaluating how detection deteriorates as sighting distance increases and by extrapolating to survey areas beyond visual detection distance. Mark-recapture studies require multiple attempts to 'capture' individuals that are mixing between attempts. For cetaceans, individual animals are usually identified - and hence 'captured' - on the basis of matching photographs of whale markings, or by genetic analysis of biopsy samples of live animals. Statistical methods are used to estimate how many animals were never captured, based on information about the probability of capture, which is inferred from instances when the animal was sometimes captured and sometimes not. Population model based abundance estimates use information from a variety of sources to build a mathematical model of how a population changes over time. Important data and parameters in such models include survival rates, productivity rates, and previous abundance estimates. By fitting (and possibly projecting) this model, an estimate of current abundance is achieved.

Many sophisticated abundance estimation methods are hybrids or extensions of these basic approaches.

This year, the Committee **endorses** the following:

- (1) a photo-id mark-recapture estimate of 2011 abundance for Bering-Chukchi-Beaufort Seas bowhead whales;
- (2) an aerial line transect estimate of 2013 abundance of East Canada / West Greenland bowhead whales;
- (3) aerial line transect estimates of 2015 abundance of East Greenland and West Greenland North Atlantic humpback whales;
- (4) ship-based line transect abundance estimates of North Atlantic humpback whales in Iceland/Faroe Islands in 2007 and 2015;
- (5) aerial line transect abundance estimates of East Greenland (2015) and West Greenland (2007 and 2015) North Atlantic minke whales;
- (6) ship-based line transect abundance estimates of North Pacific Bryde's whales for several areas and time periods;
- (7) aerial line transect abundance estimates of East Greenland (2015) and West Greenland (2005, 2007 and 2015) North Atlantic fin whales; and
- (8) genetic mark-recapture abundance estimates for Maui's dolphins in New Zealand for several years.

Table 16 summarises key information about the **agreed** abundance estimates. Full details are given in Annex Q (item 3 and appendix 3).

Attention: SC, S, C-A

Abundance estimates are a key parameter in determining status. The Committee:

- (1) **endorses** the new abundance estimates presented in Annex Q, Appendix 3 for inclusion in the IWC Table of Accepted Abundance Estimates;
- (2) **agrees** that they should be incorporated into that table and uploaded to the IWC website; and
- (3) **agrees** that the table should continue to be updated intersessionally by the Steering Group (Annex Y).

12.2 Process to review abundance estimates

Abundance estimates are needed to assess the status of cetacean populations and are used extensively by the Committee, including for providing management advice. These estimates are often computed by standard, but technically advanced methods. In addition, because of the high scientific standards found within the Committee's work, it is not uncommon for the Committee to receive estimates of abundance computed using novel methods and non-standard software/code. The review of these estimates can be complex and time consuming. At last year's meeting, the Committee noted that adequate time is needed to review abundance estimates and agreed that a process to facilitate the review of these estimates be developed (IWC, 2018c). In addition, the Committee noted that reviews would benefit if minimum requirements for the presentation of abundance estimates are established.

Table 16

Abundance estimates, CVs and 95% confidence intervals for estimates agreed at the 2018 meeting.

Whale and Region	Year	Estimate	CV	95% Confidence Interval
North Pacific Bryde's whales				
Area 1W	1995	12,149	0.41	5,579-26,454
	2000	6,894	0.47	2,872-16,549
	2011	25,158	0.38	12,202-51,872
Area 1E	1995	15,695	0.42	7,079-34,801
	2000	19,200	0.56	6,929-53,204
	2011	9,315	0.33	4,957-17-505
Area 2	1995	4,340	0.45	1,876-10,039
	2000	6,083	0.61	2,030-18,229
	2014	6,491	0.36	3,254-12,950
North Atlantic common minke whales				
East Greenland	2015	2,762	0.47	1,160-6,574
West Greenland	2007	9,066	0.39	4,333-18,973
	2015	5,095	0.46	2,171-11,961
North Atlantic fin whales				
East Greenland	2015	6,440	0.26	3,901-10,632
West Greenland	2005	9,800	0.62	3,228-29,751
	2007	15,957	0.72	4,531-56,202
	2015	2,215	0.41	1,017-4,823
North Atlantic humpback whales				
East Greenland	2015	4,223	0.44	1,845-9,666
West Greenland	2015	993	0.44	434-2272
Iceland/Faroe Islands	2007	18,105	0.43	7,226-45,360
	2015	10,031	0.36	4,962-20,278
Bowhead whales				
Bering-Chukchi-Beaufort Seas	2011	27,133	0.22	17,809-41,377
East Canada / West Greenland	2013	6,446	0.26	3,722-11,200
Gray whales

	2015	200	0.03	187-211
Maui's dolphin				
North Island, New Zealand	2016	57	n/a	44-75

This year, the Committee developed a process to improve the review of abundance estimates, including a prioritisation of the estimates according to the timeline they need to be used by the Committee. This process is described in detail in Annex Q, item 2.1. In addition, minimum requirements to present abundance estimates for review by the Committee were established. Details are given in item 2.2 of Annex Q.

The Committee noted that validation may be needed before estimates computed using novel methods and non-standard software are used to provide management advice (Annex Q, item 2.3). The Committee also noted the need to consider how estimates of abundance from population models are reviewed before they are included in the Table of Accepted Abundance Estimates (Annex Q, item 2.4).

Attention: SC, S

*The Committee **reiterates** the importance of using high quality, fully reviewed abundance estimates for its work. To achieve this the Committee **agrees**:*

- (1) to adopt the process to improve the review of abundance estimates given in Annex Q (item 2.1);*
- (2) the minimum requirements for the presentation of estimates for review by the Committee given in Annex Q (item 2.2);*
- (3) to host a pre-meeting before next year's meeting (SC68a) to develop (a) a process to validate abundance estimates computed with non-standard methods, noting the value of simulated datasets in this process; (b) a process to review estimates of abundance computed with population models is needed.*

12.3 Methodological issues

12.3.1 Model-based abundance estimates (and amendments to RMP guidelines)

The Committee noted that there was a need for RMP guidelines to be modified in order to incorporate spatial modelling approaches to estimate abundance.

Attention: SC

*The Committee noted that whilst much progress has been made with respect to considering model-based estimates (IWC, 2016c), the 'Requirements and Guidelines for Conducting Surveys and Analysing Data within the Revised Management Scheme' need to be modified. The Committee **agrees** that an intersessional steering group (Annex Y) will develop instructions and select a candidate to modify the Guidelines.*

12.3.2 Review new survey techniques/equipment

The Committee received information on the use of unmanned aircraft vehicles (UAVs) to improve estimation of abundance of river dolphins in the Amazon. Details are provided in Annex Q, item 5.

Attention: SC, G

*The Committee **looks forward** to receiving information on new survey technologies used to improve estimates of abundance of cetaceans.*

12.4 Consideration of the status of stocks

The Committee noted that further consideration on how to report status of cetacean stocks is needed.

Attention: SC

*The Committee **recognises** the need to further consider how to report status of stocks to the Commission in a consistent manner and **agrees** to address this topic at a pre-meeting to be held prior to next year's SC meeting (SC68A).*

12.5 Workplan 2019-20

The Committee **agrees** to the workplan given in Table 167

Table 17

Workplan on abundance estimates and status.

Topic	Intersessional 2018-19	SC68a	Intersessional 2019-20	SC68b
Review of Abundance Estimates	Review estimates identified at SC67B (New Zealand Blue Whales, Arabian Sea humpback whales) – Annex Y	Review intersessional progress and estimates available at SC68A	Review estimates identified at SC68A	Review intersessional progress and estimates available at SC68A
Upload the estimates accepted at the annual meeting to the IWC website and continue to update the IWC Abundance Table	Update the table with estimates accepted at SC67B (Annex Y)		Update the table with estimates accepted at SC67B	
Review and provide advice on plans for future surveys		Receive, review and provide feedback to research plans to conduct abundance estimates		Receive, review and provide feedback to research plans to conduct abundance estimates
Pre-meeting to consider: (a) validation of non-standard software and methods, (b) estimates of abundance computed from population models and (c) Status of populations	Meeting Preparation	Review of progress		
Amend the RMP Guidelines to consider abundance estimates computed with model-based methods.	Identify a candidate to update the RMP Guidelines (Annex Y)	Review an updated document of the Guidelines		
Develop simulation software to evaluate methods for abundance estimates		Review Progress		

13. BYCATCH AND ENTANGLEMENTS

13.1 Review new estimates of entanglement rates, risks and mortality (large whales)

The Committee received three papers relating to the bycatch of large whales. SC/67b/HIM03 provided information on stranded humpback whales stranded along the southeastern coast of Brazil in 2016 and 2017 including records of entanglements over the São Paulo coast. SC/67b/HIM09 focussed on ten baleen whale populations for which bycatch appears to be a component of substantial conservation problems and the authors categorised priorities for action. SC/67b/AWMP08 provided information on Bering-Chukchi-Beaufort Seas stock of bowhead whales. Discussion can be found in Annex J (item 2.1).

13.2 Reporting of entanglements and bycatch in National progress reports

Reports of large whale bycatch are summarised in Annex J (item 2.4) and the issue of partial reporting discussed. Issues related to reporting and progress reports is given under Item 3.2.

13.3 Mitigation measures for preventing large whale entanglement

Mattila, the IWC's technical advisor for reducing unintended human impacts, reported on relevant activities under the entanglement initiative. Details can be found in Annex J (item 2.5). Since last year's meeting, IWC entanglement trainings have been conducted in Sakhalin (Russia), Arica (Chile), Sortland (Norway) and Bahía Solan (Colombia). This brings the total number of trainees in this initiative to 1,130 from 27 countries. In addition, two apprentices were hosted this year, one from Chile and one from Oman. Mattila also presented the IWC's work with entanglement in two workshops at the Society for Marine Mammalogy Biennial conference (2017). The Committee thanked Mattila for his exemplary work in coordinating the Global Whale Entanglement Response Network.

13.4 Review proposal for global entanglement database

The Committee considered progress with the development of a dedicated entanglement database. This will be considered further at the June 2018 meeting of the Global Whale Entanglement Response Network (see Annex J, item 2.3).

13.5 Estimation of rates of bycatch, risks of, and mortality for small cetaceans

13.5.1 Small cetacean bycatches in Peru

The Committee received a report (SC/67b/HIM01) summarising monitoring efforts of beach-cast cetaceans in 11 locations along the Peruvian coast from 2000-2017. Full discussion can be found in Annex J (item 2.1.2) that showed clear evidence of continued high bycatch rates and some intentional takes. Burmeister's porpoises accounted for 66% of the specimens and the low proportion (25%) of dusky dolphins contrasted with 1985-1990 statistics, when dusky dolphins accounted for three quarters of all cetacean captures. This reiterated prior concerns (Van Waerebeek, 1994) about a persistent long-term trend of a significant decline in prevalence of Peruvian dusky dolphin in catch and stranding records.

The observed high mortality levels in Burmeister's porpoise are a serious concern, and action is needed to avoid the same critical situation as with the closely related vaquita. Burmeister's porpoise is already included in a preliminary list for potential Conservation Management Plan development (Genov *et al.*, 2015), and dusky dolphin could potentially also be included. The Committee reiterated recommendations from 2008 regarding bycatch monitoring programmes and mitigation efforts in these fisheries (IWC, 2009, p. 323).

Attention: C-A, CC

*The Committee **draws the attention** of the Commission to its **serious concern** over the high mortality levels from bycatches in Peru and especially those of the Burmeister's porpoise and dusky dolphin. It **stresses** that action is needed to avoid the same critical situation for Burmeister's porpoise as with the closely related vaquita. In this regard the Committee:*

- (1) **reiterates** its advice (IWC, 2009, p. 323) on bycatch monitoring and mitigation in these fisheries;*
- (2) **reiterates** that the Burmeister's porpoise is a potential candidate for a Conservation Management plan;*
- (3) **highlights** opportunities to focus on the bycatch of small cetaceans in Peru through the new IWC Bycatch Mitigation Initiative and **recommends** that they are considered as a potential pilot project; and*
- (4) **offers its assistance** to the Government of Peru; and*
- (5) **requests** that the Commission, through the Secretariat, transmits the Committee's concern and offer of assistance to the Government of Peru.*

13.5.2 Franciscana bycatch in Brazil

Considerable information was provided on the Santos Basin Beach Monitoring Project required by the Brazilian authorities for licensing oil and gas production and transport (see Annex J, item 2.1.2). This provided information *inter alia* on stranded franciscana. From October 2015 to September 2017, 1,123 carcasses were recorded stranded in the area and interactions with fishing gear was reported for over 85% of necropsied individuals with signs of human activities.

Attention: CG-A

*The Committee **draws attention** to the fact that the franciscana remains under strong pressure from human activities, especially bycatch, in Brazilian waters despite fishing net regulations established by the government. The Committee:*

- (1) **advises** that the existing regulation on gillnets, implemented in 2012, is either not being effectively enforced or is not effective in reducing bycatch; and therefore*
- (2) **recommends** the need for this to be investigated further by the Brazilian authorities.*

13.5.3 Estimating bycatch from strandings data

Estimates of common dolphin mortality in the Bay of Biscay based on strandings data (Peltier *et al.*, 2016) had been discussed at SC67a. SC/67B/HIM/05 and SC/67B/HIM/08 provided further analyses related to using stranding data to make inferences about small cetacean mortality. An intersessional group was established at SC67a to provide advice on consistent ways to estimate bycatch across both large and small cetaceans, and specifically, to review the methods applied in Peltier *et al.* (2016) focused on small cetaceans. Discussion of the report of the intersessional group and some additional related papers (SC/67b/HIM05 and SC/67b/HIM08) can be found in Annex J (item 2.1.2).

In discussion of other ways to estimate bycatch, the Committee noted that Bartholomew *et al.* (2018) had concluded that Remote Electronic Monitoring can provide a time- and cost-effective method to monitor target catch in small-scale fisheries and can be used to overcome some of the challenges of observer coverage. This requires consideration by the Committee.

Attention: CG-A, SC, G

With respect to methods for obtaining bycatch estimates the Committee:

- (1) **agrees** with the recommendations of its intersessional group regarding (a) uncertainties in bycatch estimates derived from strandings; (b) the use of bycatch estimates derived from strandings; and (c) assessing whether strandings can identify gaps in observer coverage;*
- (2) **notes** the importance of observer programmes, including electronic monitoring, and the limitations of stranding information for determining the type of fishing gear implicated in a bycatch event, or in determining reliable bycatch estimates;*
- (3) **recognises** that in small scale fisheries (a) observer programmes are particularly complicated, given the small size of vessels and (b) electronic monitoring may not capture the animals falling from the net during hauling*
- (4) **advises** that a robust evaluation of the effectiveness of bycatch mitigation measures requires a combination of monitoring measures, including well-designed and effectively implemented observer programmes, electronic monitoring and stranding programmes;*
- (5) **advises** that the above advice is relevant to the situation of the franciscana in Brazil; and*
- (6) **agrees** that given the increased use of Remote Electronic Monitoring techniques and the rapid development of camera and associated electronic technology, these techniques should be a focus topic at SC68a.*

13.6 Scientific aspects of mitigation measures

13.6.1 The IWC Bycatch Mitigation Initiative

The Committee considered the outcomes of an assessment on the potential work areas for the new IWC Bycatch Mitigation Initiative (SC/67b/HIM12). This resulted in several recommendations for the Committee in relation to potential work areas, including:

- (1) identification of priority fisheries/sites/species/populations to be considered for pilot projects based on conservation need and the establishment of bycatch baselines for relevant cetacean populations where mitigation is to be trialled;
- (2) leading in communicating the need for increased research on mitigation measures/management approaches for cetaceans to the broader scientific community;
- (3) annually reviewing mitigation measure tables;
- (4) providing technical assistance to the coordinator and the expert panel in the development of scientific trials/monitoring programmes to evaluate mitigation measures; and
- (5) collaborating with researchers identifying fishing effort using vessel monitoring and tracking systems and assessing bycatch risk, with a focus on small scale fisheries.

With respect to the identification of priorities, five criteria for the selection of pilot projects were identified:

- (1) urgency of conservation situation driven by bycatch or concern over situations with little or no data on bycatch, but suspected overlap between high risk fishing gears and vulnerable cetacean species;
- (2) enabling conditions necessary for success;
- (3) scope for IWC to contribute (e.g. enhanced international cooperation);
- (4) ability to monitor effectiveness of mitigation actions; and
- (5) potential for the project to contribute to mitigation of bycatch in other areas.

A list of information sources (including SOCER) was created at the meeting to assist Tarzia, the new BMI coordinator, to identify potential projects, after which she will consult with the expert panel to apply the above criteria, including contact with any of the governments involved, to select the projects for review by the initiative's Standing Working Group which can be presented to the Commission. The Committee suggested that identified fisheries in the Republic of Congo, Peru, Ecuador, Pakistan and India appear to fulfil many of the criteria and are locations where past or present IWC work is being carried out which is relevant to bycatch.

Attention: C-R, SC, CC

The Committee discussed the strategic assessment of the Bycatch Mitigation Initiative (BMI) and the role of the Committee. The Committee:

- (1) **welcomes** the progress made thus far under the BMI, including the Strategic Assessment;
- (2) **thanks** Tarzia for the excellent work she has carried out since her appointment as co-ordinator;
- (3) **agrees** to incorporate in its workplan the five work areas listed in its report under Item 13.6.1 and also consideration of 'rapid bycatch and risk assessment' tools;
- (4) **agrees** to the criteria listed in its report under Item 13.6.1 when identifying priority fisheries/sites/species/populations; and
- (5) **recommends** to the Commission that the BMI continues and is supported, including the provision of ongoing support for the BMI coordinator.

13.6.2 Collaboration with FAO

FAO held an Expert Workshop on Means and Methods for Reducing Marine Mammal Mortality in Fishing and Aquaculture Operations in March 2018 which had been attended by several members of the Committee. The workshop report contained a review of mitigation measures and a decision tree providing guidance on choosing a bycatch mitigation pathway. The IWC Executive Secretary and BMI Coordinator will attend the FAO Committee on Fisheries (COFI) meeting in July 2018 where the report will be reviewed.

Attention: C-R, S

The Committee **welcomes** the efforts of the FAO to consider cetacean bycatch and **recommends** that the IWC Secretariat continues to collaborate with the FAO on this issue.

13.7 New information on cetacean bycatch in the Western, Central and Northern Indian Ocean

Last year (IWC, 2018c, p. 46), the Committee had recommended that in light of the scope and scale of cetacean bycatch in the Western, Central and Northern Indian Ocean and the considerable data gaps associated with intensive and extensive gillnet fisheries, the topic be included in the work plan for this meeting and the Secretariat establish communications on the issue with the Indian Ocean Tuna Commission (IOTC). SC/67B/HIM/07 provided updated information on this topic, as discussed in Annex J (item 2.7). The IWC's Executive Secretary provided an update on engagement with the IOTC, including a recent teleconference with the IOTC Executive Secretary.

Attention: C-A, CC, SC

With respect to bycatches of cetaceans in the Indian Ocean, the Committee:

- (1) **reiterates** its willingness to collaborate with the IOTC on this issue; and
- (2) **encourages** the Secretariat to continue to work with the IOTC Secretariat.

13.8 Workplan 2019-20

The Committee's workplan on bycatch and entanglement is given in Table 18.

14. SHIP STRIKES

14.1 Review estimates of rates of ship strikes, risk of ship strikes and mortality

The Committee received information on a pilot study to better characterise ship strikes in Southeastern Alaska (see Annex J, item 3.1) and looks forward to further updates on this work.

14.1.1 Review progress on ship strike database

The IWC continues to develop a global database of ship strike incidents as discussed in Annex J (item 3.1.1). The primary task is ongoing review of previously reported records by two data coordinators in conjunction with a data review group (SC/67b/HIM11). It is expected that the review process for all historical records will be completed in the next biennium.

Attention: C-R, S

The Committee **reiterates** the importance of the global ship strikes database to its work. It therefore:

- (1) **welcomes** the work undertaken thus far;
- (2) **recommends** the continuation of this work including (a) that of the co-ordinators and Data Review Group on the review of historical records and (b) the Secretariat on upload tools.

Table 18
Workplan on bycatch and entanglement related issues.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Bycatch Mitigation Initiative		Review aspects relevant to Committee and respond to requests for advice		Review aspects relevant to Committee and respond to requests for advice
Rates and risks		Review new estimates of entanglement rates, risks and mortality		Review new estimates of entanglement rates, risks and mortality
Mitigation		Review new information on mitigation		
Inferences from strandings	Consider new information and issues that need to be addressed at SC68a	Review new information		
Rapid risk assessment		Consideration of 'rapid risk assessment' tools and outputs		
Electronic monitoring		Consideration of remote electronic monitoring and vessel tracking		
Mitigation measures tables		Develop table of mitigation measures for small cetaceans and update table for large whales from 2017 if needed.		
Global disentanglement database	Discussion at GWERN workshop	Review Progress	Advance database development if considered feasible	Review Progress
Collaboration with FAO	Secretariat attend COFI meeting	Review FAO outputs on bycatch	Continue collaboration	Continue to review
Encouraging innovative research on mitigation	BMI through existing networks, at conferences, workshops and with students – all members of Committee with relevant expertise	Review progress		

14.2 Mitigation of ship strikes in high risk areas

The Pelagos Sanctuary in the Mediterranean is a recognised high risk area for ship strikes to fin and sperm whales. In France, the REPCET reporting system became mandatory on 1 July 2017 for French passenger, cargo vessels (SC/67b/HIM04). As discussed in Annex J (item 3.2.1), 'alerting' systems such as REPCET require a trained observer and a subsequent avoidance action of some sort by the vessel in order to be considered as a mitigation tool.

The Committee had previously agreed that the available data supported a proposal to IMO to move the shipping lanes off the southern coast of Sri Lanka to reduce the risks of ship strikes to Northern Indian Ocean blue whales. In 2017, major shipping organisations represented at IMO also wrote to the Sri Lankan government requesting the routing change to reduce ship strike risks and improve maritime safety. So far, there has been no response from Sri Lanka.

The Hellenic Trench west of Greece is also an identified high risk area for sperm whales and in 2015 (IWC, 2016d), the Committee recommended that interested parties (including Greece, ACCOBAMS and the shipping industry) move forward with Greece in order to develop a proposal for routing measures.

The IUCN Marine Mammal Protected Areas Task Force process for identifying Important Marine Mammal Areas (IMMAs) may assist in identifying high risk areas for ship strikes. The Committee and the IWC's Ship Strike Standing Working Group have previously encouraged cooperation on this between the IUCN Task Force and the IWC.

Attention: C-A, CC, SC, G

The Committee has continued its work on identifying high risk areas for ship strikes and potential mitigation measures. In this regard the Committee:

- (1) **recommends** continued work to develop and evaluate mitigation measures, such as speed restrictions, that might be associated with the designation of a Particularly Sensitive Sea Area (PSSA) in the Pelagos Sanctuary area;*
- (2) **reiterates** its previous recommendations on the importance of evaluating the efficacy of the REPCET system for reducing the risk of ship strikes;*
- (3) **requests** the Commission, via the Secretariat, to remind the authorities in Sri Lanka of its previous offer of assistance from the IWC on this issue;*
- (4) **requests** the Commission via the Secretariat, to follow up on previous correspondence on the ship strike risks to sperm whales off Greece;*
- (5) **agrees** to support a workshop to evaluate how the data and process used to identify IMMAs can assist the IWC to identify areas of high risk for ship strikes; and*
- (6) **agrees** to continue ongoing IWC engagement with the process to identify IMMAs, including consideration of their utility to address other threats.*

14.3 Co-operation with IMO Secretariat and relevant IMO committees

The Committee has long recognised the importance of co-operation with IMO on matters related to shipping including ship strikes.

Attention: C-R, S

The Scientific Committee reiterates the importance of cooperation with IMO and:

- (1) welcomes the ongoing co-operation the Secretariat has maintained with IMO and its Secretariat on ship strike issues, including meetings during IMO MEPC 72; and*
(2) recommends that this dialogue continue.

14.4 Work Plan

The Committee's work plan on matters related to ship strikes is given as Table 19.

Table 19
Workplan on matters related to ship strikes

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Rates and risks		Review estimates of rates of ship strikes, risk of ship strikes and mortality		Review estimates of rates of ship strikes, risk of ship strikes and mortality
Mitigation		Review new information on mitigation		
Advice on routing measures related to ship strike risk	Provide advice as required (Annex Y)	Review advice	Provide advice as required (Annex Y)	Review advice
Follow up on previous contacts offering IWC assistance regarding high risk areas	Secretariat to contact Sri Lanka and Greek authorities	Review progress on identified high risk areas in IWC Ship Strike Strategic Plan		
Continued co-operation with IMO	Secretariat to maintain dialogue with IMO Secretariat. Attend relevant IMO meetings.	Review cooperation		
Ship strike database	Continue ongoing data entry into Ship Strike Database and validation of records	Review progress against specific deliverables and time line	Continue ongoing data entry into Ship Strike Database and validation of records	Review progress against specific deliverables and time line
Provision of AIS data	Secretariat to develop MOU with Marine Traffic for provision of data	Consider best way to handle requests for data through the MOU		
Use of IMMAs to identify high risk areas for ship strikes	Hold workshop to evaluate how the data and process used to identify IMMAs can assist the IWC to identify areas of high risk for ship strikes.	Review workshop report		

15. ENVIRONMENTAL CONCERNS

The Commission and the Scientific Committee have increasingly taken an interest in the environmental threats to cetaceans. In 1993, the Commission adopted a resolution on research on the environment and whale stocks and on the preservation of the marine environment, IWC Resolution 1993-12 (e.g. IWC, 1996; 1997; 1998; 1999; 2010). As a result, the Committee formalised its work by establishing a Standing Working Group that has met every year subsequently. This year, it has been established as a sub-committee and its report can be found in Annex K.

15.1 Pollution 2020

15.1.1 Review on intersessional progress on the Pollution 2020 initiative

The individual based model to investigate the effects of pollutants on cetacean populations (SPOC) has been finalised. A peer-reviewed paper detailing the model and applying it to a number of case studies has been published in *Environmental Pollution* (Hall *et al.*, 2018) and the model's R code is available through the repository associated with the paper. The web-based, user-friendly version is now available through the Sea Mammal Research Unit, University of St Andrews server (<http://www.smru.st-andrews.ac.uk/reports/>) and a link will be added to the IWC webpages on the Chemical Pollution page. There are new data on the combined effects of persistent organic pollutants (POPs) on the immune system of killer whales (Desforges *et al.*, 2017) and this will be integrated into the model in the next year.

As noted in Annex K (item 2.1), the contaminant mapping tool will be completed next year, with the inclusion of the data on the concentrations of mercury in cetacean tissues by time and region. This online resource that will be made available through the IWC website and will be updated with new information identified in the SOCER annual reviews.

Research to estimate how long it is likely to take for POPs in the blubber of cetaceans to observably decline, following a reduction in environmental levels, will be completed next year.

Attention: SC

*The Committee **agrees** that the Pollution 2020 initiative should be completed and presented at SC/68a. It also **encourages** a paper to be presented at SC/68a summarising the potential mitigation measures for reducing exposure of cetaceans to polychlorinated biphenyls (PCBs) in particular and persistent organic pollutants (POPs) in general.*

15.1.2 Report on mercury in cetaceans

The impact of mercury exposure is still an issue of concern for cetaceans. SC/67b/E08, reviewed mercury in cetaceans, in response to Commission Resolution 2016-4, 'Resolution on Minamata Convention'. The paper (see discussion in Annex K, item 2.2) highlights continued global exposure and potential effect of mercury on cetaceans. Although cetaceans have a unique detoxifying mechanism which may protect them from the health effects of organic mercury, the resulting mercuric-selenide complexes may cause adverse effects in individuals experiencing other physiological and metabolic challenges. Research into identifying the toxic thresholds for mercury in cetaceans is still required.

The Committee also received several papers presenting information on mercury in cetaceans including river dolphins (SC/67b/E06), humpback whales (SC/67b/E09) and gray whales off Chukotka (SC/67b/E03). The Committee highlighted the need for standardisation in reporting units. It also discussed preferred tissues for mercury analyses. Discussion of these papers can be found in Annex K (item 2.2)

Attention: SC, CG-R

The Committee continued to work on mercury in cetaceans in response to Resolution 2016-4. It therefore:

- (1) **encourages** the continued provision of information on mercury and cetaceans;*
- (2) **encourages** researchers presenting such information to report concentrations on both wet and dry weight bases; and*
- (3) **recommends** that Contracting Governments support the continued monitoring of mercury in cetaceans, as this is required in order to assess the medium- and long-term impact of the Minamata Convention.*

15.1.3 Impact of heavy fuel oils on cetaceans

There is a paucity of information on the impacts of heavy fuel oils on cetacean health (Annex K, item 2.3). However, some new information comparing the occurrence of cancer and elevated PAH levels in St Lawrence Estuary white whales with similar cancers in the local human population, was highlighted. In addition, behavioural changes in white whales in the White Sea following exposure to oil have been observed.

Attention: CG-A, SC, G

The Committee:

- (a) **reiterates** the need to estimate the risk and impact of oil spills, particularly to cetaceans in the Arctic;*
- (b) **notes** that heavy fuel oil could pose an environmental threat in many regions due to its high viscosity and chemical composition;*
- (c) **notes** that heavy fuel oil poses a special threat in the Arctic due to difficulties in recovery and potential impacts of some recovery measures (e.g. dispersant use and in situ burning); and*
- (d) **encourages** the collection of baseline data for cetaceans, including standardisation of measures.*

15.1.4 Other pollution issues

Understanding the effects of oil dispersants and dispersed oil on cetaceans is a gap in our current knowledge. To address this need, the Coastal Response Research Center (CRRRC) in the USA has co-ordinated a discussion among scientists with dispersant research expertise, as well as those with Arctic expertise, to determine the state-of-science regarding dispersants or dispersed oil, as it applies to Arctic waters. The Committee looks forward to the publication of the final report.

Attention: CG-A, SC, G

*The Committee **draws attention to** the lack of data the effects of oil dispersants and dispersed oil on cetaceans. It therefore:*

- (1) **encourages** Contracting Governments to support research on the effects of dispersants or dispersed oil to the Arctic and other ecosystems; and
- (2) **requests** that the results of such research be brought forward to future meetings of the Scientific Committee.

15.2 Cumulative effects

The Committee welcomed the summary of the Cumulative Effects Workshop (see Annex K, item 3) and looked forward to receiving the report. Overall, the Workshop found that there is considerable uncertainty in addressing this topic and thus in developing assessments and management advice.

The Scientific Committee also received a report on a workshop entitled ‘Towards understanding the overlap of selected threats and Important Marine Mammal Areas (IMMAs) across the Mediterranean Sea’, which was held jointly by the IUCN Joint Species Survival Commission/World Commission on Protected Areas (SSC/WCPA) Marine Mammal Protected Areas Task Force (the ‘Task Force’) and by the Agreement on Conservation of Cetaceans of the Black Sea, Mediterranean Sea and contiguous Atlantic area (ACCOBAMS). The workshop provided the opportunity to support the ongoing effort to map specific threats to cetaceans in the ACCOBAMS area by overlaying the Mediterranean IMMAs with the available area-explicit information on shipping and seismic surveys, thereby giving preliminary indications of new Cetacean Critical Habitats in the ACCOBAMS area and facilitating the implementation of conservation actions at the regional level.

Attention: SC, G

The Committee **recognises** the importance of understanding cumulative effects of threats on populations of cetaceans, as well as its complexity. It therefore:

- (1) **concurs** with the Cumulative Effects Workshop recommendations (see Annex K, item 3) to improve our knowledge and enable quantitative assessments;
- (2) **highlights** the recommendation that consideration needs to be given to ‘developing a widely applicable approach for providing precautionary advice for populations in which cumulative effects are of concern’;
- (3) **agrees** to establish cumulative effects as a standing item on its agenda;
- (4) **notes** the work on Important Marine Mammal Areas (IMMAs) and **encourages** additional efforts to identify the relevant threats in these, in order assist with the management of cumulative effects;
- (5) **endorses** the results of the recent IUCN/ACCOBAMS workshop entitled ‘Towards understanding the overlap of selected threats and Important Marine Mammal Areas (IMMAs) across the Mediterranean Sea’;
- (6) **encourages** that such an effort – aimed at overlaying different sources of threat and pressure on existing Important Marine Mammal Areas (IMMAs) – be continued and carried out in more detail in the other marine regions where IMMAs have already been identified; and
- (7) **offers** its assistance in such assessments.

15.3 Strandings and mortality events

15.3.1 Update on the IWC Strandings Initiative

The IWC strandings initiative was agreed by the Commission at its 2016 meeting (IWC, 2017d) and details can be found in Annex K (item 4.1). It noted that the rescue and welfare aspects of live strandings will be addressed by the Strandings Initiative but that this aspect is not within the purview of the Committee.

Attention: C-R, S, SC

The Committee **reiterates** the importance of the IWC Strandings Initiative. It therefore:

- (1) **welcomes** the excellent progress that has been made in the Strandings Initiative and the appointment of Sandro Mazzariol (Italy) as the Chair of the Strandings Expert Panel and Karen Stockin (New Zealand) as the Stranding Coordinator;
- (2) **recommends** that the Commission (a) endorses the Strandings Initiative governance structure in Annex K (appendix 2) and (b) endorses the continuation of the Strandings Coordinator position for another two years (until IWC68) subject to available funding and requests the Secretariat make the necessary arrangements;
- (3) **recommends** that the Strandings Initiative Steering Committee and Expert Panel, with the support of the Secretariat, should explore the best ways to gather information on strandings events and what basic data about these events should be recorded, focussing on what is useful for the Committee and the Commission;
- (4) **agrees** that a phased approach to this, starting with an initial pilot project, will assist in this endeavour; and
- (5) **agrees** that criteria for allocating funds for emergency responses should be developed by the Steering Committee and the Expert Panel and should be presented to the Committee at SC/68a.

15.3.2 New information on unusual mortality events

Cetacean morbillivirus continues to be a major disease issue for cetaceans and a cause of unusual mortality events in dolphins in and around the Atlantic. Focus this year was on an outbreak of cetacean morbillivirus in the South Atlantic Ocean (SC/67b/E14) that is discussed in Annex K (item 4.2).

Attention: CG-R, SC

The Committee **commends** the impressive rapid and comprehensive response to the cetacean morbillivirus outbreak in Brazilian Guiana dolphins. It therefore:

- (1) **encourages** further work on the longer-term impact of the outbreak and the investigation of the occurrence and impact of this disease in cetaceans across different geographical areas;
- (2) **draws attention to** the large number of animals that died during the outbreak (particularly mature females) and the historical high levels of human impacts affecting Guiana dolphins in Rio de Janeiro state, such as bycatch, chemical and noise pollution;
- (3) **recommends** that immediate actions should be taken to protect affected populations in order to increase the chances of population recoveries;
- (4) **draws attention to** the increase in Guiana dolphin deaths reported in Sao Paulo and Espirito Santo states in the weeks following the onset of the cetacean morbillivirus outbreak in Rio de Janeiro; and
- (5) **encourages** the monitoring of the virus presence in neighbouring coastal dolphin populations, particularly species and populations in which immunosuppressive conditions or cumulative threats are identified.

15.4 Noise
