The Committee also **agrees** that although the use of time-series of abundance estimates for species other than whales to make inferences regarding the extent of variation and the temporal auto-correlation of the rate of growth remained a good idea, the lack of such time-series at present means that this source of information cannot be pursued during the current review.

In conclusion, although considerable progress was made during the current meeting, the Committee was once again not in position to complete the review. It established a work plan (see Annex D, item 2.5) to address the final issues that need to be examined to complete the review at next year's meeting.

It **agrees** that the review will be completed at next year's meeting on the basis of the data and analyses available. It **accepts** that it is not appropriate to keep extending the time available for the review, particularly given its importance to Item 5.2 below.

5.2 Finalise the approach for evaluating proposed amendments to the *CLA*

The Committee noted that it could not complete discussions on amendments to the *CLA* until the range for MSYR values in the RMP was completed. Regarding the Norwegian proposal for amending the *CLA*, it was noted that all of the relevant trials/results had been presented in Aldrin and Huseby (2007), but that evaluation of this proposal could not occur until the review of MSY rates was complete.

5.3 Version of *CLA* to be used in trials

SC/62/RMP10 examined the sensitivity of catch limits to the level of accuracy when computing posterior distributions using the *CLA*. Four versions of programs used to implement the *CLA* were discussed. More details are given in Annex D, item 2.1.2.

The Committee **endorses** the recommendations in SC/62/RMP10 that: (a) only the Norwegian version of the *CLA* should be used when conducting future trials; (b) the Second Intersessional Workshop in an *Implementation* or *Implementation Review* will need to be carefully scheduled to ensure that all trials can be run before it takes place; (c) if special circumstances arise when it becomes necessary to run additional trials during a meeting (e.g. during the Second Intersessional Workshop), the 'intermediate' version of the Cooke implementation that is more accurate than the 'trials' version (but less accurate than the 'accurate' or Norwegian version) be used for this purpose and the results confirmed using the Norwegian 'CatchLimit' program after the meeting; and (d) a full set of revised results from the trials for North Atlantic fin whales, Western North Pacific Bryde's whales; and North Atlantic minke whales should be run using the Norwegian 'CatchLimit' program and the results placed on the IWC website.

5.4 Updates to RMP specification and annotations

In the context of applying the RMP pursuant to Item 20, the Committee identified some issues where updating and clarification of the specifications of the RMP and the accompanying annotations and guidelines was warranted (see Annex D, item 2.4).

(1) The provision for the adjustment for sources of human-caused mortality other than commercial catches, as recommended by the Scientific Committee in 2000 (IWC, 2001f, p.91), should be included in the RMP with the qualification specified by the Commission (IWC, 2001b) that the provision be limited to mortality due to bycatches, ship strikes, non-IWC whaling, scientific permit catches, and indigenous subsistence whaling. A new annotation should be added to provide the Committee with operational guidelines to implement this provision.
(2) The maximum period of validity of catch limit calculations should be extended from five to six years to be consistent with the six-year cycle of surveying specified in section 3.2.2 of the RMP, as currently implemented for minke whales in the North Atlantic.
(3) The rule for rounding of catch limits to a whole number of whales should be clarified.

(4) The guidelines for conducting surveys under the RMP and those for *Implementing* the RMP (IWC, 2005b; 2005c) should be modified to clarify that changes to the guidelines are not retroactive. That is, results from surveys conducted in accordance with earlier version of the guidelines would not become inadmissible for use in the RMP when the guidelines are changed.

Proposed amendments to the RMP and its annotations to address these issues are given in Annex D, Appendix 5, along with some background information. The Committee **recommends** adoption of these amendments to the RMP specification and annotations. The Committee further **requests** the Secretariat to prepare a proposal to next year's meeting to update the guidelines for conducting surveys and for *Implementations* to accommodate point (4) in Annex D, item 2.4.

Several amendments to the RMP specifications and annotations had been adopted since the most recent published version (IWC, 1999e). These are listed in Annex D, Appendix 5. The Committee **agrees** that the consolidated revised version be published in full in the next supplement to *J. Cetacean Res. Manage.*

6. RMP – *IMPLEMENTATIONS* AND *IMPLEMENTATION REVIEWS*

6.1 Western North Pacific Bryde's whales

6.1.1 Complete Implementation

6.1.1.1 RESEARCH PROPOSAL FOR THE 'VARIANT WITH RESEARCH'

The Committee had agreed in 2007 (IWC, 2008b) that three of the four RMP variants (1, 3 and 4) considered during the *Implementation* for western North Pacific Bryde's whales performed acceptably from a conservation perspective and recommended that those variants could be implemented without a research programme. It also agreed that variant 2 was only 'acceptable with research' because conservation performance was 'unacceptable' on three 'medium' plausibility trials incorporating stock structure hypothesis 4 i.e. two stocks of Bryde's whales in the western North Pacific, one of which consists of two sub-stocks (stock structure hypothesis 4).

In 2008, the Committee reviewed a research proposal (Pastene *et al.*, 2008) that aimed to determine whether or not sub-stocks occur in sub-area 1. Based on this review, the Committee had recommended that the *Implementation Simulation Trials* for the western North Pacific Bryde's whales be used to determine whether differences in age-compositions between sub-areas 1W and 1E could be used to resolve whether there are sub-stocks in these sub-areas and that results from previous (and any new) power analyses that assess the use of genetic methods to evaluate stock structure hypothesis 4 be included in the revised proposal.

This year, the Committee received a revised research plan (Annex D, Appendix 6) and welcomed work done to address several of its earlier recommendations. The results of the *Implementation Simulation Trials* showed that recent age structure data would not be able to distinguish between scenarios in which there is or is not age-structuring in sub-areas 1W and 1E.

The Committee **recommends** that the proposal be revised further and, in particular, that the power analyses focus more clearly on the specific hypotheses for the Western North Pacific Bryde's whales. The Committee was informed that a revised proposal will be presented next year that will focus to a greater extent on the use of genetic data.

6.1.2 Recommendations and work plan

The Committee **agrees** that its work plan for the 2011 Annual Meeting would be to review the revised research proposal for the 'variant with research'.

6.2 North Atlantic fin whales

6.2.1 Complete Implementation

Last year, the Committee had agreed that if the RMP is implemented for this species in this Region, variants 1, 3, 4, 5 and 6 (see Table 4 of IWC, 2010d) can be implemented without an associated research programme but that variant 2 (sub-areas WI+EG are a Small Area) was only acceptable with research.

This year, comparison of results from different versions of the *CLA* (see Item 5.2) revealed that variant 3 (sub-areas WI+WG+EI/F are a *Small Area*) does not have 'acceptable' performance for some of the trials and can no longer be considered to be acceptable without research but is rather only 'acceptable with research'.

Last year, the Committee had confirmed that use of variant 2 for ten years followed by variant 1 (sub-area WI is a *Small Area*) led to performance which was 'acceptable' for all trials and consequently that the requirements for stage 1 of the process for implementing a 'variant with research' had been met. The second stage of the process was for Iceland to demonstrate to the satisfaction of the Committee that a research programme has a good chance (within a 10-year period) of being able to confirm or deny that stock structure hypothesis IV is implausible.

The Committee received a research proposal (SC/62/RMP1) that followed the *pro forma* agreed by the Committee in 2007. Details are given in Annex D, item 3.2.2.

The Committee welcomed the proposal, noting that it was not final and that Iceland was inviting suggestions for how it can be improved. In discussion, it noted that the aim of the proposal should be to assess the probability of hypothesis IV relative to the probabilities for the other stock structure hypotheses. It noted that the *Implementation Simulation Trials* could be used to assess the effect sizes on which the power analyses are based.

In particular, the Committee **recommends** that the lowest rate at which the C sub-stocks mix in sub-areas EC, WG, EG, WI, EI+F, and N and the performance of variant 2 is 'acceptable' for all trials should be calculated and used when conducting power analyses. It further **recommends** that quantitative analyses along the lines of Appendix 3 of SC/62/RMP1 be conducted for each of the stock structure hypotheses.

6.2.2 Recommendations and work plan

The Committee **agrees** that its work plan for the 2011 Annual Meeting would be to review a revised research proposal for the 'variant with research' and to review any abundance estimates for use in the *CLA*.

6.3 North Pacific common minke whales

6.3.1 Initiate pre-Implementation assessment

In 2009, the Commission had agreed that the Scientific Committee should follow the option in its report (IWC, 2010e) that specified completing a full *Implementation Review* as soon as possible, ideally by the 2012 meeting. This timeline will be possible only if the *pre-Implementation assessment* can be completed this year. The Committee was undertaking a *pre-implementation assessment*, rather than immediately commencing an *Implementation Review*, because the 2003 *Implementation* had been conducted before the existing guidelines for *Implementations* had been developed and had focused primarily on 'O' stock.

Committee guidelines for *Implementations* (IWC, 2005b) state that the main focus of a *pre-Implementation assessment* is:

> 'the establishment of plausible stock hypotheses consistent with the data that are inclusive enough that it is deemed unlikely that the collection of new data during the *Implementation* process will suggest a major novel hypothesis (e.g. a different number of stocks) not already specified in the basic *Implementation Simulation Trial* structure.'

Additional foci are examination of available abundance estimates and information on the geographical and temporal nature of 'likely' whaling operations and future levels of anthropogenic removals other than due to commercial whaling.

The importance of creating a document that lists the various datasets and other information available for the *pre-implementation assessment* was recognised (this is normally provided by national scientists in the case of a new request for a *pre-Implementation assessment)*. This will be a living document, at least until the deadline is established for the consideration of no new data for the *Implementation Review* (this occurs at the First Intersessional Workshop although new *analyses* may be presented at the First Annual Meeting). A table containing this information is given in Annex D1, Appendix 2.

6.3.1.1 STOCK STRUCTURE

The goals for the *pre-Implementation assessment* with respect to stock structure were to agree to a set of inclusive plausible hypotheses consistent with the data, and to ensure that the types of information needed for the *Implementation Review* were available. Assessing the relative plausibility of alternative hypotheses regarding stock structure will be considered at the First Annual Meeting of the *Implementation Review*.

The Committee briefly discussed minimum standards for plausibility. It **agrees**, as it has in the past, that the most reasonable approach is to use best professional judgment and common sense, after considering all relevant information.

The Committee first reviewed past discussions on stock structure for western North Pacific minke whales. Details are given in Annex D1, item 5.1.

The Committee then received a number of papers providing new information relevant to stock structure. Details of these and the considerable discussions that ensued are given in Annex D1, item 5.3. The following summary focuses on issues where the Committee made specific statements.

SC/62/NMP22 provided results of a biopsy skin-sampling survey in July-August 2009 in the Okhotsk Sea. Unfortunately, none of the five biopsy samples taken could be removed from Russian waters because of CITES-related restrictions. This is discussed further under Annex D1, item 7.6. In spite of this, the Committee was pleased that that this research had been conducted within the Russian EEZ, and that it had been possible to collect biopsy samples from minke whales on the feeding grounds. The Committee **encourages** future collaborations and **strongly urges** all concerned to find ways to solve these CITES-related issues.

SC/62/NPM10 estimated the mixing proportion of 'O' and 'J' stocks in the Sea of Okhotsk using cookie-cutter shark scars from 22 animals. Based on previous research in sub-area 11 in 1996 and 1999, the maximum likelihood estimate for the proportion of 'J' stock in sub-area 12 was 0. The Committee welcomed this valuable new information, but **agrees** that the method used to estimate mixing proportions needed some refinement.

SC/62/NPM13 reviewed non-genetic biological information relevant to the stock structure of minke whales in the Yellow Sea, Sea of Japan (East Sea), and western Pacific Ocean. The review was structured to examine four key comparisons between: (1) the Yellow Sea and the Korean coast of the Sea of Japan; (2) the Korean and Japanese coasts in the Sea of Japan; (3) the Sea of Japan and Pacific coasts of Japan; and (4) coastal and offshore areas of the Pacific Ocean. The Committee welcomed this attempt to synthesise diverse types of non-genetic information that potentially can inform discussions of stock structure and found the idea of orienting the analyses around four key questions useful. The authors acknowledged that although they had attempted to be exhaustive, they might have missed some relevant biological information, particularly if it was reported outside the IWC context, and requested that any such information be forwarded to them. The Committee in particular supported the collation of information in table 3 in SC/62/NPM13 and **encourages** members to work together to complete this and provide it to the First Intersessional Meeting of the *Implementation Review*.

The Committee reconsidered Hatanaka and Miyashita (1997) that investigated feeding migration based on length data. It was pointed out that these data are consistent with the generic concept of an 'O' stock, and that the length data might be useful for mature/immature determinations to condition different migration patterns for one or more 'O' stocks. The Committee **agrees** to include these data in Annex D1, Appendix 2.

SC/62/NPM11 had two major objectives: (1) to determine the status of whales that could not be identified reliably to 'O' or 'J' stock based on analyses described in Kanda *et al.* (2009); and (2) to examine stock structure of the 'J' stock in the Sea of Japan and Yellow Sea. The Committee **appreciates** the efforts of the authors to respond to some of the suggestions for additional analyses made last year.

Two papers presented new analyses of mtDNA data. SC/62/NPM21 examined genetic variation at the mtDNA control region to evaluate the plausibility of proposed stock structure scenarios for the 'J' and 'O' stocks. SC/62/NPM20 reported on differences in mtDNA sequences and sex ratios in western North Pacific minke whales by combining information from samples collected in Korean market surveys with three Japanese datasets made available through the IWC Data Availability Agreement. SC/62/NPM27 commented on the analyses conducted in SC/62/NPM20. In discussion, it was clarified that although SC/62/NPM20 and SC/62/NPM27 largely considered the same group of samples, there were two important differences: (1) SC/62/NPM20 used market samples for Korean samples, while SC/62/NPM21 used bycatch; and (2) SC/62/NPM21 used mtDNA data that had been error-corrected subsequently whereas due to time constraints and the agreed deadlines for *pre-Implementation assessment*. SC/62/NPM20 used the original data and grouped haplotypes into haplogroups to minimize influence of the sequencing errors.

In further discussion of standards for establishing/rejecting hypotheses, the Committee **agrees** that it is important but challenging to try to find a balance between two potential errors: (1) interpreting minor differences that might be artefacts or not biologically meaningful as evidence for separate stocks; and (2) failing to recognise true stock structure because power to resolve closely related populations is low.

Discussion of these issues highlighted divergent opinions within the Committee regarding how best to deal with the inability to sample populations on their breeding grounds. In one view, the best way to approach this problem is to use results of the program *STRUCTURE* (Pritchard *et al.*, 2000) which is designed to deal with situations in which there are no reliable *a priori* ways of grouping individuals into putative populations. The other view was that this approach has elements of circularity and can result in a false sense of confidence in model results and that *STRUCTURE* has a documented inability to provide reliable results when dealing with mixtures of closely related populations. These issues have arisen previously regarding earlier versions of the genetic data analyses for North Pacific minke whales (IWC, 2010e).

The Committee **agrees** on the potential value of trying to collect samples in areas where a single stock is believed to occur, but recognises the difficulty in identifying the location of these.

Following presentation and discussion of new information, the Committee reviewed and discussed two independent attempts to generate plausible stock-structure hypotheses that synthesised both genetic and non-genetic information. The summaries of these papers and the ensuing discussion are below.

SC/62/NPM12 examined recent progress in the development of stock structure hypotheses for western North Pacific common minke whale ('O' and 'J' stocks), and conducted a preliminary evaluation of these hypotheses in the context of the available scientific information, mainly genetics, presented and discussed by the Committee in recent years. The aim was to identify stock structure scenarios that are consistent with the data. The authors of SC/62/NPM12 considered that the best available scientific evidence is consistent with the hypothesis that there is a single 'J' stock distributed in the Yellow Sea, Sea of Japan and Pacific side of Japan and a single 'O' stock in sub-areas 7, 8 and 9. They considered this hypothesis the most plausible. It is consistent with the pattern of mixing between 'J' and 'O' stocks along the Japanese coast as proposed by Kanda *et al.* (2009), the migration patterns of adult and juvenile 'J' stock whales as suggested by SC/62/NPM1, and the migration of 'O' stock whales as suggested by Hatanaka and Miyashita (1997). SC/62/NPM12 postulated three less plausible hypotheses which modify the most plausible scenario as follows:

(1) a W-stock sporadically intrudes into sub-area 9;
(2) a different stock (Y-stock) resides in the Yellow Sea and overlaps with 'J' stock in the southern part of sub-area 6; and
(3) a W-stock sporadically intrudes into sub-area 9 and a Y-stock resides in the Yellow Sea, and overlaps with 'J' stock in the southern part of sub-area 6.

These four hypotheses are further described and shown graphically in Annex D1, Appendix 3.

SC/62/NPM15 reviewed genetic and non-genetic data regarding stock structure; the authors summarised their conclusions in the context of addressing four key questions, as follows.

(1) Are whales in the Yellow Sea part of a population that migrates into the Sea of Japan?

SC/62/NPM15 summarised that migration north into the Yellow Sea, the presence of mature whales and cow/calf pairs there, and the fact that Yellow Sea whales have only autumn conception dates (*n*=124), provides evidence that a separate stock exists there. The Korean coast of the Sea of Japan showed some evidence for a mixture of two stocks, and microsatellite DNA showed seasonal differences that might be explained by a Yellow Sea stock moving along the Korean coast only in summer. In summary, the authors consider that the available data suggest that Yellow Sea whales may not be a part of the Sea of Japan stock.

(2) Are whales along the Korean coast part of the same population as whales along the western Japanese coast?

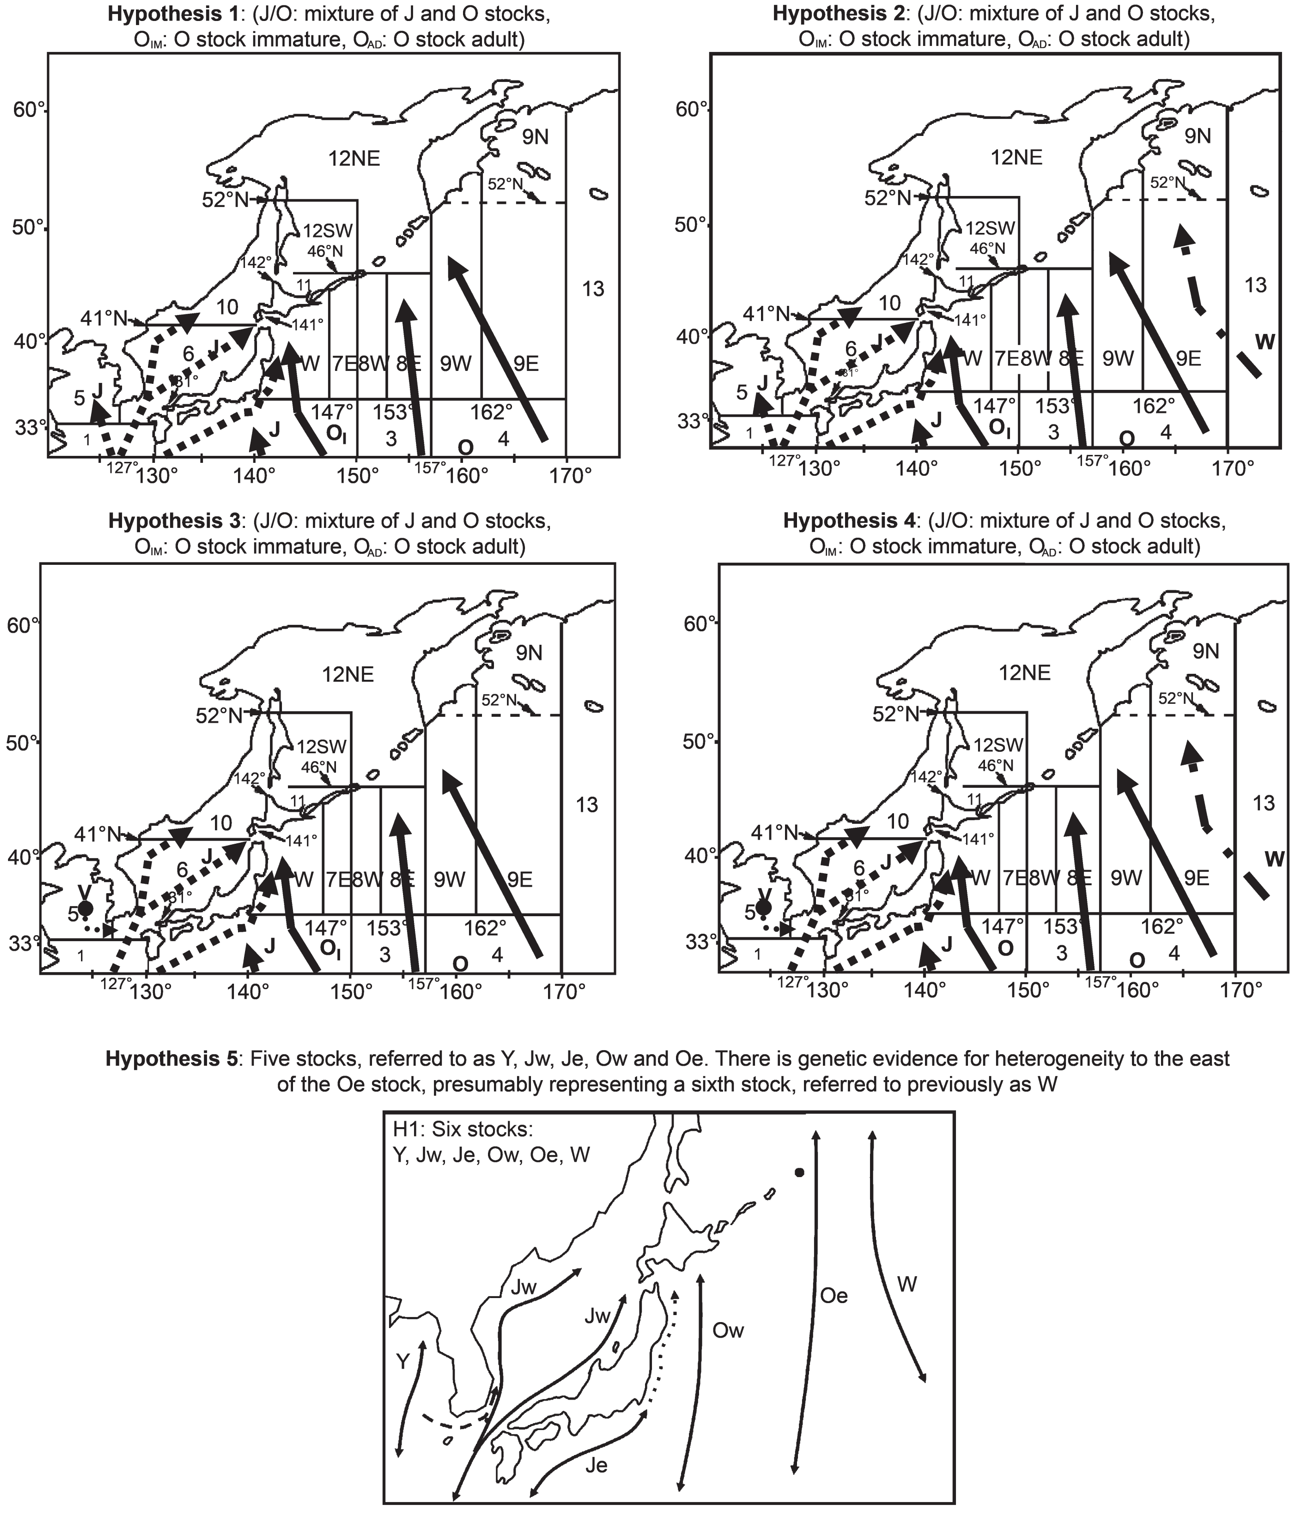
SC/62/NPM15 summarized that there is no obvious hiatus in distribution between the two coasts, and that genetic analyses showed mixed results (haplogroup and *STRUCTURE* found no difference, pair-wise mtDNA and microsatellite DNA found differences). A small sample (*n*=8) from the Sea of Japan showed a bimodal distribution of conception dates and a larger sample (*n*=63) showed two different flipper colour patterns, but these data could be explained by a mixture of whales coming into the northeast Sea of Japan from the Sea of Okhotsk. No sex bias or haplogroup-by-sex differences were found for Japanese Sea of Japan bycatch, suggesting a possible year-round presence of a non-migratory coastal stock. In summary, the authors consider that it is plausible there are different stocks on either side of the Sea of Japan, but the data are somewhat contradictory or are lacking in sufficient resolution or spatial extent to make definitive conclusions. Some genetic evidence suggesting a second stock could be most simply explained by whales from a Yellow Sea stock appearing along the coast of Korea in summer.

(3) Are so-called 'J-type' whales on the east coast of Japan the same population as on the west coast of Japan?

The majority of whales bycaught on the southern Pacific coast of Japan (sub-area 2) are assigned to be J-type and so are either part of a Sea of Japan stock or are a coastal stock separate from a Pacific Ocean ('O') stock. Whales caught in the Pacific Ocean, even from sub-area 7 coastal areas, only have winter conception dates (*n*=68) and a single flipper colour type (*n*=77); if coastal sub-area 7 had a mixture of stocks there should be autumn conception dates and a mixture of flipper colour types. There are differences in microsatellite DNA and mtDNA between the two coasts of Japan when all samples are used. Additionally, the southern Pacific coast bycatch (sub-area 2) is genetically different from bycatch along the northern Pacific coast of Japan (sub-area 7), suggesting a Pacific coastal stock might be distributed only in the Kuroshio current, and does not occur further north in the Oyashio current. In summary, the authors consider that it is plausible that there are different coastal stocks on either coast of Japan, and/or longitudinally along the Pacific coast.

(4) Is there a coastal population in Subarea 7 (east of Hokkaido and northern Honshu) that is different from offshore minke whales in the Pacific Ocean, even after accounting for Sea of Japan whales that might migrate into this area?

One hypothesis is that there is a 'pure' Sea of Japan stock (J-type whales) and Pacific Ocean stock (O-type whales). Under that hypothesis, genetic differences between Pacific coastal waters (sub-area 7W) and other areas have been interpreted to be a mixture of these two stocks. An alternate hypothesis is that this area contains a distinct stock characterised by intermediate haplotype frequencies, as seen in humpback whales, for example. Again, the lack of evidence of autumn conception dates (*n*=68) and a mixture of flipper colour types (*n*=77) in the Pacific Ocean argues



Hypothesis 1: (J/O: mixture of J and O stocks, O_{IM}: O stock immature, O_{AD}: O stock adult)

Hypothesis 2: (J/O: mixture of J and O stocks, O_{IM}: O stock immature, O_{AD}: O stock adult)

Hypothesis 3: (J/O: mixture of J and O stocks, O_{IM}: O stock immature, O_{AD}: O stock adult)

Hypothesis 4: (J/O: mixture of J and O stocks, O_{IM}: O stock immature, O_{AD}: O stock adult)

Hypothesis 5: Five stocks, referred to as Y, Jw, Je, Ow and Oe. There is genetic evidence for heterogeneity to the east of the Oe stock, presumably representing a sixth stock, referred to previously as W

Fig.1. Five plausible stock structure hypotheses for North Pacific minke whales.

against there being a mixture of stocks in coastal Pacific areas. Although it is possible that the haplotype frequencies of sub-area 7W could be explained by a complex seasonal, sex- and age-biased mixing of 2 stocks, e.g. a 'core J' and a 'core O', it is not as parsimonious as the hypothesis of a distinct stock with intermediate haplogroup frequencies. The absence of a strong haplogroup-by-sex interaction in coastal waters is inconsistent with the prediction of a sex-biased mixing of two stocks. SC/62/NPM30 concluded that there was genetic heterogeneity in the Pacific Ocean, with a strong signal in the coastal area east of Hokkaido. In summary, the authors consider that it is plausible that the unique genetic signals seen in coastal waters of the Pacific coast of Japan are due to the existence of a distinct coastal stock or stocks, rather than a mixture of a 'pure J' and a 'pure O' stock.

An additional stock-structure hypothesis based on consideration of the four questions posed above is that there are six stocks (Y, J_W, J_E, O_W, O_E, and W); this is described and shown graphically in Annex D1, Appendix 4.

In discussion, there was general agreement on answers to two of the key questions posed by SC/62/NPM15: (1) a separate J-like stock (denoted Y-stock) occurs in the Yellow

Sea and in at least some years some Y-stock whales are found in the Sea of Japan; and (2) minke whales on the east coast of Korea and on the west coast of Japan are generally part of a single stock.

In contrast, substantial disagreements remained concerning the other two questions. These disagreements centred on how to interpret results of statistical tests showing heterogeneity of allele frequencies. In one view, the results can be explained by overlapping distributions of 'O' and 'J' stock, which leads to different mixing proportions (and hence different allele and haplotypic frequencies) in different geographic areas. Under this hypothesis, it would not be surprising that comparisons of samples from areas having different fractions of the two stocks often produce statistically significant results. An alternative view to an explanation that requires complex mixing patterns is the hypothesis that the statistically significant differences reflect a distinct stock with intermediate gene frequencies.

In conclusion, in spite of the disagreements noted above, the Committee **agrees** that the set of stock-structure hypotheses based on the four proposed in Annex D1, Appendix 3 and the fifth proposed in Annex D1, Appendix 4 were inclusive and sufficiently plausible at least to take forward to the next step in the *Implementation* process (see Fig. 1).

6.3.1.2 CATCHES

The Committee noted that information was available on commercial catches for those countries that have taken the largest catches of western North Pacific minke whales. There are, however, limited data on catches for the People's Republic of China and no catch data for North Korea (if North Korea has taken western North Pacific minke whales).

The Committee reviewed information regarding incidental catches.

SC/62/NPM4 provided information on incidental catches of common minke whales off Japan and Korea. Some suggestions were made on how plausible estimates of future incidental catches can be made, as well as to how past series, now considered erroneous, can be constructed. The Committee noted that it would be useful if estimates were presented to the Preparatory Meeting for the First Intersessional Meeting of the *Implementation Review* (see Item 6.3.2 and Annex D1, item 11.2).

SC/62/NPM19 provided information on bycatch of minke whales in Korean waters from 1996 to 2008. The authors collected bycatch data from the 14 local branch offices of the Korea Coast Guard which investigates the bycatch of cetaceans. A total of 1,156 minke whales were bycaught of which 83.7% were bycaught in the East Sea; 363 animals were entangled or trapped by set nets, 316 and 303 were entangled by fish pots and gillnets, respectively.

SC/62/NPM26 provided information on incidental catches off Korea based on DNA profiling of market products (discussed under Annex J, item 9.4), which suggested that reported bycatch totals may be underestimated. The Committee was informed that the large majority of the incidental catch off Japan was taken in set nets; 119 common minke whales were bycaught in set nets and one animal in a gill net during 2009 (SC/62/ProgRepJapan).

The Committee **recommends** that available data on incidental catches and the associated effort should be analysed to develop CPUE series for possible use during the *Implementation Review*. The Committee **agrees** that sufficient information is available that alternative hypotheses regarding time-series of historical commercial and incidental catches can be developed during the *Implementation Review*. The Committee **agrees** that during the *Implementation Review* there is sufficient information to disaggregate the historical commercial and incidental catches to sub-areas and periods during the year.

The Committee received information on likely future whaling operations for minke whales in the western North Pacific. Japan aims to conduct land-based and pelagic whaling. Land-based whaling will be restricted to close to Japan while pelagic whaling will occur mainly in offshore areas. Temporal and spatial restrictions will be imposed on both types of whaling to try to reduce catching J-type animals. Korea intends to conduct land-based whaling to the east and west of Korea from March to November. These whaling plans will need to be elaborated further during the First Intersessional Workshop of the *Implementation Review*.

The work related to catches that needs to be completed prior to the Preparatory Meeting for the First Intersessional Workshop of the *Implementation Review* is:

(1) construction and GLM standardisation of CPUE series using the incidental catches and the associated fishing effort (see also Annex D1, item 8.3);
(2) development of a format for reporting incidental catches by Japanese and Korean scientists to the Secretariat and the provision of these data in the agreed format to the Secretariat; and
(3) development of alternative hypotheses regarding time-series of past and future commercial and incidental catches.

6.3.1.3 ABUNDANCE ESTIMATES

The Committee reviewed information available on abundance surveys and estimates of abundance.

SC/62/NPM2 provided estimates of abundance for the JARPN II survey area (sub-areas 7, 8 and 9, excluding the Russian EEZ) for the early (May and June) and late (July and August) seasons for 2006 and 2007. SC/62/NPM16 analyzed sightings data from recent surveys conducted by Korea in the Yellow Sea (sub-area 5) and the East Sea (sub-area 6) to estimate the abundance of common minke whales. Details are given in Annex D1, item 7.1.

SC/62/NPM24 reported on a sighting survey for minke whales and other cetaceans in the East Sea from 21 April to 30 May, 2009. An provided oversight on behalf of the Scientific Committee and the survey was undertaken in accordance with IWC guidelines. The plan had been presented to the 2008 Annual Meeting (Choi *et al.*, 2008) and was endorsed by the Committee. Details are given in Annex D1, item 7.1. The Committee expressed its appreciation to the Government of Korea for its continued commitment to surveys for minke whales in Korean waters, and to An for his role of oversight on behalf of the Committee. The Committee **agrees** that data from the 2009 survey off Korea are suitable for use in the RMP.

SC/62/NPM7 summarised the sighting surveys for minke whales in the western North Pacific conducted by Japan and Korea since 2000. The survey period for 'J' stock was April-June, and that for 'O' stock July-September. The areas covered were the Korean EEZ in sub-areas 5 and 6, the Japanese EEZ in sub-areas 6 and 10, the Russian EEZ in sub-area 10, the Sea of Okhotsk (sub-areas 11 and 12) and east of the Kurile archipelago and Kamchatka (sub-areas 8, 9 and 12), including the Russian EEZ. A total of 505 minke whale schools (560 animals) were sighted on 27,045 n.miles on primary search effort in 22 cruises.

SC/62/NPM8 updated the integrated abundance estimates for minke whales in sub-areas 5, 6 and 10 using new information on abundance and *g*(0). SC/62/NPM14 reviewed the proposed method in SC/62/NPM8 for integrating surveys for use in the *Implementation Simulation Trials*. Details are given in Annex D1, items 7.1 and 7.3.

The Committee **endorses** the method used to combine sightings data over time to estimate the extent of additional variance, but not necessarily the methods proposed for dealing with abundance across spatial areas in this case because of concerns over migration during the survey and extrapolation (see also Annex D1, item 7.3). The Committee did not review the abundance estimates in SC/62/NPM8 *inter alia* because it is unclear whether the sub-areas used for reporting abundance estimates will be used in the *Implementation Simulation Trials* developed during the First Intersessional Meeting. It was noted that although models can be used to interpolate abundance for unsurveyed regions, if a region has never been surveyed, the abundance estimate for that region should be set to zero when calculating catch limits under the RMP.

The Committee discussed possible migration patterns of 'J' stock minke whales in the Sea of Japan, as well as whether some component of the 'J' stock may not migrate to a substantial extent, in relation to how abundance estimates are computed and used in *Implementation Simulation Trials* and when applying the *CLA*. The Committee **agrees** that care needs to be taken to avoid double-counting animals when computing abundance estimates. In relation to animals in the Sea of Japan and the Yellow Sea, the Committee **agrees** that the *Implementation Simulation Trials* will capture hypotheses regarding the migration patterns of western North Pacific minke whales and that the models underlying these trials would be specified accordingly. The abundance estimates used for conditioning will be allocated to the appropriate time periods to avoid double counting.

The Committee **agrees** that there are several abundance estimates available for possible use when conditioning trials. Annex D1, table 1 provides a summary of the sightings surveys for the sub-areas used in the last set of *Implementation Simulation Trials* and those conducted since. The Committee did not discuss the acceptability or otherwise of the use of these surveys for conditioning the *Implementation Simulations Trials*.

The Committee noted that it was not necessary to select the abundance estimates for use in the *CLA* at the present meeting; this will take place during the First Intersessional Meeting of the *Implementation Review*. The selection of abundance estimates for use in *CLA* will need to take account of whether or not the surveys and their analysis followed the Requirements and Guidelines for Conducting Surveys and Analysing Data within the RMP (IWC, 2005c). Some of these surveys (e.g. those from JARPN II) have not been reviewed by the Committee for use in the RMP.

SC/62/NPM9 provided revised estimates of *g*(0) and abundance for western North Pacific common minke whales. The main changes from the previous analyses were the addition of new data, particularly for the Okhotsk Sea for 2003 and 2005. Details are given in Annex D1, item 7.5. The Committee welcomed this analysis which substantially reduced the previous range for *g*(0) but there was insufficient time for an in-depth review. The Committee **agrees** to review the method used to estimate *g*(0) and the resultant estimates further at the First Intersessional Workshop.

The Committee received information on plans for future sighting surveys by Korea and Japan (SC/62/NPM17 and SC/62/NPM4). Japan noted that it was not currently planning to conduct surveys in sub-areas 6 and 10, but may revise that decision in future. It was noted that the results of the *Implementation Simulation Trials* may provide information on which programme of surveys will lead to the best performance of the RMP, and that Japan and Korea may wish to modify their survey plans once the results of initial trials become available.

More specifically, SC/62/NPM25 described plans for a sighting survey in the Yellow Sea in April-May 2011, with the objective to obtain information on the distribution and abundance of minke whales. Details are given in Annex D1, item 7.6. The Committee was pleased to see that distance and angle estimation will be tested and **requests** that the results of analyses of these and previous data be presented to future meetings. It was noted that the survey could be conducted to eliminate the possible implications of migration during the survey. The Committee appointed An to provide oversight on behalf of the Committee.

SC/62/NPM23 described plans for a sighting and biopsy sampling survey for common minke whales in the Okhotsk Sea during summer 2010. The aim of the survey is to collect sightings data for abundance estimation and information on stock identification. To overcome CITES-related issues, genetic analysis using biopsied skin samples will be conducted on the research vessel. The Committee noted the importance of estimating the proportion of 'J' and 'O' stock animals in the survey area. It **recommends** that Japan explore ways that are not constrained by CITES to facilitate extracting relevant information from biopsy samples collected from the EEZ of Russia which could be used to examine stock structure and mixing. Specific suggestions for this are given in Annex D1, item 7.6. The Committee appointed Miyashita to provide oversight on behalf of the Committee.

6.3.1.4 OTHER ISSUES

Regarding information for estimating dispersal rates and mixing proportions, the Committee noted that SC/62/O30 outlined an approach for estimating mixing rates between stocks using microsatellite data.

Values for the biological parameters for use in *Implementation Simulation Trials* for the western North Pacific common minke whales had been assembled for the previous *Implementation* (IWC, 2004).

The previous trials were based on values for MSYR(mat) of 1% and 4%. These values should be used in any new trials unless the current review of MSY rates (Annex D, item 2) leads to a recommendation for a change to this range.

The Committee noted that CPUE data had been assembled and used to compare alternative stock structure hypotheses (Yasunaga *et al.*, 2009, Appendix II). It **recommends** that relevant commercial and incidental catch and effort data, along with the information identified by the 1987 CPUE Workshop (IWC, 1989), should be assembled, GLM standardised where possible, and be available at the First Intersessional Workshop of the *Implementation Review*. Data on flipper colour and conception dates should also be assembled and presented to the Preparatory Meeting of the First Intersessional Workshop of the *Implementation Review*. Initial discussions of future experimental and analytical ways to distinguish among competing hypotheses are given in Annex D1, item 10.

6.3.2 Recommendations

The Committee **agrees** that it has successfully addressed all of the items required for a *pre-Implementation assessment* and therefore **agrees** that the *pre-Implementation assessment* is completed.

The Committee **recognises** that there is a considerable amount of work that needs to be done to complete the *Implementation Review*. Specifically, there is a need: (a) to assemble the data so that they can be used when conditioning the operating models on which the *Implementation Simulation Trials* are based; (b) to specify and code the operating models themselves; and (c) to fit the operating models to the agreed data sets (conditioning).

The Committee **agrees** that it is infeasible to conduct all of the work in a single meeting (the First Intersessional Meeting). Rather, it **agrees** that the probability of completing the work during the first year of the *Implementation Review* will be maximised if two meetings occur. The main objective of the first (the Preparatory Meeting) would be to determine the structure (time-steps, sub-areas and population components) of the operating models so that all relevant data can be assembled at the appropriate spatial and temporal resolutions in time for the First Intersessional Workshop, and to start to specify the operating models and how they will be conditioned. The second step would be to complete work scheduled at the First Intersessional Workshop.

Annex D1, Appendix 9 outlines the work plan in more detail, including tentative dates for deadlines and holding the Preparatory Meeting and the First Intersessional Workshop.

6.4 North Atlantic common minke whales

6.4.1 New information on stock boundaries and abundance estimates

Some of the *Small Areas* boundaries for North Atlantic minke whales were changed during the 2003 *Implementation Review* but not all boundaries were fully specified. The Committee **recommends** that a point at 63°N, 12°W be introduced to fill the 'hole' between the CM and CIP *Small Area*, and that boundaries around the southern tip of Greenland be defined as shown in Annex D, fig. 1. It also **recommends** that the *Small Areas* in Annex D, fig. 1 be adopted for use when the applying the RMP for North Atlantic minke whales.

SC/62/RMP6 presented a method for estimating *g*(0) from single platform line transect data in which both the forward and perpendicular distances have been recorded. More details are given in Annex D, item 3.3.2. The Committee noted that attempts had been made in the past to estimate *g*(0) using data from a single platform. It **encourages** efforts to develop methods to achieve this. The Committee **recommends** that the robustness of the method proposed in SC/62/RMP6 to model structure uncertainty, measurement error, and diving pattern be examined.

SC/62/RMP7 summarised a sightings survey conducted in the North Sea area within *Small Area EN* during summer 2009. More details are given in Annex D, item 3.3.2. The Committee **welcomes** this information and noted that these data would be included in a future abundance estimate for the North Atlantic common minke whales.

SC/62/RMP5 presented estimates of abundance for common minke whales in the Central Atlantic from the North Atlantic Sightings Survey conducted by Icelandic and Faroese vessels during June/July 2007. More details are given in Annex D, item 3.3.2.

The Committee **agrees** that the methods in SC/62/RMP5 followed the relevant RMP Guidelines. Annex D, table 1 lists the estimates of abundance in SC/62/RMP5.

The Committee **agrees** to adopt the estimates of abundance for 2007 for the CG and CIP *Small Areas* presented in Annex D, table 1 for use in the RMP.

The Committee **endorses** abundance estimates for the CM *Small Area* and for the Eastern *Medium Area*, by *Small Area*, for use in the RMP given in Annex D, table 2.

6.4.2 Recommendations and work plan

The Committee **recommends** that the boundaries in Annex D, fig. 1 be adopted for use when applying the RMP for North Atlantic minke whales. It also **recommends** that abundance estimates in Annex D, tables 1 and 2 be adopted for use in the RMP. The Committee **agrees** that its work plan for the 2011 Annual Meeting will include the review of any new abundance estimates.

7. ESTIMATION OF BYCATCH AND OTHER HUMAN-INDUCED MORTALITY (BC)

The report of the Working Group on Estimation of Bycatch and Other Human-Induced Mortality is given as Annex J. This subject was introduced onto the Agenda in 2002 (IWC, 2003c) because as part of the Revised Management Procedure, recommended catch limits must take into account estimates of mortality due to *inter alia* bycatch, ship strikes and other human factors in accordance with Commission discussions at the 2000 Annual Meeting (IWC, 2001a), although of course such mortality can be of conservation and management importance to populations of large whales other than those to which the RMP might be applied. Subsequently, the issue of ship strikes has become of interest to the Commission's Conservation Committee (IWC, 2006a).

7.1 Collaboration with FAO on collation of relevant fisheries data

The effort to compile a comprehensive database of entanglement data in the national progress reports, an element of collaboration with FAO, has continued; the IWC Secretariat has now entered data from 2004-09.

7.2 Progress on joining the Fisheries Resource Monitoring System (FIRMS)

The information potentially to be developed in collaboration with FIRMS includes an inventory of fisheries, including gear characteristics and some indicators of fishing effort. The IWC will be eligible to move from observer status to full partnership in FIRMS after completion of the entanglement database (see Item 7.1, above). Details are provided in Annex J.

7.3 Estimation of bycatch mortality of large whales

7.3.1 Mortality in longline fisheries

The Committee received a global review of operational interactions between cetaceans and longline fisheries (SC/62/BC6). It reported deaths of humpback and Bryde's whales. In addition, mortality of southern right whales has been recorded elsewhere (Best *et al.*, 2001). Depredation by some species of cetaceans such as sperm and killer whales (Kock *et al.*, 2008; Kock *et al.*, 2006; Purves *et al.*, 2005) is of economic importance to some fisheries. Research to mitigate depredation and mortality can potentially contribute to estimating both fish and cetacean mortality rates.

7.3.2 Bycatches in Korea and Japan

Genetic analysis of samples of cetacean meat collected in markets in Korea in 2004-05 suggested that 90 common minke whales were represented (SC/62/NPM26). Details of the analyses are given in Annex J. The small number of samples from the same individuals suggests that the whales pass through the market rapidly. The reported bycatch for Korea for 2004 was 61. The detection of a minimum of 90 whales in the market indicates that the true bycatch was greater than reported. The reported bycatch for 2009 is 54. The results of the 2004-05 market survey analyses suggest that this is likely an underestimate.

The Committee welcomed publication of a recent paper describing incidental entanglement of minke whales in the Republic of Korea (Song *et al.*, 2010). This contained information that had been previously been requested of Korea by the Committee.

The Committee noted the need for time series of bycatch for the *Implementation Simulation Trials* for North Pacific common minke whales (see Item 6.3) for Japan and the Republic of Korea. The Committee reviewed the method presented in SC/62/NPM4 to estimate past incidental catches of minke whales in Japan (details are given in Annex J). Concern was raised regarding the multiplicative factor used to adjust reported catch figures for the period 1979-2000. It was noted that there was considerably more variability in the early reported figures, with CVs for the 1980s and 1990s three to six times higher than since 2001. For this reason, some members suggested that a multiplicative adjustment was not appropriate and that the reports of zero bycatch for some years, (which also resulted in zero estimates) were implausible. Other members considered that estimates in SC/62/NPM4 are an improvement compared to the previous assumption of 100 animals each year over a 100-year period. Butterworth commented that point estimates of zero for some years did not necessarily invalidate the method as a basis for estimating cumulative bycatch mortalities over time, which was the primary input required for *Implementation Simulation Trials*; nevertheless he encouraged refinement of the method presented.

In conclusion, the Committee **recommends** that additional analyses to arrive at time-series of bycatches in the region be undertaken for presentation to the preparatory meeting for the first intersessional workshop. In response to a suggestion from some members that bycatch in fisheries other than set nets warrants further examination, including historical information on past fisheries, e.g. the Japanese squid driftnet fishery of 1978-1992 (Yatsu *et al.*, 1994); it was noted that bycatches occur only rarely in types of gear other than set nets in Japanese waters, as reported in the national progress reports of Japan.

7.4 Estimation of risks and rates of entanglement

7.4.1 Report of intersessional workshop

The Committee noted relevant information on entanglement mortality in an advance copy of the report of the Commission's intersessional Workshop on Welfare Issues Associated with the Entanglement of Large Whales (IWC/62/15). The Workshop concluded that:

(1) all species of large whales are at risk of entanglement to varying degree, but common minke, humpback, right (both North Atlantic and southern) and gray whales are the most frequently reported;
(2) all types of stationary or drifting gear (i.e. not actively towed) pose potential risk to entangle, but pound, set and fyke-type nets, along with gill nets and various pot-type gear were most frequently implicated;
(3) entanglements can occur wherever this type of gear and large whales overlap in distribution, and isnot limited to feeding grounds but also includes breeding grounds as well as migratory pathways;
(4) given the cryptic nature of large whale entanglements in combination with the paucity of experienced observers and lack of formal reporting networks, entangled whales are severely underreported globally; and
(5) regional shifts in fisheries and gear types can produce major differences in the character of entanglements and reporting frequency (e.g. coastal versus offshore gear placement).

Based on these conclusions, the Workshop made the following relevant recommendations:

(1) that coastal nations establish adequate programmes for monitoring entanglement of whales; and
(2) that member countries improve reporting to the IWC through National Progress Reports.

The Committee **endorses** these recommendations. In addition it **recommends** that:

(1) all member countries which have coastal fishing operations be encouraged to more accurately report the occurrence and nature of large whale entanglements and establish entanglement response programmes where applicable;
(2) existing and new programmes communicate with each other to standardise the data collected to maximise their usefulness; and
(3) members be encouraged to facilitate thorough examinations of carcasses, at a minimum to record whether fishing gear is present, or fresh scars which might have resulted in mortality are visible, as well as facilitating necropsies on all large whales whenever possible. Such investigations should be conducted irrespective of population status, since this will be required to better estimate entanglement mortality rates including for species and populations that may be subject to whaling.

Additional details reported concerning the entanglement response networks of various nations are given in Annex J.

7.4.2 Entanglement mortality in Oman

An analysis of scars in the peduncle region indicates that 30-40% of whales observed in the isolated and severely depleted population of humpback whales in the western Arabian Sea (known as Breeding Stock X) were likely to have been involved in entanglements (SC/62/SH20). Of 10 stranded baleen whales, three were entangled in gill nets. Fishing effort, including use of drifting and set gillnets and fish traps, is increasing rapidly in the region. The Committee **welcomes** the establishment of a national stranding committee by the Government of Oman, and **recommends** that all member states that do not have national stranding networks to establish these. The importance of indications of fishing effort was also emphasised. The possibility of this population being considered as a candidate for a conservation management plan is discussed under Item 11.2.2.4.

7.5 Progress on including information in National Progress Reports

The data on entanglements and ship strikes reported in this year's National Progress Reports are summarised in Appendix 2 to Annex J. The Committee last year considered a proposal for developing a mechanism for online submission of the information; progress on issues related to online submission of bycatch and other information is discussed further under Item 3.2 and 25 and in Annex P.

7.6 Review of methods to estimate mortality from ship strikes

7.6.1 New data on ship strikes

The Committee received a report on ship strikes affecting southern right whales in Uruguayan waters (SC/62/BC2); between 2003 and 2007, seven whales were observed with large wounds due to collision and five were stranded dead. The Committee **welcomes** this information, noting that this is the type of information requested to be included in the national progress reports; in combination with data on shipping traffic, it may allow comparative analysis of ship-strike rates along the Atlantic coast of South America.

After consideration of a report of a 'near miss' between a humpback whale and a cruise ship in the Antarctic (see Annex J, item 10.1), it was **agreed** that a study of near-miss data (it is known that ferry operators in Hawaii collected such data) may yield additional insight into the dynamics of ship strikes and provide input for modelling risk (see below).

7.6.2 Progress in modelling risk

A report was received on progress in a series of winter and summer surveys of fin whale distribution and abundance in the Mediterranean Sea especially near the Italian coast and in the Pelagos Sanctuary. These surveys are in part intended to improve evaluation of population level effects of human-induced mortality including ship strikes. Details of the results are in Annex J. Plans to collect data on ship traffic were also detailed. The Committee **encourages** continuation of this effort that makes an important contribution towards the modelling of risk and assessing population level effects.

7.7 Progress in developing global database of ship strikes

This effort has been underway since 2007, with associated activities by IMO and ACCOBAMS. Tasks identified at last year's meeting have been completed or are nearly completed. Progress has relied on informal arrangements among the Secretariat, members of the data review group, and an external contractor. In view of the increasing workload and proposed intersessional tasks, detailed in Annex J, Appendix 3, the Committee **recommends** that consideration be given to the appointment of a dedicated coordinator; this is the practice for other similar successful databases of this scale. Funding requested to support intersessional work including data validation, the creation of a handbook and for work on data entry is discussed under Item 24.

The Committee **endorses** the policy on release of information in the database in response to requests from the public detailed in Annex J, Appendix 3. Information from nine fields in the database will be eligible for release on a down-loadable basis. Only data on confirmed ship strikes will be released. Requests for full access will be dealt with on an individual basis.

The Committee noted that IWC and ACCOBAMS will hold a joint workshop in Monaco from 21-24 September 2010 on reducing risk of ship strike and that some agenda items will be relevant to data gathering and estimating numbers of collisions. The IWC also continues to collaborate with IMO on efforts to minimise the risk of ships strikes and to reduce underwater noise from commercial shipping (Annex K, item 9.4).

7.8 Other issues

7.8.1 Methods for assessing mortality from acoustic sources

There was no new information on this topic. However, the Committee noted development of an improved method for handling and analysis of gas embolisms found in stranded cetaceans (Bernaldo de Quiros *et al.*, 2010); such embolisms may be linked with acoustic sources. A workshop entitled 'Diving marine mammals gas kinetics' was held in Woods Hole, MA, USA in April 2010 and the Committee looks forward to receiving the report at next year's meeting.

7.8.2 Methods for assessing mortality from marine debris

Methods used in a study modelling co-occurrence of debris and cetaceans (SC/62/BC5) have potential value for assessing mortality from debris. The Committee **recommends** that full necropsies be conducted on all stranded large whales, irrespective of population status, to detect incidents of mortality associated with ingested debris (and see the earlier recommendation on entanglement).

7.8.3 Other potential sources of human-induced mortality

The Committee noted that while there have been no confirmed reports of whale mortality due to collisions with marine renewable energy developments, the potential exists for such (SC/62/E7 and E8) and see Carter *et al.* (2008).

7.8.4 Actions arising from intersessional requests from the Commission

The Committee was asked to review Annex {DNA} of IWC/62/7rev. This contains a section on market sampling. Although the proposed scheme has the purpose of acting as a deterrent to illegal activity, the Committee noted that it might also potentially provide information for estimating bycatch. A workshop and simulation studies were conducted in the past by the Committee to assess the possibilities for developing a market sampling system to estimate bycatch (details in Annex J).

8. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT PROCEDURE (AWMP)

This item continues to be discussed as a result of Resolution 1994-4 of the Commission (IWC, 1995a). The report of the SWG on the development of an aboriginal whaling management procedure (AWMP) is given as Annex E. The Committee's deliberations, as reported below, are largely a summary of that Annex, and the interested reader is referred to it for a more detailed discussion. The primary issues at this year's meeting comprised: (1) *Implementation Review* of eastern gray whales; (2) various aspects of providing management advice for Greenlandic hunts; and (3) review of management advice for the humpback whale fishery of St. Vincent and The Grenadines. This represented a significant workload. The Chair of the SWG noted that its work this year had been considerably assisted by the progress made at the intersessional Workshop on Greenland fisheries held in Roskilde, Denmark (SC/62/Rep3).

In addition, he recalled that two years ago (IWC, 2009c), the Committee had tested and agreed a safe method to provide interim advice (i.e. catch limits for up to two 5-year blocks) such that the catch limit is 2% of the lower 5th percentile of the most recent estimate of abundance.

8.1 Sex ratio methods for common minke whales off West Greenland

The Committee has been evaluating assessment methods for common minke whales off West Greenland that rely on the relationship between the observed sex ratio of catches and that inferred from population models parameterised in terms of carrying capacity, productivity and how the distribution of males may have changed relative to that of females. This concept was introduced in 2005 (IWC, 2006b; Witting, 2005). The major factor which suggests that sex-ratio data may be informative about population size is that catches have consistently been female-dominated. 'Best' estimates of population size from sex ratio based methods are infinite, in effect indicating that any level of past catches would not have impacted this population of minke whales. However, it is standard Scientific Committee practice, in accordance with a precautionary approach, to base management advice primarily on lower confidence bounds for such estimates. The Committee has therefore focussed attention on developing the novel assessment approach required to calculate these bounds.

Considerable technical work was undertaken by the SWG during the intersessional period with a view to being able to test the approach with an initial set of robustness trials as described in SC/62/Rep3. However, implementation of the new method is proving extremely difficult. The details of this are complex and can be found in Annex E, item 3.1.3 but in short can be said to be due to the continued difficulties the SWG has faced with the likelihood function that underlies the sex-ratio approach.

Several remedies were considered by the SWG. The most promising of these was to re-parameterise the analysis by replacing *K* (carrying capacity) with a suitable transformation. This can be thought of as a high-risk/high-reward option: it could provide an adequate basis for estimation thereby eliminating many of the intricacies that continue to plague the current framework, but it may introduce new difficulties.

The Committee **endorses** the SWG recommendation that this approach receive the highest priority during the next intersessional period. If a transformed analysis could be completed and agreed at the 2011 Scientific Committee meeting, the sex-ratio method could be used as a basis for abundance estimation and submitted to appropriate simulation trials to test performance and robustness. If these trials are passed, the approach could then be used for providing management advice and as a basis for a long-term *SLA* (Item 8.3).

The SWG also considered a number of other options which would not require such a drastic change but which it considered had less chance of being successful, as can be seen in Annex E. An option to try raising the current truncation point was shown not to solve the issue as a result of runs undertaken after the SWG had completed its work.

The SWG had agreed that the continued difficulties in successfully implementing a sex-ratio approach required a re-evaluation of its work plan. The original motivation for this work had been the Committee's inability to provide management advice for this hunt. Thus, reflecting the priorities of the Scientific Committee and the Commission, work on a sex ratio estimation of abundance for West Greenland common minke whales has been the dominant focus of SWG effort for a number of annual meetings and three intersessional workshops.The participants have devoted considerable research effort to this task, the work has been scientifically challenging and methodologically innovative and the potential gain in terms of providing adequate management advice extremely high. However, despite enormous effort, no satisfactory conclusion has been achieved to date. Last year, the Committee had agreed an abundance estimate for common minke whales off West Greenland that, in conjunction with the agreed approach to provide safe interim advice for up to two five-year blocks, meant that the Committee was able to provide satisfactory management advice for the first time.

Therefore, the SWG had concluded that it would no longer prioritise development of the sex ratio approach unless a comprehensive final analysis could be endorsed at the 2011 Scientific Committee meeting. Although it would be regrettable to abandon the sex ratio effort without obtaining an agreed abundance estimate, there are many other urgent issues to which the SWG must turn its focus. The Committee **concurs** with this view.

8.2 Conduct *Implementation Review* of eastern North Pacific gray whales

In 2004, (IWC, 2005d), the Committee presented the Commission with its recommended Gray Whale *Strike Limit Algorithm* (the *Gray Whale SLA*) and this was endorsed by the Commission. The scheduled 2009 *Implementation Review* had been postponed because a number of key analyses would not be ready in time.

The purpose of an *Implementation Review* is to update information on catch history and abundance and to determine whether any other new information that has become available in the intervening (normally) 5-year period indicates that the present situation is outside the region of parameter space tested during *SLA* development. If this is the case, additional trials will need to be developed to test the performance of the *SLA* in this new region. If performance is found to be unacceptable under these new trials, revisions to the *SLA* will be required.

Full details of the parameter space investigated in the development of the *Gray Whale SLA* can be found in IWC (2005d). In practical terms, the most important issues relevant to the present *Implementation Review* relate to the issues of stock structure and updated information on abundance/trends.

8.2.1 The issue of the DAA and the conduct of this Implementation Review

Implementation Reviews are subject to the Committee's Data Availability Agreement incorporating a timetable of events. Although many datasets and analyses were completed within the appropriate timelines, unfortunately, just before adoption of its report, the SWG had realised that the photo-id and genetics data central to its discussions of stock structure and movements had not formally been submitted to the IWC under the DAA (although the papers themselves had met the appropriate deadlines). The same is also true for the telemetry data that, while not central to the conclusions reached, was also discussed under that Agenda Item; in this case the paper also did not meet the appropriate deadline.

The Committee recognised that discussions of these data cannot be considered as part of the *Implementation Review.* Thus although the *Implementation Review* is considered complete with respect to the discussions involving the data properly made available under the DAA, it **recommends** that a new *Implementation Review* takes place at the next Annual Meeting. This is to enable the SWG to take properly into account the important new information received this year that had not met the DAA timeline and that could indicate that the original trial structure was not sufficiently broad (see Item 8.2.7). This issue is referred to, where appropriate, in other parts of this report. A mechanism to ensure that this unfortunate event does not happen again is discussed under Item 8.2.8.

8.2.2 Stock structure

In the development process for the *Gray Whale SLA*, the possibility of a summer feeding aggregation along the Pacific coast between California and southeast Alaska was noted (e.g. IWC, 2001h) but the Committee had agreed that a single stock scenario was the most appropriate (IWC, 2002d).

Considerable new information has been collected since that time on the animals feeding along the Pacific coast and the SWG received three papers of relevance to stock structure at this meeting (unfortunately, as noted above, these did not meet all of the DAA requirements). Although different names have been used in the past by different authors (e.g. the southern feeding group, the Pacific Coast Feeding aggregation), the Committee **agrees** to refer to the animals that spend the spring, summer and autumn feeding in coastal waters of the Pacific coast of North America from California to southeast Alaska as the Pacific Coast Feeding Group or PCFG.

SC/62/AWMP1 presented an analysis of the genetic differentiation between the PCFG (using samples from Vancouver Island) and the larger population (using samples from Baja California). The authors concluded that their results suggest that the matrilines of the southern feeding group are demographically independent from those of the rest of the population, and therefore require separate management consideration.

SC/62/BRG32 reported the results of an 11-year (1998-2008) photo-id study examining the abundance and the population structure of eastern gray whales that spend the spring, summer and autumn feeding in coastal waters of the Pacific Northwest. With respect to stock structure, it concluded that there is one group of whales that return frequently and account for the majority of the sightings in the Pacific northwest during summer and autumn (i.e. the PCFG) and a second group of whales are apparent 'stragglers' encountered in this region after the main migration.

The discussion was also informed by consideration of telemetry data (SC/62/BRG21) and the details can be found in Annex E, item 2.2.

The Committee thanked the authors for these comprehensive papers. There was considerable discussion of them and their implications for stock structure. Despite some differences in interpretation and recognising that further analyses could be carried out, the Committee **endorses** the SWG's conclusion that the hypothesis of a demographically distinct PCFG was plausible and warranted further investigation. The implications of this for the *Implementation Review* are discussed under Item 8.2.7.

Telemetry data may provide the best estimator of residency times for PCFG gray whales in order to evaluate their relative vulnerability with respect to the spatial and temporal characteristics being considered for the Makah hunt. Analogous data from non-PCFG whales may also help determine if there are differences between PCFG and non-PCFG whales with regard to their migrations (distances from shore, water depths or timing) or other behaviours. Therefore, the Committee **recommends** that the satellite tagging work should continue and that these data be analysed with the goal of providing input (e.g. as required in mixing matrices, etc.) for any future trials of the *Gray Whale SLA*.

8.2.3 Catch data

Allison informed the SWG that the catch series had been updated to incorporate new information. The complete series can be found in Annex E, table 1.

8.2.4 Abundance and trends

Two papers relating to calf counts were considered, one from migration and one from the breeding grounds.

SC/62/BRG1 presented calf counts from shore-based surveys of northbound eastern North Pacific gray whales that have been conducted each spring between 1994 and 2009 in central California. Estimates were highly variable between years, with no sign of a positive or negative trend. Calf production indices, ranged between 1.6 - 8.8% with an overall average of 4.2%. The authors hypothesised that a late retreat of seasonal ice may delay access to the feeding areas for pregnant females and reduce the probability that existing pregnancies will be carried to term.

SC/62/BRG36 reported on changes in the abundance of gray whales inferred from boat surveys at Laguna Ojo de Liebre and Laguna San Ignacio between the late 1970s to the present. There was a decrease in the numbers of cow-calf pairs in both lagoons during 2007 to 2009, similar to the results from shore-based surveys at Piedras Blancas during the northbound migration. The counts of cow-calf pairs in both lagoons in 2010 were the lowest over the last 15 years.

In discussion, it was noted that the calf production indices were particularly low (<3%) during two periods (1999-2001 and 2007-09). During the first period, calf counts were low and high numbers of strandings also occurred. However, although the calf counts were low during 2007-09, there is no evidence for higher numbers of strandings during these years. The Committee noted that the calf production indices are being used in its discussion of MSY rates (see Item 5.1). Although the time-series of calf counts is now 16 years long, this is only just long enough to allow estimation of these parameters.

The Committee therefore **recommends** that these data continue to be collected and are reviewed during future *Implementation Reviews*. The series of cow-calf counts in lagoons, which provide a relative index not absolute estimates, are consistent with the calf counts given in SC/62/BRG1.

The Committee noted that the calf count data had been used during the initial development and *Implementation* for eastern gray whales and **agrees** that the new information did not indicate a need to modify the trials structure.

The Committee had two new papers relating to total abundance estimates. The first, SC/62/BRG8 reported a promising new approach that has recently been adopted for the counts of southbound migrating whales at Granite Canyon, California, which form the basis of abundance estimation for the eastern gray whales. The authors recognised the need for new calibration data to evaluate the different biases of new counting methods and new observers before count data can be reliably rescaled to estimate abundance.

The Committee welcomed this report, noting the importance of ensuring comparability among years in any long-term monitoring effort. It **recommends** that data be collected to re-evaluate pod size bias given the change in survey protocol and that variance estimates for future survey estimates of abundance account for the uncertainty associated with calibration of abundance estimates computed using different survey protocols.

The second paper, Laake *et al.* (2009), re-evaluated the data from all 23 seasons of shore-based counts for the Eastern North Pacific stock of gray whales conducted throughout all or most of the southbound migration near Carmel, California using a common estimation procedure and an improved method for treatment of error in pod size and detection probability estimation.

In addition to these papers, the Committee noted that the telemetric information in SC/62/BRG21 provided the first confirmation of day/night migration rates since the original

Table 2

Time-series of agreed abundance estimates of eastern gray whales for use in the *Gray Whale SLA* (taken from Laake *et al.*, 2009).

Year	Estimate	CV	Year	Estimate	CV
1967/68	13,426	0.094	1979/80	19,763	0.083
1968/69	14,548	0.080	1984/85	23,499	0.089
1969/70	14,553	0.083	1985/86	22,921	0.081
1970/71	12,771	0.081	1987/88	26,916	0.058
1971/72	11,079	0.092	1992/93	15,762	0.067
1972/73	17,365	0.079	1993/94	20,103	0.055
1973/74	17,375	0.082	1995/96	20,944	0.061
1974/75	15,290	0.084	1997/98	21,135	0.068

1976/77	18,377	0.080	2001/02	16,033	0.069
1977/78	19,538	0.088	2006/07	19,126	0.071
1978/79	15,384	0.080			

radio tag information that has been used when estimating abundance from the southbound census. The Committee thanked the authors for this comprehensive and careful review of this extremely valuable time-series of absolute abundance estimates. It **recommends** that the estimates of abundance given in Table 2 be **adopted** for use in the *Implementation Review* and for use when applying the *Gray Whale SLA*.

SC/62/BRG32 referred to under Item 8.2.2, also used the photo-id data to estimate the abundance of the PCFG. Abundance estimates for whales present in summer and autumn were estimated using both open and closed population models. Methods were proposed to remove the 'stragglers' from both types of analyses, to estimate abundance only of regularly returning whales. Three methods and four geographic scales revealed the abundance of animals that regularly return to the Pacific Northwest to be at most a few hundred individuals.

The Committee **agrees** that these data will be extremely useful during the proposed 2011 *Implementation Review*, along with telemetry data, to determine the probability that animals from the putative feeding aggregation in the Pacific Northwest are at risk of being caught during hunts in that area (see Annex E, item 2.6). The estimates in SC/62/BRG32 will also be useful to condition any trials developed to examine the performance of *SLA* variants for this feeding aggregation.

8.2.5 Assessment

SC/62/AWMP2 fitted an age- and sex-structured population dynamics model to data on the catches and abundance estimates for the ENP stock of gray whales using Bayesian methods. The prior distributions used for these analyses incorporated the revised the estimates of abundance in Laake *et al.* (2009) and SC/62/BRG1, and account explicitly for the drop in abundance caused by the 1999-2000 mortality event. A series of sensitivity analyses were conducted. The baseline analysis estimated the population to be above MSYL and the 2009 population size (posterior mean of 21,911) to be at 85% of its carrying capacity (posterior mean of 25,808); conclusions were consistent across all the model runs. SC/62/AWMP2 only estimated an extra mortality parameter for 1999-2000 based both on calf and strandings data and the analysis of Brandon and Punt (2009a; 2009b) in which annual parameters were estimated for reproduction and survival.

The Committee thanked the authors of SC/62/AWMP2 for the updated assessment. It **agrees** that the results of the assessment are within the bounds considered during the *Implementation*. Although the base operating model used to estimate the *Gray Whale SLA* did not explicitly include the 1999-2000 event, robustness tests involving catastrophic mortality events were conducted and the *Gray Whale SLA* performed adequately for these tests.

8.2.6 Strandings data

SC/62/BRG25 provided a summary of all gray whale strandings in California, Oregon and Washington between 1 January 2010 and 31 May 2010. The Committee welcomes this information, **agrees** that it showed that stranding levels were now similar to 'normal' years, and **recommends** that these data continue to be collected and presented to the Committee.

8.2.7 Consideration of need for new trials (and, if applicable, results of those)

The Committee refers to its earlier comments on the situation with respect to the DAA and the need for an *Implementation Review*.

Although some of the papers/data available could not be considered in terms of the 2010 *Implementation Review*, the Committee **agrees** that the information provided on the PCFG was such that its existence represents a plausible hypothesis, not considered in the original *Implementation.* In accord with Committee guidelines for this process (IWC, 2005b), this is sufficient to trigger a new *Implementation Review* in 2011. The reason that this hypothesis is important from an AWMP perspective relates to the potential harvesting in this region by the Makah Tribe and thus the need for the SWG to provide advice/develop an *SLA* to fulfil both the 'conservation' and 'user' objectives given by the Commission. It noted that the situation for PCFG is not the same as for the Greenlandic feeding aggregation of humpback whales; the latter case involves a feeding aggregation that does not occur (even in the short-term during migration) with animals from other feeding aggregations in the waters where the hunt takes place. In the case of the proposed area for the Makah hunt, both PCFG and migrating whales from the other feeding areas co-occur at least some of the time. In fact the situation is more similar to that of Gulf of Maine humpback whales.

The Committee therefore **agrees** that the information on stock structure and hunting warranted the development of trials to evaluate the performance of *SLA*s for hunting in the Pacific northwest at the 2011 *Implementation Review*. The Committee also noted that the assessment work discussed above (Item 8.2.5) showed that the population as a whole is in a healthy state. It **agrees** that for the purposes of the 2011 *Implementation Review*, the primary focus should be the PCFG.

That being said, it also **agrees** that over the next few years (i.e. in time for an *Implementation Review* in about 2016), further work should be undertaken to investigate the possibility of structure on the northern feeding grounds, especially in the region of the Chukotkan hunts. It **recommends** that relevant information be collected from the Chukotkan region, in particular, where possible, including genetic samples and photographs from the hunt). In addition, the collation of information on the geographical and temporal distribution of the hunt will be valuable.

Annex E, item 2.6 provides some general guidance for the 2011 *Implementation* Review. The Committee **agrees** that any acceptable future *SLA* for the hunt in the Pacific northwest must include a feedback mechanism. It also requests that the Chair of the SWG discuss its requirements for need envelopes with the hunters and members of the

US delegation. The Committee **agrees** that the following would assist, but are not required for beginning, the trial development process:

(1) Collection/analysis of genetic data that would allow more robust comparison of such data from animals in the northern and southern feeding areas;
(2) Collection/analysis of genetic data from Kodiak Island to California to further examine the probable range of the PCFG;
(3) Collection/analysis of genetic data to compare further animals seen in only one year ('stragglers' in SC/62/BRG32) with animals that are frequently seen within the hunting area;
(4) Collection/analysis of additional information (including telemetry data) on the relative temporal 'availability' of PCFG animals within the hunting area (e.g. by month); and
(5) An updated analysis of any additional data to obtain the most recent abundance estimate for the PCFG at the time of the 2011 *Implementation Review.*

8.2.8 Conclusions and recommendations

In light of the DAA difficulties discussed earlier, the Committee **agrees** that it has completed the *Implementation Review* on the basis of the data that had been made available to it in accord with the DAA. However, given the new information available that did not meet the DAA conditions, it **agrees** that a new *Implementation Review* should occur in 2011 to take into account information provided on the PCFG which was presented outside the DAA as noted under Items 8.2.2 and 8.2.7. The Chair of the SWG **agrees** to ensure that all likely contributors to the review are made aware of the DAA requirements as well as the guidelines for genetic analyses and data. The draft guidelines for *Implementation Reviews* referred to under Item 8.4 will also assist this process. The Committee also **agrees** that preparatory discussions for the 2011 *Implementation Review* take place at the proposed intersessional workshop (see Item 21). Management advice for this population can be found under Item 9.2.2.

8.3 Continue work on developing *SLA*s for the Greenlandic fisheries

In 2009, the Committee agreed an approach for providing safe interim advice on catch limits that is valid for up to two five-year blocks. In doing so, this provides time for the SWG to develop long-term *SLA*s for the Greenlandic fisheries. Work on this has progressed in general terms (e.g. see discussion in SC/62/Rep3 and Annex E, items 3.3 and 4.2). However, particularly given the complexity of the multispecies hunt in Greenland, the Committee **agrees** that this must be given high priority for the future work of the SWG, such that suitable *SLA*s can be developed and tested before the interim advice expires.

Simulation evaluation of *SLA*s requires the development and parameterisation of a set of operating models. Unlike the situation for West Greenland common minke whales, the SWG has an assessment for West Greenland fin whales which means that it is in a better position to develop an *SLA* for fin whales. Last year, it was agreed that the set of RMP trials developed to evaluate variants of the RMP for North Atlantic fin whales would be an appropriate starting point for developing such trials and this year the SWG was presented with a summary of the stock structure hypotheses underlying those trials. These will need to be modified to focus more on the uncertainties pertinent to West Greenland if they are to form the basis for evaluation of *SLA*s for fin whales. Unfortunately, the SWG did not have time to consider this further at the present meeting.

With respect to common minke whales off West Greenland, the SWG had previously been awaiting the outcome of the evaluation of a sex ratio method approach before addressing the issue of long-term *SLA*s; the decision potentially to cease work on a sex-ratio abundance estimate in 2011 (see Item 8.1) does not affect the need to begin work on an *SLA* as soon as possible. As noted in SC/62/Rep3, consideration of existing RMP trials for North Atlantic common minke whales may again prove a useful starting point for discussions.

In conclusion, the Committee **re-emphasises** the importance of developing *SLA*s for Greenlandic fisheries as soon as possible. It **agrees** that this should form the primary item for discussion at the intersessional workshop.

8.4 Consider lessons learned from the bowhead whale *Implementation Review*

Two main issues arising from the bowhead *Implementation Review* relating to: (1) stock structure and in particular genetic samples; and (2) data availability. In relation to the first of these two issues, the Committee noted that there are now guidelines for DNA data quality (IWC, 2009h).

In relation to the general question of data availability, a number of issues were raised in the SWG (see Annex E, item 8). One reason for the difficulties encountered was the lack of explicit guidelines for conducting *Implementations* and *Implementation Reviews* for the AWMP process, noting how valuable these had proved for the RMP process. The Committee **agrees** that Donovan should develop a draft of such a document for consideration at next year's meeting.

8.5 Aboriginal Whaling Scheme (AWS)

In 2002, the Committee strongly recommended that the Commission adopt the Aboriginal Subsistence Whaling Scheme (IWC, 2003a, pp.22-23). This covers a number of practical issues such as survey intervals, carryover, and guidelines for surveys. The Committee has stated in the past the AWS provisions constitute an important and necessary component of safe management under AWMP *SLAs* and it **reaffirms** this view. It noted that discussions within the Commission of some aspects such as the 'grace period' are not yet complete.

8.6 Other

8.6.1 Conversion factors for edible products for Greenland fisheries

IWC/62/9 is the report of a Small Working Group (Donovan, Palka, George, Hammond, Levermann and Witting) established by the Chair of the Commission to provide advice on conversion factors for the Greenlandic hunt. The report of the group was presented to the intersessional Commission meeting to consider Greenlandic strike limits. In discussion of the report at that meeting, it was agreed that there was no need for the report to be reviewed in detail by the Scientific Committee but that individual scientists should send comments to the authors so that the report could be revised, if necessary, by the Commission meeting in Agadir. That request and the document itself was circulated to the Scientific Committee with a request for comments by 6 June 2010. However, it had been agreed that this issue would be added to the SWG agenda.

A short summary of the report, which has been available on the IWC website since February 2010, is given in Annex E, item 9.1[2].

---

[2] The full 52 page report can be found at *http://www.iwcoffice.org/_documents/commission/IWC62docs/62-9.pdf.*

In discussion of IWC/62/9 during the present meeting, one member provided a number of comments on the underlying approach to calculating conversion factors, as well as to the quality of the data used by the authors. Points raised included whether conversion factors should be based only upon what product yield has been achieved in the past, or whether it should consider what could be achieved with significant improvements in processing efficiency. He also commented on the likely inaccuracy and unreliability of the hunter collected data. He suggested that Greenland be asked to come back next year with data of verifiable quality on length and product yield, and/or that the Committee be given details of the new data collection methods, together with information on the process by which the reliability of the product yield data is verified. In response, the authors noted that they had spent considerable time and effort in investigating the original data, recognising that it had not been collected by scientists for the purposes of estimating conversion factors. The large sample size and the consistency with edible product information collected by scientists in the North Pacific, revealed that the data for common minke whales were sufficient to calculate a robust conversion factor (as well as showing the flensing process to be efficient). The limitations of the conversion factors provided for the other species were recognised in the report and considered interim pending the recommended collection of additional data on length correction and edible products. They had offered to assist in appropriate experimental design. They also noted that it would take some time to obtain sufficient sample sizes for some species. They concluded that matters of efficiency were appropriate for discussion by the Commission.

The Committee endorsed the **recommendations** of the report. In particular, it supported the recommendations for further work that data on both 'curved' and 'standard' measurements are obtained during the coming season for common minke whales, fin whales and bowhead whales and that new data on edible products be collected using properly-design protocols, analysed appropriately and reviewed. It also supported the recommendation that the work be undertaken by scientists, hunters and wildlife officers since this would improve the ability of hunters, particularly those in remote areas, to obtain more accurate length and weight measurements. The Committee was informed that Greenland has already begun to implement some of the recommendations of the Small Working Group and they will be implementing all of them in the next season. There is now increased collaboration between hunters, scientists and managers and improved estimates of the three types of edible product should be possible by having each product stored in separate bins and weighed. It was also noted that collaboration between hunters from Alaska and Greenland was underway with the respect to flensing techniques for bowhead whales. Finally, the Committee **requests** Greenland to provide information on its sampling scheme and data validation protocols to next year's meeting.

9. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT ADVICE

9.1 Eastern Canada and West Greenland bowhead whales

9.1.1 Assess stock structure and abundance of Eastern Canada and West Greenland bowhead whales

The Committee has agreed at the previous three Annual Meetings to consider a single stock of bowhead whales in this region as the 'working hypothesis' while acknowledging that there is still some uncertainty about the population structure of bowhead whales in eastern Canada and western Greenland (e.g. IWC, 2009d). Last year, the Committee had expressed some disappointment that the expected genetic analyses had not materialised to take discussions further. It had noted that use of the term 'working' hypothesis implies that alternative hypotheses can still be considered and thus there should be consideration of both one stock and two stock hypotheses. The Committee was therefore pleased to receive this year a number of stock structure papers, some of which include the use of genetic data.

SC/62/BRG26 presented work on genetic differentiation of bowhead whales in Eastern Canada and Western Greenland. The study included sequence data for 346 individuals from Baffin-Bay-Davis-Strait and 197 individuals from Hudson-Bay-Foxe-Basin. There was a slight but significant genetic difference between the two areas in terms of F_{ST} based on haplotype frequencies. However, there was no differentiation between Hudson Bay-Foxe Basin and Cumberland Sound, an area presumed to be within the range of the putative Baffin Bay-Davis-Strait stock. In the context of other biological information available (SC/62/BRG23 and SC/62/ BRG25), the authors consider the observed F_{ST} to be consistent with the one stock hypothesis.

SC/62/BRG25 reported on the re-identification patterns of genetic markers from bowhead whales sampled in Eastern Canada and West Greenland. From the total of 647 identified individuals, 91 were re-identified within the same location and year. Of the remaining 556 individuals (208 males and 348 females), the authors found 16 re-identifications between years. Three of these were between sampling areas and all three had moved from the Hudson Bay-Foxe Basin area to the Baffin Bay-Davis Strait area. In addition, of the 20 new satellite tags put out in 2009 in Disko Bay, four animals had crossed assumed boundaries between putative stocks. The authors concluded that: (i) the low number of re-identifications between years indicates that the population is relatively large; and (ii) the high proportion of re-identifications and movements of satellite tagged animals between areas indicate a high rate of movement between the areas. In the authors' view, these results indicate that there is only one stock of bowhead whales in Eastern Canada and Western Greenland.

SC/62/BRG23 reported on the sexual segregation of bowhead whales sampled in Eastern Canada and West Greenland. Genetic samples (the same as used in the previous two papers) were obtained from one location in West Greenland: Disko Bay (April-June 2000-09) and four locations in Eastern Canada: Pelly Bay (September 2000-02), Cumberland Sound (June-August 1997-2006), Foxe Basin (July-August 1994-2007) and Repulse Bay (September 1995-2005). The sex-ratio was significantly different from 1:1 in Disko Bay (76% females), but this was not the case in the remaining areas. The authors also reviewed available field observations and historical whaling records in the region, which provided further evidence of segregation. They concluded that Baffin Bay is mainly used by adult males and resting/pregnant females, whereas the Prince Regent, Gulf of Boothia, Foxe Basin and northwestern Hudson Bay areas are used by nursing females, calves and sub-adults. The Committee noted that the available information is consistent with some form of structured movement, but that this movement is still not well understood.

There was considerable discussion of these papers and their strengths and weaknesses in their ability to distinguish among stock structure hypotheses as can be seen in Annex F, item 4.2. Some members of the Committee interpreted the seasonal movements and resighting patterns between the two areas to mean that there is a single stock whilst others believed that these movements and the observed shallow population structure between some areas are still consistent with the two-stock hypothesis. The Committee **agrees** that the degree of population structure requires further work with additional molecular markers (nuclear loci) before a final conclusion can be reached and it also **recognises** the importance of the successful satellite tracking study. It **encourages** the continuation of work on structure in order to allow it to conduct a more in-depth analysis next year.

The Committee also received two papers on abundance (Annex F, item 4.2.2). SC/62/BRG28 reported the results of an aerial survey of the late-summer concentration of bowhead whales in Isabella Bay, Nunavut, Canada in September 2009. The resulting abundance of 1,105 (95% CI: 532-2,294) was corrected for whales that were submerged during the passage of the survey plane, but not for whales missed by the observers because >90% of the sightings were detected by both platforms.

SC/62/BRG34 summarised a preliminary evaluation of the potential to use photographs and capture-recapture analyses to estimate the size of the Eastern Canada-West Greenland stock(s) of bowhead whales. The large and often remote summer range of these animals makes it difficult to obtain an aerial survey estimate of abundance. On the other hand, photographic surveys benefit from mixing among the separate sampling areas and have been successfully used to estimate abundance of the B-C-B stock of bowhead whales. The authors proposed that photographic surveys be directed at areas of known summer aggregations. Photography methods and analyses for the proposed surveys would follow methods used for the 2004 B-C-B bowhead population estimate (Koski *et al.*, 2009), which has been accepted by the IWC. The Committee **welcomes** these papers and looks forward to further analyses at next year's meeting.

9.1.2 Review recent catch information

SC/62/BRG27 reported that two female and one male bowhead whales were taken in April-May 2009 and three females in April-May 2010 for subsistence purposes in Disko Bay, West Greenland (no whales were struck in 2008 and no whales were struck and lost in 2009 and 2010). In light of the uncertainties surrounding eastern Arctic bowhead stock structure and abundance, the Committee **requests** the Secretariat to contact Canada to try to obtain data on Canadian catches.

9.1.3 Management advice

In 2007, the Commission agreed to a quota for 2008 to 2012 of two bowhead whales struck annually off West Greenland but the quota for each year shall only become operative when the Commission has received advice from the Committee that the strikes are unlikely to endanger the stock. In 2008, the Committee was pleased to have developed an agreed approach for determining interim management advice (IWC, 2009c), that is valid for two five-year blocks. The Committee again **agrees** that the current catch limit for Greenland will not harm the stock (noting that this applies whichever stock structure hypothesis prevails)**.** It was also aware that catches from the same stock have been taken by a non-member nation, Canada. It **agrees,** as in previous years, that should Canadian catches continue at a similar level as in recent years, this would not change the Committee's advice with respect to the strike limits agreed for West Greenland.

The Committee reviewed the catch limits in Table 4 of the Report of 'Proposed consensus decision to improve the conservation of whales from the Chair and Vice-Chair of the Commission' (IWC/62/7rev). For Eastern Canada/West Greenland bowhead whales, the Greenland strike limit is 2 per year (plus a carryover provision of two unused strikes from the previous year). The Committee **agrees** that the strike limits for Eastern Canada/West Greenland bowhead whales that are listed in table 4 of IWC/62/7rev are in accord with its advice, recognising that the normal regular review is also intended as part of IWC/62/7rev. However, the Committee notes that Canada may allow for regular catches from this stock. If the size of Canadian catches increases then the Committee's advice may change in that the total number of removals may exceed the safe limit determined by the agreed approach. If the Canadian catch increases, then the Committee wishes to draw attention to the fact that the total number taken from the stock may be greater than what is safe. Given the importance of this issue, the Committee **recommends** that the Secretariat should contact Canada requesting information about catch limits for bowhead whales.

9.2 Eastern North Pacific gray whales

9.2.1 Summary of previous season's catch data

A total of 115 gray whales (58 males, 57 females) was harvested in Chukotkan waters in 2009 and 1 was lost. A total of 6 of the 115 individuals were considered as unfit for consumption in 2009 (samples were taken from all 6). Biological sampling was conducted on 61 gray whales.

9.2.2 Management advice

As noted under Item 8.2, the Committee **agrees** that it has completed the *Implementation Review* but that a new *Implementation Review* should take place next year. In this context, the Committee **agrees** that its position with respect to the provision of management advice was unchanged from last year, i.e. the *Gray Whale SLA* remains the appropriate tool to provide management advice for eastern North Pacific gray whales. This remains the case, at least until the 2011 *Implementation Review* is completed.

In line with the values in table 4 of the proposed consensus decision (IWC/62/7rev), the Secretariat ran the *SLA* using the updated information on catches and abundance agreed at this meeting. This confirmed that an annual strike limit of 145 animals will not harm the stock (note that 145 is the maximum catch that can be taken in any one year; the annual average catch is 129 whales). The additional five whales added to the annual maximum in any one year from that previously considered (140) was intended to account for 'stinky' whales (IWC/62/7rev). In providing its advice, the Committee **draws attention** to the need for a new *Implementation Review* next year with a focus on PCFG whales. It was noted that although the table included strike limits for 10 years, the proposed consensus decision envisages the usual periodic reviews of strike limits for indigenous whaling.

Borodin commented that the annual strike limit should include the actual number of struck-and-lost whales and 'stinky' whales (e.g. in 2009 the numbers were 1 and 6, respectively). If hunting is on large whales then the number of struck-and-lost whales will be higher. Within that context, he noted that the annual strike limit should not exceed 150 whales (the number included in the *Gray Whale SLA* trials for the early period of catches during the development process).

9.3 Bering-Chukchi-Beaufort (B-C-B) Seas stock of bowhead whales

9.3.1 Review catch information and new scientific information

The Committee was pleased to receive two papers dealing with broad-scale aerial surveys from the northeastern Chukchi (SC/62/BRG13) and Alaskan Beaufort (SC/62/BRG14) Seas respectively. Details can be found in Annex F, item 4.1.1.

SC/62/BRG13 presented preliminary analyses of broad-scale aerial surveys for large whales in the northeastern Chukchi Sea that were conducted in 2008 and 2009, and compared these with results from similar surveys conducted in that region from 1982-91. The distribution of bowhead whale sightings during the light ice years of the early period (1982, 1986, 1989 and 1990) was similar to the distribution of bowhead sightings during 2008-09. There did not appear to be any major shifts in cetacean distribution between the early and late surveys although there were unexpectedly no gray whale sightings in the offshore shoal areas during 2008-09. In general, it was noted that analysing cetacean distribution in relation to environmental factors like sea-ice was complicated with this data set because the timing of the surveys was not consistent between years.

SC/62/BRG14 presented a similar preliminary study for the Alaskan Beaufort Sea, using data from the Bowhead Whale Aerial Survey Project (BWASP) in 2000-09, with comparisons to historical data. Bowhead distribution was similar in 2000-09 compared with the observed distribution from earlier years with light ice cover.

The Committee **recommends** that these surveys continue on an annual basis in the future in light of their capacity to monitor the effects of climate change and other factors (including anthropogenic activities) on cetacean distributions in the Beaufort Sea.

SC/62/BRG17 provided information about acoustic monitoring during attempts to count migrating bowhead whales near Point Barrow, Alaska in 2009 and to test new acoustic equipment. Results demonstrated the efficacy of a new seafloor array procedure and indicate that it can be used in the future as the method for obtaining acoustic data for the bowhead census and population estimation process. The Committee **welcomes** this report and **encourages** the use of autonomous seafloor acoustic recorders when monitoring migrating bowhead whales.

The Committee also received information on summarised preliminary analyses on identifying yearling bowhead whales in aerial photographs (SC/62/BRG29) and recent efforts to estimate the population size of this stock of bowhead whales (Annex F, item 4.1.1). The Committee welcomed this new information and notes that a full survey effort is being planned again in 2011. In discussion, the importance of monitoring the tails of the distribution of migrating whales was noted in the light of information from this year's migration.

9.3.2 Management advice

SC/62/BRG18 provided information on the 2009 Alaskan hunt. A total of 38 bowhead whales were struck resulting in 31 animals landed). Challenging sea ice conditions and weather contributed to a poor spring hunt. Of the landed whales, 12 were males, 18 were females, while sex was not determined for one animal. Hunters mistakenly harvested two female calves (lengths of 6.2m and 6.6m) in the autumn thinking they were small independent whales. Autumn calves are close in body length to yearlings and it is difficult to determine their status when swimming alone. Other details are given in Annex F, item 4.1.2. It was reported that there were no catches of bowhead whales by Russia this year.

The Committee **reaffirms** its advice from last year that the *Bowhead SLA* remains the most appropriate tool for providing management advice for this harvest. The results from the *SLA* show that the present strike limits are acceptable.

The next *Implementation Review* for B-C-B bowhead whales is scheduled in 2012. The purpose of the *Implementation Review* is to evaluate new information which has become available since the last *Implementation Review* and assess whether the current state is outside the realm of plausibility covered by the *Implementation* trials. If so, it may be necessary to conduct further trials incorporating such information. Therefore, the Committee **encourages** researchers to present relevant papers and new information for consideration during next year's meeting, so that preparations for the next *Implementation Review* can proceed efficiently.

The Committee reviewed the catch limits in table 4 of 'Proposed consensus decision to improve the conservation of whales from the Chair and Vice-Chair of the Commission' (IWC/62/7rev). For B-C-B bowhead whales, the maximum strike limit is 67 per year (plus a carryover provision of 15 unused strikes from the previous year) for total landed of 560 (580 written in footnote 8 is a typo). The Committee **agrees** that the strike limits for B-C-B bowhead whales listed in table 4 are in accord with the management advice provided by the *Bowhead SLA*, noting that the normal regular review is also intended.

9.4 Common minke whale stocks off Greenland (AWMP)

9.4.1 West Greenland

9.4.1.1 SUMMARY OF PREVIOUS SEASON'S CATCH

In the 2009 season, 153 minke whales were landed in West Greenland and 11 were struck and lost. Of the landed whales, there were 105 females, 47 males, and one whale of unreported sex. Genetic samples were collected for 97 of the 153 minke whales landed in 2009.

9.4.1.2 MANAGEMENT ADVICE

In 2007, the Commission agreed that the number of common minke whales struck from this stock shall not exceed 200 in each of the years 2008-12, except that up to 15 strikes can be carried forward. Prior to last year, the Committee has never been able to provide satisfactory management advice for this stock. Last year, the Committee was for the first time able to provide management advice for this stock. It had adopted a new abundance estimate and agreed method for providing interim management advice. Such advice can be used for up to two five-year blocks whilst *SLAs* are being developed (IWC, 2009c). Based on the application of the agreed approach, and the lower 5th percentile for the 2007 estimate of abundance (i.e. 8,918), the Committee **repeats its advice** of last year that an annual strike limit of 178 will not harm the stock.

9.4.2 East Greenland

9.4.2.1 SUMMARY OF PREVIOUS SEASON'S CATCH DATA

Three males and one female common minke whale were struck (and landed) off East Greenland in 2009 (no animals were struck and lost; see SC/62/ProgRepDenmark). Genetic samples were obtained from two of these whales. Catches of minke whales off East Greenland are believed to come from the much larger Central stock of minke whales.

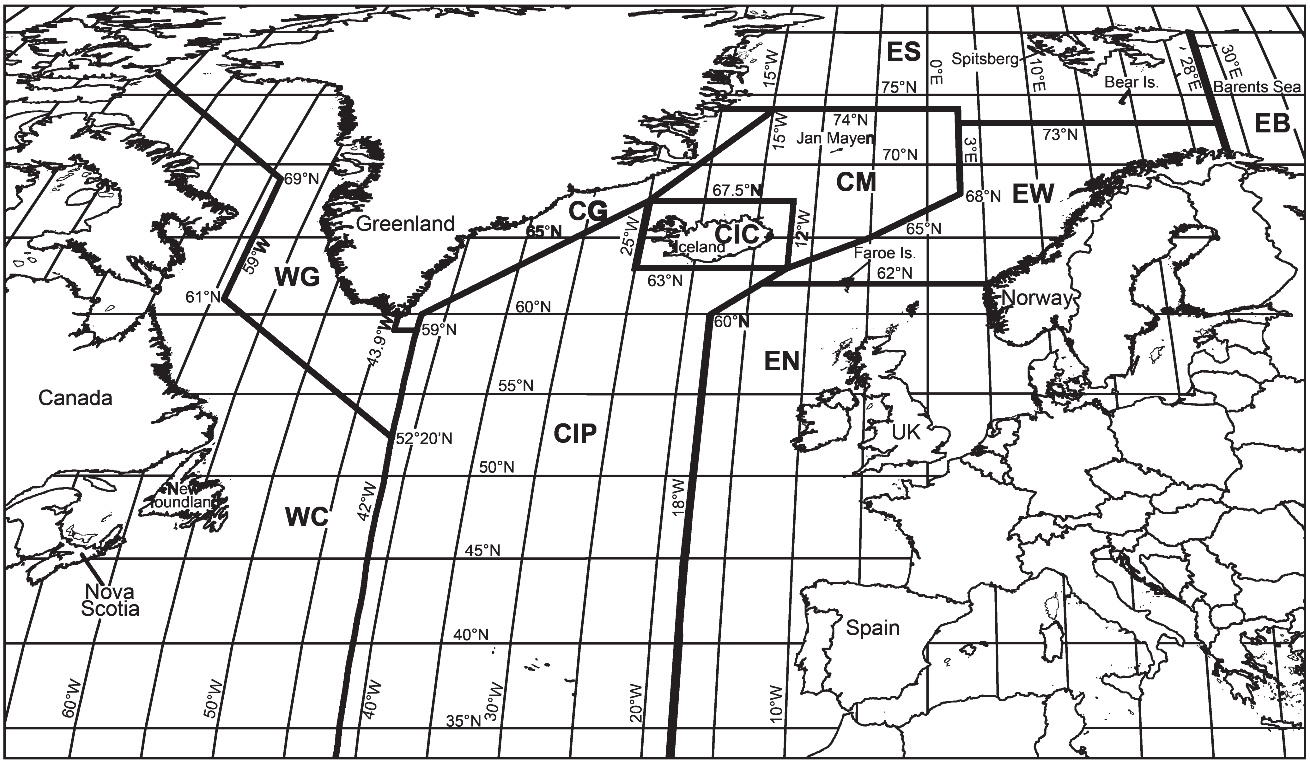

Fig. 2. The specifications for the Small Areas for the North Atlantic minke whales.

Table 3

Most recent abundance estimates for minke whales in the Central North Atlantic.

Small Area(s)	Year(s)	Abundance and CV
CM	2005	26,739 (CV=0.39)
CIC	2007	10,680 (CV=0.29)
CG	2007	1,048 (CV=0.60)
CIP	2007	1,350 (CV=0.38)

9.4.2.2 MANAGEMENT ADVICE

In 2007, the Commission agreed to an annual strike limit of 12 minke whales from the stock off East Greenland for 2008-12, which the Committee stated was acceptable in 2007. The present strike limit represents a very small proportion of the Central Stock (see Fig. 2 and Table 3). The Committee **agrees** that the present strike limit will not harm the stock.

9.5 Fin whales off West Greenland

9.5.1 Summary of previous season's catch data

A total of 8 (1 male; 7 females) fin whales were landed, and 2 struck and lost, in West Greenland during 2009 (SC/62/ProgRepDenmark). Genetic samples were collected for 5 of the 8 fin whales harvested during 2009.

9.5.2 Management advice

In 2007, the Commission agreed to a strike limit (for the years 2008-12) of 19 fin whales struck off West Greenland. The Committee agreed an approach for providing interim management advice in 2008 and this was confirmed by the Commission. It had agreed that such advice could be used for up to two five-year blocks whilst *SLA*s were being developed (IWC, 2009c). Based on the application of the agreed approach in 2008 (IWC, 2009c), the Committee **agrees** that an annual strike limit of 19 whales will not harm the stock.

9.6 Humpback whales off West Greenland

In 2007, the Committee agreed an approach for providing interim management advice and this was confirmed by the Commission. It had agreed that such advice could be used for up to two five year blocks whilst *SLA*s were being developed (IWC, 2009c). Using this approach, as last year, the Committee **agrees** that an annual strike limit of 10 whales will not harm the stock.

9.7 Humpback whales off St Vincent and The Grenadines

9.7.1 Summary of previous season's catch data

The Committee was advised that three females (lengths 34', 34'3" and 43'2") were taken during 2010. Neither genetic samples nor photographs were available for these animals. The Committee has encouraged St Vincent and The Grenadines to submit as much information as possible about any catches to the Committee via an Annual Progress Report.

The Committee **strongly recommends** collection of genetic samples for any harvested animals as well as fluke photographs, and submission of these to appropriate catalogues and collections. In respect of genetic samples, the Committee again **agrees** that the North Atlantic Whale Archive maintained by Per Palsbøll is an appropriate facility.

9.7.2 Management advice

In recent years, the Committee has agreed that the animals found off St Vincent and The Grenadines are part of the large West Indies breeding population. The Commission adopted a total block catch limit of 20 for the period 2008-12. The Committee **agrees** that this block catch limit will not harm the stock.

10. WHALE STOCKS

10.1 Antarctic minke whales (IA)

The Committee is currently continuing an in-depth assessment of the Antarctic minke whale. To complete this assessment, agreed abundance estimates from CPII and CPIII[3] are needed. Two different abundance estimation methods have been developed during the last few years, and although they give quite different point estimates, both are consistent in that they show an appreciable decline from CPII to CPIII. During the JARPA review in 2009, the quality of the Japanese ageing methods was questioned with implications for the catch-at-age analyses. During the present meeting, the priority topics discussed included: the two abundance estimation methods; the reasons for the differences between CPII and CPIII; age reading and the catch-at-age assessment models.

10.1.1 Produce agreed abundance estimates of Antarctic minke whales using IDCR/SOWER data

Skaug reported on work conducted by the Abundance Estimation Intersessional Working Group. Tasks to be considered by the group were directed towards elucidating possible causes for the difference in abundance estimates for Antarctic minke whales from the IDCR/SOWER data from the recent OK (Okamura and Kitakado, 2009) and SPLINTR (Bravington and Hedley, 2009) models. In completing most of these tasks, substantial progress had been made towards this in two regards: (i) development of a reference dataset for model comparisons; and (ii) Bravington had completed a non-spatial version of the SPLINTR model. For (i), a number of internal inconsistencies in the 'standardised' dataset were identified; as noted in IWC (2010f), it is essential that when comparing models, the data are identical. Since the purpose of this dataset is to allow appropriate comparisons between the models, the Committee **agrees** that this dataset is suitable for this purpose.

SC/62/IA14 provided results from applying the IWC 'standard' method (Branch, 2006), and the OK and SPLINTR models to simulated data, focussing on the latter two. In general, both models performed well, although when bias did occur, it tended to be positive for the OK model and negative for SPLINTR. The Committee thanked Palka for co-ordinating this extensive study. The simulated datasets have proved valuable in helping to develop and refine the models and for examining the differences between them. No simulated scenarios show the level of difference between the OK and SPLINTR estimates that the real data analyses reveal. This suggests either that the magnitudes of factors currently in the simulations do not cover the ranges found in the real data (either singly or in combination), or that there are additional factors not currently in the simulations that are important for modelling the real data.

During the pre-meeting and using the reference dataset, the OK and non-spatial SPLINTR outputs were compared. Estimated mean school sizes, effective strip half-widths, and encounter rates were combined using the simple line transect formula for estimating abundance. The resulting examination revealed that: (1) these estimated quantities from each model were being combined correctly to estimate abundance; (2) the effective strip half-widths for OK were about half of those of SPLINTR (i.e. the estimated abundances were approximately doubled, highlighting a need for further investigation); and (3) that the difference between the two models was not due to the data used and was probably not due to differences in mean school size. The Committee questioned whether sufficient progress had been made to determine whether further investigation was likely to determine the reason for the difference between the models. It **agrees** that if the Work Plan, including an intersessional workshop, is accomplished, there is a reasonable chance that this will be the case. It therefore **agrees** to proceed with these investigations until the 2011 Annual Meeting. The Committee also **agrees** a number of technical points related to this intersessional work (Annex G, item 5.1.8).

However, contingency plans (e.g. producing model-averaged estimates of abundance) will also need to be considered if it does not prove possible to resolve the difference in the estimates. Skaug compared estimates from OK, SPLINTR and a model-averaged estimate on the simulated data and found that the model-averaged estimator had smaller bias than either of the two individual models. There was some discussion on the appropriateness of using model-averaged estimates on the real data. However, as noted above, given the progress made this year, it is anticipated that the best outcome would be a resolution of the issue as a result of the intersessional work.

SC/62/IA3 and SC/62/IA12 presented the following 'survey-once' estimates (see Branch and Butterworth, 2001b) of abundance for the CPII and CPIII surveys from the OK and SPLINTR models respectively, as summarised in Table 4.

The Committee thanked both sets of authors for producing estimates and for the substantial amount of intersessional work, much of it collaborative. As last year, the issue is not that either set of diagnostics suggests not accepting the estimates, but rather that the estimates themselves are so different. This leads to the need to consider three – not necessarily unrelated – issues for next year: (1) pursuing the work to explain the differences; (2) the implications, if any, for future surveys; and (3) the procedural question of what the Committee should do if (1) does not succeed. As part of IWC/62/7rev, the Committee is expected to undertake an RMP *Implementation* for Antarctic minke whales in 2015 (and see Item 20). There is thus a pressing need for agreed absolute abundance estimates for the past surveys and an agreed method for analysing data from future surveys.

The Committee **strongly recommends** that the work plan and timeline set out in Annex G, Appendix 3 to finalise estimates be followed and completed. A workshop, to be held by February 2011 at the latest (see Item 21), is an essential component of this.

10.1.2 Conduct an analysis of aging errors that could be used in catch-at-age analyses

Lockyer presented the results of the Antarctic minke whale ageing exercise (SC/62/IA11) which she had carried out intersessionally following the 'blind' experimental design agreed by the Scientific Committee (IWC, 2009e, p.209). The study was assisted by staff from the laboratory at the Tokyo University of Marine Science and Technology, under the supervision of Kitakado. This had involved reading 250 earplugs from 1974/75-2005/06, i.e. including both Antarctic commercial and JARPA samples. The primary aim of the work was to determine whether evidence exists of a drift in reader performance, and, if so, to quantify it. A secondary aim was to quantify age-reading error variability.

The Committee thanks Lockyer and the Japanese graduate students who had assisted her, and for the professional manner in which they conducted the experiment. It also

---

[3] CPII and CPIII refer to the second and third set of IWC cruises, referring to 1985/86-1990/91 and 1991/92-2003/04, respectively.

Table 4

Comparison of 'survey-once' estimates of abundance, by Management Area, from the OK and SPLINTR models. Estimates shown have been extracted from the papers SC/62/IA3 and SC/62/IA12 and rounded, with CVs incorporating additional variance given in parentheses.

	Area I	Area II	Area III	Area IV	Area V	Area VI	Total
CPII							
OK	209,000	261,000	187,000	104,000	635,000	90,000	1,486,000
	(0.35)	(0.38)	(0.42)	(0.37)	(0.29)	(0.39)	(0.17)
SPLINTR	117,000	141,000	87,000	61,000	282,000	59,000	747,000
	(0.38)	(0.39)	(0.55)	(0.36)	(0.34)	(0.40)	(0.19)
CPIII							
OK	65,000	93,000	126,000	79,000	244,000	105,000	712,000
	(0.34)	(0.37)	(0.33)	(0.45)	(0.33)	(0.34)	(0.17)
SPLINTR	35,000	56,000	59,000	36,000	140,000	57,000	382,000
	(0.33)	(0.35)	(0.31)	(0.33)	(0.31)	(0.33)	(0.17)

endorses the recommendation by Lockyer that a standard reference set of minke earplugs be maintained for age-reading training purposes.

SC/62/IA2 explored the impact of period/reader on age-determination by comparing age-estimates for the above 250 earplugs for the control reader (Lockyer) and three Japanese readers (Masaki, Kato and Zenitani). Overall, the results demonstrated that the Japanese readers and the control reader differed in terms of both expected age given true age and variance in age-estimates. The results also suggested that the expected age and random uncertainty in age-estimates differed among the Japanese readers although the differences were not severe. This work will assist in determining how catch-at-age data are used in the statistical catch-at-age analyses and in future virtual population analyses.

The Committee **welcomes** this study as an important advance. It was noted that: (a) Lockyer tended to report greater ages than the Japanese readers; (b) differences amongst the Japanese readers were slight; and (c) that there was no indication of a trend in bias in Japanese readings over the period examined (i.e. from commercial whaling to special permit whaling). It was also noted that SC/62/IA11 does not provide any information about the accuracy of the age readings in absolute terms, given the absence of known-aged individuals. The absence of known-aged individuals is also the general norm for fish populations although for a number of these there are indications that layers were formed seasonally. Similarly, studies of fin whales, as well as corpora counts and information from animals with known histories, all indicate that the growth layers groups used to estimate whale ages are laid down annually.

In conclusion, the Committee **agrees** that no further experiments or analyses on age reading errors are needed to resolve ageing related problems raised in e.g. the JARPA review.

The Committee also **recommends** that, where they do not already, national or other guidelines for dealing with stranded animals include encouragement to obtain samples which could provide information on the animal's age.

10.1.3 Continue development of the catch-at-age models

SC/62/IA6 examined the impact of allowing for ageing error based on the analyses of the above (Item 10.1.2) age-reading experiment when conducting assessments for Antarctic minke whales in Areas III-E, IV, V and V-W using statistical catch-at-age analysis by means of sensitivity tests. These sensitivity tests explored three scenarios: (a) no ageing error; (b) ageing error is modelled as in previous base-models; and (c) ageing error is based on the results from SC/62/IA2. Time-trajectories of total (1+) population size and recruitment were qualitatively the same, irrespective of how age-reading error was modelled.

In discussion, it was noted that while estimates from recent years of recruitment and abundance for the three different assessments were close, absolute values showed relatively large differences until the 1960s, and estimation variance would be expected to be much higher over this period.

Though the Committee **agrees** that no further experiments or analyses on age reading errors are necessary. This decision did not, however, imply that other issues associated with the data and analyses, such as reasons for the different length distributions at age for younger-aged commercial and JARPA, had been resolved.

Completion of the work on investigation of catch-at-age based assessments requires undertaking the tasks as detailed in Annex G, item 5.2.4. These investigations will require an extension of permission from Japan for use of their Antarctic minke whale catch-at-age data, and would be improved if data from the most recent JARPA cruises could also be made available. The Committee **recommends** that such an approach be made to Japan under Procedure B of the DAA. Kato indicated that corpora count data were available, and that these data would be provided if necessary. An intersessional steering group under Punt was established to co-ordinate this work (see Annex Q).

10.1.4 Continue to examine the difference between abundance estimates from CPII and CPIII

Estimates from the OK, SPLINTR and standard methods (Branch, 2006) were consistent in that they showed a decline from CPII to CPIII. Conclusions reached about the reasons for these changes should integrate information from other sources such as changes in ice coverage during the survey periods concerned. Until recently, there was little quantitative information on the number of Antarctic minke whales that might be present within the pack ice. This year the Committee was pleased to receive several papers reporting on, and analysing data from, surveys of whales within the pack-ice.

SC/62/IA4 investigated trends of sea ice in the period of IWC IDCR/SOWER circumpolar surveys from CPI to CPIII (1978-2004). The sea ice trends are fundamental information to understand the year-to-year sea ice variability. The authors concluded that the difference in abundance estimates between the CPII and CPIII surveys can be partly explained by the change in the amount of open sea areas within the sea ice field. The Committee **agrees** that further region-specific investigation is necessary to examine the extent of the role changes in sea ice may play in examining the change in abundance estimates between CPII and CPIII. In this context the Committee received a progress report from the intersessional working group established to examine this issue (SC/62/IA5). The authors have made progress importing satellite sea ice data from Area II into a GIS database but the work is not expected to be completed until the next Annual Meeting. The Committee **recommends** that every effort be made to complete this important work on time. Although the exact nature of any models relating minke whales densities in open water to those in the ice was not discussed, it is important to continue investigation of the relationships between whale density and ice characteristics.

This requires investigation of at least: (1) the relationship between whale density and days after sea-ice melt; and (2) the relationship between estimates of abundance and sea ice characteristics. The Committee **agrees** the detailed plan for this work given in Annex G, item 5.1.8. Bravington, Murase, Kitakado and Kelly will co-operate in this work.

This year, the Committee was pleased to receive reports (SC/62/IA8 and SC/62/O15) from two aerial survey programmes: the Australian East Antarctic programme (which co-ordinated in 2009/10 with the SOWER survey) using a fixed wing plane; and the German programme surveying the area in the Weddell Sea from a helicopter launched from the ice breaker vessel, the *Polarstern* (which was also used as a Platform of Opportunity for cetacean sightings). These programmes represent some of the first attempts to gather quantitative data to estimate densities of minke whales in the pack ice. Preliminary analyses from each programme can be found in SC/62/IA9 and SC/62/IA13.

The Committee **welcomes** this work and a full discussion can be found in Annex G, item 5.1.6.2. It thanked the governments of Australia, Germany and the Netherlands for supporting this research. It also was **pleased** to see the successful collaboration (both in collection of data, and in regular communications and data exchanges) between the Australian programme and the SOWER survey.

10.2 Southern Hemisphere humpback whales

The report of the Committee on the assessment of Southern Hemisphere humpback whales is given in Annex H. This assessment has been on the agenda of the Scientific Committee since 1992. The Committee currently recognises seven breeding stocks (BS) in the Southern Hemisphere (labelled A to G - IWC, 1998b), which are connected to feeding grounds in the Antarctic (Fig. 3). Preliminary population modelling of these stocks was initiated in 2000 (IWC, 2001g) and in 2006 (IWC, 2007a), the Scientific Committee completed the assessment of BSA (eastern South America), BSD (western Australia) and BSG (western South America). The assessment of BSC was completed in 2009 (IWC, 2010g). Since then, the completion of the assessment of BSB (western Africa) has been considered a priority by the Committee (IWC, 2010g, p.234).

10.2.1 Breeding Stock B

10.2.1.1 DISTRIBUTION

The Committee received several papers addressing the distribution, new records or habitat use of humpback whales along the central and northern Atlantic coast of Africa (Bamy *et al.*, 2010; Carvalho *et al.*, In review; Picanço *et al.*, 2009; Weir, 2010).

10.2.1.2 POPULATION STRUCTURE

It has been hypothesised that there may be two humpback whale sub-stocks in the eastern South Atlantic (IWC, In press). Breeding sub-stock B1 winters along the central West African coast and around the northern islands of the Gulf of Guinea and sub-stock B2 has been observed off the west coast of South Africa (WSA), in an area which appears to serve as a feeding site or possibly a migratory corridor. The breeding site of sub-stock B2 is unknown. A boundary between these two sub-stocks has been tentatively placed in the vicinity of 18°S (IWC, In press), see Fig. 4. At this meeting, the Committee further evaluated the evidence for BSB substructure, in light of new information.

SC/62/SH30 presented three stock structure hypotheses that were used in the assessment models. These hypotheses included: (1) a single, fully-mixed stock; (2) two breeding stocks that mix only on the feeding grounds and (3) two breeding stocks with partial migratory overlap along the west coast of Africa. SC/62/SH8 described temporal population structure in humpback whales on the west coast of Africa using maternally (mitochondrial DNA control region) and bi-parentally (10 microsatellites) inherited markers. Results showed significant genetic differentiation, low gene flow and

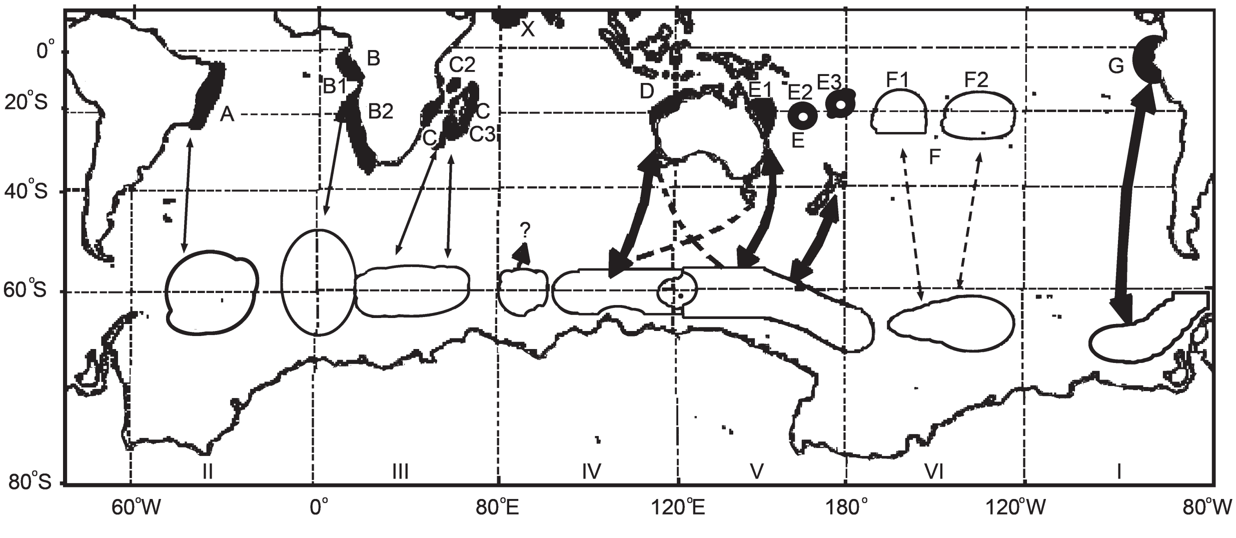

Fig. 3. Southern Hemisphere humpback whales, breeding stocks and feeding grounds (IWC, in press).

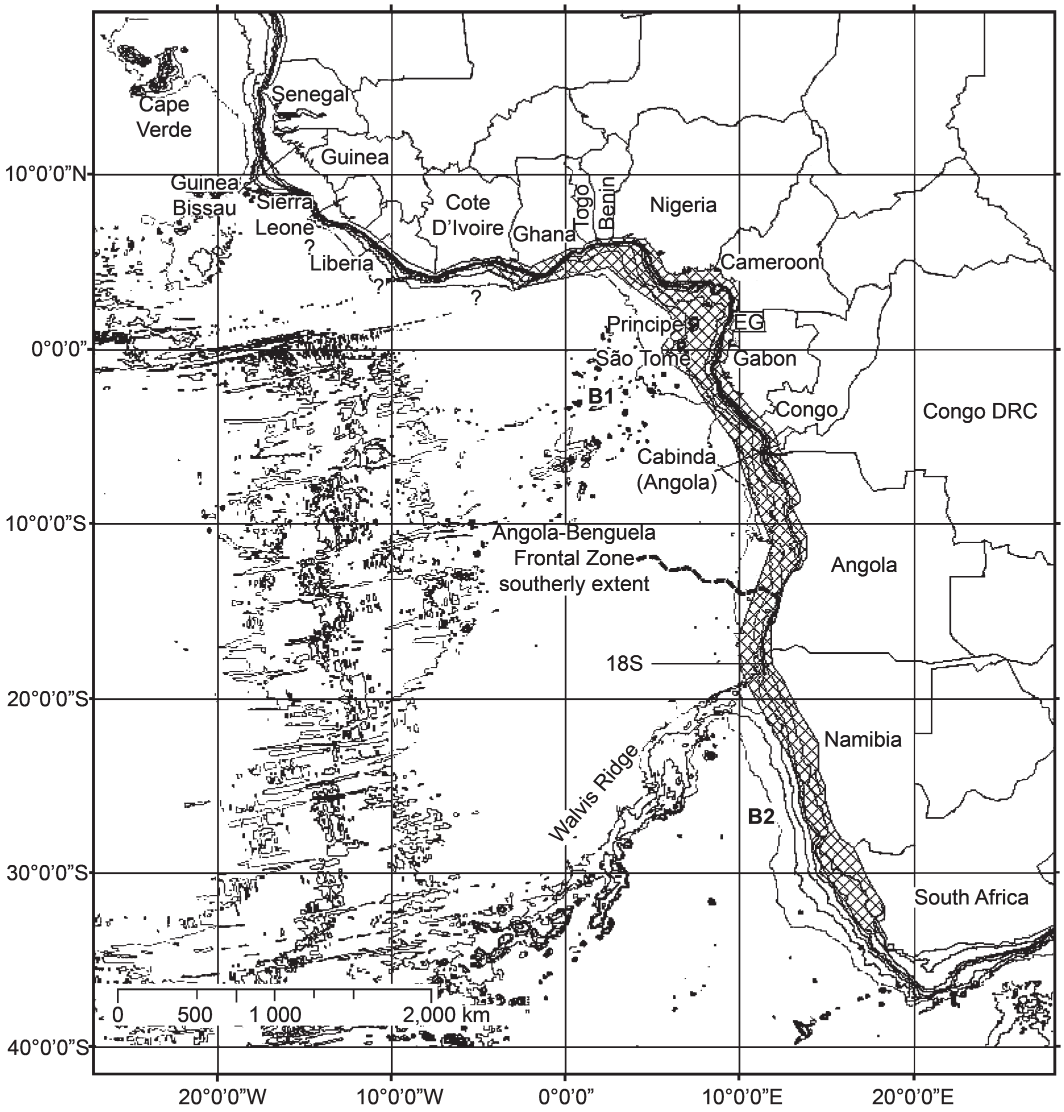

Fig. 4. Distribution of humpback whales in west Africa. The boundary between B1 and B2 has been proposed to be near 18°S (IWC, in press).

seasonal differences between WSA and Gabon. Movements of genetically identified individuals, both males and females, indicate that interchange occurs between these two region, with all movements to date being from north to south.

SC/62/SH15 examined humpback whale genetic structure in the Antarctic and evidence of connectivity to breeding grounds using biopsy samples collected during the 2006/2007 SOWER cruises. An updated analysis of the mitochondrial DNA (mtDNA) data presented in this paper was received during the meeting. Population structure was evaluated for the feeding grounds associated with BSB and BSC, under the catch allocation Hypotheses 1 and 2 developed by the Committee last year (Findlay *et al.*, 2010, fig.1). Under Allocation Hypothesis 1, Gabon was found to be significantly different from the Nucleus feeding areas of both BSB (10°W to 10°E) and BSC (30°E to 60°E). For Allocation Hypothesis 2, samples from Gabon were found to differ significantly from the BSB Nucleus (10°W to 10°E) and BSB/BSC Margin (10°E to 40°E). WSA was significantly different from BSB and BSC Nucleus, as well as the BSB/C margin area. Feeding grounds of BSB and Margin of B/C were found to be significantly different from the Nucleus area associated with BSC under Allocation Hypothesis 1. No significant differentiation was found across feeding areas under Allocation Hypothesis 2.

An analysis of mtDNA on feeding grounds (10°W-10°E) by latitudinal gradient revealed that no significant difference between Gabon and samples collected north of 60°S. WSA differed from samples obtained both north and south of 60°S on the basis of F_{ST} but significance was only found for samples obtained north of 60°S. These results were interpreted as indicative of some type of latitudinal variation in the distribution of whales from BSB in the Antarctic.

The Committee welcomed the genetic studies described above; this research is relevant to the assessments of Southern Hemisphere humpback whale stocks. The Committee **recommends** that a mixed stock analysis be performed to better inform stock structure assumptions and to increase the available data for population dynamics modelling.

The Committee also considered new photo-id matching results relevant to the stock structure of BSB. SC/62/SH10 presented preliminary results of photographic matching between Gabon, WSA and Antarctic Areas II and III. A total of three matches were found between Gabon and WSA. SC/62/

SH31 reported no matches resulted from the comparison of a photo-id catalogue from WSA and another from the south coast of east South Africa and southern Mozambique (BSC1). It was noted that a substantial number of images held by Oceans and Coast (the South African governmental agency from BSC1) have not been compared to WSA. In this regards, the Committee **recommends** comparisons of the WSA fluke photographs to the Oceans and Coast catalogue and **requests** that the relevant photographs and associated information be made available.

Barendse *et al.* (2010) described the results of shore-based observations on humpback whales off Saldanha Bay, WSA. This area was presumed to be a migration corridor for whales from the postulated BSB2 breeding sub-stock. The authors concluded that the area off WSA is not strictly a migration corridor, but also a primary or supplementary feeding ground. Discussion of this paper is given in Annex H, item 2.1.2.

SC/62/SH5 reviewed the catch history, seasonal and temporal trends in availability and the migrations of humpback whales along the west coast of southern Africa. After the initial decline in availability in all areas pre World War I, the catch history in Gabon differed markedly from those in the three southern grounds, especially off South Africa. This suggests some degree of stock sub-structure within BSB. A hypothesis of a single breeding ground (in the Gulf of Guinea) but separate, maternally-directed migratory routes to and from different feeding grounds was proposed.

The Committee concluded that the following points were relevant to the development of stock structure hypotheses based on its extensive review of information:

(1) there is probably more than one genetically distinct humpback whale population in the eastern South Atlantic;
(2) Gabon is a breeding ground and WSA exhibits characteristics of both a feeding ground and a migratory corridor;
(3) at least some of the animals sampled at Gabon migrate to the Antarctic to feed and that migration may follow an inshore route (via WSA), an offshore route or both (if the latter individual migrants maintain fidelity to a particular route or maintain alternate routes);
(4) some of the whales that breed at Gabon may maintain maternal feeding site fidelity to west South Africa, such that they do not migrate to the Antarctic; and
(5) individuals observed at WSA may migrate to an unidentified breeding site that is distinct from Gabon (if so, some fraction of those individuals may pass by Gabon, *en route* to that breeding site) or the breeding ground of these individuals may lie between Gabon and WSA.

In light of the new information presented above, the Committee indentified new stock structure hypotheses and progressed with exploratory population dynamics model runs. Results of these analyses are presented under Item 10.2.1.4 below. A minority statement in relation to item (5) above is found in Annex H, item 2.1.2.

10.2.1.3 ABUNDANCE ESTIMATES

The Committee received two papers with abundance estimates based on capture-recapture data. SC/62/SH2 reported on within-region photo identification and genotypic matching for WSA. Resightings between six different time-periods and five different datasets (three from photo-id data, one from microsatellite data and one combined) resulted in estimates of abundance ranging from 223 (CV=0.35) to 939 (CV=0.38) individuals. SC/62/SH11 presented estimates of abundance for humpback whales in Gabon for the period 2001-06 using photographic and genotypic data. While the estimates themselves provided in this paper were not discussed, the capture-recapture data were used in preliminary assessment models presented at the meeting (SC/62/SH30). Details of these papers and the data therein are presented under item 2.1.3 in Annex H.

10.2.1.4 POPULATION ASSESSMENT

After initial discussion of the assessment models in SC/62/SH30, the Committee developed additional stock structure hypotheses on the basis of the new information presented in Item 10.2.1.2. Additional model runs were then undertaken to inform the Committee about possible implications of various stock structure hypotheses and input data selection for population model outputs. Preliminary results suggested that the assessment model parameter estimates were relatively robust across the proposed stock structure hypotheses and input data for sub-stock B1 (Gabon). However, the population trajectories varied widely for sub-stock B2 (WSA). Based on these results, the Committee concludes that additional modelling was required and **agrees** upon a suite of stock structure hypothesis that would probably be used in the assessment of BSB (Annex H, item 2.1.4). The Committee selected three priority hypotheses that it **recommends** should be used in further population assessment (Fig. 5).

The Committee also discussed model input data and possible sensitivity analysis when evaluating the results of the stock assessment models (details in Annex H, item 2.1.4). Input data included allocation of breeding and feeding ground catches, values for minimum past population sizes (N_{min}), type of capture-recapture data (photo-id, genotype), proportions of whales migrating to breeding and feeding grounds, and rate of struck and lost whales. The Committee **agrees** to a selection of input data to be used as the reference cases and sensitivity scenarios in the population dynamic models, as presented in Table 5.

The Committee **agrees** that considerable progress was made during the meeting. However, there was insufficient time to complete the assessment of BSB. In this regard, the Committee notes that last year it had agreed to complete the assessment of BSB as a single stock if an assessment at the sub-stock level was not possible. However, in light of the new information brought forward this year, the Committee **agrees** that a considerably more robust assessment could be finalised if additional work was conducted intersessionally. The Committee **agrees** that the completion of the assessment of BSB by 2011 is a matter of the highest priority for the sub-committee on other Southern Hemisphere humpback whales. It **strongly recommends** that the strict work plan outlined in Table 6 be followed to facilitate completion at next year's meeting. Regular progress on these tasks will be monitored and reported by Zerbini to an intersessional group (Annex Q). The Committee **recommends** a pre-meeting to the Annual Meeting to ensure the timely completion of this work.

The modelling required to complete the assessment has financial implications for the Committee and this is discussed under Item 24.

The Committee **agrees** that it will conclude the assessment of BSB humpback whales at next year's meeting. Therefore, the Committee **recommends** that assessments of BSE and BSF humpback whales should be initiated and a progress report be presented at SC/63. An intersessional e-mail group was established under Jackson to assemble all the relevant

Table 5

Input data reference cases and sensitivities selected for use in population modelling for the assessment of BSB.

Data category	Population	Reference case	Sensitivity analysis
Capture-recapture	Gabon	Microsatellites, males-only* (see note below)	Flukes; microsatellites (both sexes)
Capture-recapture	WSA	Microsatellites* (see note below)	Right dorsal fin; flukes
Minimum past population	Gabon	$N_{min} = 68$	None
Minimum past population	WSA	$N_{min} = 24$	None
Catch allocation (north of 40°S)	Gabon	Congo and 50% Angola	Congo and Angola; Congo only
Catch allocation (north of 40°S)	WSA	50% Angola, Namibia and WSA	Namibia and WSA; Angola, Namibia and WSA
Catch allocation (south of 40°S)	Gabon	Allocation Hypothesis 1 developed last year	None
Catch allocation (south of 40°S)	WSA	Allocation Hypothesis 1 developed last year	None
Migration to unknown breeding ground	Gabon	25%	None
Migration to Antarctic	WSA	50%	100%; 0% (does not migrate)
Struck and loss rate	Both	0.15 (as presented in SC/62/O2)	0

*Microsatellite data will only be used as a reference case for capture-recapture data if genotyping errors can be incorporated into assessment models. Otherwise flukes will be used.

Table 6

Intersessional tasks to finalise the assessment of BSB humpback whales.

Task	Responsible persons	Final deadlines: Circulation to group for consideration	Final deadlines: Decision regarding use in model
Work on data inputs to model and possible refinements to stock hypotheses			
Inspection of mark-recapture data within and between Gabon and WSA for consideration in stock structure hypothesis refinement.	Barendse and Collins	15/12/10	31/01/11
Investigate and update estimates of potential and realized error in genetic and photo-identification data.	Carvalho, Collins, Rosenbaum, Cerchio	15/12/10	31/01/11
Re-analyse mark-recapture data from WSA using multi-year Program MARK (or equivalent) models to examine the effects of heterogeneity (for fluke data), tag loss (for dorsal fin data) and genotype error on abundance estimates, and assess the most appropriate data on interchange.	Barendse, Cerchio, Best	15/12/10	31/01/11
Conduct feeding-breeding ground mixed-stock analysis in order to estimate stock mixing proportions between Gabon and WSA and the Antarctic in order to further refine stock structure hypotheses for assessments.	Rosenbaum, Carvalho, Loo	15/12/10	31/01/11
Examine catch data for incorporation in population models, which should be sex-disaggregated, if possible.	Best and Butterworth	15/12/10	31/01/11
Comparison of WSA catalogue to South African government Oceans and Coast Catalogue (advantageous but not critical).	Barendse, Findlay and Meyeo	01/12/10	31/01/11
Modelling work			
Development of assessment models consistent with stock structure hypotheses selected by the Committee. Highest priority is for the models in Annex H, table 2. To the extent time permits variants of these models will be considered as sensitivities (Annex H, table 3).	Butterworth, Muller, Johnston	Some initial runs for highest priority stock hypotheses	Final runs for at least highest priority stock hypotheses
The assessment models should use the input data identified as the reference cases and sensitivities in table 2 above. Data output should include the posterior median and the 90% probability interval for the year for which the abundance prior corresponds.		15/01/10	One week before pre-meeting
Present results for at least highest priority hypotheses.			

data needed for these assessments. The assessment of BSD humpback whales (western Australia) had been completed at the SC meeting in 2005 (IWC, In press), but because of extensive mixing in the feeding grounds with other stocks (e.g. BSE) this stock might needed to be re-assessed along with BSE and BSF. The intersessional group will also consider the inclusion of BSD humpback whales in the assessments of the two other stocks.

The Committee **agrees** that a new item will be added to its agenda to consider new information on the Arabian Sea humpback whale population.

10.2.2 Review new information on other breeding stocks

10.2.2.1 BREEDING STOCK A

The Committee welcomed two papers with new information relevant to BSA. SC/62/SH27 reported a photographic match of a female humpback whale between Abrolhos Bank, Brazil (BSA) and the east coast of Madagascar (BSC3), which represents a new mammalian distance record. SC/62/SH28 presented a new line-transect abundance estimate of 9,330 whales (95% CI=7,185-13,214; %CV=16.13) for the coast of Brazil in 2008. This stock appears to be undergoing a steady growth, but further studies are necessary to reduce uncertainties associated with *g*(0) estimation and other potential sources of bias. Further details are described in Annex H, item 2.2.1.

10.2.2.2 BREEDING STOCK D

Two papers provided information relevant to Breeding Stock D. These are summarised below, with additional details provided in Annex H, item 2.2.2. SC/62/SH21 reported on the deployment of 23 satellite tags on southward migrating whales off Kimberley coast, northwestern Australia. In total, 263 days of location data tracked whales over a total distance of nearly 20,000km. This work has provided the most detailed movement data off northwestern Australia to date and revealed an unexpected 1,200km movement from the coast into the Indian Ocean.

SC/62/SH24 described an unusual peak in recorded mortalities (n=47) of humpback whales in Western Australia

Model Ia	Model IIa	Model III
		Model description: model assumes two independent breeding sub-stocks which can mix on Antarctic feeding grounds. Whales from breeding sub-stock B1 feed in the Antarctic and migrate to Gabon for breeding. Whales from breeding sub-stock B2 feed off WSA and migrate along the West African coast through Gabon to a separate unidentified breeding ground. Additionally, some portion of B2 animals migrate to Antarctic feeding grounds. Variants on this model were not considered priority for the assessment of BSB.	*Model description:* model assumes two breeding sub-stocks, B1 and B2. B1 has two migratory components, B1E and B1W. Whales from B1W migrate from Antarctic feeding grounds directly to Gabon while whales from B1E migrate through waters off west South Africa before continuing on to the Gabon breeding grounds. Whales from sub-stock B2 feed primarily off WSA, do not migrate past Gabon and migrate to a separate unidentified breeding area. In addition, some portion of animals from sub-stock B2 migrates to Antarctic feeding grounds. Variants on this model were not considered priority for the assessment of BSB.	*Model description:* model assumes a single breeding stock, B1, with two migratory components B1W and B1E. B1W migrates directly to Gabon from Antarctic feeding grounds while B1E migrates through waters off west South Africa before continuing on to the Gabon breeding grounds. The proportion of animals using each migratory route may change over time.

Fig. 5. Stock structure hypotheses selected as priority for use in the BSB assessment.

in 2009. Only a few mortalities have been reported per year in previous decades. The authors hypothesised that this event could represent:

(1) an artefact of searching effort and coastal oceanography;
(2) a temporary increase in mortality rates; or
(3) the start of an increasing trend in mortality.

They considered the latter two hypotheses to be the most plausible, but noted that additional research would be required to discriminate between them. The Committee noted the importance of continued stranding monitoring to clarify the cause of such unusual events.

10.2.2.3 BREEDING STOCKS E AND F

The Committee welcomed papers on Breeding Stocks E and F and noted these will be relevant for the forthcoming assessment of these stocks. Two papers provided new information on the distribution and habitat use of humpback whales along the east coast of Australia (BSE1).

SC/62/SH21 described results from 13 satellite tags from northward migrating humpback whales off Evans Head, eastern Australia. In total, 371 days of location data tracked whales for nearly 21,000km. The results represent the first detailed movement data of this species in their proposed calving area around the southern Great Barrier Reef.

SC/62/SH25 described the first on-water photo-id study of humpback whales in the Great Barrier Reef Marine Park Cairns/Cooktown Management Area. Thirty percent of the 28 groups observed contained young calves, indicating that this may be an important nursery area for BSE1. Seven individuals were matched to sightings in other areas of east Australia in previous years. Group size, composition, distribution and behaviour were also discussed. Further work is planned and data are available for collaborative research.

Three papers provided new information on the population structure and dynamics of BSE and BSF. SC/61/SH14 presented annual realised growth rates and survival of post-yearling BSE1 humpback whales off New South Wales, Australia (1994-2009). Several caveats were noted and suggestions for further analysis of these data are described in Annex H, item 2.2.2.

SC/62/SH7 reported on a large collaborative comparison of microsatellite genotypes from the migratory corridor along eastern Australia (n=734), the South Pacific Islands (n=1,086) and Antarctic feeding Areas I-VI (n=175). Breeding ground interchange was detected between Eastern Australia-New Caledonia (n=11) and Eastern Australia-Tonga (n=1). The only matches made to feeding grounds were between Eastern Australia and Antarctic Area V (n=3), despite larger sample sizes from Areas IV and VI. The authors concluded that breeding sub-stocks may be mixing on both their breeding and feeding grounds.

They also highlighted the feasibility of this type of collaborative research for studying migratory interchange on a large-scale. SC/62/SH18 reported photographic and genotypic mark-recapture estimates of abundance for humpback whales breeding at the South Pacific Islands (BSE2, BSE3 and BSF) for the period 1999-2003 and concluded that total combined abundance for these breeding stocks likely lies between 2,361 and 3,520 whales. No significant trend in abundance for this population was detected.

Additional details on the discussion of papers on BSE and BSF can be found in Annex H, item 2.2.3.

10.2.2.4 BREEDING STOCK X (ARABIAN SEA POPULATION)

The Committee received two papers with new information on the status of breeding stock (BSX). It had been given this name at a 2006 workshop on Southern Hemisphere humpback whales (IWC, In press). The population is believed to be resident to the Arabian Sea, is currently estimated at 82 individuals (95% CI=60-111) (Minton *et al.*, In press) and recently listed by the IUCN as endangered (Minton *et al.*, 2008). The Committee **agrees** to henceforth call this the Arabian Sea population.

SC/62/SH6 reported on the genetic distinctiveness and current population status of the Arabian Sea population. Genetic analyses based on 11 microsatellite markers and mtDNA sequences revealed significant differentiation between whales sampled off the coast of Oman (n=67), relative to the North Pacific and four Southern Hemisphere regions. Estimated levels of differentiation are among the highest recorded for humpback whale populations worldwide.

It is very unlikely that there is currently any exchange between the Arabian Sea and the Southern Indian Ocean stocks. Tests of population expansion suggest that the population has not yet started recovering and may still be in decline. SC/62/SH20 discussed the anthropogenic threats facing this population and challenges faced in monitoring this endangered population. Baleen whales in this region are potentially vulnerable to impacts from fishing, coastal development, shipping and noise and impacts. At least one live humpback whale entanglement in a gillnet is known to have occurred during the period 2007 and 2009. Research effort has been severely limited in recent years.

The Committee thanked the authors for this new information, noting its **great concern** over the status of this population. The Committee **strongly recommends** the continuation of research on humpback whales in the Arabian Sea in light of the small population size and escalating threats (see also Annex J, item 9.3). It further recognised the difficulty of undertaking such studies for small populations in remote areas.

The Committee also makes the following **recommendations** (in order of priority) for this population:

(1) studies that enable identification and quantification of threats to the Arabian Sea population should be initiated, including an in-depth investigation into the impact of bycatch;

(2) studies and surveys in Oman should be continued and expanded in scope to include more detailed genetic, acoustic and behavioural studies, as well as satellite telemetry studies;

(3) surveys should be encouraged in additional locations in confirmed range countries (Kuwait, India, Iran, Iraq, Oman, Pakistan, Sri Lanka, United Arab Emirates, Yemen), with particular focus on those countries with large coastal regions, such as Pakistan and India - in this regard, abundance surveys should be repeated on a regular basis in order to enable determination of population abundance and trend;

(4) further investigation into humpback whale occurrence in suspected/potential range countries (Bahrain, Maldives, Qatar, Saudi Arabia) should also be conducted; and

(5) studies and surveys to determine the population identity of whales in the Seychelles Exclusive Economic Zone should be performed.

The Committee further noted that given that this is a small population with known anthropogenic threats, it may well benefit from the development of a conservation management plan, following the model for western gray whales described under Item 10.4 and based upon Donovan *et al.* (2008). The Committee **agrees** that this should be explored further, perhaps within the context of conservation management plans being discussed by the IWC Conservation Committee

Further discussion of the Arabian Sea population is found in Annex H, item 2.2.4

10.2.2.5 FEEDING GROUNDS

SC/62/SH3 described a pilot study of cetacean distribution off Adélie Land that was launched by the French Polar Institute (IPEV) as part of the Southern Ocean Research Partnership (SORP). One photo-id match supported a migratory link between BSE and Area V. The Committee **recommends** the continuation of this programme, noting its relevance and utility for the forthcoming assessments of BSE and BSF.

SC/62/O12 presented a preliminary report of a joint Australian-New Zealand Antarctic Whale Expedition. Thirty humpback whales were satellite tagged on the Southern Ocean feeding grounds, and over 60 biopsy skin samples and approximately 60 individual fluke photographs were also collected. The Committee welcomed this research, which will make an important contribution to forthcoming assessments, and **recommends** its continuation. It also **recommends** that photo-id, biopsy sampling and satellite tagging research be conducted in other poorly surveyed areas of the Southern Hemisphere. The Committee **appreciates** the data sharing that has occurred post-expedition; this has been very productive with respect to matches identified with the East Australian breeding region and it **recommends** the continuation of such open collaborations. Finally, the Committee further **recommends** that long-term studies of humpback whales be undertaken and continued in the Southern Hemisphere.

SC/62/SH19 reported molecular genetic species identification of 281 whale bones collected between 2006 and 2007 in South Georgia. The prominence of humpback, fin and blue whale bones correspond to the early catch record in this area. Historical and contemporary humpback whale mtDNA haplotype diversity will be compared to measure the extent of the 'exploitation bottleneck' of stocks around South Georgia. The Committee **welcomes** this work and strongly **encourages** the continuation of bone collection for 'historical' DNA analysis. It further noted that this research will be important for the comparison of historic and current population abundance and diversity.

10.2.2.6 PRELIMINARY MULTI-STOCK ASSESSMENT

SC/62/SH33 reported preliminary results from the development of a population model that aimed to include all seven Southern Hemisphere humpback whale breeding stocks in a single joint assessment, with the purpose of allowing high-latitude historic catches to be allocated to breeding stocks in proportion to abundance, rather than on set ratios. The Committee **encourages** the further development of this model and the presentation of results in future meetings.

10.2.3 Antarctic Humpback Whale Catalogue

SC/62/SH17 described the progress of the Antarctic Humpback Whale Catalogue (AHWC). A total of 899 photographs of 721 individuals were catalogued from Antarctic and Southern Hemisphere waters for the interim period. Images were submitted by 21 individuals and research organisations. These submissions bring the total number of catalogued whales identified by fluke, right dorsal fin/flank and left dorsal fin/flank photographs to 3,665, 413 and 407, respectively. New inter-area matches were as follows: BSG-Antarctic Peninsula (19), BSG-Chile (3), BSA and BSC3 (1; see SC/62/SH27) and BSE-Antarctic Peninsula (2; see Robbins *et al.*, 2008). Re-sightings were also made at the Antarctic Peninsula (3) and within BSG (11). Progress continues to encourage contributions from researchers and eco-tourism. A new on-line catalogue using Flickr is in development and can be viewed at *http://www.flickr.com/ahwc*. The Committee noted the importance of this IWC-supported work and **recommends** its continuation.

10.3 Southern Hemisphere blue whales

In 2002, the Committee recommended that the assessment of blue whales be started in 2005, after the completion of the IDCR/SOWER review (IWC, 2003a, p.41). In 2008, the Scientific Committee completed a circumpolar assessment of Antarctic blue whales (IWC, 2009f) and recommended that area-specific analysis be examined to evaluate whether separate assessments can be done for each IWC Management Area (IWC, 2009f). The Committee also recommended gathering data relevant for the assessment of non-Antarctic (pygmy-type) blue whales. Detailed discussions from this year can be found in Annex H, item 3.

10.3.1 New information

The Committee welcomed new abundance estimates of blue whales off Chile. A new analysis of line transect data collected as part of the 1997/98 SOWER cruise off Chile (Williams *et al.*, 2009b) resulted in an estimate of 303 individuals (95% CI=217-455). Aerial line transect surveys conducted off Isla Chiloé in 2007, 2009 and 2010 resulted in estimates of 97 (CV=0.51), 154 (CV=0.32) and 163 (CV=0.39) individuals, respectively. Further details of these surveys are presented in Annex H, item 3.1.

At last year's meeting, the Committee noted that available line transect estimates probably do not represent the total size of the population(s) present and recommended other approaches be used to estimate blue whale abundance. Progress was reported on the Alfaguara Project's field season off Isla de Chiloe (southern Chile), and particularly its continuing blue whale photo-id research. A preliminary mark-recapture abundance estimate was also presented for pygmy blue whales at the Perth Canyon, Western Australia. Further description of that on-going work is provided in Annex H.

The Committee **recommends** that new or revised estimates of abundance be provided to next year's meeting; specifically from Chile (Galletti and Hucke-Gaete). For Western Australia (Perth Canyon) the level of research necessary to improve the mark recapture data (which is currently very sparse in recaptures) for updated abundance estimates is unlikely to be affordable in the coming year. The Committee also **recommends** that the intersessional e-mail group under Bannister continues to work toward providing new estimates of mark-recapture abundance of blue whales and to report new information at next year's meeting.

The Committee was informed of progress on the development of a cooperative Southern Hemisphere blue whale photo-identification catalogue (SHBWC). Nine groups have joined the SHBWC, including researchers in Chile, the Eastern Tropical Pacific, Australia, Sri Lanka, and Antarctica. Photo-id data from the Japanese Institute for Cetacean Research (ICR) Whale Research Program under special permit in the Antarctic (JARPA 1987/88-2004/05 seasons) has also been submitted to the IWC Secretariat and will be added to the SHBWC through the appropriate data availability channels. The Committee **welcomes** the update on the work of the SHBWC and **recommends** its continuation. It **recommends** that the photographs from the ICR catalogue should be compared to those already held at the Southwest Fisheries Science Center.

SC/62/SH29 reported on archiving and matching of blue whale photographs collected by the IDCR/SOWER cruises between 1987/88 and 2008/09. Over 23,000 photographs were obtained from all six IWC Management Areas, with 219 individual whales identified. Results suggest some degree of residency within a summer feeding season.

The Committee **recommends** that work on the Southern Hemisphere Blue Whale Catalogue (SHBWC) be continued. Over the next two years this will require completion of the matching from the three regions. Budget implications are given under Item 24.

SC/62/SH21 reported on satellite tagging of pygmy blue whales off southwestern Australia. Three tags were deployed (two males, one female) and the whales were tracked for over 8,000km. The tag with greatest longevity (137 days) provided definitive evidence of a link between whales that feed offshore of the Perth Canyon and those that occur around eastern Indonesia, such as the Banda Sea where reports of blue whales appear to be increasing.

The Committee welcomed a number of studies on blue whale acoustics. SC/62/SH26 described the migratory patterns and estimated population sizes of pygmy blue whales traversing the Western Australian coast. An analysis of passive acoustic data estimated that 662-1,559 pygmy blue whales passed the sampling instrument during the 2004 southbound migration. The Committee noted that the acoustic approach to estimating population size reported here represents an important theoretical development, but noted that a number of assumptions of this method needed to be explored in more detail before it could be considered to produce robust estimates of abundance. The Committee also encouraged the continuation of this work.

Gedamke and Robinson (2010) reported the results of an acoustic survey for whales and seals in eastern Antarctic waters (30-80°E) between January and February 2006. Blue whales were the most commonly recorded species identified. They were detected in large concentrations where relatively extensive sea ice remained off the continental shelf and the more eastern waters off the Prydz Bay region. Two detections of pygmy blue whales represent the most southerly recordings of these species.

SC/62/SH13 described results from passive acoustic monitoring for the presence of baleen whales off the coast of Northern Angola, off the Congo River outflow. A series of pygmy blue whale calls were detected by two marine autonomous recording units deployed between March and December 2008, 15km and 24km offshore. This represents the first confirmed modern documentation of this sub-species in Southeast Atlantic waters north of 60^{o}S since the cessation of commercial whaling for blue whales in the region. The calls were of the type attributed to the Sri Lanka population of pygmy blue whales, and not previously recorded outside of the Indian Ocean. Antarctic blue whale calls were not detected. The recording of Sri Lanka pygmy blue whale calls in the Atlantic Ocean was considered to be of great interest.

Progress was reported on a genetic study of Antarctic blue whales, which has been carried out with access to 218 IDCR/SOWER biopsy samples provided by the IWC. More than half of the haplotypes detected thus far have not previously been described. Analysis of the samples is ongoing and the results will be used to estimate the minimum historical population abundance of the Antarctic blue whale. The Committee welcomed this work and **recommends** its continuation. It was observed that this study expands on the haplotype data originally reported by LeDuc *et al.* (2007); the additional haplotypes reported here likely originated from IWC Management Areas II and III (Donovan, 1991), which were under-sampled in the previous study.

The Committee welcomed information on an upcoming study of the global taxonomy of blue whales using mitogenomic and nuclear sequence data. This work aims to conduct a comprehensive genetic assessment of blue whale taxonomy using next-generation sequencing methods to sequence whole mitogenomes and a large number of nuclear regions, for phylogenetic analysis. The project will particularly focus on determining the sub-specific status of blue whales in the North Pacific. The Committee **strongly encourages** continued collaborative efforts to acquire blue whale samples globally, and welcomed further updates on the results of the study

Four blue whale genetic projects are currently in progress: (1) genetics of blue whales in Geographe Bay, Western Australia, as part of a southern Australian study (11 samples collected, 11 analysed and archived, Möller, see SC/62/ProgRepAustralia); (2) a genetic population structure study of blue whales in the southeast and Eastern Tropical Pacific regions (Flores-Torres); (3) a global taxonomy study of blue whales (Lang); and (4) a genetic analysis of the diversity of IDCR/SOWER Antarctic blue whale biopsy samples and South Georgia whalebones (Sremba). The Committee **encourages** continuation of this research and **recommends** that results from these studies be reported when they become available.

10.4 Western North Pacific gray whales (BRG)

10.4.1 New scientific information

Considerable information was presented, and this is discussed in Annex F, item 6.1. Only a brief summary of that work is given here.

In SC/62/BRG11, data generated using a panel of 13 microsatellite loci were combined with updated information from mtDNA control region sequences to further assess the population structure of gray whales in the North Pacific. The results are consistent with the possibility that there may be some dispersal between two populations but that observed genetic differentiation is supportive of two populations.

SC/62/BRG10 presented the results of a paternity analysis conducted on the western gray whale population. The results suggest that some males that contribute to reproduction in this population may not regularly use the primary Sakhalin feeding ground. This highlights the need to collect genetic samples from animals recorded in other areas of the western gray whale's range. The results also provide evidence of interbreeding among animals that show fidelity to the Sakhalin feeding ground.

SC/62/BRG5 presents the first analysis of genetic (mtDNA) data obtained from the gray whales migrating along the Japanese coast (n=6) and incorporated comparison of these with a sample of animals from the Chukotkan hunt in 2008 (n=7). In summary, while recognising the small sample size: (a) all of the mtDNA haplotypes found had been previously reported; (b) the level of genetic diversity within samples was surprisingly high; (c) no genetic heterogeneity in haplotype frequencies was detected between the two samples; and (d) phylogenetic analysis of the haplotypes detected no distinct cluster for the Japanese whales.

The Committee **welcomes** these analyses. It **encourages** the collection of more samples from areas outside Sakhalin feeding ground when they are available and **recommends** a more detailed analysis of samples currently available and a number of suggestions are given in Annex F, item 6.1.

The Committee also received a number of papers on distribution and abundance. A number of points of interest were raised by these papers including:

(1) the potential for western gray whales to reoccupy parts of their former range if the currently small population expands (SC/62/BRG3);
(2) significant annual variation in whale densities among years within the Piltun and offshore feeding areas (SC/62/BRG4);
(3) updated information on an industry-sponsored monitoring programme using photo-id included the movement of animals between Sakhalin and Kamchatka and mother-calf pairs in Olga Bay, Kamchatka (SC/62/BRG9);
(4) updated information from the 2009 collaborative Russia-U.S. research programme (SC/62/BRG6);
(5) comparison of age at sexual maturity in western and eastern gray whales suggesting that the range 6-12 yrs is appropriate for both populations although further data would be welcome (SC/62/BRG2); and
(6) updated information on research and conservation in Japan including information on skeletal studies and an educational programme for fishermen (SC/62/O7).

The Committee **welcomes** all of the new information on this critically endangered population. It **encourages** further work and as in previous years, re-emphasises the importance of continued long-term monitoring. The Committee **recommends** that, if the observed density of gray whales in the Piltun feeding area continues to decline or remains lower than in previous years, future studies should investigate whether this reflects natural variation (e.g. in prey availability), industrial disturbance or some other factors.

Donovan reported on progress with the telemetry programme on western gray whales that has been recommended by the Committee (e.g. see IWC, 2010c). He reported that the programme is progressing and that all involved are grateful to Ilyashenko and his colleagues at IPEE for their work to try to ensure that this project goes ahead, particularly at this stage with respect to the permit issue. An overall administrative and scientific structure has been agreed between the participating institutions and companies, the IWC and IUCN. The scientific steering group is continuing to work on finalising the protocols that will ensure that the IWC Scientific Committee safeguards and guidelines are met as it has been tasked by the Committee; the final protocols will be drawn up in co-operation with IPEE and OSU. IWC, IUCN and the funding companies are also working hard on difficult budgetary issues. It is hoped that it will be possible for the programme to take place this summer.

10.4.2 Conservation advice

The Committee again **recognises** that the problem of net entrapment of western gray whales is a range-wide issue. It **welcomes** the efforts of Japan to reduce mortality, including the educational programme, and notes that net entrapments could occur in other range states. Brownell summarised plans for seismic surveys off Sakhalin Island in 2010. There is concern that anthropogenic sound, especially from seismic surveys, will negatively affect western gray whales in their primary feeding area. Previously, the Commission expressed concern and passed resolutions on this topic. Two seismic surveys in or near the feeding area are planned for 2010. It was noted at the recent meeting of the IUCN Western Gray Whale Advisory Panel that the company (Rosneft) planning the later survey has not followed the same procedures in regard to monitoring and mitigation as the company planning the first survey (by Sakhalin Energy). As currently planned, the Rosneft survey will occur while the highest number of feeding gray whales, including cow and calves, are present. The Committee is **extremely concerned** about the potential impact on western gray whales and **strongly recommends** that Rosneft postpone their survey until at least June 2011 The Committee also **recommends** that Rosneft use monitoring and mitigation measures similar to those used by Sakhalin Energy (see Annex F, Appendix 4), which have been independently reviewed by experts, and that all energy companies operating in the feeding areas of western gray whales should use comprehensive monitoring and mitigation measures to protect western gray whales.

As in previous years, the Committee **acknowledges** the important work of the IUCN Western Gray Whale Advisory Panel (WGWAP). This year's update on the panel's activities is given in Appendix 4 of Annex F. Noting that the WGWAP's present contractual five year life span ends after December 2011, the Committee **re-emphasises** its view that its work is important and should be **continued** if at all possible, and the Committee **requests** the Secretariat to send a letter to IUCN in this regard.

In 2009, the Committee welcomed the report of the IUCN range wide workshop (IUCN, 2009). An important conclusion of that workshop was the need for the development of a conservation plan for western gray whales and this recommendation was endorsed by the Scientific Committee.

This year, the Committee was extremely pleased to receive the first draft of this important Plan (SC/62/BRG24). It **commends** the authors, who include scientists from range states as well as elsewhere, for this important document. The Plan follows the guidelines developed for such plans by Donovan *et al.* (2008) that were endorsed by the Committee (IWC, 2009a). Much of it is based on the report and recommendations of the IUCN rangewide workshop that have also been endorsed by this Committee. The Committee emphasised that the Plan should be supported and endorsed by many stakeholders, including national and local governments, industry, and non-governmental organisations, as well as international organisations such as IWC and IUCN. The overarching goal of the Plan is to reduce mortality related to anthropogenic activities to zero as quickly as possible. The Plan includes 11 focussed actions (related to co-ordination, public awareness, conservation research, monitoring and mitigation) of high importance for the conservation of this critically endangered population. The most immediate, in terms of ensuring the success of the Plan is the appointment of a Steering Committee and of finding funds for and appointing a full-time Co-ordinator. This is also critical to the need, identified by the authors, to engage broad stakeholder participation in the Plan as soon as possible.

The Committee **strongly endorses** this Plan and **commends** it to the Commission and range states. It also **recommends** that it is broadly distributed, including being posted on the IWC and IUCN websites. Consideration is being given to it being published by the *JCRM*. The Committee **recommends** the Plan as a model for the development of other conservation plans for cetacean populations.

10.5 Southern Hemisphere right whales

10.5.1 Australian and New Zealand areas

The Committee received a number of papers on southern right whales from these areas. Details can be found in Annex F, item 5.3. A number of points of interest from these are given below:

(1) genetic comparison of animals around the subantarctic Auckland Islands and the main islands of New Zealand provided documented evidence for the first time of the movement between the two regions and, along with other available data, is most consistent with either the one stock or the extirpation/recolonisation hypotheses (SC/62/BRG16);
(2) results from satellite telemetry provided data on migratory movements of three whales tagged at the Auckland Islands revealed that animals from this nursery area/breeding ground can move north to their feeding ground - the reverse of the generally accepted migratory pattern for southern right whales (SC/62/BRG19);
(3) information on acoustic contact calls from southern right whales near the Auckland Islands (SC/62/E13); and
(4) updated information on long-term aerial survey monitoring programme along the southern Australian coast results in an annual increase rate for cow/calf pairs of around 7.5% (95%CI 3.2, 12.0) for the period 1993-2009 and a minimum population size of 2,530, with a total Australian population of about 3,000.

Difficulties or complications experienced in obtaining permits for biopsy sampling of right whale calves were discussed. Although there were legitimate concerns over possible disturbance to mother-calf pairs, no adverse effect had been shown on subsequent calving interval in a study of the effects of biopsying over 100 cow-calf pairs off South Africa, although the statistical power was low (Best *et al.*, 2005). Given the potential value of such sampling, particularly in establishing issues of paternity the Committee **recommends** that permitting authorities should view requests for biopsy sampling of cow-calf pairs on their scientific merit and apply appropriate safeguards to limit the degree of disturbance where necessary.

10.5.2 South America area

The primary item discussed under this item was the report of a workshop (convened by Brownell) held at the Centro Nacional Patagónico (CENPAT) in Puerto Madryn, Argentina from 15-18 March 2010. The goal of the workshop was to investigate the causes of the high mortality of southern right whales around Península Valdés, Argentina. Participants included experts on the ecology and marine environment of the Península Valdés region, scientists studying right whales in the South Atlantic and international experts on whale strandings and mortality.

Small numbers of strandings have been recorded in the region since 1971. However, since 2003, when the Southern Right Whale Health Monitoring Program (SRWHMP) was established, a total of 366 right whale deaths have been recorded, with peaks in 2003 (31), 2005 (47), 2007 (83), 2008 (95) and 2009 (79). Over 90% of the deaths have been of first-year calves. After investigating thoroughly a range of possible causes for these first year deaths, the workshop agreed three leading hypotheses (it was not possible to determine which was most likely and some combination of factors may have occurred, at least in some years): (1) reduced food availability for adult females; (2) biotoxins; and (3) infectious disease.

The workshop recommended a number of steps to build a better understanding of the cause or causes as listed in Annex F, item 5.3.2.

Of these, continuation of the long-term aerial photo-id programme, other complementary monitoring effort and the SRWHMP are highest priority. The workshop agreed that cooperation and collaboration among research groups is essential for addressing complex questions concerning the die-offs. A western South Atlantic right whale consortium (the North Atlantic right whale consortium) could be used to establish and maintain links among researchers and to share information (this should also include researchers in different parts of the range). Efforts to improve such cooperation and collaboration should be a high priority for local and national governments, NGOs and INGOs.

It was also agreed that the absence of conclusive information regarding the cause(s) of exceptional right whale mortality should not preclude authorities from proceeding with some management measures, particularly in relation to kelp gulls, where gull lesions are clearly harmful to the whales, especially the calves.

The workshop also recognised: (1) the considerable efforts of the researchers in Argentina (and abroad) to investigate the die-offs in the face of fiscal and logistical constraints; and (2) the importance of governmental commitment to the long-term conservation of right whales in Argentina.

The Committee thanked Brownell for his presentation and **endorses** the workshop report. The Committee **welcomes** the announced intention of the Argentine authorities to introduce this year a pilot plan for the control of nuisance gulls.

As in previous years, the Committee **recognises** the value of the long-term photo-id programme of right whales at Península Valdés that had now lasted 40 years, particularly in being able to describe the significance of the recent die-off events and test certain causation hypotheses. It **strongly recommends** its continuation. It also noted that this year emergency funding had been provided by the US Marine Mammal Commission to enable the necropsy programme to take place and strongly **recommends** the continuation of this programme to investigate the reason(s) for the die-off.

The Committee also considered SC/62/BRG15, a preliminary assessment of the genetic structure of the southern right whales from Península Valdés, Argentina. A number of comments to assist in future analyses were raised in discussion (Annex F, item 5.3.2) and the Committee looks forward to an updated analysis next year.

The Committee was pleased to receive information on the 2009 flights of an aerial survey programme off Brazil and it **recommends** the continuation of the surveys.

10.5.3 South Africa area

The Committee was pleased to receive updated information on demographic parameters obtained from the long-term monitoring programme of South Africa (SC/62/BRG30). The results are discussed in Annex F, item 5.3.3 but key features include an annual growth rate of about 7% (95% CI 6.5%, 7.5%); a mean calving interval of about 3.2 years; and a population size in 2006 as about 4,100 animals. SC/62/BRG31 examined the possibility of changes in some demographic parameters for right whales off South Africa through the analysis of re-sighting data for females with calves over the 1979-2006 period. No statistically significant change in adult survival rate or population growth rate was found but a reduction in mean calving interval from 3.2 to 3.1 years was detected.

SC/62/BRG33 reported on the recent announcement of the intention to drill exploratory boreholes for natural gas in eight districts of the coastal region of the southwest coast of South Africa, three of which included nearshore waters that were home to the largest concentration of cow-calf pairs on the African coastline. About 75% of cow-calf pairs on the southern African coast occur in this region in spring, some of which are resident for up to three months, while the westward coastal movement seasonally means that an even larger proportion of the population almost certainly uses the region.

The Committee viewed this potential development with concern, noting the current lack of information available on the proposed activities. It **recommends** to the South African government that all permits issued for exploratory activities should contain mandatory mitigation measures to avoid disturbance to right whales, including confining all marine drilling activity to the season when right whales are absent (January to May). It also **recommends** that if gas production is ultimately planned for the region, the use of closed areas or the development of further mitigation measures such as directional drilling should be considered.

The Committee **endorses** a proposal for the establishment of a Southern Ocean Right Whale Photo-identification Catalogue (the Antarctic Humpback Whale Fluke catalogue). The intention is to provide a resource that could be consulted when researchers holding images taken in coastal waters wished to establish linkages with feeding grounds in pelagic waters (see Appendix 2 of Annex F for detail). It was confirmed in discussion that this would be supplementary to such coastal catalogues. The Committee looks forward to receiving a progress report at its next meeting. Funding is dealt with under Item 24.

10.5.4 Plans to review southern right whales

Brownell reported on progress in preparing for the Southern Right Whale Assessment Meeting, planned to be held at Puerto Madryn, Argentina, in September 2011. Given that this meeting would be held very shortly after next year's IWC meeting a budget would have to be prepared at this meeting (and reserved until 2011). A small group was set up to draw up the budget and draft the Terms of Reference for the meeting (see Annex F, Appendix 3). The Committee **agrees** that this should be funded next year.

10.5.5 Other

The Committee recognises the importance of long-term studies, to provide biological information from photo-id and information on trend and population size from sighting and mark-recapture analyses. It **strongly recommends** the continuation of such long-term studies in relevant areas.

10.6 Other stocks of right whales and small stock of bowhead whales

10.6.1 North Atlantic right whales

An update was provided on North Atlantic right whales for the period May-October 2009, as an addendum to information presented in Pettis (2009). The summary reflects the work of the North Atlantic Right Whale Consortium (NARWC). A shared photographic catalogue was used to produce a 'best' estimate of population size of 438 for 2008. This total did not explicitly account for unphotographed whales in the population and may change slightly as additional data are incorporated into the catalogue. One right whale death was documented during the report period, but the cause was not determined. Additionally, there were three new entanglement cases and eight previous entanglement cases that had not yet been resolved.

The Committee **agrees** that the documented growth in the catalogue plus successive years of improved calf production gave grounds for cautious optimism over the future status of this population. However, while welcoming the management measures that have been taken to date, the Committee **repeats its previous recommendations** on this population that it is **a matter of absolute urgency** that every effort be made to reduce anthropogenic mortality to zero.

10.6.2 North Pacific right whales

SC/62/BRG3 reviewed past sightings of North Pacific right whales off western Kamchatka from spring to autumn. A number of sightings of these whales were made during Japanese-led surveys from 1989 to 2003; these were mostly restricted to the southern portion of study area. However, there were also a few sightings in earlier years by Soviet scientists, including in the northern part of the area. These sightings also highlight the need for directed research and monitoring of right off western Kamchatka in areas overlapping with fishery and oil and gas development activities.

SC/62/NMP22 provided results of observations of North Pacific right whales during the common minke whale sighting and biopsy survey conducted in the Okhotsk Sea in summer 2009. The research area was set north of 46°N, south of 57°N and west of 152°E in the Okhotsk Sea including the Russian EEZ. 17 schools (29 animals) of North Pacific right whales were found, mainly in the offshore waters deeper than 200m. Of these, 16 schools were targeted for photo-id research and 22 animals in 15 schools were individually identified (there are no re-sightings among them).

The Committee welcomes the sighting and photo-id information from these cruises and **encourages** continuing these studies in the area.

Wade *et al.* (2010) used photographic and genotype data to calculate the first mark-recapture estimates of abundance for right whales in the Bering Sea and Aleutian Islands. The estimated abundance data reveal this to be an extremely small population of perhaps around 30 animals. The results will be updated using more samples and images from another survey planned in the eastern North Pacific this year and the Committee looks forward to receiving this information.

Noting the extremely small size of this population, and also the potential for disturbance and ship-strike mortality from greatly increased ship traffic resulting from the likely opening of the northeast or northwest Passages due to sea ice retreat, the Committee considers it **a matter of absolute urgency** that further research be conducted on eastern North Pacific right whales, and **recommends** that this research focus on assessing status and identifying any current sources of anthropogenic mortality.

10.6.3 Small stocks of bowhead whales

SC/62/BRG3 summarised sightings of bowhead whales off western Kamchatka from existing published literature and other available sources. Okhotsk Sea bowhead whales were recorded only a few times in the study area during the spring-autumn period, with one sighting during winter; however it is known from historical whaling data that this species was abundant in the area, particularly in the northern regions during periods of open water.

SC/62/BRG20 reported the results of a survey for bowhead whales conducted in the Fram Strait during 29 March-14 April 2010. Two observations were made, but it was determined based on identifiable scars that both encounters were of the same individual.

Witting reported that 12 sighting of bowhead whales were made in the Northeast Water Polynia off Northeast Greenland during an aerial survey for walrus during August 2009. He also reported that a female with a calf was seen off Norske Island, Northeast Greenland in July 2009. In discussion, it was noted that two passive acoustic recorders were deployed in the Fram Straight during 2008-09 and that these instruments detected numerous bowhead sounds including songs.

The Committee welcomes the above information and **encourages** future updates and research.

10.7 Antarctic cruises

10.7.1 General review of 2009/10 cruise

The planning meeting for the 2009/10 IWC/SOWER cruise was held in Tokyo, Japan in September 2009 (SC/62/Rep6). The cruise took place in Area IV and had two main objectives: (1) to undertake a sightings survey in collaboration with an Australian Antarctic Division aerial survey; and (2) to continue research on the priority species (southern right, blue, fin, and humpback whales). The total number of minke whales sighted in the research area was 83 groups, comprising 152 animals; humpback whales were the most frequently sighted species (174 groups comprising 322 animals). Biopsy samples and individual identification photographs were taken from 21 and 45 humpback whales and 22 and 26 southern right whales, respectively. A total of 28 groups of southern right whales (38 animals) were sighted (SC/62/IA1).

The Committee thanks the Government of Japan for generously providing the vessel and crew for this survey, and also thanks the Cruise Leader for her efforts. Noting that this was the last IDCR/SOWER cruise, the Committee also extended its appreciation to all member nations and researchers who had contributed to this extensive programme, and particularly to the governments of Japan and the former Soviet Union, for providing the survey vessels. The data collected during the programme provide an unparalleled source of information on Antarctic cetaceans. The experience gained from these surveys will continue to be of use in planning future studies, in the Southern Ocean and elsewhere. The Committee **agrees** that a Special Issue of the *JCRM* on the IDCR/SOWER surveys is warranted and re-establishes the working group to progress this idea (see Annex Q).

10.7.2 Plans for cetacean sighting surveys in the Antarctic in the 2010/11 season

SC/62/O17 described a dedicated, systematic cetacean sighting survey which was being planned to take place from December 2010 to February 2011 in order to obtain estimates of abundance for use in the RMP. The research area will be south of 60ºS in Area V and the western part of Area VI (130ºE-145ºW), including the Ross Sea. This survey will be conducted in relation with the Japanese Whale Research Programme under special permit in the Antarctic (JARPA II). Two dedicated, sighting survey vessels, *Shonan-Maru No.2* and *Yushin-maru No.3*, will be used and the survey procedures will be based on the standard

SOWER search modes; closing (NSC) mode and passing with the independent observer (IO) mode.

In order to minimise difficulties associated with survey design, an intersessional Working Group was established under Matsuoka (Annex Q). The Committee **agrees** that Matsuoka is responsible for IWC oversight.

10.8 North Pacific cruises

10.8.1 Recommendations for 2010 cruise and short term objectives

During the last year's Scientific Committee meeting, Japan presented a proposal for a medium- to long-term research programme involving sighting surveys to provide information for cetacean stock management in the North Pacific. The Scientific Committee welcomed the initiative and agreed the value of a large-scale, medium-long term integrated research programme in the North Pacific and encouraged this in the context of international collaboration under IWC auspices.

A meeting to discuss the North Pacific survey programme was held in Japan in September, 2009 (SC/62/Rep3). The meeting agreed four terms of reference:

(1) review the Scientific Committee's issues in the North Pacific;
(2) review the past and ongoing survey activities and available data in range states;
(3) consider possible line transect survey plans and additional data collection (e.g. photo-id and biopsy) for the 2010 season; and
(4) prepare a proposal for an intersessional workshop (to be held between SC/62 and SC/63) on future surveys beyond 2011.

SC/62/IA15 was provided in response to the first term of reference from the meeting and provided a summary of the Scientific Committee issues relating to North Pacific sei, common minke, Bryde's, right and blue whales. The distributions of these whale species were described and requirements for further surveys, in order to estimate abundance and investigate stock structure, were considered.

SC/62/IA10 presented the research plan for an IWC/Japan whale sighting survey taking place in summer 2010. The plan had been drawn up following guidelines agreed at the North Pacific programme intersessional meeting. The research area (170°E-170°W) had been chosen because for some species it spans proposed stock boundaries and has been poorly covered by previous surveys, representing an important information gap for several large whale species. The cruise will collect line transect data to estimate abundance, and biopsy/photo-id data contributing to the work of the Scientific Committee on the management and conservation of populations of large whales in the North Pacific. It will provide:

(1) information for the proposed future in-depth assessment of sei whales in terms of both abundance and stock structure;
(2) information relevant to *Implementation Reviews* (e.g. common minke whales) in terms of both abundance and stock structure;
(3) baseline information on distribution and abundance for a poorly known area for several large whale species/populations, including those that were known to have been depleted in the past but whose status is unclear; and
(4) biopsy samples and photo-id photos to contribute to discussions of stock structure for several large whale species/populations, including those that were known to have been depleted in the past but whose status is unclear.

The cruise will last about 60 days (including transit time) between July and August. In order to adequately cover the longitudinal range, the latitudinal range is restricted between a southern boundary at 40°N and a northern boundary at the Aleutian Islands chain. Four researchers can be accommodated on this cruise; US and Korean scientists will participate. The cruise will follow the requirements for reports and documentation developed for cruises that could provide data for use under the RMP and will be the responsibility of the Japanese scientists.

The Committee thanked the Government of Japan for its generous offer of a vessel for this survey. Matsuoka was assigned responsibility for IWC oversight.

Brownell reported that a scientist from SWFSC had now been identified for the cruise, but major problems regarding CITES permits remain; these issues are similar to those described in SC/62/NPM22 that were encountered between Japan and Russia for the collection of minke whale biopsy samples in the Russian EEZ. There are CITES issues for both inside and outside the US EEZ, because samples collected outside the US EEZ have to enter US waters and then all samples must be exported to Japan. A possible solution (institutional permits) has been proposed to Japan and it is being considered. If these problems are not worked out, it will not be possible to collect any biopsy samples (inside or outside the US EEZ) during this cruise. This would be a major scientific loss to advancing our understanding of the stock structure of baleen whales in the North Pacific, specifically sei whales. The Committee **recognises** the importance of the CITES issue and agreed that it should be resolved among parties concerned expeditiously. The Committee **endorses** the working group's report, and **recommends** that the investigations regarding the use of Institutional permits to exchange biopsy samples proceed as soon as possible, with the results of the investigations being reported to the Planning Meeting scheduled for October 2010.

SC/62/O16 described two sighting surveys for cetaceans, taking place in the North Pacific in 2010, to examine the distribution of sei, Bryde's and minke whales and to estimate abundance for use in the RMP. Both surveys are in the middle part of the Western North Pacific. The main target species are sei and minke whales for the first survey and Bryde's whale for the second survey. The Committee assigned responsibility to Matsuoka for IWC oversight.

10.8.2 Mid- to long-term plans for the North Pacific Survey Programme

In addition to plans for a 2011 cruise, the Committee **recommends** that a coherent multi-year plan be developed for the survey programme in accordance with the discussion given in SC/62/Rep3. A Steering Group to oversee the IWC North Pacific surveys was established under Kato (Annex Q). It was proposed that a meeting of the Steering Group should be scheduled immediately prior to the Planning Meeting for the 2011 cruise, in order to develop the programme of research to be undertaken over the next few years.

10.9 Other

The precise taxonomic relationships and species delineations within the Bryde's/Eden's whale complex are currently uncertain. In South Africa, 'inshore' and 'offshore' forms of Bryde's whale have been described (Best, 1977), and there has been some uncertainty as to whether they should be referred to as *B. edeni* and *B. brydei* respectively. The Committee received a proposal for opportunistic collection of biopsy samples of Bryde's whales during a forthcoming research cruise between the Strait of Gibraltar and Cape Town, South Africa. These samples would be used to facilitate more in-depth genetic analysis of the relationship between the 'offshore' form and other more well sampled Bryde's whale species. The Committee **recommends** this proposal, assuming that relevant permits will be acquired. The Committee also **recommends** that biopsy samples from other whales be obtained, where legally permitted to do so.

11. STOCK DEFINITION (SD)

This Agenda Item was established in 2000, and has been handled since then by a Working Group; see IWC (1999d, p.83) for the original Terms of Reference. The term 'stock' has been used with different meanings in different contexts at different times, both within IWC and in other management and conservation contexts. These multiple meanings have sometimes hindered the Committee's ability to provide management advice. The Working Group was set up to clarify the issue of 'stocks' in a management context (see Item 11.3), to create a bridge between IWC and the expertise of the wider population genetics community (see Items 11.2 and 11.3), to develop software that evaluates the management utility of various population genetic analyses (see Item 11.2), and to develop guidelines for preparation and analysis of genetic data within an IWC context (see Item 11.1). These issues are of fundamental importance to the Committee's discussions on assessments and to the development of management advice. The Report of the Working Group is given as Annex I.

11.1 Statistical and genetic issues related to stock definition

11.1.1 Guidelines on DNA data quality

The Committee has previously endorsed a general set of guidelines for ensuring sufficient quality in genetic data used for management advice (IWC, 2009g; *http://www.iwcoffice.org/sci_com/handbook*). These guidelines constitute a 'living document' that will be updated as necessary. Since the issues involved are complex, the guidelines currently lack any numerical reference points, and the Committee again **encourages** suggestions accordingly. The intersessional e-mail group established in 2008 (Annex Q) was unable to report back this year, but will be continued in the coming year. The item remains on the agenda for the 2011 Annual Meeting.

11.1.2 Guidelines on genetic and statistical analysis

In parallel with the development of data quality guidelines, the Committee is developing guidelines for some of the more common types of statistical analyses of genetic data that are employed in IWC management contexts. These guidelines, which are being developed through another intersessional working group, are at an earlier stage of development than the DNA data quality guidelines. The proposed structure of the document, including a motivating example, was shown last year (IWC, 2009h).

This year, the Committee reviewed a preliminary version of the guidelines (SC/62/SD1), with drafts of several of the sections. Some further work is required, but after one further iteration, the guidelines should be able to appear on the IWC website. Following review of the text so far, a number of suggestions were made for the next iteration, including an 'FAQ' and the possible use of simulated datasets from TOSSM (see Item 11.2) as worked examples. The full list may be found in Annex I. This document will entail a great deal of effort, but should be of lasting importance. It deserves to be published, both online via IWC and in peer-reviewed literature.

11.1.3 Other approaches to stock identification

The Committee has previously considered the utility of acoustic data in questions of stock definition (IWC, 2005e, pp.248-49). Acoustics may be an efficient tool for proposing stock distinctions and boundaries, but interpretation can be difficult unless *inter alia* the stability of individual acoustic behaviour over time is known. This year, paper SC/62/SD2 presented results from acoustic monitoring of fin whales in different seasons and regions of the Mediterranean. The Strait of Gibraltar and Alborán Sea areas experience an influx, during the breeding season only, of fin whales that are acoustically consistent with Icelandic or Norwegian animals, but distinct from other Mediterranean fin whales. The results suggest a possible explanation for the low levels of gene flow that have been found between Mediterranean and North Atlantic fin whale populations. The Committee noted the value of these new data in suggesting rather precise areas where stock mixing and/or separation may occur, and consequently in assisting development of economical sampling design. It **encourages** plans to follow up this study with biopsy sampling.

11.2 TOSSM (Testing of Spatial Structure Models)

The aim of the TOSSM project is to facilitate comparative performance testing of population structure methods intended for use in conservation and management planning. From an IWC perspective, the TOSSM software package allows evaluation of methods for detection of genetic structure, in terms of how well the methods can be used to set spatial boundaries for management. As noted last year, the framework is now complete and the software is available for all to use; simulated datasets exist for three of the five stock-structure archetypes previously proposed by the Committee (IWC, 2009a, p.51). To date, ten methods have been tested on datasets from the two simplest Archetypes (single-stock panmixia, and two populations with limited migration sampled and harvested on the breeding grounds). No new results were received this year. Just as last year, though, the Committee noted the relevance of Archetype IV to North Pacific common minke whale discussions, where program STRUCTURE (Pritchard *et al.*, 2000) is receiving extensive use. It may well be possible to use TOSSM datasets to investigate the likely performance of STRUCTURE in a North Pacific minke whale-like setting, not merely in terms of overall 'boundary setting' but also in terms of specifics such as ability to assign individuals to specific stocks.

Mark-recapture data are another powerful tool for investigating stock issues. These have not yet been considered in TOSSM; next year, the Committee will consider the feasibility of incorporating mark-recapture data into TOSSM datasets. Another potentially powerful tool is the suite of coalescent-based methods but no coalescent-based approaches to boundary-setting have yet been considered in TOSSM. The Committee hopes to consider results of a TOSSM on the coalescent-based software MDIV next year.

There has been much discussion of how to interpret results from the program STRUCTURE, specifically in assigning individuals either to a smaller number of stocks which mix to a different extent in different places, or to a larger number of ‘new’ stocks that are less mixed. The Committee **encourages** the submission of papers investigating the performance of STRUCTURE for this question, and noted that datasets from TOSSM (existing ones, or new ones if necessary) might be a good starting point for such investigations.

11.3 Unit-to-conserve

‘Unit-to-conserve’ is a standing item on the SD Working Group agenda. It provides for discussion of potential ‘definitions of stock’ in a management context, including their operational implications for measurement and management. No new proposals were considered this year.

12. ENVIRONMENTAL CONCERNS (E)

The Commission and the Scientific Committee have increasingly taken an interest in the possible environmental threats to cetaceans. In 1993, the Commission adopted Resolutions on research on the environment and whale stocks and on the preservation of the marine environment (IWC, 1994a; 1994b). A number of resolutions on this topic have been passed subsequently (IWC, 1996a; 1997; 1998a; 1999b; 1999c; 2001c). As a result, the Scientific Committee formalised its work on environmental threats in 1997 by establishing a Standing Working Group that has met every year since then. Its report this year is given as Annex K.

12.1 State of the Cetacean Environment Report (SOCER)

The SOCER aims to provide Commissioners and Scientific Committee members with a non-technical summary of events, developments and conditions in the marine environment relevant to cetaceans. The report is compiled annually, in response to IWC (2001c), with a focus on one pre-selected region each year plus a global section.

The 2010 SOCER was focused on the Arctic and based on peer-reviewed papers published between 2008 and 2010. The overwhelming issue for the Arctic was climate change – e.g. rate of ice loss and ecosystem shifts – but many of the papers in the review period had already been summarized in previous Committee reports because of their global significance. There were few pollutant studies specifically on cetaceans in 2008-10, but the Arctic Monitoring and Assessment Programme (AMAP) 2009 Assessment of Arctic Pollution Status (*http://www.amap.no/*) provides a comprehensive review of pollutant levels in the Arctic. Globally, the environmental issue that received the most attention over the past year was underwater noise, especially disturbance from boat traffic, impacts of sonar on beaked whales and the acoustic impacts of wind farms. Of note, a bibliometric analysis showed that there has been a shift in focus in the cetacean research literature from basic biology topics, which were prevalent in the literature in the 1970s, to conservation topics in recent years. Next year the SOCER will focus on the Southern Ocean.

12.2 Review progress in planning for POLLUTION 2000+, Phase II

The IWC-Pollution 2000+ programme was initiated to investigate pollutant cause-effect relationships in cetaceans, and arose from a Workshop on chemical pollution and cetaceans held in Bergen, Norway in 1995 (Reijnders *et al.,* 1999). Following the Bergen workshop, a planning meeting was held in 1997 (Aguilar *et al.,* 1999a) and a workshop was held in 1999 (Aguilar *et al.*, 1999b), where Phase I of the POLLUTION 2000+ programme was launched. Phase I had two objectives: (1) to select and examine biomarkers for exposure to and/or effects of PCBs; and (2) to validate/calibrate sampling and analytical techniques. The results of Phase I were reviewed and a general framework for POLLUTION 2000+ Phase II was outlined (IWC, 2008a). Discussion for Phase II studies since that time has determined the need to: (1) produce a framework for modelling the effect of pollutants on cetacean populations; (2) identify cetacean populations to be studied under Phase II; and (3) develop a protocol for validating biopsy samples and applying this protocol to any large whale species selected.

Last year, the Committee had proposed the following modified goals for the Phase II programme:

(1) develop an integrated modelling and risk assessment framework to assess cause-effect relationships between pollutants and cetaceans at the population level, building on the progress made during Phase I and on recent research, using modification of a tiered risk assessment paradigm;
(2) extend the work to new species and contaminants as appropriate; and
(3) validate further biopsy sampling techniques for use in addressing issues related to pollution, including legacy contaminants and new contaminants of concern and associated indicators of exposure or effects.

In February 2010, an expert workshop (with expertise in chemical contaminants, toxicology, cetacean biology, veterinary medicine and biomarkers) was held to further develop proposals for Phase II of the programme (SC/62/Rep4). Presentations were made on risk assessment frameworks, chemicals of emerging concern, contaminant exposure, modelling approaches and case studies. Biomarkers of chemical exposure and effects were also discussed, with the workshop purposefully selecting those that have been validated in cetaceans. An international prioritisation survey for chemical contaminants was developed and will be distributed to subject matter experts, with a final report on survey results to be presented at the 2011 IWC Scientific Meeting.

The Committee **endorses** four **recommendations** made at the Workshop:

(1) to improve existing concentration-response (CR) function for PCB-related reproductive effects;
(2) to derive additional CR functions to address other endpoints (i.e., survival) in relation to PCB exposure;
(3) to integrate improved CR components into a population risk model (e.g., individual-based model) for one or more case study species (e.g. bottlenose dolphin and/or humpback whale); and
(4) to develop new biomarkers and improve the linkages between lower and higher levels of organisation (molecular - individual - population). The highest priority for biomarker development should include those with direct relevance to population-level endpoints such as reproduction and survival.

A plan to make progress on Phase II can be found in Annex K. The Committee noted data gaps and research needs identified at the Workshop, specifically noting that progress on this topic will require initiating new studies or additional support of existing efforts

The ICES Working Group on Marine Mammal Ecology (WGMME) met in April 2010 in part to ‘Review the current contaminant loads reported in marine mammals in the ICES area, the cause-effect relationships between contaminants and health status, and the population-level effects of environmental impacts.' The SWG had reviewed recommendations made by the WGMME with regard to pollutants in marine mammals (*http://www.ices.dk/reports/ACOM/2010/WGMME/wgmme_final_2010.pdf*). and the Committee **endorses** these recommendations.

The Committee received new information (SC/62/E9) on the development of a suite of sensitive biomarkers from non-lethal sampling to evaluate the toxicological status of Bryde's whale in the Gulf of California. A 'multi-trial-biomarker-tool' was developed, combining protein biomarkers with concentrations of organochlorines and polycyclic aromatic hydrocarbons. A second biomarker study (SC/62/E10) examined a multi-response *in vitro* method to detect toxicological effects of contaminant mixtures on skin samples from cetaceans in the Mediterranean Sea. Preliminary findings indicate that the combination of protein biomarkers, gene expression levels and tissue contaminant levels may be a useful tool in determining 'multiple toxicological stress' in free-ranging cetaceans. The Committee **welcomes** these studies but **emphasises** the importance of standardisation of contaminant concentration reporting.

The Committee received an overview of the oil spill that followed the explosion on board and subsequent loss of the drilling structure 'Deepwater Horizon' on 20 April 2010, approximately 50 miles southeast of Louisiana in the Gulf of Mexico. The incident claimed the lives of 11 workers. Immediately after the spill, response networks for marine mammals, sea turtles, and birds were established, including four facilities for de-oiling of manatees, dolphins, and sea turtles.

As of 4 June, 31 dead dolphins and 277 dead sea turtles had been documented, with numerous accounts of large and small cetaceans seen swimming in oil-contaminated waters. The Committee **commends** all groups that are responding to impacted marine mammals and turtles in the region.

It also **agrees** that it is extremely important to learn as much information as possible from this tragedy in order to accurately assess impacts and be better prepared for potential future oil spills. In this regard, the Committee **strongly recommends** that the government of the USA, range states of the Gulf of Mexico and the responsible parties:

(1) search for and examine as many cetacean carcasses as possible that may have been impacted by the spill through detailed necropsies and thorough tissue sampling;
(2) analyse tissues for contaminants specifically related to spilled oil (i.e. polycyclic aromatic hydrocarbons, dispersants and mixtures of the two);
(3) provide detailed chemical composition of the dispersants that have been used in the Gulf of Mexico;
(4) develop and examine a suite of biomarkers that will be useful for understanding impacts from the spilled oil and use of dispersants in the Gulf of Mexico; and
(5) conduct biomarker studies of cetacean populations in the Gulf of Mexico, especially bottlenose dolphins, sperm whales and Brydes whales.

The situation in the Gulf of Mexico also emphasises the need for adequate environmental baseline data *before* oil and gas exploration, development, or production occurs in any region and for these data to inform mitigation and management decisions. Therefore, for member governments with on-going or planned offshore oil and gas activities within their territories the Committee **strongly recommends** the collection of baseline data to include:

- contaminant levels in cetaceans, their prey, and in sediments, especially polycyclic aromatic hydrocarbons (PAHs) and other contaminants that may interact with PAHs;
- biomarker levels in cetaceans and their prey;
- abundance and distribution of cetaceans and their prey; and
- condition of cetacean habitats (i.e. water quality, sediment quality, etc.).

Finally, the Committee **strongly recommends** contingency planning and training for oil spill responses in areas of oil and gas development. It looks forward to receiving an update on the studies into the effects of this spill at future meetings.

12.3 Review progress of CERD Working Group

The CERD working group was established in response to the report of a workshop on infectious and non-infectious diseases of marine mammals and impact on cetaceans that was held in 2007 (IWC, 2008d). The Committee received an update on its intersessional accomplishments and plans (Annex K, item 8), which are summarised in five categories: (1) skin disease; (2) diagnostic laboratories and veterinary experts; (3) prioritization of pathogens; (4) emergency response; and (5) enhancement of capacity and communications among stranding networks. With regard to the last category, capacity building workshops were held in four regions: West Africa, Caribbean, Brazil and India. Drawing information from the ICES working group and the IWC Ship Strike Working Group, a global inventory of stranding networks has been developed and the CERD working group is developing recommendations to maintain and provide access to the inventory.

The Committee also noted a prioritisation of cetacean pathogens developed on behalf of the US Working Group on Marine Mammal Unusual Mortality Events, from a survey that evaluated 76 pathogens based upon five factors. Of the pathogens included in the survey, most were potentially zoonotic, while others were associated with emerging/re-emerging human diseases in the United States. The ten highest priority pathogens among small cetaceans were morbillivirus, parapoxvirus, *Brucella* spp. anisakis, calicivirus, herpesvirus, nasitrema, *Clostridium* spp., and toxigenic *Escherichia coli*. Although the CERD WG is not tasked to compare cetacean-borne pathogens to those in terrestrial species, the Committee expressed interest in this broader approach, which is consistent with the global *One Health* approach to medicine (*http://onehealthinitiative.com/index.php*). Specifically, *One Health* highlights the importance of integration of surveillance systems in wildlife, domestic animals, public health and environmental health. The Committee **commends** projects that integrate a *One Health* approach to build capacity in countries that are responding to diseases that are shared by people and wildlife. Further, it **recommends** that marine species be considered by all organisation that are implementing the *One Health* approach. Finally, the Committee **commends** the many and varied accomplishments of the CERD WG and **endorses** the work plan for 2011 (Annex K, Appendix 3).

12.4 Review new information on anthropogenic sound: focus on 'masking sound'

The Committee's SWG on environmental concerns has included an item on underwater sound on its agenda each year since 2004 (IWC, 2005f, p.268). In 2009, a presentation on low-frequency 'masking sound' precipitated adopting it as a focal-topic. Low-frequency (LF) ocean noise has increased substantially in recent decades, concomitant with a three-fold increase in commercial shipping and other offshore industrial activities. The Committee reviewed a mechanistic model that dramatically demonstrates the reduction in the 'communication space' of baleen whales that now occurs, especially near shipping lanes and busy ports (Annex K, item 9). It then reviewed a variety of evidence with regard to the masking sound and its possible effects on whales, including: (1) altered calling patterns and frequency in the presence of LF sound from shipping and seismic airguns shown by fin whales in the western Mediterranean Sea and humpback whales off the coast of Northern Angola; (2) chronic exposure of the small population of humpback whales in the Arabian Sea to LF sound from construction, shipping and seismic surveys; and (3) the elevation of LF sound levels at distances from 450 to 2,800km from a seismic survey area south of Tasmania in the Southern Ocean. Based on the aggregate information presented to the SWG with regard to masking sound from anthropogenic sources, the Committee **recommends** that:

(1) seismic surveys be regulated in the same legal frame, whether for scientific or commercial purposes;
(2) baseline data be collected, satisfactorily analysed and modelled using appropriate techniques, regarding the seasonal and spatial distribution of whales in areas of interest to the geophysical community (scientific and commercial) before survey operations;
(3) the masking potential of anthropogenic sources be quantified and acoustic measurements be standardized to ensure that datasets among researchers are comparable; and
(4) in studies examining potential changes in whale acoustic behaviour, the ability to detect whale calls during periods of exposure and non-exposure to anthropogenic LF sound be quantified.

Further, the Committee **strongly recommends** that further research be conducted on the Arabian Sea humpback population (and see Item 10.2.2.4), including studies directed at quantifying the impacts of acoustic disturbance and masking to support conservation planning and protection for this small population.

The SWG had reviewed available information on plans for seismic surveys in support of oil and gas development planned for the Russian Far East, including the Sea of Okhotsk, Anadyr Gulf, the East Siberian and Chukchi Seas (Annex K, item 9.1). The scale of these activities is 'matched' by plans for broad-scale seismic surveys in the US Chukchi and across the US-Canadian Beaufort sea region. At least six endangered whale species (e.g. North Pacific right whales and Okhotsk Sea bowhead whales) occur in low numbers in waters offshore western Kamchatka, where seismic surveys are anticipated during summer 2010.

In light of this, the Committee **recommends** that additional surveys to provide baseline information on cetaceans be conducted in waters off western Kamchatka, and that seismic surveys and other potentially disturbing industrial activities should be conducted during times of lower cetacean abundance in all ocean regions whenever possible (e.g. see the mitigation and monitoring plan for a seismic survey in the Sakhalin region developed under the auspices of IUCN's Western Gray Whale Advisory Panel, and information regarding other seismic survey issues specific to western gray whales under Item 10.4 above). When informed that industry has initiated research into alternative (quieter) technology (vibroseis), the Committee **strongly encourages** this research and **recommends** continued development of such methods.

The conclusions from the workshop on 'Cumulative Impacts of Underwater Noise with Other Anthropogenic Stressors on Marine Mammals' were reviewed (Annex K, item 9.3). That workshop had agreed that cumulative impact assessments (CIAs) are needed to account for sub-lethal effects of human disturbance. The Committee **recommends** that member governments work to develop a quantitative approach for assessing cumulative impacts, including ways that anthropogenic sounds might impact cetaceans and their prey.

In regard to reducing LF sounds from shipping, the SWG (Annex K, item 9.4) had noted rapid progress, especially in the past three years, towards addressing this issue, including both the formation of a Correspondence Group within the Marine Environment Protection Committee (MEPC) of the International Maritime Organization (IMO) and the granting of IMO 'observer status' to the IWC (IWC/62/4). With reference to the IWC's awareness of the critical nature of acoustic communication to whales and that interference, or masking, of this communication is to some extent preventable, the Committee **strongly recommends** that:

(1) the goal of noise reduction from shipping advanced in 2008 (i.e., 3dB in 10 years; 10dB in 30 years in the 10-300Hz band) be actively pursued;
(2) new and retro-fit designs to reduce noise from ship propulsion be advanced within the goals of the IMO, when and wherever practicable; and
(3) the IWC and IMO continue to work collaboratively to advance the goal of worldwide reduction of noise from commercial shipping when and wherever practicable including reporting progress on noise measurements and implementing noise reduction measures.

12.5 Review progress on work from the 2nd Climate Change Workshop

The 2nd Climate Change Workshop (IWC, 2010j) resulted in a series of recommendations summarised under three headings corresponding to working groups established at the workshop: Arctic; Southern Ocean; and Small Cetaceans (and see Annex K, item 10). With regard to the Arctic, three study themes were established: (a) Single Species-Regional Contrast; (b) Trophic Comparison; and (c) Distribution Shift. With reference to theme (a), planning discussions have been completed for a comparison of physical indicators of climate change and available data on population dynamics and behavioural ecology of the Bering-Chukchi-Beaufort Seas and Hudson Bay-Davis Strait populations of bowhead whales. In the Southern Ocean, the SWG was provided an update on the responses of the southern right whale population of Península Valdés, Argentina to climate driven changes on their feeding grounds off South Georgia. As was reported in the Southern Right Whale Die-Off Workshop (SC/62/Rep1 and see Item 10.5 above), one of three possible hypotheses to explain recent peaks in calf mortalities is a decline in food availability for adult females on their feeding ground during the year or two prior to calving. This hypothesis will be explored by updating an analysis on the relationship between changes in sea surface temperature and calving success. The Committee reviewed a draft agenda for a Small Cetaceans and Climate Change Workshop planned for November 2010, where the main focus will be: (1) restricted habitats – estuaries, reefs, environmental discontinuities, rivers and shallow waters; and (2) range changes – i.e. evidence of changes in distributions, reasons and consequences; and (3) with a review planned for small cetaceans in the Arctic Region and suggested that the definition of restricted habitat be broadened (Annex K, item 10). Noting that last year the Committee had recommended that countries should pay more attention to tertiary concerns arising from climate change, the Committee noted that Alter *et al.* (2010) provide arguments suggesting that tropical, coastal and riverine cetaceans are particularly vulnerable to those aspects of climate change that are mediated by changes in human behaviour.

12.6 Other habitat related issues

There has been a rapid expansion of marine renewable energy devices (MREDs) in European seas as governments strive to meet renewable energy commitments. Today there are some 89 such sites in various stages of development (most of these are wind farms), representing a five-fold increase in numbers since 2000, with a concomitant major increase in the size of planned developments. The SWG reviewed concerns associated with the construction, operation, maintenance and (ultimately) decommissioning of wind, tidal and wave renewable energy technologies (Annex K, item 11.1) and the Committee **strongly recommends** that countries co-operate to limit impacts on marine wildlife from these sources. The SWG subsequently discussed the ICES WGMME recommendations with regard to the effects of wind farm construction and operation on marine mammals (Annex K, item 11.1) and the Committee **endorses** those recommendations.

The French Agency for Marine Protected Areas (AAMP) has initiated the REMMOA project, a series of surveys across the French EEZ to identify hotspots of abundance and diversity. Extensive surveys have been conducted across the EEZ of Martinique and Guadeloupe, off Guiana and in the southwest Indian Ocean region. The South Pacific regions will be surveyed during 2010-11 (French Polynesia) and 2011-12 (southwest Pacific Ocean around New Caledonia and Wallis and Futuna) and the Atlantic survey is planned for 2012-13. The Committee also received information on systematic monitoring of density and abundance of the most common cetacean species of the Pelagos Sanctuary and in the seas surrounding Italy. The aim of this work, funded by the Italian Government, is to inform conservation measures throughout the Mediterranean Basin. It also responds to priority actions in a number of other international bodies (e.g. the Sanctuary Management Plan, ACCOBAMS, the Specially Protected Areas and Biodiversity Protocol under the Barcelona Convention, the EU Habitat Directive and the Convention on Biological Diversity). The Committee **commends** both of these studies and encourages their continuation. It noted the impressive advancements of current methods giving the authors the ability to correlate cetaceans with specific habitat features as well as other megafauna.

Finally, there has been limited progress since the update on the Madagascar Mass Stranding Event (MMSE) given in 2008 (IWC, 2009a, p.71). Two potential scenarios to move forward with an Independent Scientific Review Panel (ISRP) were identified: (1) a National Office of the Environment (ONE) to request and oversee an ISRP; or (2) the Environmental Governance Commission to serve as an intermediary body between the Government and/or ONE to promote the need for an ISRP to assess the results of the MMSE. The Committee welcomed this update and thanked The Wildlife Conservation Society and its partners' continuing efforts to bring the results of the MMSE to an appropriate conclusion through an ISRP process, as well as keeping the SWG updated on the current challenges and progress.

13. ECOSYSTEM MODELLING

The Ecosystem Modelling Working Group was first convened in 2007 (IWC, 2008c). It is tasked with informing the Committee on relevant aspects of the nature and extent of the ecological relationships between whales and the ecosystems in which they live. This advice is important to other responsibilities of the Committee: it can be used to simulate an ecosystem framework in which to evaluate management strategies; it can provide a bio-physical context within which to try to understand spatial or temporal (e.g. interannual, interdecadal, or long-term climate-driven) variability in cetacean population dynamics, distribution, behaviour, and health; it can provide insight into interactions between whales and fisheries; and it may inform the prioritisation and design of future IWC research projects by identifying critical information gaps and offering recommendations of when, where and how field efforts should be conducted to successfully collect new data that are necessary for providing insight into key questions. The Commission has stated their interest in such work in a number of resolutions (IWC, 1999a; 2001c; 2002a). Each year the Working Group reviews the progress in developing ecosystem models relevant to the work of the IWC, which is a broad task encompassing the evaluation of model inputs, assumptions, structure and outputs. In addition, the Working Group has placed a priority on discussions and collaborations with institutions outside of the IWC to facilitate the exchange of information on the state of the science of ecosystem modelling and, where applicable, to collaborate to achieve a common goal. No primary ecosystem modelling papers were received this year, so the Working Group dedicated its time to three general tasks: (1) reviewing ecosystem models and modelling approaches that were developed outside of the IWC; (2) learning about the Climate Impacts on Oceanic Top Predators (CLIOTOP) project; and (3) discussing and planning the future role of this Working Group within the Scientific Committee. The report of the Working Group is given as Annex K1.

13.1 Review ecosystem models relevant to the Committee's work

This year, Lehodey introduced the CLIOTOP project and in particular the ecosystem model that he and his colleagues developed to analyse and predict the spatio-temporal dynamics of tuna populations under the influence of environmental and fishing pressures (Lehodey *et al.*, 2008). The model has been applied to skipjack, bigeye, yellowfin and albacore tuna in the Pacific Ocean (Lehodey and Senina, 2009) and also been used to investigate potential influences of climate change on tuna population dynamics (Lehodey *et al.*, 2010).

CLIOTOP is a global project implemented under two International Geosphere-Biosphere Programme (IGBP) international research programmes: Global Ocean Ecosystem Dynamics (GLOBEC) and Integrated Marine Biogeochemistry and Ecosystem Research (IMBER). Its general objective is to enhance the understanding of oceanic top predators in their ecosystems in the context of both climate change and fishing, and to develop new tools leading to the evaluation of management strategies. CLIOTOP and the IWC share many common scientific interests, including: studying the behaviour, movement patterns and habitat of large predators; developing and applying technology for animal tracking; estimating food consumption rates; understanding and modeling predation by, and competition among, large predators; modelling and acoustic monitoring of prey fields; investigating various approaches to ecosystem modelling; and addressing issues of bycatch. The Committee **encourages** the establishment of collaborations between the IWC and CLIOTOP.

As part of its remit to preview general developments in ecosystem modelling to identify new modelling approaches and develop an evaluation framework that may be of benefit to the Committee's work, four recently published papers were reviewed (A'Mar *et al.*, 2009; Allen and Fulton, 2010; Buckley and Buckley, 2010; Hannah *et al.*, 2010). These covered issues of model structure, assumptions, complexity and validation. In discussion, it was noted that some existing research suggests that management strategies relying on empirical data through fisheries statistics performed better than those that incorporated ecological information; however, ecological data are valuable for constructing and constraining the range of ecosystem models that could be used to evaluate management strategies within the Scientific Committee.

13.2 Recommendations on the role of this Working Group within the Committee

SC/62/EM1 motivated discussions about the future of the Ecosystem Modelling Working Group. It provided background into the initial objectives and the history of the Working Group; reiterated the distinction between 'tactical' models (those used to set catch limits or to make other management advice) and 'strategic' models (those used to simulate an environment in which to test simpler models); listed some of the ecological and analytical issues that have been recurrent in Committee discussions to date; and introduced several recommendations to help the Committee evaluate ecosystem models, given the numerous uncertainties inherent in the modelling process. As did the Working Group, the Committee **agrees** to the following recommendations, based on those in SC/62/EM1:

(1) standardised templates should be developed for documenting metadata and analytical techniques;
(2) performance criteria should be established, including testing model fit to historic or present data and assessing its ability to generate ecologically reasonable predictions into the future;
(3) sensitivity analyses should be conducted to quantify and provide insight into the importance of model inputs (which can guide data collection priorities) and assumptions on model outputs;
(4) Scientific Committee members should be given access to relevant background information (such as the full mathematical specification) used in any presented ecosystem models that may inform management decisions (via the Secretariat);
(5) the Scientific Committee should explore various ecosystem modelling approaches for a system in order to compare performance across models;
(6) intersessional meetings should be used, when necessary, to allow in-depth examination of competing models; and
(7) the EM Working Group should continue to convene every year at the annual meetings to address issues relevant to the Scientific Committee and to remain informed about new developments in the ecosystem modelling field.

The Committee **emphasises** that the Working Group is an important forum for evaluating ecosystem model inputs, structure, assumptions and predictions related to its work. *Inter alia*, it is also the appropriate sub-group within the Committee for reviewing the ecosystem aspects of ongoing special permit whaling programmes.

The Committee **recognises** the need to involve outside experts in the Working Group. Work is underway to establish an avenue for exchanging information about new developments in ecosystem modelling and its feedback into management, and to solicit feedback on how ecosystem models could inform IWC management decisions.

The Committee **agrees** that the activities of the Working Group should be structured around the timetable of RMP assessments and *Implementations*, enabling ecosystem models relevant to a specific stock being assessed to be reviewed prior to the assessment; the North Pacific is the appropriate region for 2011. The Working Group will take efforts during the intersessional period to engage researchers involved in the North Pacific Marine Science Organization (PICES) and the North Pacific Research Board (NPRB) to collaborate on primary papers for next year's meeting on how North Pacific ecosystem models can be used to inform the RMP process. Two additional issues were highlighted for discussion next year, if primary papers can be prepared in advance. One is a review of functional responses, and the second is a review of methods for evaluating ecosystem models. It is expected that the latter will result in a framework that the Committee will use to guide future ecosystem model evaluations, providing model developers specific details regarding the information required to determine whether the input data and parameters, the model and the resulting predictions should be considered acceptable to inform the work of the Committee.

13.3 Work plan

The work plan is detailed under Item 24. The Working Group requests no funds for the upcoming year.

14. SMALL CETACEANS (SM)

The Committee has been discussing issues related to small cetaceans since the mid-1970s (IWC, 1976). Despite the differences of views over competency (IWC, 1993), the Commission has agreed that the Committee should continue to consider this item (IWC, 1995c). The report of the sub-committee on small cetaceans is given as Annex L.

14.1 Review taxonomy, population structure and status of small cetaceans of northwestern Africa and the Eastern Tropical Atlantic (ETA)

The priority topic this year was the review of the status of small cetaceans of northwestern African and eastern tropical Atlantic waters (Fig. 6), a region with a variety of ecosystems and coastal habitats. The review was greatly assisted by the availability of published review papers and documents prepared for this meeting by scientists working in Canary Islands (Spain), Mauritania, Cape Verde, Guinea, Ghana, Togo, Benin, Nigeria, São Tomé and Príncipe, Cameroon, Gabon, Congo and Angola.

The following sections represent a short summary of the extensive review. Details can be found in Annex L.

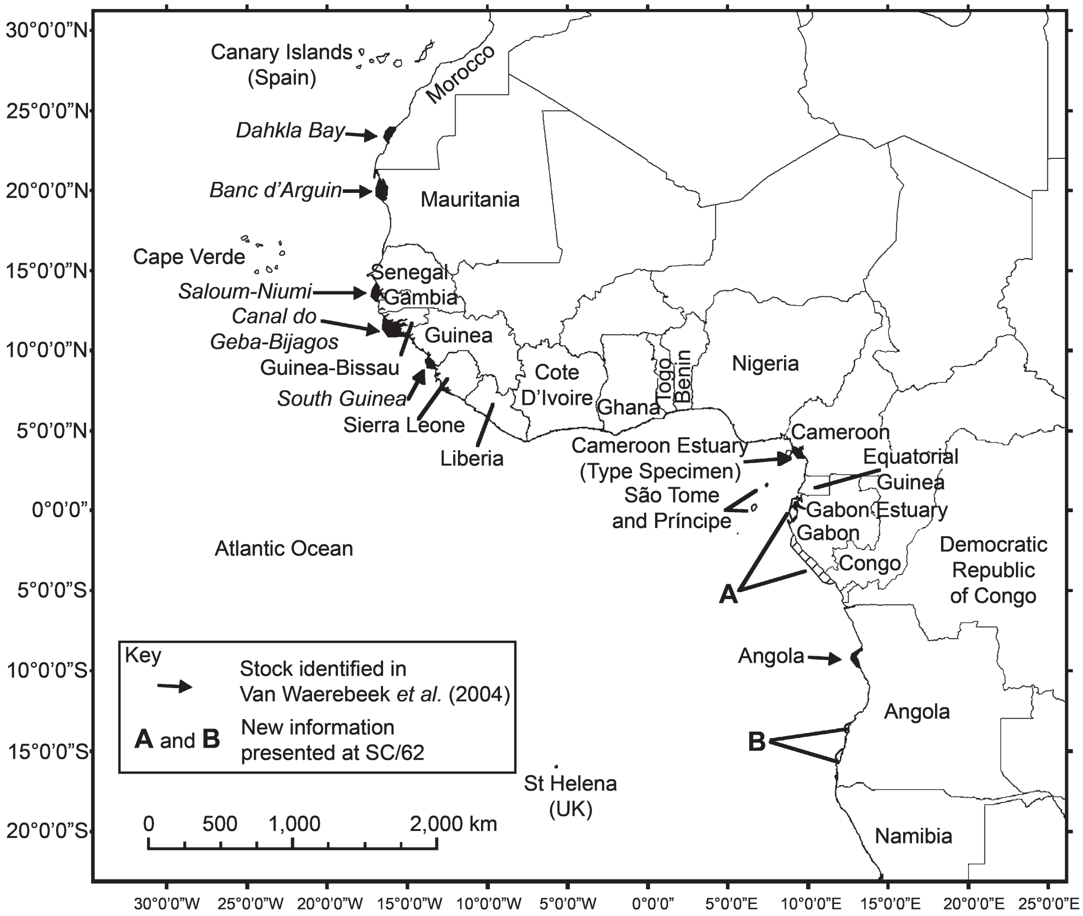

Fig. 6. Map of the northwestern and western African countries relevant to the cetacean distribution review. A=Information from SC/62/SM9. B=Information from SC/62/SM6.

Weir (2010) reviewed cetacean occurrence (sightings, strandings, direct captures, bycatch) in West African waters from the Gulf of Guinea to Angola, updating Jefferson *et al.* (1997). At least 21 odontocetes (including at least 17 delphinids) have been documented in the region. The author stressed that the region's cetaceans face several threats including bycatch, direct capture (e.g. in Ghana and Togo) and threats to them and their habitat, e.g. due to oil and gas development. Moore *et al.* (2010) reported information on cetacean bycatch from interview surveys in 2007 and 2008 in fishing communities of seven countries: Sierra Leone, Cameroon, Nigeria, Tanzania, Comoros, Malaysia and Jamaica They provided information on reported cetacean bycatches in Sierra Leone and Cameroon.

Further information on the region's cetaceans came from a number of papers focussing on country reports.

SC/62/SM9 reviewed recent information on Atlantic humpback dolphins in Gabon and Republic of Congo. Both countries have large and diverse national park systems that include protected coastal habitat. Given the low human population densities and the extent of relatively undisturbed habitat in Gabon and northern Congo, this region may represent a stronghold for the species. However, bycatch and evidence of dolphins in the bushmeat trade give cause for concern, particularly as the demand for fish in cities increases. The Committee commends the authors for their efforts in the region and **recommends** that research, monitoring and conservation efforts for humpback dolphins along the coast of Gabon and Congo continue.

The Committee received two papers covering Nigeria (SC/62/SM12 and SM1). Cetaceans occur throughout Nigerian coastal waters in the Gulf of Guinea, although there has been little directed cetacean research. Potential threats include: bycatches (a reported zero bycatch rate for Nigeria obtained in an interview survey by Moore *et al.* (2010) is not credible, probably due to low sample size); direct catches of delphinids (SC/62/SM1) for sale as 'marine bushmeat' (Clapham and van Waerebeek, 2007) which may be widespread; and habitat degradation (e.g. uncontrolled trawling operations, indiscriminate dumping of non-biodegradable nylon and plastic products and household items). The absence of monitoring may explain the lack of detailed information on direct catches. SC/62/SM1 reiterated the suggestion by Van Waerebeek *et al.* (2004) that Atlantic humpback dolphins inhabited the Niger Delta before large-scale oil exploration and extraction altered the coastal environment.

Information on Ghana was provided in SC/62/SM10 with an emphasis on the captures of small cetaceans in artisanal fisheries, mainly using drift gill nets. Cetaceans have been documented from three fish landing ports since 1995 but these landings do not represent the total for the country. It is often unclear if 'bycaught' cetaceans in Ghana are the result of unintentional or intentional taking. The species most frequently 'bycaught' are the clymene dolphin (24.5%), pantropical spotted dolphin (12.3%) and common bottlenose dolphin (12.3%). SC/62/SM10 suggested an increasing trend in the scale of landings between 1999 and 2010, and particularly since 2002-03. Once the practice of catching and marketing cetacean products becomes established, it can escalate rapidly as implied in the existing catch series. Although aquatic mammals are protected by law, there are no explicit regulations concerning the use of cetaceans killed in nets and the use of dolphin meat as bait in shark fisheries and for human consumption is not considered illegal. This means that catches are not concealed for fear of sanctions and therefore catch statistics can be obtained. This makes it feasible to study trends and carry out biological studies based on carcass sampling protocols.

As stated in SC/62/SM10, traditional taboos against catching dolphins are rapidly eroding in the Volta Delta region. This seems to happen in some areas of Nigeria as well. One important development is that the monetary value of a small cetacean is now roughly equivalent to that of a similar-sized large billfish. In fact, more money can be earned by selling the cetacean carcasses for shark bait as the export market in Asia for shark fins is lucrative and growing.

The Committee thanks the researchers working in Ghana for their efforts and notes that the evidently close cooperation with fisheries officials is encouraging.

Tchibozo summarised the current knowledge on small cetaceans along the 124km coastline of Benin (Tchibozo and van Waerebeek, 2007). The presence of four species has been confirmed: Atlantic spotted dolphins, common bottlenose dolphins, false killer whales and *Delphinus* sp. There have been no systematic studies on the distribution, abundance or ecology of small cetaceans in Benin. Although bycatch of cetaceans is known to occur in fisheries along the entire coast, no monitoring programme is in place.

SC/62/SM11 confirmed the presence of four small cetaceans in Togo's coastal waters: pantropical spotted dolphins, common dolphins, pilot whales and killer whales. However, there is no information concerning abundance, natural history or ecology. The main potential threats are:

(1) bycatch in fisheries, with the possibility that this has led or soon will lead to directed taking as has been observed elsewhere; and
(2) severe chemical pollution due to the mining of phosphorites and discharge of phosphate-rich mud into coastal waters.

Bamy *et al.* (2010) reported that four odontocetes occur along Guinea's 300km coastline: common bottlenose dolphins, Atlantic humpback dolphins, Atlantic spotted dolphins and pygmy sperm whales. It is probable that short-finned pilot whales, rough-toothed dolphins and common dolphins also occur there. This information comes mainly from observations during irregular, largely opportunistic surveys of fishing communities in 2001-03 by personnel from Guinea's Centre National des Sciences Halieutiques de Boussoura (CNSHB). There is no evidence of substantial directed or incidental takes (e.g. at the scale reported in Ghana) but monitoring and reporting have been limited. There is evidence that bycaught small cetaceans and a stranded whale were used for human consumption. The authors expressed concern about even occasional catches of Atlantic humpback dolphins.

During discussion, reference was made to the study by Brashares *et al.* (2004) on the relation between declining fish supplies in West African waters and the increase in hunting for 'bushmeat' and consequent declines in wildlife populations.

SC/62/SM8 updated Picanço *et al.* (2009) with information on small cetaceans off São Tomé and Príncipe. At least four species of small cetaceans are known to occur there with the common bottlenose dolphin and pantropical spotted dolphin being the most numerous.

Several species of small cetaceans were hunted historically in the Cape Verde Islands using hand harpoons. Despite protective legislation, cetaceans are still captured occasionally and their meat is sold and consumed (Hazevoet and Wenzel, 2000; Reiner *et al.*, 1996).

Vely summarised cetacean occurrence in Mauritania between 1987-95 based on dedicated surveys in two main areas: (a) between the southern border with Senegal and the village of Nouamghar at the northern entrance of the National Park of Banc d'Arguin (PNBA); and (b) within the PNBA. Species observed at sea were common bottlenose dolphins, Atlantic humpback dolphins and killer whales. Stranded specimens included harbour porpoises, clymene dolphins, common dolphins, Risso's dolphins, melon-headed whales, short-finned pilot whales, pygmy sperm whales, dwarf sperm whales and Cuvier's and Gervais' beaked whales.

Smit *et al.* (2010) summarised information on the presence and distribution of small cetaceans off the coast of La Gomera (Canary Islands), where a total of 21 species were observed at sea. The five most abundant species (87% of sightings) were common bottlenose dolphins, short-finned pilot whales, Atlantic spotted dolphins, short-beaked common dolphins and rough-toothed dolphins.

The Committee thanks all of the contributors but noted that its review was characterised by rather scarce information from the northwest African countries (see Annex L). However, enough new information was available from West Africa to update and make some corrections to the existing state of knowledge on cetaceans along the west African coast (see table 1 of Annex L).

IUCN Red List status for 21 out of 22 species is either Least Concern or Data Deficient (2008). The Atlantic humpback dolphin is listed as Vulnerable. There is a general lack of relevant information on many of the species, not only for western African waters but also globally, on taxonomy, population structure, abundance, life history and ecology.

The scarcity of information prevented the Committee from being able to make a reliable evaluation of the status of any of the species in the region. That being said, the information available in the review showed that nearly all species are taken either intentionally or unintentionally (SC/62/SM1, SM10 and SM11; see also Bamy *et al.*, 2010; Van Waerebeek *et al.*, 2008; and Weir, 2010). Especially for one species, the clymene dolphin, the Committee **expresses serious concern** about the ongoing observed landings in Ghana.

The Committee then reviewed two species on which there was a little more information.

Killer whales

Killer whales observed off Angola, Gabon and São Tomé were similar in external appearance to, and their appearance was consistent with, the Type A 'nominate' killer whale form described by Pitman and Ensor (2003). Weir *et al.* (2010) summarised published records from Liberia, Côte d'Ivoire, Ghana, Annobón Island (Equatorial Guinea) and Gabon as well as 31 sightings from Angola, Gabon and São Tomé, and a single record from Cameroon. De Boer (2010) provided an additional record of killer whales in the offshore waters of Gabon. Most sightings have been recorded since 2001, corresponding with the onset of dedicated survey work in the region. Bamy *et al.* (2010) found no confirmed records for the stretch of coast from southern Senegal (Casamance) to Liberia. They also questioned whether killer whales venture into the shallow waters of Guinea-Bissau, Guinea and Sierra Leone.

No information was received regarding recent intentional takes although one killer whale was recorded as landed in Ghana between 1998 and 2000 (SC/62/SM8).

The killer whale can be considered a regular component of the cetacean community off Angola and in the Gulf of Guinea. However, more survey work is required throughout the region to clarify its status and biology off tropical West Africa (Weir *et al.*, 2010). The IUCN Red List status of the species is Data Deficient.

Atlantic humpback dolphin

The Atlantic humpback dolphin - an endemic species for this region - was a priority species in 2002 (IWC, 2003b) but at that time the review focused on the Indo-Pacific humpback dolphin.

The taxonomy of the genus *Sousa* remains largely unresolved. Although three putative or nominal species have been widely discussed (*chinensis*, *plumbea* and *teuszii*), the IWC presently recognises only two, the Atlantic species *S. teuszii* and a geographically widespread Indo-Pacific species *S. chinensis*. Although the Committee was informed by Rosenbaum of a collaborative study to clarify the taxonomy of *Sousa*, the Committee **agrees** to retain its present nomenclature until formal publication of this information. It also **recommends** that samples from *S. teuszii* be provided to Rosenbaum as soon as possible so that they can be included in the ongoing efforts described above, which are essential for resolving questions questions concerning taxonomy and population structure.

Van Waerebeek *et al.* (2004) reviewed the state of knowledge on Atlantic humpback dolphins and proposed eight provisional management stocks based on the fragmentary information available to them. Six were confirmed as extant based on recent records: Dakhla Bay (Western Sahara), Banc d'Arguin (Mauritania), Saloum-Niumi (Senegal, Gambia), Canal do Gêba-Bijagos (Guinea-Bissau), South Guinea and Angola. The other two – Cameroon Estuary and Gabon – were considered historical. Those authors also noted the 'potential existence' of a western Togo stock. They concluded that there were nine confirmed range states: Morocco (including Western Sahara), Mauritania, Senegal, The Gambia, Guinea-Bissau, Guinea-Conakry, Cameroon, Gabon and Angola.

Van Waerebeek *et al.* (2004) stated that the species was limited to tropical and subtropical waters very near shore from Western Sahara in the north to Angola in the south; the distribution is patchy and limited to particular stretches of coastline separated by gaps of absence or very low density. In many cases, it was unclear whether the absence of records from an area means the species naturally does not occur there, or it has been extirpated in the area, or search effort and reporting have been insufficient.

Bamy *et al.* (2010) considered as uncertain the degree of distributional continuity and gene flow between the provisionally defined 'South Guinea stock' and other provisionally defined stocks (Van Waerebeek *et al.*, 2004). As in Guinea-Bissau, most of Guinea's coastline has features suitable as humpback dolphin habitat: warm and shallow waters on a shelf extending up to 200km from shore, with extensive mangrove creeks around four main river mouths. The lack of sighting records is probably partly due to the small amount of near-shore survey effort. Ghana represents a confirmed gap (SC/62/SM10).

Although much remains unknown about distribution and the extent to which it has changed over time as a result of human activities (e.g. bycatch, habitat degradation), current understanding is that there are regional pockets of relatively high density, such as in Senegal-The Gambia-Guinea-Bissau-Guinea-Sierra Leone, Gabon-Congo and Cameroon-Angola-Namibia.

Although its typical habitat was thought to be shallow coastal waters, especially estuaries, mangrove systems and sheltered bays (Van Waerebeek *et al.*, 2004), new information on the presence, distribution and behaviour of Atlantic humpback dolphins was received from Flamingos (southern Angola), Gabon and Congo (SC/62/SM9), also see Weir *et al.* (2009). In Gabon, Congo and elsewhere in the southern range of the species, humpback dolphins are regularly observed on open coastlines.

The loss and fragmentation of habitat due to expanding coastal communities, coastal development, dredging, trawling, deforestation, mangrove destruction, pollution, eutrophication and oil spills also threaten this species. Its preference in many areas for shallow, nearshore and estuarine habitat would render it particularly vulnerable to ubiquitous inshore set gillnets, beach seines and disturbance.

The Committee **agrees** that there is ample evidence for serious concern about the conservation status of this species (SC/62/SM1; SM6; SM9-SM11, and see also Bamy *et al.*, 2010). Although quantitative data or even good qualitative data (e.g. confirmation of species presence/absence) are lacking for much of the known or suspected range, the information available from areas where cetaceans have been consistently studied (e.g. Ghana, Guinea) indicates that the overall population is fragmented, bycatch (if not also directed catch) is occurring, and habitat conditions are deteriorating. Populations in Gabon and northern Congo appear healthy, but recently documented bycatches and utilisation in Congo may be indicative of a growing reliance on non-fish marine wildlife, including dolphins, as food.

In view of the growing concern (e.g. summarised in SC/62/SM6) that the Atlantic humpback dolphin faces some of the same threats that led to the extinction of the baiji and caused the vaquita to become critically endangered, the Committee **recommends** that IUCN reassess the Atlantic humpback dolphin's status in the light of new information.

It also **recommends** the following items for further conservation and research action for Atlantic humpback dolphins, taking into account *inter alia* the CMS regional action plan for the conservation of West African small cetaceans[4].

(1) Coordinated data collection should be facilitated in order to improve knowledge of the abundance, distribution and conservation status of *S. teuszii* throughout its known range. Specifically:
    (a) estimates of abundance and distribution are urgently required (including where feasible photo-id);
    (b) tissue samples should be obtained at every opportunity from stranded or bycaught Atlantic humpback dolphins. These need to be appropriately preserved and provided to scientists for genetic analyses investigating population structure;
    (c) critical habitats should be identified, including areas of high density and regular occurrence ('hotspots') and migratory pathways (if such exist), as candidates for focused conservation effort; and
    (d) overviews of existing knowledge, national species lists, specimen collections, research centres and protected areas should be compiled.

(2) Identify and mitigate known and potential threats to *S. teuszii*, particularly entanglement in fishing gear, and directed take and anthropogenic noise. Specifically this should include:

---

[4] Action Plan for the Conservation of Small Cetaceans of Western Africa and Macronesia, ratified in 2008 by West African member nations of CMS.

(a) improving the understanding of the causes, levels and impacts of bycatch on *S. teuszii*;
(b) assessment of the causes, level and intensity of directed small cetacean takes;
(c) efforts should be made to minimise the ecological impacts of fisheries on, and direct takes of, *S. teuszii* through the implementation of explicit fisheries management measures; and
(d) ensure that all littoral developments and activities take into account their potential for having negative effects on small cetaceans and the environment.

(3) The designation and management of national and transboundary marine protected areas that include *S. teuszii* habitat based on scientific data and broad stakeholder involvement should be encouraged.

The Committee also specifically **recommends** that regional or sub-regional research projects be conducted that would allow the preparation of management plans for the conservation of Atlantic humpback dolphins in particular areas. Candidate areas are: (a) off Flamingos, Angola; (b) along the coasts of Gabon-Congo; (c) Senegal-The Gambia-Guinea-Bissau-Guinea-Sierra Leone where the humpback dolphin population(s) may be transboundary and where bycatch is a serious concern; and (d) Mauritania where humpback dolphins were observed regularly in Banc d'Arguin National Park and environs over many years, but may have declined recently (Van Waerebeek and Perrin, 2007).

The Committee **strongly encourages** scientists in the range states to submit collaborative proposals for funding so that transboundary problems can be addressed in a comprehensive way, possibly cooperating with the staff of National Parks.

General recommendations relevant to all species

In general, the Committee **acknowledges** that the failure to manage industrial fisheries sustainably has often caused coastal artisanal and subsistence fisheries to suffer and, in turn, has led local people to seek alternative resources for consumption, including cetaceans.

Given the observed threats and the existing knowledge, the Committee makes the following general **recommendations** applicable to all small cetacean species in the west and northwestern Africa.

(1) The tallying of cetacean landings should be implemented as a standard procedure for fisheries observers at the national level, including the collection of photographic material, recognizing that small cetaceans are a *de facto* exploited marine living resource and therefore need to be monitored on a permanent basis.
(2) An intensive biological sampling programme based on fresh carcasses, collecting data on morphological variation, reproduction, growth, feeding, stock identification, genetics, migratory habits, etc. of cetacean species should be implemented.
(3) Use of platforms of opportunity should be intensified to collect data on distribution, relative abundance and behaviour of cetaceans.
(4) Further assessment of the links between declining fish catches and increasing takes of small cetaceans in West Africa should be made.

In at least three west African countries, Ghana, Togo and Guinea, the ongoing activities represented good examples of how the first two of these recommendations could be realised. The Committee **acknowledges** the contributions already being made by scientists in Nigeria and Benin and recognised that there is a great need for capacity building and financial support before such programmes can be implemented. The same is true for São Tomé and Príncipe where the status of small cetacean populations has not been fully assessed and for the Cape Verde Islands, where no study of small cetaceans has ever been conducted. With regard to the third recommendation, the Committee noted and commended the published work by Weir (2007; 2010) and de Boer (2010), much of which was based on data from platforms of opportunity (e.g. seismic survey vessels, oceanographic research vessels); these are seen as excellent examples of how this recommendation can be realised in more areas.

In conclusion, the Committee **recommends** international collaboration for funding and capacity building to support programmes for monitoring, management and conservation of coastal marine living resources in this region.

14.2 Review report from the working group on climate change and small cetaceans

The Committee received a summary on the ongoing plans for an IWC workshop on the effects of climate change on small cetaceans. The workshop plan (10-12 invited participants meeting for 3 days) was agreed last year but the workshop was not held in the last intersessional period as the final *tranche* of funding was only confirmed late in the year. The steering group and convener (Simmonds) are now finalising plans for the workshop, which will probably be held in Vienna in November 2010 (see Appendix 2 of Annex L). The focal topics are: (a) restricted habitats; (b) range changes; and (c) the Arctic region. During discussion it was suggested that pathogens should also be discussed.

The Committee **re-confirms** its support for the meeting and looks forward to receiving a full report of this workshop at the next annual meeting in 2011.

14.3 Review progress on previous recommendations

IWC Resolution 2001-13 (IWC, 2002b) directs the Scientific Committee to review progress on previous recommendations related to critically endangered species and stocks of cetaceans on a regular basis and the Committee noted that its previous recommendations stand until new information is received and considered.

14.3.1 Vaquita

The Committee reviewed new information on the critically endangered vaquita. SC/62/SM3 reported on a survey in the Upper Gulf of California that was conducted from mid-September, through October and November 2008 in a joint effort between the governments of Mexico and the US. The primary objective was to test alternative acoustic detection technology as a means of monitoring trends in vaquita abundance. Total abundance (based on both acoustic and visual data) was estimated as 250 animals (95% CI 110, 564). The estimate for waters inside the Vaquita Refuge was 123 (95% CI=64-239). The total estimate for 1997 had been 567 (95% CI=177-1,073). Analyses strongly support a population decline over the 11 years from 1997 to 2008. The overall distribution did not change between the two surveys, indicating that the apparent decline was not an artifact of a distributional shift. Approximately half of the population appears to be present inside the Vaquita Refuge area at any time, with individuals moving freely into and out of the refuge. Hence, they are at risk of interaction with fishing operations when outside of the refuge, and this means that protection from bycatch is only partial. Fishermen consider waters inside the Refuge to be a prime shrimping area and thus fishing activity is very intensive immediately outside its borders. The buyout programme begun by the Mexican government in 2007 has reduced the fishing effort by about 40%, but over 600 artisanal boats (*pangas*) are still fishing and those fishermen who remain active are strongly committed and unlikely to accept the buy-out offers from the government. This makes it crucial to develop alternative fishing methods that do not involve the risk of vaquita bycatch.

The Mexican government made a commitment to reduce the vaquita bycatch to zero within three years starting in 2008. There are no data to confirm that the bycatch rate has been reduced apart from an inference from the reduction in fishing effort; because of the regulatory situation, fishermen generally no longer report and deliver bycaught vaquitas to authorities. This makes the implementation of regulations particularly challenging.

SC/62/SM5 reported on the development of a monitoring plan to assess trends in vaquita abundance based on acoustics using C-POD. It is anticipated that the scheme will be in operation by the end of this year (2010). Jaramillo-Legorreta acknowledged the financial support provided to this work by a number of agencies and organisations in addition to the Mexican government: National Marine Fisheries Service, WWF, the Cousteau Society, Ocean Foundation, US Marine Mammal Commission and International Fund for Animal Welfare.

The Committee thanks Jaramillo-Legorreta for this update and commends those involved for their hard work and commitment to saving the vaquita. The Committee **agrees** that it would be useful to document (in working papers or publications) all of the costs of the vaquita conservation and monitoring efforts for future reference for other Countries with similar bycatch problems.

The Committee **remains gravely concerned** about the fate of the vaquita and it **reiterates its previous recommendation** (IWC, 2010h, p.324) that, if extinction is to be avoided, all gillnets should be removed from the upper part of the Gulf of California. The Committee further **recommends** intensified development and testing of alternative fishing gear (e.g. through a smart-gear competition) that fishermen can use in place of entangle gears. It **strongly encourages** Mexico to continue and intensify its efforts to conserve the vaquita.

14.3.2 Harbour porpoise

No primary papers on harbour porpoises were presented at this meeting.

A joint workshop of ASCOBANS/ECS recommended a revision of EU regulation 812/2004 on monitoring and mitigation of cetacean bycatch in gillnet and pelagic trawl fisheries, as at present it does not include small vessels of less than 15m length. The Committee **recommends** that the EU regulation should be reviewed if realistic total estimates of bycatch are to be provided.

Available information for the German North Sea and Baltic from 2003 to 2009 suggests an increasing trend in bycatch. As last year, the Committee **expresses concern** about the ongoing evidence of large-scale bycatch in this region, including the western Baltic (as discussed last year when the Committee called for more research). The Committee **notes**, in particular, that the harbour porpoise population in the Baltic proper is considered Critically Endangered. Better information on both the scale of incidental mortality and the stock affinities of the affected porpoises is essential.

Attention was drawn to the vulnerability of the recently identified a isolated Iberian population of harbour porpoises. The Committee **recommends** further study of this population.

14.3.3 Franciscana

The franciscana, endemic to the eastern coasts of Brazil, Uruguay and Argentina, is regarded as one of the most threatened small cetaceans in South America due to high bycatch levels as well as increasing habitat degradation throughout its range. It is classified as Vulnerable by IUCN. Secchi *et al.* (2003) proposed four management stocks (known as Franciscana Management Areas or FMAs): three in Brazil (FMA I-III), one in Uruguay (FMA III) and one in Argentina (FMA IV).

Mendez *et al.* (2010) stressed that considering all franciscana genetic analyses to date, there is strong evidence for the existence of at least three populations in Brazil (FMAs I, II and III), one in Uruguay (FMA III) and three in Argentina (FMA IV).

The Committee welcomes the new information concerning franciscana stocks in Argentina and encourages the continuation of research and conservation efforts on the species there, particularly in light of the high bycatch rates. It **recommends** that the possibility of further population structure within the range of the franciscana be investigated.

SC/62/SM7 presented information on distribution and provided the first estimate of abundance of franciscanas in FMA II (Brazil) from aerial surveys conducted in December 2008 and January 2009. Coverage included an area believed to correspond to a hiatus in the distribution between FMA I and FMA II. Sightings were confined to the coastal stratum, but offshore effort was low due to poor weather conditions. Corrected abundance was estimated to range between 8,000 and 9,000 individuals (CVs=0.32-0.35) although some additional sources of possible bias require investigation. Current estimates of incidental mortality in FMA II correspond to 3.3-6.2% of the estimated population size presented here, which is likely unsustainable.

The Committee **welcomes** this paper that addresses recommendations from previous years (IWC, 2005g, p.309). It notes that the estimates of abundance were probably negatively biased because of limited coverage of the offshore stratum and because estimates of group size from aircraft are consistently smaller than those from boats and land observation sites.

With regard to the aerial surveys in FMA II, the sub-committee commends Zerbini and his co-workers for their excellent work and **recommends** that further studies be carried out to:

(1) improve estimates of visibility bias;
(2) evaluate potential biases in the estimation of group sizes; and
(3) estimate franciscana diving parameters in areas where such information is not available.

The Committee also **recommends** that bycatch be estimated in additional areas and assessments be carried out of other possible threat factors such as underwater noise, chemical pollution from coastal development and industrial and human waste discharge, oil and gas exploration activities and vessel traffic.

14.3.4 Narwhal

Last year (IWC, 2010h, p.325), the Committee noted that new estimates of narwhal abundance had recently become available. Subsequently, the results of aerial surveys in Canada indicating total abundance greater than 60,000 narwhals were published (Richard *et al.*, 2010). The NAMMCO Scientific Committee considered new estimates from Greenland in its management advice given in April 2009 (IWC/62/4). At its 2009 meeting, the NAMMCO Council (NAMMCO Annual Report 2009, pp.96-97) considered the new information on narwhal abundance and revised its management advice accordingly. The 2005 NAMMCO assessment had concluded that narwhals in West Greenland were highly depleted and that annual sustainable harvest levels would be as low as 15-75 animals. However, population modelling with the new survey data from 2007 and 2008 indicated that overall abundance was at 51% (95% CI: 27-79%) of carrying capacity, with a 2009 modelled abundance of 12,000 (95% CI: 6,200-26,000), and NAMMCO concluded that its management objectives would be met at 70% probability with annual total removals of 310 (West Greenland) and 85 (East Greenland).

The Committee **thanks** the NAMMCO observer for providing information and **encourages** closer links between the NAMMCO and IWC Secretariats in sharing information, e.g. catch data. The possibility of a joint special meeting or workshop on monodontids (involving IWC, NAMMCO, Canada-Greenland Joint Commission on Narwhal and Beluga) should be considered in the near future, assuming that a data availability agreement can be established in advance. The next meeting of the Joint NAMMCO SC and JCNB scientific working group on narwhal and beluga will probably be in 2012, leaving adequate time to explore the potential of a joint meeting/workshop. The Committee **agrees** that an e-mail working group convened by Bjørge will follow up this possibility during the intersessional period and report back next year.

14.3.5 Irrawaddy dolphin

The freshwater population of Irrawaddy dolphins in the Mekong River is Critically Endangered (Smith and Beasley, 2004).

SC/62/WW4 reported on dolphin-watching tourism in the Mekong where photo-id studies indicate dolphins exhibit high site fidelity to particular deep-water pool areas that are very limited in size (1-2 km^2). The authors argued that an adaptive, precautionary approach is essential to managing tourism that targets small, closed, resident communities of cetaceans such as in this case. SC/62/WW4 recommended a range of management interventions, all aimed at decreasing the exposure of dolphins to dolphin-watching vessels.

The Committee received information from World Wide Fund for Nature (WWF)-Cambodia indicating that there are fewer than 100 dolphins based on a photographic mark-recapture analysis. At least 92 dolphins (>63% of them classified as calves) died in the period 2003-09, likely due primarily to entanglement in fishing gear and conservation efforts have focussed on the elimination of gill nets in the core habitat for dolphins in the 200km stretch of the Mekong between Kratie town and the Lao border. The conservation of dolphins in the Mekong is primarily the responsibility of the Commission on Dolphin Conservation and Ecotourism Development (Dolphin Commission). Despite its efforts, the mortality rate has remained high and the population apparently is continuing to decline. Dolphin conservation efforts in Cambodia reportedly have been hindered by inadequate funding for the Dolphin Commission and the lack of regulations that could help to reduce or eliminate the use of gill nets. There is also a need for much better cooperation among the Dolphin Commission, the Fisheries Administration and WWF. WWF and the Fisheries Administration are currently working to develop protected areas and other regulatory tools to protect dolphins. WWF and local NGOs are also working with local communities to reduce gill net use and to develop alternative livelihoods in order to reduce fishing pressure in core dolphin habitat.

The Committee **expresses grave concern** about the rapid and not fully explained decline of this riverine population. It commends the efforts by Cambodian government agencies and WWF-Cambodia to diagnose the cause(s) of the decline, and **strongly recommends** that every effort be made to stop and reverse it, e.g. by immediately eliminating entangling fishing gear in the pool areas used most intensively by the dolphins and by taking immediate steps to reduce the exposure of the dolphins to tour boat traffic.

14.3.6 Other

The Committee received an update (SC/62/SM2) of Amaral *et al.* (2009), the goal of which is to revise the model of worldwide population structure of common dolphins, genus *Delphinus,* using a multilocus approach. It has become clear that the long-beaked population in the northeastern Pacific is highly differentiated from all other populations based on both nuclear and mitochondrial markers. The differentiation between short-beaked populations occurring in different oceans is even higher than suggested in Amaral *et al.* (2009). Future analyses will estimate divergence times and migration rates between the different populations. This study also highlighted the difficulty of obtaining informative molecular markers other than mitochondrial DNA and microsatellites, due to the low overall level of polymorphism in the nuclear genome of common dolphins.

The Committee **encourages** the continuation of this global study of the genus. It also **recommends** that efforts should be made to obtain samples from regions where both short-beaked and long-beaked forms occur, as is the case in West Africa and the southeastern Pacific.

14.4 Other information presented

SC/62/BC6 presents a preliminary global review of operational interactions between odontocetes and the longline fishing industry and potential approaches to mitigation. This is a global problem for both cetaceans and fishermen. Mitigation strategies are needed to ensure the sustainability of both the odontocete populations and the longline fisheries. Bycatch occurs in many longline fisheries and involves at least 13 species but there are few quantitative data. The inadequacy of life history and population data adds to the difficulty of assessing the sustainability of the bycatch in most cases. Considerable effort has been devoted to solving the depredation problem and potential solutions have included acoustic and physical tools. Acoustic approaches to mitigation have proven problematic but recent trials using physical depredation mitigation devices have yielded promising results.

In discussion it was noted that longline fisheries for halibut and Greenland halibut in the northern North Atlantic have increasingly experienced problems with depredation of catches by northern bottlenose whales (*Hyperoodon ampullatus*).

New information was presented on the ongoing commitment of the Italian government (Ministry of the Environment) to conduct systematic abundance aerial surveys of small cetaceans in Italian waters (Ligurian, Tyrrhenian, Sardinian and Ionian seas) and in the Pelagos Sanctuary. Initial scientific and technical support was provided by the IWC Head of Science. The surverys are a priority action common to the Sanctuary Management Plan, ACCOBAMS and RAC/SPA UNEP. Among the preliminary conclusions from the completed surveys were: (1) the Sanctuary does not cover the full population range of striped dolphins; and (2) there is substantial seasonal variation in the density and abundance of striped dolphins (higher in summer). These density and distribution data from the surveys will be instrumental to the proposed ACCOBAMS basin-wide survey and will help guide the development of a long-term monitoring programme. The Committee also **welcomes** news of a complete survey of the Adriatic Sea funded by the Italian Government in July-August 2010.

The ACCOBAMS observer reported that a basin-wide survey of cetaceans in the Mediterranean and Black Seas remains one of ACCOBAMS' highest priorities. Activities are underway with the aim to start such a survey in the next triennium (2011-13).

The Committee **welcomes** the new information and **supports** continuation of such efforts in the Mediterranean Sea and adjacent areas. It specifically **endorses**, as it has in the past, implementation of the ACCOBAMS basin-wide survey, as soon as possible.

14.5 Review of takes of small cetaceans

At the last meeting, the sub-committee discussed various problems associated with the compilation of data on takes of small cetaceans including both direct catches and bycatch (IWC, 2010h, pp.326-28). It recommended a series of changes in how the data should be compiled, reported and interpreted. The process of setting up a system for direct electronic submission of these data by national representatives is still ongoing. The information retrieved by the Secretariat from national progress reports was reviewed. Data on bycatch of small cetaceans was presented in 12 National Progress Reports (Annex L, table 2).

The Committee **reiterates** the importance of having these data submitted and **encourages** all countries to do so.

The observer from NAMMCO advised that catch data from member countries are routinely published in the NAMMCO Annual Reports that are available on the website *http://www.nammco.no*.

Concern was expressed about the information from 12 West African countries indicating human consumption of cetaceans, exchange of cetacean meat in markets or direct capture of cetaceans (see Annex L, table 1); consumption and exchange can lead to targeted and unregulated direct hunting.

Information was received on small cetacean interactions with fishing gear in Machalilla National Park, Ecuador. Four species of cetaceans were caught incidentally: common bottlenose dolphins, dwarf sperm whales, Risso's dolphins and pantropical spotted dolphins. The Committee **expresses concern** about the implications of the bycatch documented in this preliminary study and looks forward to a more detailed report next year on the scale of the fisheries involved and therefore the implied magnitude of the cetacean bycatch.

14.6 Voluntary Fund for Small Cetaceans Conservation Research

The Committee discussed a proposed mechanism and procedure for allocating project support for high priority conservation projects (e.g. improving status of threatened species, capacity building) from the IWC Small Cetacean Research Fund. Australia's recent contribution to the fund is intended to support high priority research that demonstrably links to improving conservation outcomes for small cetaceans globally, particularly those that are threatened or especially vulnerable to human activities. Preference for funding will be based on a determination of need, the quality of the research application and the demonstration of links between research and conservation outcomes. Proposals that demonstrate a capacity building legacy will be viewed favourably.

In order to maximise the number of projects supported by the fund, and hence enhance conservation outcomes for small cetaceans, any single proposal will be limited to a maximum of £34,000. Other IWC member governments will also be encouraged to provide additional voluntary donations to the fund to further support small cetacean research.

A funding application form is being developed and made available via the IWC Secretariat. Applications should be received by the Secretariat at least 60 days prior to the start of the Committee's Annual Meeting. A Review Group will be appointed by the Convenor of the Small Cetacean sub-committee to review proposals in accord with agreed criteria. The group will make recommendations for funding to the Small Cetaceans sub-committee. It may suggest improvements to proposals where appropriate and can solicit the assistance of other researchers in the review process if necessary.

The recommended projects and budgets will be reviewed by the Small Cetacean sub-committee and the full Scientific Committee. Recommended proposals will be added to the Committee's budget as a specific request to the Voluntary Research Fund for Small Cetaceans. The Secretariat will organise contracts for the projects that are approved for funding by the Commission.

The Committee **emphasises** the importance of ensuring that proposal review and project selection meet the criteria and priorities of the sub-committee on small cetaceans. In addition to a call for proposals via a circular from the IWC Secretariat to all members of the Scientific Committee, a broader announcement mechanism will be developed.

The Committee **expressed** its gratitude to the Government of Australia for its generous contribution to the Voluntary Fund for Small Cetacean Conservation Research, which will make a significant difference to the Fund's ability to pursue its conservation priorities.

The Committee also **emphasises** the importance of building the Fund by obtaining donations from other sources. It was noted that good outcomes from the funded research should encourage more countries to contribute.

14.6.1 Project Proposal for the Voluntary Fund for Small Cetacean Conservation Research

A proposal for funding by the Small Cetacean Conservation Research Fund entitled '*Threatened Franciscanas: Improving Estimates of Abundance to Guide Conservation Actions*' was presented (Annex L, Appendix 3). The proposed work is directly linked to previous recommendations of the sub-committee, and responds directly to recommendations made at the present meeting based on consideration of SC/62/SM7 (see Annex L).

The sub-committee **strongly supports** the proposal, based on the following considerations:

(1) the franciscana is threatened by a variety of human activities in the region, particularly artisanal fishing;
(2) the proposal addresses a clear conservation need as expressed in present and previous recommendations; and

(3) more robust estimates of franciscana abundance (along with improved, more nearly complete estimates of bycatch as well as assessments of other threat factors) are needed to assess the status of populations and develop appropriate mitigation efforts.

The proponents have a strong track record (e.g. as reflected in the quality of the work described in SC/62/SM7).

The Committee therefore **recommends** that the proposal be funded by the Voluntary Fund for Small Cetacean Conservation Research and that a full report on the results be provided for consideration at a future meeting.

14.7 Work plan

The sub-committee on small cetaceans reviewed its schedule of priority topics which currently includes:

(1) systematics and population structure of *Tursiops*;
(2) status of ziphiids worldwide; and
(3) fishery depredation by small cetaceans.

The Committee **agrees** that the priority topic for the next annual meeting will be the status of ziphiids (beaked and bottlenose whales) worldwide.

Further discussion of potential future topics can be found in Annex L. As part of the discussion it was agreed to establish an intersessional correspondence group convened by Ritter to consider whether the issue of the consumption of cetaceans ('marine bushmeat') as some type of substitute for other resources that are becoming scarce should be added to the priority topic list. The group will collate information intersessionally and report back at the next annual meeting.

The Committee will also review the report from the Workshop on climate change and small cetaceans.

15. WHALEWATCHING (WW)

The report of the sub-committee on whalewatching is given as Annex M. Scientific aspects of whalewatching have been discussed formally within the Committee since a Commission Resolution in 1994 (IWC, 1995b).

15.1 Proposal for a large-scale whalewatching experiment (LaWE; including reports from the intersessional steering group and the advisory group)

The Committee received a proposal from the large-scale whalewatching experiment (LaWE) intersessional steering group. The report elaborated on the objectives, aims, methodology, design, management and funding considerations for this initiative (Annex M, Appendix 2).

Three options were presented for procedural mechanisms to manage the different components of the LaWE project, ranging from top-down (in which the IWC would play a steering group role) to decentralised (in which the IWC would play a coordinating role (Annex M, item 5.1, fig. 1). After discussion, the Committee **agrees** that a transitional process is preferable, with a top down approach (hierarchical structure) at the initial stage of the project progressing into a mechanism where the IWC would play more of a coordinating role (network structure). Discussions are detailed in Annex M, item 5.1.

IWC member nations will be able to use the results of the project as the basis for appropriate scientific management of whalewatching. The information collected during LaWE will also provide data on general biology and life history parameters of cetaceans that are relevant to other aspects of the Committee's work. There are a variety of potential funding sources for the LaWE effort including:

(1) IWC membership: funding derived from fees/contributions from member nations;
(2) national/regional initiatives: funding derived from national or regional governments involved in the support/promotion of whalewatching;
(3) NGOs: funding derived from national/international NGOs involved in the conservation of cetaceans;
(4) whalewatching operators: funding derived from whale/dolphin-watching operators; and
(5) hybrid model: targets key operators in high profile whalewatching areas with additional funding sought from host countries, IWC, NGOs, and other sources.

The Committee **recommends** that an e-mail correspondence group be formed to further develop the budget for the LaWE, although it noted that until power analyses are completed and species and sites are chosen, only approximate budgets can be created.

The Committee **agrees** to combine the two previous LaWE intersessional groups into one 'steering group' to maximise collaborative discussions (see Annex M, item 5.1).

The budget request to assist the LaWE intersessional work to develop procedural mechanisms to centralise data received from research groups relevant to LaWE with the Secretariat and commence power analysis for key parameters depending on data received is discussed under Item 24. In addition, funding is requested for a pre-meeting of the LaWE steering committee to review and advance intersessional progress on all aspects of the project, including reviewing data received, advancements in power analysis, and the selection of appropriate study species and sites.

There was no formal report from the advisory group, as the LaWE is not yet at the point of selecting research sites.

15.1.1 Other

SC/62/WW5 presented a summary of progress from a working group tasked with developing a formal mathematical structure from the US National Academy of Sciences Population Consequences of Acoustic Disturbance (PCAD) conceptual framework. The working group decided to develop three statistical models to provide the linkages from disturbance to population dynamics. Work has focused on the first models (disturbance to physiological conditions). First implementations with simple systems (southern elephant seals at-sea movement) proved extremely successful and body condition time series could be estimated and validated against body weight when the seals returned to the colony. A similar, albeit more complex, model was developed for coastal dolphin population case studies and will be implemented over the next year.

Discussions on the motivational state-space approach to the PCAD model and concern about the restrictions on the remit of the PCAD project are detailed in Annex M, item 5.1.

15.2 Review of whalewatching off North Africa

SC/62/SM8 reported on cetacean sightings, local human activities and conservation off São Tomé (São Tomé and Príncipe), Gulf of Guinea, West Africa. This region seems to be an important area for cetaceans; however, the status of species or populations has not been assessed due, in part, to lack of information and effort. A similar situation may exist in the Cape Verde Islands where there are resorts and a significant number of tourists. It was noted that several measures regarding the conservation of natural populations of cetaceans are needed for these areas (including international standards of operation, educational programmes and research) to reinforce a change to a more conservation-oriented perspective with direct involvement of local communities.

The Committee welcomed the report and noted the lack of information on whalewatching activities in western and northern Africa. Furthermore, it **expresses concern** at the potential for expansion of whalewatching activities in the region without sufficient scientific information on cetaceans and called for an assessment of the scope of activities to be made by relevant authorities as soon as possible.

An overview of whalewatching activities in the Mediterranean will be prepared under ACCOBAMS. More information is available on the Agreement's official website, *http://www.accobams.org*.

15.3 Assess the impact of whalewatching on cetaceans

SC/62/WW4 reported on the critically endangered Irrawaddy dolphin population inhabiting the Mekong River. Studies indicate dolphins exhibit high site fidelity during the dry season, have low genetic diversity and a high mortality rate. The locations of dolphin-watching areas are at two of the critical habitats for the remaining population in the river, numbering less than 100 individuals. Initially, at both locations, the dolphin-watching industry was land-based, with a few row-boats occasionally taking tourists into the pool to view dolphins. By the early 2000s this expanded to approximately 15 larger motorised boats that offered dolphin tours. Now it numbers more than 20. The authors believe that an adaptive, precautionary approach is essential to managing tourism that targets small, closed, resident communities of cetaceans and that for this Critically Endangered population, a 'no vessel-based dolphin tourism' policy is desirable. It was noted that the issues associated with Cambodian cetacean-watching tourism may be generic to developing countries.

The Committee reiterated **its concern** over the critically endangered Mekong River Irrawaddy dolphin population. In 2006, it had noted that there was compelling evidence that the fitness of individual odontocetes repeatedly exposed to tour vessel traffic can be compromised and that this can lead to population level effects (IWC, 2007b). It also stated that, in the absence of data, it should be assumed that such effects are possible until indicated otherwise – particularly for small, isolated and resident populations. Accordingly, the Committee **strongly recommends** that the Cambodian government and relevant agencies make every effort to reduce the exposure of dolphins to vessel-based tourism in deep-water pools in the Mekong River.

SC/62/WW1 reported on behavioural responses of southern right whales to human approaches in Bahia San Antonio, Rio Negro, Argentina. Results are listed in Annex M, item 6. The Committee noted the small sample size but commended the before-during-after experimental design.

SC/62/WW2 summarised recent advances in whale-watching research. Noren *et al.* (2009) investigated the prevalence of 'surface active behaviours' (e.g. spy hops, breaches) in the vicinity of boats in southern resident killer whales; Arcangeli and Crosti (2009) conducted a study on an Australian common bottlenose dolphin (*Tursiops truncatus*) population in the coastal waters of Bunbury; Christiansen *et al.* (2010) used a Markov chain analysis to investigate changes in Zanzibar Indo-Pacific bottlenose dolphin (*T. aduncus*) behavioural states in relation to boat traffic; Scarpaci *et al.* (In press) reported on the impact of swim-with-cetacean tourism on bottlenose dolphins within a 'sanctuary zone' in Port Phillip Bay, Australia; Sousa-Lima and Clark (2009) used automated acoustic recordings to monitor and track the singing behaviour of male humpback whales in Abrolhos Marine National Park, Brazil, a major humpback whale breeding ground; Stamation *et al.* (2010) monitored the behaviour of groups of humpback whales off Queensland Australia from both whalewatching vessels and land-based platforms; Filla and Monteiro (2009) investigated various types of whalewatching on estuarine or 'guianensis' dolphins (*Sotalia guianensis*) in Cananéia, southeast Brazil; and Jensen *et al.* (2009) found that common bottlenose dolphin and pilot whale (*Globicephala macrorhynchus*) communication calls could be masked substantially by small outboard engine noise. Summaries are presented in Annex M, item 7.

The Committee **welcomes** this review and encouraged the author to prepare a similar review for the next meeting. It was clarified that these reviews are not critiques of methods or results but rather a compilation of new research results of interest.

SC/62/WW3 reported on the US National Oceanic and Atmospheric Administration's efforts to develop management plans to reduce the exposure of resting spinner dolphins (*Stenella longirostris*) to human activity in Hawaiian waters. One management approach under consideration focuses on time-area closures to reduce the number and intensity of interactions between humans and dolphins during critical rest periods in particular bays. Research will combine boat-based and land-based visual observations with passive acoustic monitoring and is an international collaboration between researchers from American, Australian and Scottish universities. Time area closures will not be implemented until a full year of pre-closure data collection has been completed. The authors highlighted this study as a possible candidate project for inclusion in the Large-scale Whalewatching Experiment (LaWE) initiative, as it incorporates many facets that the LaWE initiative strives to achieve.

The Committee **commends** this study and deems it relevant to the LaWE initiative.

SC/62/WW8 presented a precaution on interpreting the results of impact study data analysis. The paper discussed the possibility of confounding variables when interpreting correlations between whalewatching exposure and reproductive parameters of female humpback whales (see Weinrich and Corbelli, 2009). Discussion is presented in Annex M, item 7.

The Committee **welcomes** this paper as an important consideration in impact analyses. It was noted that this contribution clarifies that whalewatching is essentially another habitat variable, and should be treated as such in multivariate models.

Parrot *et al.* (2010) report on an agent-based simulation platform to assess the characteristics of interactions between whales and vessels under different scenarios. The simulation is composed of a spatial environment in which a whale individual-based model and a boat agent-based model can evolve. It simulates the spatiotemporal movement of marine mammals and vessel traffic in the St Lawrence Estuary. It estimates movement parameters from long-term data collected using both onboard GPS and vessel monitoring systems for vessels and a variety of land-based and boat-based focal follows as well as sightings for marine mammals from whalewatching boats.

This platform can be used to inform decision-making by simulating different vessel and whalewatching traffic scenarios.

This project is highly relevant to the LaWE objectives and offers an avenue to simulate boat interaction consequences for cetaceans using behavioural statistical models of disturbance effects. The Committee **welcomes** this effort.

The Committee noted that its work on whalewatching has been influential with other research initiatives to understand effects of disturbances on cetacean populations.

At last year's meeting, there was discussion on the impacts of aerial whalewatching (IWC, 2010i). Groch noted that she was not able to analyse behavioural data collected in previous years during southern right whale photo-id surveys from a helicopter in Brazil. Sironi reported that a trial was conducted to record before-during-after behavioural observations during the 2009 southern right whale photo-id aerial survey in Argentina from a fixed-winged aircraft. Dedicated flights are required to obtain more accurate behavioural data.

15.4 Review reports of intersessional working groups

15.4.1 Online database for worldwide tracking of commercial whalewatching/associated data collection

Robbins summarised the status of an online database for tracking whalewatching operations and associated data collection programmes. This database was originally described in Robbins and Frost (2009) and is intended to facilitate studies of whalewatching impact as well as to allow better assessments of the scientific value of data collection programmes. Database development has made considerable progress intersessionally and should be available to go online prior to next year's meeting. The Committee **recommends** that the intersessional working group continue and report back next year (see Annex Q).

15.4.2 Swim-with-whale operations

Rose reported that due to time constraints, no progress was made intersessionally on field-testing a questionnaire to further assess the extent of swim-with-whale operations. However, a draft questionnaire is ready to be distributed and plans are in place to do so in the Dominican Republic and possibly Australia before next year's meeting. The Committee welcomes the commitment of funding for this effort by the Pacific Whale Foundation and **recommends** that the intersessional working group continue and report back next year (see Annex Q).

15.5 Other issues

15.5.1 Consider information from platforms of opportunity of potential value to the Scientific Committee

Progress continues in efforts to stimulate submission of opportunistic data from ecotourism cruise ships in the Southern Ocean to the Antarctic Humpback Whale Catalogue (AHWC). The availability of these data has broadened understanding of the exchange between areas and in some cases provided information that was previously not available. Ritter (2010) reported on a near-miss event involving a large vessel and humpback whales off Antarctica (see Annex M, item 9.1).

Smit *et al.* (2010) reported on opportunistic research off the coast of La Gomera, Canary Islands (Annex M, item 9.1). The study highlights the importance and the potential of mutual long-term co-operation between whalewatching operators and scientists. The Committee welcomes the reports and reiterated the value of collaboration between researchers and whalewatching operations and other platforms of opportunity.

15.5.2 Review of whalewatching guidelines and regulations

The compendium of whalewatching guidelines and regulations around the world is in the process of being updated and will be available on the IWC's website in August. SC/62/WW2 described several papers relating to guidelines and compliance including Noren *et al.* (2009), Williams *et al.* (2009a); Stamation *et al.* (2010); Sousa-Lima and Clark (2009); and Jensen *et al.* (2009).

Summaries of the reports are found in Annex M, item 9.2.

15.5.3 Review of risk to cetaceans from collisions with whalewatching vessels

No new information was brought to the meeting this year. Some members indicated that papers on this item would be submitted to next year's meeting. The Committee noted that this issue will be discussed at a joint workshop with ACCOBAMS in Monaco from 21-24 September 2010.

15.5.4 Future of the sub-committee on whalewatching

The Committee took note of IWC/62/CC8 and the possible interface between the Conservation Committee's work and its own work on whalewatching. The Conservation Committee has established a Standing Working Group on Whalewatching and intends to develop a draft strategic plan for five years (2010-15). IWC/62/CC8 made reference to the work of the Committee and various scientific issues and the section on Capacity Building and Development states that actions 'may include… provision of expert assistance through the Scientific Committee's sub-committee on whalewatching'.

The Committee requests clarification on the mechanism by which this expert assistance will inform the work of the Standing Working Group. It welcomes the opportunity to liaise with the Conservation Committee and Commission, but noted its own terms of reference, and believes that the advice it offers should be within that framework. One possible mechanism, for example, would be to designate a representative from the Committee to work directly with the CC on this issue, thereby providing a formal interface.

The Committee is also seeking clarification on the envisioned management objectives for whalewatching, as IWC/62/CC8 states both 'growth' and 'sustainability' objectives. Clarification will guide the scientific work of the Committee for Objective 7 of the LaWE project ('Develop an integrated and adaptive management framework for whalewatching that accounts for uncertainties, and includes monitoring and feedback mechanisms').

The Committee draws the attention of the Conservation Committee to the definitions of whale ecotourism developed at previous meetings (IWC, 2006c) and considered it important that the Conservation Committee takes a strategic view of what it might achieve in the five years. It also **stresses** the importance of a good scientific basis for the work that it is recommending to the Commission.

It was noted that it would be valuable to increase communication with and explore possibilities for collaborate with the UN World Tourism Organisation, as its remit complements the work of the sub-committee in a number of aspects. Lusseau agreed to liaise for this purpose.

15.5.5 Other

Eisfield *et al.* (2010) reported on the behaviour of a female solitary sociable dolphin studied on the southeast coast of England in 2007, previously addressed by the Committee. The report is summarised in Annex M, item 9.5.

The Committee **reiterates its recommendation** of 2008: habituation of solitary dolphins can make them vulnerable to harm, including being killed, and should be avoided.

16. DNA TESTING (DNA)

The report of the Working Group on DNA is given as Annex N. This particular Agenda Item has been considered since 2000 (IWC, 2001d; 2001e; 2001h) in response to a Commission Resolution (IWC, 2000).

16.1 Review genetic methods for species, stock and individual identification

No new documents were submitted under this Item this year. Last year, the Committee had reviewed Cipriano and Pastene (2009), which provided a comprehensive review of current knowledge of techniques to extract DNA from 'difficult' samples.

16.2 Review results of the amendments of sequences deposited in GenBank

During the first round of sequence assessment (IWC, 2009i, p.347), some inconsistencies were found for some sequences assigned to right and minke whales. These appeared to have been due to a lag in the taxonomy recognised by *GenBank* or uncertainty in taxonomic distinctions currently under investigation (e.g. the number of species and appropriate names for recently described species of 'Bryde's whales').

Last year, the Committee noted that the original submitter would be notified of the inconsistencies and a suggestion made that an amendment be made to the entry. Pastene reported that he had contacted *GenBank* officers to make the above indicated amendments. He was informed that only the original submitters of the sequences can make amendments to their submissions. In view of this he contacted the relevant scientists encouraging them to make the relevant amendments. As a result, the notification regarding Bryde's whale taxonomy (IWC, 2010c, p.73) was made. Amendment work by the original submitters of right and minke whale sequences is ongoing and this work will be completed during the next intersessional period.

The Committee thanked Pastene for his work in this regard.

16.3 Collection and archiving of tissue samples from catches and bycatches

The collection of tissue samples in Norway is from the commercial catches of North Atlantic common minke whales from 1997 to 2009. A total of 484 whales were landed in 2009 (see Annex N, Appendix 2).

The collection of samples in Japan is from special permit whaling in the Antarctic (JARPA II) and North Pacific (JARPN II), bycatches and strandings. The collection includes complete coverage for 2009 and the 2009/10 Antarctic season. A total of 506 genetic samples of the Antarctic minke whale and one of the fin whale were collected from the 2009/10 austral summer survey of JARPA II. From JARPN II in the western North Pacific (NP) samples stored in 2009 were: NP common minke whale, n=162; NP Bryde's whale, n=50; NP sei whale, n=100; and NP sperm whale, n=1. The samples from bycatch stored in 2009 were: NP common minke whale, n=119; NP humpback whale, n=3. Genetic samples were stored for the following stranded whales in 2009: NP common minke whale, n=3; NP humpback whale, n=1 and NP sperm whale, n=1 (see Annex N, Appendix 3).

The collection of samples from Iceland in 2009 was from commercial catches of North Atlantic common minke whales (n=81) and fin whales (n=125). Samples are currently in hand for all whales taken in 2003-09 (see Appendix 4 of Annex N).

The Committee welcomes this information from Norway, Japan and Iceland.

16.4 Reference databases and standards for diagnostic registries

Genetic analyses have been completed and data on mtDNA, microsatellites and sex entered in the Norwegian register for years up to 2007. The laboratory work on the 2008 samples is completed but has not yet been analysed. Laboratory work is ongoing for the 2009 samples (see Annex N, Appendix 2).

For the Japanese register, the genetic analyses based on mtDNA have been completed for North Pacific common minke, Bryde's, sei and sperm whales taken by special permit whaling up to 2009. Laboratory work on microsatellites for these samples is ongoing.

The genetic samples of Antarctic minke whales obtained by JARPA II have not yet been analysed, except for sex and for microsatellites of 190 samples taken in 2006-07 (six loci) and 551 taken in 2007-08 (six loci). For bycatch samples, genetic analyses based on mtDNA have been completed for all samples up to 2009. Laboratory work on macrosatellites for these samples is ongoing. Laboratory work is ongoing for stranded animals in 2009 for both mtDNA and STR (see Annex N, Appendix 3).

For the Icelandic register, genetic analyses (mtDNA and microsatellites) have been completed for common minke whales taken by special permit whaling in 2003-07. Laboratory work of samples taken under commercial whaling in 2006-09 is ongoing. Genetic analyses were completed for fin whale commercial samples collected in 2006 and 2009 (see Appendix 4 in Annex N). It was noted that only whales intended for export from Iceland were currently being genotyped for inclusion in that country's registry and that other whale samples will be genotyped as soon as possible.

The Committee **recommends** the adoption of a standard format for the updates of national DNA register to assist with the review of such updates in the future and agrees that the format used by the Norwegian registry update provides a suitable model. Pastene will work intersessionally with colleagues from Norway, Japan and Iceland to agree on the standard format. In addition, the Committee **agrees** that it would be useful to add a 'per cent completed' column for genetic analysis of tissue samples to assist in the annual review.

Whilst agreeing with these recommendations, Víkingsson reminded the Committee that Norway, Japan and Iceland are providing updates of their registries to the Committee on a voluntary basis.

The Committee noted that full technical specifications for the Japanese and Icelandic DNA registries have not been received or reviewed. Although such information is provided voluntarily, such a review would be helpful for the Committee's annual review of the status of DNA registries under its standing agenda items. The Committee recalled that updates of registers should include a list of references including the relevant documents on protocols used.

16.5 Other

SC/62/O19 describes a proposal to the IWC DAG under Procedure B, requesting access to the Japanese DNA register for the purposes of evaluating the technical aspects of traceability/trackability of sei, fin and Antarctic minke whale products purchased at commercial outlets in Santa Monica, USA and Seoul, South Korea. SC/62/O19 requested that the proposal be considered for endorsement by the Group.

The Committee could not reach an agreement on whether or not to endorse the proposal in SC/62/O19 of the current policy of Japan, Norway and Iceland regarding DNA registers access and market survey, although it recognised that the matching exercise proposed would, in principle, be valuable for testing functionality of DNA registers for identifying and tracking whale products.

16.6 Work plan

Members of the Committee were encouraged to submit papers in response to requirements placed on the Committee by the IWC Resolution 1999-8 (IWC, 2000). Results of the 'amendments' work on sequences deposited in *GenBank* will be reported next year.

17. SCIENTIFIC PERMITS (SP)

This Agenda Item was discussed by the Working Group on Special Permits in an evening session to enable all Committee members who wished to do so to attend. Bjørge was elected Chair of the Working Group. Reeves acted as Rapporteur, and the report has been directly incorporated here.

17.1 Review of activities under existing permits

All cruise reports from Japanese scientific permits from 1987 to the present are publicly available on the website of the Institute for Cetacean Research[5]. As in recent years, documents describing activities carried out in the preceding year were received by the Committee but not presented or discussed, except for points of clarification. Authors' summaries are included below. Full discussions will occur during the periodic reviews (see Item 17.3).

17.1.1 JARPN II

SC/62/O4 presented the results of the eighth full-scale survey of the Japanese Whale Research Program under Special Permit in the Western North Pacific-Phase II (JARPN II)-offshore component-, which was conducted from 10 May to 29 July 2009 in sub-areas 7, 8 and 9 of the western North Pacific. A total of five research vessels was used: one trawl survey vessel equipped with scientific echo sounder (TSV), one dedicated sighting vessel (SV), two sighting/sampling vessels (SSVs) and one research base vessel. A total of 6,374n.miles was surveyed. During that period 63 common minke, 482 sei, 93 Bryde's and 287 sperm whales were sighted. A total of 43 common minke, 100 sei, 50 Bryde's and one sperm whales was caught by the SSVs. All whales caught were examined on board the research base vessel. A total of 53 kinds of samples and data were obtained from each whale. A total of 16 skin biopsy samples were collected from blue (6), sei (9) and sperm (1) whales. As in previous surveys, common minke whales fed mainly on Pacific saury (*Cololabis saira*) and Japanese anchovy (*Engraulis japonicus*). Bryde's whales fed mainly on Japanese anchovy and oceanic lightfish. Sei whales fed mainly on copepods, Japanese anchovy and mackerels. Dominant preys in the stomach of one sperm whale were various kinds of squids, which inhabit the mid- and deep-waters. Qualitative and quantitative data on stomach contents will be used in the development of ecosystem modelling.

SC/62/O5 outlined the results of the sixth JARPN II survey (coastal component), conducted off Sanriku, northeastern Japan (i.e. the middle part of sub-area 7). The survey was carried out from 22 April to 21 May 2009 using four small sampling vessels and one echo sounder-trawl survey vessel. The research area was set within 50n.miles of Ayukawa port in the Sanriku district. The prey species survey was also conducted by the echo sounder-trawl survey vessel. A total of 4,756n.miles (464 hours) was surveyed and 111 schools (112 individuals) of common minke whales were sighted. No other large cetacean species was sighted. A total of 60 common minke whales were caught (27 males and 33 females) and landed at the JARPN II research station for biological examination. Only one individual in each sex was sexually mature. In addition the female was pregnant. The dominant prey species found in the forestomach was adult Japanese sand lances (*Ammodytes personatus*). The Japanese anchovy (*Engraulis japonicus*) and krill (*Euphausia pacifica*) were also observed but their frequency of occurrence was much lower. The prey species survey revealed high density of Japanese anchovy in the sampling area for common minke whale. These results suggest that during the 2009 survey common minke whales had prey preference for Japanese sand lance.

SC/62/O6 reported the results of the seventh JARPN II survey (coastal component), conducted off Kushiro, northeastern Japan (i.e. the northern part of sub-area 7). The survey was conducted from 5 September to 17 October 2009 using four small sampling vessels. The research area was set within 50n.miles of Kushiro port. The total searching effort by the sampling vessels was 5,136n.miles (494 hours) and 106 schools of common minke whales (107 individuals) were sighted; 59 animals were caught (36 males and 23 females) and landed at the research station. Of the males, 12 were sexually mature. None of the females sampled had attained sexual maturity. The walleye pollock (*Theragra chalcogramma*) was the most dominant prey species in the forestomach, followed by krill (*Euphausia pacifica*), Japanese anchovy (*Engraulis japonicus*), and Japanese common squid (*Todarodes pacificus*). Pacific saury (*Cololabis saira*) was not observed this year. All the animals feeding on walleye pollock were sexually immature. These results were almost the same as in the previous coastal surveys off Kushiro. The results suggest differences in feeding habits between immature and mature common minke whales off Kushiro in autumn. During the survey, other baleen whales were also sighted: 51 fin, 5 sei, and 22 humpback whales. They were observed in the vicinity of sampling positions of common minke whales that were feeding on krill.

17.1.1.1 POINTS OF CLARIFICATION

In response to a question regarding what new information of value in ecosystem modelling could be learned from the taking of one sperm whale last year (relative to the large number that had been caught and examined, with similar results regarding prey, in previous commercial whaling), the proponents stated that previous data on sperm whale diet from commercial catches were non-quantitative and did not consistently identify prey items to species level. They stated that this limited their utility in models such as ECOSIM and ECOPATH, and that data obtained from JARPN II were effectively used for ecosystem modelling. Others considered that this was not the case, and reiterated their view, and that of the JARPN II Review Panel (IWC, 2010a), that the catch of sperm whales in JARPN II is not scientifically justified.

---

[5] *http://www.icrwhale.org/CruiseReportJARPA.htm* and *http://www.icrwhale.org/CruiseReportJARPN.htm*.

17.1.2 JARPA II

SC/62/O3 presented the results of the third full-scale survey of the Japanese Whale Research Program under the Special Permit in the Antarctic-Second Phase (JARPA II), which was conducted during the 2009/10 austral summer season. Two dedicated sighting vessels (SVs), two sighting and sampling vessels (SSVs) and one research base ship were engaged in the research for 97 days from 14 December 2009 to 20 March 2010 in Areas III East (35°E-70°E), IV (70°E-130°E), V West (130°E-165°E) and part of Area V East (165°E-175°E). The total searching distance was 8,232n.miles. Eleven species including six baleen whales (Antarctic minke, blue, fin, sei, humpback and southern right whales) and two toothed whales (sperm and southern bottlenose whales) were identified during the research period. A total of 986 groups (2,242 animals) of Antarctic minke whales were sighted. It was the dominant species in the research area followed by the humpback whales (603 groups, 1,187 animals), and fin whales (56 groups, 186 animals). The number of sightings of the Antarctic minke whales was about 1.9 times higher than that of humpback whales in this survey. A total of 506 Antarctic minke whales and one fin whale were caught. All whales caught were examined on board the research base vessel. A total of 55 kinds of samples and data were obtained from each whale sampled. A total of 8 blue, 110 humpback and two southern right whales was photographed for natural marks. A total of 86 skin biopsy samples were collected from fin (1), humpbacks (84) and southern right (1) whales. To investigate vertical sea temperature profiles oceanographic surveys were conducted at 57 points using TDR. The main results of this survey were as follows: (1) whale composition in the research area was stable compared to previous JARPA II surveys in this area; (2) the ice-free extent of the research area was substantially larger than in past seasons and high density areas of Antarctic minke whales were observed near the continental shelf; (3) mature females of Antarctic minke whale were dominant in Prydz Bay; and (4) humpback whales were widely distributed in the research area and its density index was higher than that of the Antarctic minke whales in Areas IV West and V East. The 1994/95 IWC/SOWER cruise was conducted in similar areas and periods as in the present survey. In 1994/95 Antarctic minke whales were the most dominant species. The number of sightings of Antarctic minke whales in 1994/95 was about five times higher than that of humpback whales. According to the authors of SC/62/O3, comparison of whale abundance between these two surveys suggests that humpback whales were increasing and expanding into the research area.

17.1.2.1 POINTS OF CLARIFICATION

In response to a question on information on whether vomiting and faecal observations (SC/62/O3 table 7) referred to ‘natural’ events or were due to harpooning, the proponents explained that the recording of such observations was for the purpose of helping to evaluate the relative merits of lethal versus non-lethal sampling, and thus that there was no value in including observations of vomiting due to harpooning.

17.1.3 Planning for final review of results from Iceland’s scientific take of North Atlantic common minke whales

Víkingsson summarised the status of Iceland’s analytical work on the 200 common minke whales taken as part of its scientific research programme between 2003 and 2007; annual reports had been provided while the programme was still active. Last year it had been expected that most analyses would be completed and available in 2011; this would have allowed a formal review of the programme in 2012 following the Committee’s guidelines (IWC, 2009j) provided the appropriate deadlines had been met. He reported that most of the laboratory analyses are either completed or in a final stage (see SC/62/ProgRepIceland). There had been changes and delays in some components, particularly those involving outsourced chemical analyses that required CITES permits. In addition, the serious economic difficulties experienced by Iceland in recent years have affected the programme and delayed completion of some analyses. Nonetheless, the necessary adjustments had been made to the workplan and he remained optimistic that the work would be completed on schedule.

In discussion, Víkingsson clarified that some of the analyses indicated in SC/62/ProgRep Iceland concerned species and specimens other than the 200 minke whales caught and sampled under Special Permit. Iceland’s Special Permit programme had ended when the last of the 200 minke whales was taken in 2007.

In summary, an update on progress will be provided at the next Annual Meeting and approximately three months later a document will be submitted by Iceland that initiates the process leading to external review of the final results of this programme.

17.2 Review of new or continuing proposals

The Chair noted that both JARPA II and JARPN II are continuing on the basis of plans already submitted and reviewed in the Scientific Committee. There was no further discussion of this item. However, a statement in relation to this Agenda Item was received and can be found in Annex U. This statement reflects the view of many members. The response to this statement can be found in Annex U.

17.3 Procedures for reviewing Scientific Permit proposals

The Chair recalled that the Scientific Committee had spent considerable time in the past discussing this matter, and agreement on a process had been reached in 2009 (IWC, 2009j, colloquially known as ‘Annex P’) that had been used for the review of results of JARPN II. He noted that criticism by some members following the JARPN II review centred on how the procedures in ‘Annex P’ had been implemented rather than on the adequacy of the procedures themselves. Specifically, concerns had been expressed about the ‘independence’ of the specialists who served on the review panel, the Chair’s decision not to request panel members to submit a conflict-of-interest declaration and the Chair’s decision not to allow additional observers to attend the specialist workshop. The Chair noted in that regard that he also had not allowed scientists affiliated with the JARPN II programme to attend the deliberations of the expert panel.

Last year, it had been agreed to revisit at this meeting the question as to whether changes are needed to ‘Annex P’. However, the Chair identified two factors weighing against the idea of having a full discussion at this time. First, given the ongoing discussions of the ‘consensus package’ prepared by the Commission Chair and Vice-Chair, it would be sensible to wait for outcome of those discussions before further discussion of ‘Annex P’. Secondly, he believed that the dissatisfaction of some with the performance of the procedures for reviewing JARPN II was related to how these were implemented, rather than the wording of procedures themselves. In any event, Bjørge stressed that if the Committee decides to open ‘Annex P’ to revision, in his view such revision should be limited to only those aspects that have been controversial, i.e. the selection of experts to the review panel and the admission of observers. In discussion, it was further noted that given the schedule for reviewing the Iceland programme (as summarised under Item 17.1.3), there should be no need to implement 'Annex P' during the upcoming intersessional period. The Committee **agrees** that no further discussion of the procedures was needed at this time.

Childerhouse asked whether the adoption of a 'consensus package' would mean that Special Permit whaling would therefore end and preparations for reviews should begin. Bjørge replied that he was not in a position to advise on that, but he assumed that if the Commission reaches a decision that includes Special Permit whaling, it would then be incumbent on the Commission to provide guidance to the Scientific Committee on how permit reviews should be handled in the future.

18. WHALE SANCTUARIES

In the major discussion about sanctuaries in 2004, the Committee recommended procedures to facilitate the review of future proposals and future sanctuary reviews (IWC, 2005a, pp50-51). No new proposals for Sanctuaries were received this year. The item will remain on the Agenda for future meetings.

19. SOUTHERN OCEAN RESEARCH PARTNERSHIP

The Southern Ocean Research Partnership (SORP) was proposed by the Australian Government to the IWC in 2008 (IWC/60/16) with the aim of developing a multi-lateral, non-lethal scientific research programme that will improve the coordinated and cooperative delivery of relevant scientific information to the IWC. A framework and set of objectives for SORP were presented, discussed and endorsed last year (IWC, 2010c, pp.80-82).

At this year's meeting it was agreed to hold discussions at an evening session to allow all members who wished to attend to be able to do so without conflict with other sub-group meetings; that session was chaired by Gales and rapporteured by Childerhouse. It was agreed that the report of those discussions would be incorporated directly into the Plenary report.

19.1 Intersessional progress

SC/62/O9 reported on the intersessional progress on SORP. Progress was made on the following major items:

(1) establishment of a SORP Steering Group (SSG) with associated terms of reference;
(2) the holding of a Workshop further develop the SORP in Seattle in December 2009 (SC/62/O8);
(3) identification of seven proposed projects that will form the basis for SORP work into the future (SC/62/O10);
(4) the development of a funding mechanism for SORP projects (see below); and
(5) the holding of a first cruise of the joint Australia-New Zealand Antarctic Whale Expedition, AWE (SC/62/O12).

These items are covered in more detail below. It was noted that a full discussion of SC/62/O12 had taken place in the sub-committee on Southern Hemisphere whales (Annex H). The brief discussion under the present item focussed on suggested improvements in future cruises related to estimating abundance, the representativeness of the study area, the use of faecal sampling, the effect of satellite tagging on animals and some comments on the ability of the project to meet its objectives.

19.2 Report of the SORP Workshop, Seattle, December 2009

The SORP workshop (SC/62/O8) was hosted and supported by the Government of the USA and attended by 15 people from five nations. Its main aims were to continue developing the mechanism by which SORP would conduct its business and achieve its objectives. The workshop agreed that a focused approach to the research was required and this was best achieved through the development of research projects that were consistent with both the agreed SORP objectives and priority issues identified by the IWC Scientific Committee. To address this latter issue, a summary document of recommendations relevant to the Southern Ocean had been compiled. The proposed draft SORP projects that were developed at the workshop are described below.

19.3 Summary and consideration of proposed SORP projects

Several draft research projects were presented to the Committee in order to obtain comments and advice (SC/62/O10). The selection process had followed a lengthy consultation process starting at the Sydney SORP workshop (Southern Ocean Research Partnership, 2009) where broad themes were developed and these themes were endorsed by the Committee last year (IWC, 2011). *Inter alia* these draft projects developed at the Seattle SORP workshop are those that were considered to benefit from large scale, multi-regional participation and were consistent with both SORP objectives and IWC priority issues. The purpose of presenting these draft projects to the Committee this year was to seek initial comments and perhaps general endorsement of the overall approaches. The intention is that the project leaders will take any comments made into account when developing the projects intersessionally. It was clarified that there was no intention for the Committee to approve the draft budgets appended to the projects at this stage. These and other aspects of the proposals would require further development and should be re-submitted using the agreed funding mechanism (see Item 19.4) at the 2011 Annual Meeting.

19.3.1 Killer whales in the Southern Ocean

A short project description of 'Distribution, relative abundance, migration patterns and foraging ecology of three ecotypes of killer whales in the Southern Ocean' was presented. There are three ecotypes of killer whales described from Antarctic waters. Little is known about these ecotypes and it is important to understand these populations as killer whales play a key role in the Antarctic marine ecosystem. This is especially true with respect to the impacts that they have on prey populations including marine mammals, fish and penguins.

This project will investigate factors related to their ecosystem impact in Antarctica and adjacent waters, by focusing on their systematic relationships, abundance, distribution, movement patterns and prey preferences. It will include analyses of lipid, isotopes and contaminants from biopsy samples. Collaborators are from USA, Brazil, France and Brazil/Canada.

In discussion, it was agreed that this was an ambitious and valuable project outline. It was noted that the proposal required considerably more detail on the proposed analytical methods before it can be properly evaluated and that this was true for most of the draft projects presented. It is also important that any final proposal includes information on the conceptual and analytical and framework linking the sub-projects together. Suggested additional potential collaborators included Lauriano from the Italian Antarctic Programme and Bester from South Africa who is undertaking related work at Marion Islands.

19.3.2 Foraging ecology and predator prey interactions of whales and krill

A short project description of 'Foraging ecology and predator/prey interactions between baleen whales and krill: a multiscale comparative study across Antarctic regions' was presented. Little is known about the dynamics of predator-prey interactions and the response of baleen whales to the distribution of their prey in the Antarctic. As an important marine ecosystem (e.g. with respect to issues of climate change impacts as well as international management of marine living resources), research focused on cetacean foraging ecology in the Antarctic should help to fill a critical data gap. The project will use novel tagging technologies combined with traditional scientific hydroacoustic methods to quantify the types and frequency of prey consumed and daily consumption rates of poorly understood yet ecologically integral and recovering krill predators in the Antarctic: the humpback whale and the Antarctic minke whale. Collaborators are from USA and Australia for phase 1 and potentially Brazil, South Africa and Germany for phase 2.

In discussion, it was noted that this was an ambitious and valuable project. In addition, the proposal generally provides a good example of the level of detail required to allow for a full scientific evaluation. There were some methodological issues that required additional thought, including how the results from detailed studies collected at a fine spatial scale would be expanded to the medium and large scale, and also about the reliability of the method for estimating gulp volume. In response, it was noted that this project represents a step along the line in estimating consumption rates and that moving out from very fine to middle to large scale will be represent a challenge and needs further consideration. The similarity between aspects of this project and the Committee's SOWER 2000 project (IWC, 2000) developed but never implemented was noted and it was suggested that this may provide some useful additional ideas and information for the developers of the current project.

19.3.3 Oceania humpback mixing

A short project description of 'What is the distribution and extent of mixing of Southern Hemisphere humpback whale populations around Antarctica? Phase 1: East Australia and Oceania' was presented. An improved understanding of the movements and mixing of humpback whales around Antarctica has been identified as a priority for the Committee as part of its Comprehensive Assessment of Southern Hemisphere stocks. This information is integral to assessing the recovery of depleted populations. A key step in assessing recovery is estimating pre-exploitation size which requires knowledge of stock identity and appropriate allocation of historic catches to correct stocks. An improved understanding of the migratory and feeding behaviour of humpback whales should allow an appropriate allocation of catches made in this region to breeding stocks, which will improve the accuracy of recovery assessments and estimates of pre-whaling population sizes. Collaborators include New Zealand, Australia, USA, France, Samoa, Tonga and Chile.

In discussion, it was noted that when exploring allocation of past catches to breeding stocks, additional information would need to be considered given the potential temporal and spatial mixing of different breeding stocks and sexes on the feeding grounds and given the relatively small number of SOWER/IDCR samples available from this region. Similar work was being undertaken by other researchers (e.g. low to high latitude matches from Japanese and SOWER/IDCR data sets) which would help broaden the context for this work. It was noted that the outline study presented represents only Phase One; the focus is on Oceania and will include all the SOWER/IDCR data available. Future work is already being planned and there are plans to collaborate with researchers across the Southern Hemisphere (e.g. Africa, Chile, Brazil, Australia) using both mitochondrial and microsatellite data. It was suggested that the telemetry component of the study would be better structured if animals were tagged on the feeding rather than breeding grounds as this would provide more information on mixing. In response, it was noted that this had been the plan of the AWE but due to technical failure with the tags this had not been achieved. The issue of collaboration and inclusiveness was raised (as it had been at the IWC workshop on Southern Hemisphere humpback whales held in 2006) and it was noted that the proposal did not include all potentially valuable datasets. The Committee agreed that it was important that SORP projects are open to all researchers who hold appropriate datasets.

19.3.4 Fin and blue whale acoustics

A short project description of 'Acoustic trends in abundance, distribution, and seasonal presence of Antarctic blue whales and fin whales in the Southern Ocean' was presented. This initiative aims to implement a long term acoustic research programme that will examine trends in Southern Ocean blue and fin whale population growth, distribution, and seasonal presence through the use of passive acoustic monitoring techniques. Current understanding of blue and fin whale life history characteristics, population abundance, and any post-whaling recovery is extremely limited. While obtaining accurate absolute abundance estimates is currently beyond the reach of passive acoustic methods, measures of relative abundance and trends are more easily obtainable and can be conducted in a consistent manner. Comparison of relative abundance estimates from individual locations across many years collected by acoustic surveys can provide a precise measure of population growth. Comparison of relative abundance estimates within and between locations and years can further be used to assess trends in distribution and seasonal presence over time. Collaborators are from Australia, France, USA and Germany.

In discussion, it was noted that the primary focus was on the Indian Ocean. The Committee agreed that it would be useful to consider including similar acoustic data from other sources (e.g. the GLOBEC acoustic data that had been collected for six years at the Antarctic Peninsula) and was pleased to hear that the inclusion of such data is planned and that GLOBEC researchers will be approached soon. The plan to develop less expensive acoustic loggers was welcomed as an excellent step forward in the use of acoustics as a tool for monitoring. There was some thought that the timetable to complete the feasibility stage of the project (one year) may be too ambitious. As for other projects, more detail of the analytical methodology was requested. In terms of assessing the extent to which the project would meet its objectives (i.e. estimation of trends), it was noted that it would be helpful to see the detection range of the loggers as the small number of loggers planned to be deployed would cover a relatively small part of the Southern Ocean. It was recognised that complete coverage of the South Ocean was not possible given logistical constraints (i.e. the limited number of vessels in the area and where they go) but part of the future planning was to consider the best sites for deployment to maximise the usefulness and representativeness of those sites and to try and capture representative variability. It was suggested that it would be useful for the loggers to collect environmental as well as acoustic data which would help to provide context for any variability seen, provided this could also accommodate the objective of keeping the units small and affordable. The Committee noted that using such data to estimate absolute abundance is a long term and extremely ambitious objective of the project. The project leaders acknowledged that this would not be easy, noting that the project would start by estimating relative abundance to quantify trends and work towards absolute abundance. With respect to the long-term aim, it was suggested that the developers of the programme approach scientists such as Len Thomas (University of St Andrews) who had made some progress in the development of new analytical approaches to estimate density from acoustic data.

19.3.5 Year of the Blue Whale 2013/14

As one of the major initiatives within the SORP, the Committee discussed a proposal for a multi-vessel, circumpolar research project to focus on Antarctic blue whales in the austral summer of 2013/14. The proposed objectives for this 'Year of the Blue Whale' would be to:

(1) provide a circumpolar abundance estimate of Antarctic blue whales based on data collected during a single-season, multi-vessel survey design that incorporates acoustic localisation of blue whales and traditional sightings surveys;
(2) improve our understanding of Antarctic blue whale stock structure through the collection of genetic, photographic and acoustic data;
(3) improve understanding of linkages between blue whale feeding and breeding grounds using satellite telemetry; and
(4) characterise foraging habitat of blue whales on the basis of sightings surveys and satellite telemetry data.

It was recognised that any research effort to satisfy these ambitious objectives in a single year of field work will require substantial methodological development (e.g. to determine how to combine visual and acoustic survey techniques) as well as a need to build in provisions for substantial 'off-survey' activities (e.g. satellite tagging, biopsy sampling and individual photo-id). The project will also require substantial logistical planning to access and coordinate shipping and research activities around Antarctica within a single season. It had been proposed that a small scientific steering committee be established with the task of: (1) developing a full research proposal for the Year of the Whale; (2) determining the optimal scale of shipping and research effort required to fulfil the objectives; (3) initiate processes towards accessing these shipping resources; and (4) reporting back to the 2011 Annual Meeting.

In discussion, there was broad agreement about the general concept and draft proposal and several members expressed an interest in participating in planning for the SORP Year of the Whale. There was a short discussion of a suggestion that fin whales could be included in the proposal but it was noted that high density areas of blue and fin do not always overlap and that to include fin whales might dilute the effort with respect to blue whales. The Committee agreed that the inclusion of other species, while desirable, must be considered in light of the primary objective of assessing blue whales. Recent experience during the AWE had demonstrated that acoustics was a practical method of finding blue whales and that this would allow a blue whale cruise to minimise the amount of time searching and maximise the amount of time spent with blue whales. Recognising the ambitious nature of the project, it was suggested that the timeframe of 2013/14 was optimistic and that a delay in 1-2 years might be considered, given the enormous coordination and organisational effort required to ensure the success of such a large project. Consideration may also need to be given to spreading effort out over two years. The Committee **agrees** that until the proposal is more fully developed, it will not be possible to assess the logistical requirements necessary to complete the work. It was suggested that a small group of survey and other specialists, including those familiar with organising large multi-vessel multinational projects, should work together to further develop the proposal and report back to the SSG and the Committee next year (see Item 21); Gales agreed to co-ordinate this. Their task would *inter alia* be to determine the level of resources required, provide an outline of research methods (and analyses) and survey design, and assess the feasibility and timeframe of the project (if that group deemed it necessary, a short workshop might be considered).

19.3.6 Whales and climate change

This project has been identified as a potential project since the Sydney SORP workshop and it has been further discussed at the second IWC climate change workshop (IWC, 2010c), last year's Scientific Committee meeting and the recent Seattle SORP workshop. Long-term southern right whale datasets have been identified as the most likely existing data for correlation with long term climate changes. Leaper *et al.* (2006) demonstrated the utility of the long-term Argentinean study for assessing correlations with climate variables. It has been proposed that a project along these lines could be developed using a common method that can be applied to the Australian, South African and Brazilian long-term datasets, provided an initial examination revealed them suitable for this purpose. In this regard, consideration should be given to the development of recommendations about how existing programmes/datasets could be improved/modified to make them more suitable for future work along these lines.

As the Committee has previously recognised, an understanding of these issues requires long-term data on prey and/or climate as well as long-term whale data; this will require incorporation of relevant experts in these fields in the project. The Committee also agreed that it was worth examining the potential use of time series of whale oil production, provided that suitable climate data over the same period can be found. Investigation of long-term datasets from other species in the same ecosystem could also be valuable. The Committee **agrees** that formal proposals for work under a climate change project would be welcome for consideration at the 2011 Annual Meeting.

19.3.7 Non-lethal research techniques workshop

This proposal is for a technical conference/workshop to review the strengths and weaknesses of available non-lethal research methods for studies of living whale in the Southern Ocean and their ecological roles in the Southern Hemisphere. The objectives are to advance the synergies of non-lethal methods for investigations addressing a range of research themes. Presentations at the workshop will focus on methodological or technological advances to non-lethal methods, including those that are still under development, or with specific applications to populations in the Southern Hemisphere. Preliminary planning has been undertaken and it is likely to be held in Chile in late 2011.

It was suggested that the workshop could take place in association with the proposed Assessment workshop on southern right whales planned for Argentina in September 2011. A draft Agenda for this workshop can be found in Annex R.

19.4 Funding mechanism for SORP

The Committee **endorses** the process for evaluating requests for funding under the IWC/SORP research fund given in Annex R. It agrees that the IWC Head of Science and Chair of Scientific Committee should be included in the SORP Steering Committee.

20. ACTIONS ARISING FROM INTERSESSIONAL REQUESTS FROM THE COMMISSION

As part of the Commission's work on the Future of the IWC, the Chair and the Vice-Chair of the Commission, based on discussions within the Chair's Support group and the Small Working Group on the Future of the IWC, developed the 'Proposed Consensus Decision to Improve the Conservation of Whales'. The Committee received a short PowerPoint presentation explaining the background to the document, focussing on issue of relevance to the Scientific Committee. In particular, the Committee was asked, via the Small Working Group on the Future of the IWC, to provide scientific advice on a number of aspects of the proposed Consensus Decision; the Terms of Reference for our work are given in Annex G of IWC/62/6 rev. They are also given as Annex S to this report.

The parts of the report requiring review and advice, along with the sub-groups of the Committee that took the initial review can be summarised as follows:

(1) Review of Annex {DNA} on DNA registers and market sampling – jointly by the Working Group on DNA and the Working Group on the estimation of bycatch and other human induced mortality – see Annex N, item 9;
(2) Reviews of Annex {SI} on scientific information required from the catch and Annex {OI} review of operational information – the sub-committee on the RMP – see Annex D;
(3) Review of the potential workplan for the Scientific Committee – relevant sections were reviewed by the sub-committee on the RMP and the sub-committee on in-depth assessments (Annexes D, and G, respectively); and
(4) Review of the report of the Scientific Assessment Group (IWC/M10/SWG6) in the light of the numbers in table 4 of IWC/62/7rev (the table of catch limits) - relevant sections were reviewed by the sub-committee on the RMP, the working group on the *pre-Implementation assessment* of common minke whales in the western North Pacific, the sub-committee on in-depth assessments, the sub-committee on other Southern Hemisphere whale stocks (Annexes D, D1, G, and H, respectively).

The discussions within the sub-committees form the basis of the Committee's advice given below.

With respect to tasks (1)-(3) above, the complete Annexes incorporating our recommendations are included in Annex T, as is an updated timetable.

20.1 Review of Annex {DNA} on DNA registers and market sampling schemes

The Committee was requested to review Annex {DNA} of IWC/62/7rev for clarity and completeness. Annex {DNA} of IWC/62/7rev is based on the report of an earlier specialist workshop held from 7-9 March 2005 (IWC/M05/RMSWG 5). The objective of the review is to ensure that the Annex remains a cost-effective, robust, independent and transparent system in conjunction with the other monitoring and control measures.

To address the above objectives, the Committee **recommends** that the text given in Annex S replaces Annex {DNA} of IWC/62/7rev. Here follows a summary of the recommended changes.

1. SPECIFICATIONS FOR THE ESTABLISHMENT/ MAINTENANCE OF A DIAGNOSTIC DNA REGISTER/ TISSUE ARCHIVE
1.1 Laboratories
1.1.1 Minimal laboratory requirements

1.1.1 (6)	to clarify the length of time that archived samples were to be stored;
1.1.1 (7)	to clarify requirements that a variety of error-checking procedures should be followed and that sample quality should be checked routinely prior to genetic analysis.
1.1.1 (9)	to take into account several different factors in calibration exercises.
Footnote text	a more comprehensive definition of 'diagnostic DNA register'.

1.2 Sample collection
1.2.1 Size of the samples
1.2.2 Preservations

1.2	to specify training of and information to be collected by persons who may be involved in the collection of genetic samples for DNA registries other than commercial, scientific and indigenous catches (e.g. bycatches or stranded animals).
1.2.1 and 1.2.2	to clarify the sample preservation requirements.

1.4 Markers and methods of analysis
1.4.1 Mitochondrial DNA
1.4.2 Microsatellites
1.4.3 Sex identification

1.4.1, 1.4.2 and 1.4.3	to clarify that the analytical methods adhering to the quality standards as specified in the IWC genetic data quality guidelines must be approved by the international expert group.

1.7 External audit of DNA registers

1.7	to specify that the international expert group shall submit an annual report to the Secretariat of the IWC for distribution to contracting governments and the Commission (and, if necessary subsidiary bodies of the Commission) at least two months before it must be considered.

1.8 Submission procedure for samples for comparison with registers

The Committee considered all of section 1.8 in light of the stated objective of Annex {DNA}: 'to ensure a robust, independent and transparent system'. Item 1.8 makes a crucial contribution to these objectives, by providing a mechanism for sample verification that is not reliant on national market sampling schemes, and is also not reliant on the international expert panel, whose role is to audit the system rather to focus on individual samples. The Committee **agrees** that the current wording of item 1.8 does not fully make clear the intent of the mechanism and has thus provided new clarifying wording (including in the heading).

It also **agrees** to a new item 1.9, to specify the submission of DNA profiles to the IWC' central register from contracting governments under whose jurisdiction whales and whale products may be legally marketed.

2. SPECIFICATIONS FOR THE ESTABLISHMENT/ MAINTENANCE OF MARKET SAMPLING SCHEME
2.2 Development of appropriate market sampling schemes including audit

New 2.2 (4)	to take into account that some 'degraded' and/or 'processed' samples from market surveys could not be analyzed using exactly the same procedures as those currently used for 'fresh' and 'unprocessed' samples, but that methods could be developed to allow accurate comparison of such samples with profiles in DNA registries.

2.4 Reporting

2.4	a slight revision of the text concerning reporting to the IWC by the international expert group: the international expert group shall submit an annual report to the Secretariat of the IWC for distribution to contracting governments and the Commission (and, if necessary bodies of the Commission) at least two months before it must be considered.

20.2 Review of Annex {SI} to IWC/62/7rev – scientific information requirements

The draft Annex was based on previous recommendations of the Committee in the context of RMS discussions (IWC, 1995d). The Committee reviewed the Annex. In discussion it was recalled that the Committee has previously agreed that bulla do not provide a reliable means for estimating age (IWC, 2002c, p.12). It also noted that earplugs do not provide reliable age estimates for North Atlantic common minke whales. Walløe and Víkingsson reported that lengths could not always be recorded for minke whales in North Atlantic in the manner specified, although estimates of length are reported to the Secretariat.

Given the above the Committee **recommends:**

(1) reference to 'bulla' be removed from point 2(b); and
(2) the following footnote be added to point (a) 'Onboard small coastal whaling vessels such as those participating in Norwegian and Icelandic operations, it may be difficult to obtain accurate length measurements because whales are handled on a limited space. It is recognised that measurements in these cases may not be as accurate as those taken in ideal situations.'

The full revised Annex is given as Annex T.

20.3 Review of Annex {OI} to IWC/62/7rev – operational information requirements

The Committee **endorses** the operational information requirements as given in the proposed Annex.

20.4 Review of proposed timetable for future *Implementations* and *Implementation Reviews* (IWC/62/7rev Appendix B, p. 37)

The Committee **concurs** with the SAG that the schedule in Section 5 of IWC/62/7rev, updated following its deliberations as Table Y below, is ambitious. It noted that *Implementations* and *Implementation Reviews* can (and do) involve considerable time and resources from national scientists and, especially in cases when *Implementation Simulation Trials* are required, the Secretariat. Moreover, delays can occur when conducting *Implementations* given that the same members of the Committee are involved in many of the *Implementations* and *Implementation Reviews*.

The Committee has previously agreed that it can only conduct one *Implementation* at a time. The schedules for Western North Pacific Bryde's whales, and for North Atlantic common minke and fin whales given in IWC/62/7rev match the schedules expected from the *Implementations* for these species in terms of the Committee's agreed guidelines (IWC, 2005b). The Committee has previously been able to complete an *Implementation Review* during a single meeting, provided that no *Implementation Simulation Trials* are required.

The Committee therefore cannot conduct *Implementations* for Western North Pacific sei and Antarctic minke whales at the same time. The SAG had considered it more important to conduct an *Implementation* for Western North Pacific sei whales first given the size of current catches and the estimates of abundance for this stock. However, the Committee noted that there are also reasons to conduct an *Implementation* for Antarctic minke whales starting in 2012. After discussion of the relative amount of preparatory work required for *In-depth* and *pre-Implementation assessments* of North Pacific sei whales compared to Antarctic minke whales, the Committee **recommends** to deal with North Pacific sei whales before minke whales, as in IWC/62/7rev, and further **recommends** the schedule given in 20.5.3.4 below.

The Committee **recommends** that two years should be allowed for the *pre-Implementation assessment* for Antarctic minke whales irrespective of when the *Implementation* for these whales starts (under the current schedule, the first year of the *pre-Implementation assessment* would be 2014). It was also recognised that the current *Implementation* for these whales is sufficiently dated (1993) that it was unreasonable to expect that this 1993 *Implementation* can simply be reviewed after almost 20 years of developments in how to *Implement* the RMP.

The Committee therefore **recommends** that '/IR' (for *Implementation Review*) be deleted from the box for 2015 for Antarctic minke whales.

20.5 Review of the Scientific Assessment Group (SAG) Report

As part of the Commission's discussions on the Future of the IWC, the Commission's Chair and Vice-Chair developed the document 'Proposal Consensus Decision to Improve the Conservation of Whales' (IWC/62/7rev). During the development process but before finalisation of IWC/62/7rev, a small Scientific Assessment Group (SAG) was established to provide a report (IWC/M10/SWG6) of a concise scientific review on whether proposed catches were such that the long-term status of the populations concerned would be negatively affected. The numbers in table 4 of the proposed consensus decision (i.e. proposed whale catches for the period 2010/11-2019/20) are below those considered by the SAG. The terms of reference developed by the Small Working Group on the Future of the IWC (SWG) for the Committee's review of the SAG report in the light of the numbers in table 4 of IWC/62/7rev are given in Annex S and summarised below.

The Committee shall follow the terms of reference of the SAG (IWC/M10/SWG, Annex B), recognising:

(a) the need to be concise;
(b) the fact that there are a number of different approaches to evaluating short-term catches and no single method will be appropriate in all circumstances; and

(c) that the report should provide an integrated, pragmatic view on whether or not the proposed short-term catches (i.e. before the RMP can be used) are likely to negatively affect the long-term (i.e. RMP simulation framework timeline of 100 years) status of the stock *given* the timetable for RMP work.

It had also been requested that the Chair of the Scientific Committee should ensure that the time spent on this review should be such that it does not interfere with the Committee's focus on completing RMP-related work as soon as possible.

The SAG had noted that there were two categories of stocks for which advice was required: those for which the RMP could be applied immediately, and those for which it could not. The report below follows a similar pattern, focussing initially on the application of the RMP (western North Pacific Bryde's whales, North Atlantic common minke whales, North Atlantic fin whales) and then turning to those stocks for which it cannot immediately be applied (Antarctic minke whales, Southern Hemisphere fin whales, western North Pacific common minke whales, and western North Pacific sei whales).

20.5.1 General issues related to using the RMP

20.5.1.1 CATCH LIMIT CALCULATIONS (ACTIVATION, YEARS, INPUTS AND OUTPUTS)

As part of the SAG process, the RMP was applied to three species-Region combinations (western North Pacific Bryde's whales; North Atlantic minke whales; and North Atlantic fin whales) upon instruction from the Chair of the Commission. The calculations reported are therefore the results of applying the RMP itself, although results are also shown for tunings other than the Commission-agreed 0.72 tuning (the 0.6 tuning). The Committee repeated the RMP catch limit calculations for these stocks. Differences from the SAG's calculations are documented in the following sections. When applying the *CLA*, the phase-out rule was applied for each *Small Area* after the catch limit was cascaded to the *Small Areas* from the *Medium Area* rather than applying the phase-out rule before cascading the *Medium Area* catch limit to *Small Areas*, in accordance with RMP specifications (RMP specification 3).

20.5.1.2 TUNING LEVELS

The SAG report (and Annex D, Appendix 8) provides results for the 0.72 and 0.6 tunings of the RMP because the whaling countries in the Commission's support group had requested the latter tuning. This issue is discussed more fully in the SAG report.

The Committee noted that although the 0.6, 0.66 and 0.72 tunings of the *CLA* were recommended to the Commission by the Committee, having been subjected to testing during the development of the RMP, the *Implementation Simulation Trials* have only been conducted by the Committee for the 0.72 tuning of the RMP. Norwegian scientists have run the *Implementation Simulation Trials* for minke whales in the Northeast Atlantic for the 0.6 tuning of the RMP, but these calculations were not undertaken nor reviewed in detail by the Committee. In addition, which RMP variants are 'acceptable' may change if the tuning level is changed. The Committee **agrees** that the tuning level which was used when calculating catch limits using the *CLA* should be that which is tested in *Implementation Simulation Trials*; in this case only the 0.72 tuning. In principle, the *Implementation Simulation Trials* could be repeated for a new tuning if requested by the Commission. However, the criteria used to evaluate whether performance of an RMP variant is 'acceptable', 'borderline' or 'unacceptable' is linked to the 0.6 and 0.72 tunings of the RMP. The present criteria may need to be investigated if the Commission requested that a different tuning of the RMP should be considered.

20.5.1.3 OTHER ISSUES

The Committee notes that its advice is based on the schedule of RMP *Implementations* proposed in Appendix B of the Chair's and Vice-Chair's proposal (IWC/62/7rev). The Committee brings to the attention of the Commission its concern that delays in completion of these implementations may increase risks to whale populations. Attention is drawn to the two-year schedule for completion of an *Implementation* as set out in the Committee's agreed guidelines (IWC, 2005b) - proposals made in this report follow from the Committee's intent to progress work in terms of this schedule.

On a more general issue, the Committee draws the Commission's attention to the fact that the RMP and AWMPs are designed to provide advice on catch and strike limits for periods of up to 6 years. Further work may be needed to assess the risks associated with setting catch limits for longer periods than 6 years.

20.5.2 Application of Stocks/Regions for which the RMP can immediately be applied

The Committee reviewed the specifications (provided by the Secretariat) of how the RMP was applied during the SAG meeting to western North Pacific Bryde's whales, North Atlantic minke whales, and North Atlantic fin whales. The following items summarise the modifications to the initial applications by the Secretariat made by the Committee in reaching its agreed applications: these primarily involve clarifications with respect to time-stamps of abundance estimates and the addition of newly agreed abundance estimates. Table 7 lists the resulting catch limits from the 0.72 and 0.6 tunings of the *CLA*. The format used to document the input and present the results (see Annex D, Appendix 8 for the final format) illustrates the calculations made, and emphasises the results calculated using the Commission-agreed 0.72 tuning.

20.5.2.1 WESTERN NORTH PACIFIC BRYDE'S WHALES

The application of the RMP to western North Pacific Bryde's whales was based on a single abundance estimate for the *Region* (time-stamped at 2000). The Committee requested that the time-stamps for the *Small Areas* when applying catch cascading be set to the effort-weighted years.

It was noted that survey data were available for 1988-96 and some of these data were used when computing the additional variance for the 1998-2002 surveys (Shimada *et al.*, 2008). An abundance estimate can be computed for 1988-96, but the Committee has only accepted the estimate from the 1998-2002 surveys (IWC, 2009b). Although abundance estimates could be calculated using the 1988-96 data, account would need to be taken of the correlation of these estimates with those for 1998-2002 if they were included in RMP calculations of catch limits. However, the presently-coded version of the RMP does not allow input of a variance-covariance matrix for the abundance estimates. The Committee therefore **recommends** that:

(1) the program for the *CLA* be modified to allow variance-covariance matrices to be input (Annex D, item 2.4); and
(2) the data and resulting abundance estimates from the 1988-96 surveys should be reviewed for possible use in the RMP during the next *Implementation Review*.

Table 7

Summary of the application of the RMP (full details of the inputs to the RMP as well as relevant intermediate calculations are given in Annex D, Appendix 8). Phaseout has been applied where applicable.

Year	WNP Bryde's whales	North Atlantic fin whales		North Atlantic minke whales					
Sub-area	1W+1E	WI (variant 6)	WI (variant 2)	CIC	CM	ES	EB	EW	EN
Catch limits based on the 72% tuning (Commission's agreed value)									
2010	**5**	**46**	**87**	**224**	**135**	**58**	**92**	**152**	**70**
2011	**3**	**46**	**87**	**224**	**135**	**58**	**92**	**152**	**70**
2012	**1**	**46**	**87**	**224**	**135**	**46**	**92**	**152**	**70**
2013	**0**	**46**	**87**	**224**	**135**	**35**	**92**	**152**	**56**
2014	**0**	**46**	**87**	**224**	**108**	**14**	**92**	**152**	**42**
Catch limits based on the 60% tuning									
2010	33	90	155	345	208	122	195	322	148
2011	19	90	155	345	208	122	195	322	148
2012	4	90	155	345	208	97	195	322	148
2013	0	90	155	345	208	73	195	322	118
2014	0	90	155	345	166	29	195	322	89

The final specifications for how the RMP was applied to these whales are listed in Annex D, Appendix 8A.

20.5.2.2 NORTH ATLANTIC MINKE WHALES

The Committee **recommends** the following changes to the abundance estimates for minke whales in the Central North Atlantic:

(1) use the estimates in Annex D, Table 1 to construct an abundance estimate for *Small Areas* CG+CIP and include this abundance estimate in that for the C *Medium Area* for 2006;
(2) use the estimate for the CM *Small Area* in 2005 of 12,043 (CV 0.28) in place of the estimate of 6,174 (CV 0.36) because the former estimate is based on surveys which covered more of the CM *Small Area*; and
(3) use the revised version of the estimate of abundance for 2005 of 26,739 (CV 0.39) in place of the estimate of 24,890 (CV 0.45);

Allison recalculated the CVs for the abundance estimates for the C *Medium Area*.

The Committee **recommends** that the catch limits for the minke whales in the eastern North Atlantic be based on the latest sex ratio data (i.e. 2005-09) rather than 2004-08 as was used for the SAG report. The final specifications for how the RMP was applied to North Atlantic minke whales are listed in Annex D, Appendix 8B.

20.5.2.3 NORTH ATLANTIC FIN WHALES

The Committee had no changes to the application of the RMP used in the SAG report. The specifications for how the RMP was applied to North Atlantic fin whales are listed in Annex D, Appendix 8C. As noted under Item 6.2.1, the Scientific Committee has already confirmed that *Variant 2* would be acceptable for 10 years, followed by *Variant 1*, if accompanied by an acceptable research programme. No final research proposal to distinguish between stock structure hypotheses has yet been adopted. Therefore, *Variant 2* is not an available option at this time. However, a preliminary proposal was submitted and discussed at this meeting. The Scientific Committee made two specific recommendations for improvement. The proposal will be modified accordingly, in consultation with an advisory committee appointed by the Scientific Committee, and submitted to the next Annual Meeting for adoption.

20.5.3 Advice on Stocks/Regions for which the RMP cannot immediately be applied

20.5.3.1 ANTARCTIC MINKE WHALES

Information on the timetable for undertaking an *Implementation* of Antarctic minke whales is given under Item 20.4. If this timetable can be met, it is expected to be completed in 2016.

20.5.3.2 SOUTHERN HEMISPHERE FIN WHALES

Section 2.6 of IWC/M10/SWG6 considered Southern Hemisphere fin whales. It is proposed that catches would be taken alternately in the Indian Ocean (between 35°E-130°E) and Pacific Ocean (between 130°E and 145°W) sectors of the Antarctic. A total of 10 annual catches would be taken in the period 2010/11-2012/2013, starting in the Pacific Ocean sector. Catches would be reduced from 10 to 5 individuals from 2013/14 until 2019/2020.

The Committee noted that in the past there was extensive exploitation (nearly 750,000 fin whales were killed in the 20th Century), and that recent information on fin whales in the Southern Hemisphere is poor. The Committee also noted that there were additional abundance estimates for this population, derived from IDCR/SOWER surveys, which had not been considered by the SAG (e.g. Branch and Butterworth, 2001a; Butterworth and Geromont, 1995). Branch and Butterworth (2001) estimated that the circumpolar abundance of fin whales south of 60°S was 2,100 (CV=0.36), 2,100 (CV=0.45) and 5,500 (CV=0.53) for CPI, CPII and CPIII respectively. These estimates are negatively biased since the areas north of 60°S were not covered[6].

It is unlikely that sufficient information will become available in the interim period (up to 2020) for an RMP *Implementation* to occur. Nevertheless, some members noted that if the *CLA* of the RMP was used it would result in a catch limit of 0. The Committee **concurs** with the general conclusions of the SAG, i.e. that it is unlikely that the proposed catches will affect the long-term status of the stock[s]. Some members were concerned about providing *ad-hoc* advice on catch limits without any likelihood of a formalised procedure being available in the foreseeable future. They did not want this exercise to set a precedent for providing *ad-hoc* advice.

---

[6] IWC (1996b) reports IDCR estimates extended to south of 30°S by using Japanese Scouting Vessel survey results to provide an index of relative abundance.

20.5.3.3 WESTERN NORTH PACIFIC COMMON MINKE WHALES

Information on the timetable for undertaking an *Implementation Review* of western North Pacific common minke whales is given under Item 20.4. Given the progress made at this meeting (see Annex D1), it is expected that this will be completed in 2012.

The Committee noted that it was not possible to apply the RMP to the data for these minke whales owing to the considerable changes to the understanding of stock structure in recent years. It **agrees** that the present uncertainty precludes giving adequate advice regarding the catches in Table 4 of IWC/62/7rev The Committee generally **agrees** with the conclusions of the SAG; the Committee summarised its conclusions as follows.

(1) The *Implementation* process should be completed as quickly as possible. Completing the *Implementation Review* will allow advice on catches to be based on the RMP, which has been selected to ensure that catches are sustainable.

(2) A high priority should be accorded to research to determine the proportions of 'O' and 'J' stock in sub-area 12 because the implications of any proposed catches for both 'O' and 'J' stock clearly differ depending on this proportion. In this respect, the Committee welcomed the survey of sub-area 12 planned for summer 2010 and **emphasises** the importance of collecting as much data as possible to estimate stock proportions in sub-area 12.

(3) The proposed catches by coastal whalers in Table 4 of IWC/62/7rev may not help to improve the status of 'J' stock compared to current JARPN II catches. The incidence of 'J' stock in the catch decreases with distance offshore. The Committee received an analysis which estimated the number of 'J' stock animals under catch levels of 150 inshore and 70 offshore (Annex G1, Appendix 8). The Committee recognised the value of analysis such as those in Annex G1, Appendix 8 and **recommends** that further analyses be conducted using a finer spatial resolution and quantifying the uncertainty associated with the predictions, including the likely level of inter-annual variation in catches of 'J' stock animals.

(4) The Committee was unable to agree on the impact of the proposed catches on the 'O' stock. However it **agrees** that the risk to the 'O' stock will be minimised if the *Implementation Review* is completed as soon as possible so that advice can be based on the RMP and hence also **agrees** that catches of 'O' stock should not exceed present levels.

Table 8

Scientific Committee work plan for RMP *Implementations.*

	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	202
Western North Pacific Bryde's whales				IR					IR		
NA common minke whales - eastern and central medium areas					IR						IR
NA fin whales - central medium area					IR					IR	
Western North Pacific common minke whales	PIA		RMP	[RMP]					IR		
Western North Pacific sei whales		IDA		PIA	RMP	[RMP]					IR
Antarctic minke whales					PIA	PIA		RMP			

IR= *Implementation Review* (often possible to complete in one year). PI = *pre-Implementation assessment* (may take more than one year). RMP completed *Implementation* (takes two years once the PIA is completed IDA= in-depth assessment, usually takes two years or more and feeds in a *pre-Implementation assessment.* As explained in the text, the plan ambitious and it may not be possible to achieve all of the work by t years indicated. Square brackets are used to express possible but perhap less likely dates.

20.5.3.4 WESTERN NORTH PACIFIC SEI WHALES

Information on the timetable for undertaking an *Implementation* of western North Pacific sei whales is given under Item 20.4. If the *Implementation* turns out to be as simple as suggested there, it is expected to be completed by 2014.

The SAG report was based on the assumption that the In-depth Assessment for North Pacific sei whales would be conducted in 2010 as planned last year. This year, the Committee has concluded that in view of the relatively simple information available on the population, the In-depth Assessment and *pre-Implementation assessment* could most efficiently be combined into a single exercise, and **agrees** a compromise date of 2013 for the combined assessment, with RMP catch limits to be set the following year if no complications arise. The Committee **concurs** with the SAG that priority for the Committee should be to complete the RMP *Implementation* as soon as possible rather than to develop formal interim management advice. The Committee was unable to agree on the impact of the proposed catches on sei whales. The Committee **recommends** that as a minimum there should be no increase in the present level of catches until the RMP *Implementation* has been completed. Catches for North Pacific sei whales resumed in 2002 and the annual catch since 2004 has been 100 animals.

Table 9

Workshops and intersessional meetings planned for 2010/11.

Subject	Agenda item	Venue	Dates	Steering Group
North Pacific sighting survey workshop	Item 10.8.1; Annex G	Tokyo	28-30 September 2010	Q15
North Pacific 2011 cruise: planning	Item 10.8.2; Annex G	Tokyo	24-26 September 2010	Q15
Small cetaceans and climate change workshop	Item 12.5; Annex K	Vienna	28 November- 1 December 2010	Q24
Abundance of Antarctic minke whales workshop	Item 10.1.1; Annex G	Bergen?	January 2011	Q13
North Pacific minke whale preparatory meeting	Item 6.3; Annex D1	Tokyo	25-27 September 2010	Q4
North Pacific minke First Intersessional Workshop	Item 6.3; Annex D1	Korea	14-17 December 2010	Q4
Workshop on AWMP	Items 8.2; 8.3; Annex E	TBA	March 2011	Q1

Possible pre-meetings immediately before SC/63 depending on intersessional progress: AWMP gray whale *Implementation Review*; western North Pacific common minke whale *Implementation Review;* assessment of humpback whale Breeding Stock B.

21. RESEARCH AND WORKSHOP PROPOSALS AND RESULTS

Table 9 lists the proposed intersessional meetings and workshops. Financial implications and further details are dealt with under Item 24.

Results from last year's intersessional IWC workshops are dealt with under the relevant Agenda Items.

21.1 Review results from previously funded research proposals

Results from IWC funded projects are dealt with under the relevant agenda items.

21.2 Review proposals for 2010/11

No unsolicited research proposals were received. The Committee has **agreed** mechanisms for reviewing proposals under the SORP programme (Item 19) and the Small Cetaceans Voluntary Fund (Item 15).

22. COMMITTEE PRIORITIES AND INITIAL AGENDA FOR THE 2011 MEETING

Revised Management Procedure (RMP)

The following issues are high priority topics:

GENERAL MATTERS

(1) complete review of the range of MSYR values for use in the RMP;
(2) finalise approach for evaluating proposed amendments to the *CLA*;
(3) evaluate the Norwegian proposal for amending the *CLA*;
(4) consider implications that the phase-out rule in the RMP is applied by *Small Area* when catch cascading is applied and the abundance estimates are based on multi-year surveys; and
(5) modify the Norwegian 'CatchLimit' program to allow variance-covariance matrices to be specified for the abundance estimates.

***IMPLEMENTATION REVIEW* FOR NORTH PACIFIC COMMON MINKE WHALE**

(1) review results of intersessional workshops; and
(2) complete the work assigned to the 'First Annual Meeting' in accord with our guidelines.

***IMPLEMENTATION* FOR THE WESTERN NORTH PACIFIC BRYDE'S WHALES**

(1) review the research proposal for the 'variant with research'.

***IMPLEMENTATION* FOR THE NORTH ATLANTIC FIN WHALES**

(1) review revised research proposal for the 'variant with research'; and
(2) review abundance estimates for use in the *CLA*.

***IMPLEMENTATION* FOR THE NORTH ATLANTIC MINKE WHALES**

(1) review any new abundance estimates.

Aboriginal Whaling Management Procedure (AWMP)

The following issues are high priority topics:

(1) work on developing appropriate long-term management advice for the Greenlandic fisheries with the primary focus on:
    (a) completing work on a sex-ratio based assessment of common minke whales off west Greenland; and
    (b) progress on developing *SLA*s for West Greenland fin and common minke whales;
(3) the *Implementation Review* for the eastern North Pacific gray whales; and
(4) consider any new scientific information related to conversion factors for edible products for Greenland fisheries.

Bowhead, right and gray whales (BRG)

The following issues are high priority topics:

(1) perform the annual review of catch information and new scientific information for B-C-B stock of bowhead whales and prepare for the 2012 *Implementation Review*;
(2) review stock structure and abundance for Eastern Canada and West Greenland bowhead whales;
(3) review scientific information on North Pacific and North Atlantic right whales;
(4) review progress towards southern right whale workshop;
(5) review new information on western gray whales;
(6) review information on other stocks of bowhead whales; and
(7) review new information on eastern gray whales (not relevant to *Implementation Review*).

In-depth assessment (IA)

The following issues are high priority topics:

(1) resolve the reasons for the differences between estimates of abundance of Antarctic minke whales between the OK and SPLINTR models;
(2) continue development of the catch-at-age models of Antarctic minke whales, including sensitivity tests to examine various assumptions regarding ageing errors and age-length keys; and
(3) continue examination of the differences between minke abundance estimated from CPII and CPIII, by further investigation of the relationship between sea ice and minke whale abundance.

Bycatch and other human-induced mortality (BC)

The following issues are high priority topics:

(1) collaboration with FAO on collation of relevant fisheries data and joining FIRMS;
(2) review progress in including information in National Progress Reports;
(3) continue development of the international database of ship strike incidents;
(4) consider methods for estimating risk and rates of bycatch and entanglement;
(5) consider methods and data sources for establishing time series of bycatch;
(6) review methods to estimate mortality from ship strikes; and
(7) review methods for assessing mortality from acoustic sources and marine debris.

Stock definition (SD)

The following issues are high priority topics:

(1) furtherance of guidelines for genetic analyses;
(2) updates on guidelines for DNA Data Quality;
(3) statistical and genetic issues concerning stock definition;
(4) TOSSM; and
(5) unit-to-conserve.

DNA (DNA)

The following issues are high priority topics:

(1) review genetic methods for species, stock and individual identification;

(2) review of results of the 'amendments' work on sequences deposited in GenBank;
(3) collection and archiving of tissue samples from catches and bycatches; and
(4) reference databases and standard for diagnostic DNA registries.

Environmental concerns (E)
The following issues are high priority topics:

(1) SOCER;
(2) review progress on POLLUTION 2000+;
(3) review new information impact of oil and dispersants on cetaceans;
(4) review progress of the CERD Working Group;
(5) review progress on recommendations from 2010 focus sessions on masking sound;
(6) review approaches as available from other international forums with regard to mitigation of effects of anthropogenic sound on cetaceans;
(7) review progress on work from the 2nd Climate Change Workshop; and
(8) review of marine renewable energy development.

Ecosystem modelling (EM)
The following issues are high priority topics:

(1) review ecosystem models from the North Pacific that may be relevant to assessments and RMP *Implementations*;
(2) review other issues relevant to ecosystem modelling within the Committee; and
(3) review ecosystem modelling efforts undertaken outside the IWC.

Southern Hemisphere whales other than Antarctic minke whales (SH)
The following issues are high priority topics:

(1) humpback whales-complete the assessment of breeding stock B;
(2) blue whales (Antarctic and pygmy): population estimates and continue work on the Southern Hemisphere blue whale catalogue;
(3) prepare for assessment of humpback whale breeding stocks D, E and F;
(4) review new information on the Arabian humpback populations.

Small cetaceans (SM)
The following issues are high priority topics:

(1) the status of status of Ziphiidae (beaked and bottlenose whales) worldwide;
(2) directed takes of small cetaceans;
(3) review report from climate change-small cetaceans workshop;
(4) other topics e.g. marine bushmeat; and
(5) review of progress on previous recommendations.

Whalewatching (WW)
The following issues are high priority topics:

(1) assess the impacts of whalewatching on cetaceans;
(2) review reports from intersessional working groups:
    (a) large-scale whalewatching experiment (LaWE) Steering Group;
    (b) LaWE Budget Development Group;
    (c) on-line database for world-wide tracking of commercial whalewatching and associated data collection; and
    (d) swim-with-whale operations;
(3) consider information from platforms of opportunity of potential value to the Committee;
(4) review of whalewatching guidelines and regulations; and
(5) review of collision risks to cetaceans from whalewatching vessels.

Scientific Permits
The following issues are high-priority topics:

(1) Review of activities under existing permits.
(2) Review of new or continuing proposals.
(3) Procedures for reviewing scientific permit proposals.
(4) Planning for final review of results from Iceland's scientific take of North Atlantic common minke whales.

23. DATA PROCESSING AND COMPUTING NEEDS FOR 2010/11

The Committee identified and agreed the requests for intersessional work by the Secretariat given in Table 10.

Table 10

Computing tasks/needs for 2010/11.

RMP – preparations for *Implementation*
Run a full set of trials using the Norwegian 'CatchLimit' program for North Atlantic fin whales, Western North Pacific Bryde's whales; and North Atlantic minke whales and place the results on the IWC website (Item 5.3).

AWMP
Work in preparation for/arising from the proposed workshop (Item 21).

NPM
Update the control program for North Pacific minke whales and undertake any work arising from the Preparatory Meeting and the First Intersessional Workshop including assembling the catch data at the appropriate spatial and temporal resolutions and coding and conditioning the operating models themselves (Item 6.3.2).

In-depth assessment
Validation of the 2009/10 SOWER cruise data for incorporation into the DESS database; complete validation of the 1995-97 blue whale cruise data and incorporate into the DESS database; prepare a catch series for North Pacific sei whales (Item 10.9.1).

Southern Hemisphere whale stocks
Documentation of the catch data available for Antarctic minke whales in preparation for the *pre-Implementation assessment* (Item 20.4).

Bycatch
Input bycatch data from the last season (2009) and for previous seasons (from 2003 back) into the bycatch database (Item 7.1).

24. FUNDING REQUIREMENTS FOR 2010/11

Table 11 summarises the complete list of recommendations for funding made by the Committee. The total required to meet its preferred budget is £316,700. The Committee **recommends** all of these proposed expenditures to the Commission. This is slightly above the projected amount available for funding (£315,750). The Committee **agrees** that the final column given in the table represents a budget that will allow progress to be made by its sub-committees and Working Groups in its priority topics.

A summary of each of the items is given below, by sub-committee or standing Working Group. Full details can be found in the relevant Annexes as given in Table 11.

The Committee was pleased to note that procedures have been agreed to review proposals for funds from the Small Cetaceans Voluntary Fund and the Southern Ocean Research Partnership (Items 14 and 19). One proposal under the former has been recommended (see Item 14.6.1). The Committee was also pleased to note that funding has been found for the Workshop on Small Cetaceans and Climate Change (see Item 12.5).

Table 11

Summary of budget requests.

Revised Management Procedure

(1) ANALYSIS AND USE OF TIME-SERIES OF DATA ON CALVING RATES AND INTERVALS FOR USE IN THE MSYR REVIEW

The Committee is conducting a review of the range of MSYR values to include in simulation trials when selecting among variants of the RMP. The third intersessional workshop on the review of MSYR assembled a number of datasets on calving rates and calving intervals for baleen whales. Efforts were made following the workshop to fit models which accounted for both process and observation error to the data on calving rates and calving intervals. However, numerical problems were encountered when implementing these models. Funding is required for researchers to overcome these problems to provide the inputs needed to apply the Bayesian hierarchical method adopted by the Committee for computing a posterior distribution for r_0.

North Pacific minke whales

(2) PREPARATORY MEETING AND FIRST INTERSESSIONAL WORKSHOP TOWARDS THE IMPLEMENTATION REVIEW FOR WESTERN NORTH PACIFIC COMMON MINKE WHALES

The schedule for an *Implementation Review* specifies that between the finalisation of the *pre-Implementation assessment* and the following annual meeting of the Scientific Committee, an intersessional workshop shall be held to address a number of issues. Given the complexity of this *Implementation Review*, it is important to hold a preparatory meeting before the First Intersessional Workshop.

Aboriginal Whaling Management Procedure

(3) WORKSHOP ON GREENLANDIC FISHERIES/PREPARATION FOR GRAY WHALE IMPLEMENTATION REVIEW

The Committee has a number of priority areas related to Greenlandic fisheries and an intersessional Workshop is required to address:

(1) progress on developing *SLAs* for West Greenland fin and common minke whales;
(2) progress on the development of the sex-ratio method; and
(3) preparation for the *Implementation Review* for eastern North Pacific gray whales.

(4) AWMP DEVELOPERS FUND

The developers fund has been invaluable in the work of *SLA* development and related essential tasks of the SWG. It has been agreed as a standing fund by the Commission. The primary development tasks facing the SWG are for the Greenlandic fisheries. These tasks are of high priority to the Committee and the Commission. The fund is essential to allow progress to be made.

Bowhead, right and gray whales

(5) SOUTHERN OCEAN RIGHT WHALE PHOTO-ID CATALOG

For several decades, extensive photo-id surveys have been carried out for southern right whales in the coastal waters of South America, southern Africa and Australia during winter and spring, and much valuable data on the demographics of these populations has been collected. Together with genetic information, these data also provide the opportunity to investigate interchange and mixing between the coastal populations. However, because of its geographic limitations it is uninformative about the links between these populations and those found (generally at higher latitudes) in summer where extensive catches were taken in pelagic whaling. Funding is requested to address this gap by compiling images of southern right whales taken away from coastal waters of the continents, in a catalogue and associated database.

In-depth assessments

(6) INVESTIGATE THE RELATIONSHIP BETWEEN SEA ICE CHARACTERISTICS AND ANTARCTIC MINKE WHALE ABUNDANCE ESTIMATES

No conclusions have yet been reached on the reasons for the appreciable decline in abundance estimates from CPII and CPIII. Changes in sea ice characteristics, such as its extent and configuration, have been considered as one of the most likely influential factors. In order to investigate this carefully, funding is required to enable the preparation of the following sea ice related data sets:

(1) timing of the ice melt index for the entire time series of CPII and CPIII; and
(2) sea ice characteristics (e.g. area of sea-ice-field) in the south of ice edge for the entire time series of CPII and CPIII.

(7) RESOLVING DIFFERENCES IN MINKE WHALE ABUNDANCE ESTIMATES

Over the past two years, two methods have been presented to estimate abundance from the CPII and CPIII IDCR/SOWER cruise data. However, there are large differences between the estimates. These differences are much greater than statistical uncertainty, and than generally seen in the simulated datasets. Following intersessional work by correspondence a workshop is required to attempt to finally resolve the difference between the two approaches.

(8) IMPORT 2009/10 SOWER DATA AND ASSIST ABUNDANCE WORKING GROUP

Funds are required to enable the 2009/10 IWC/SOWER data to be incorporated into DESS and to provide general support to the IWC Secretariat regarding DESS. Errors will be corrected in the 'standard' and IDCR/SOWER datasets before the 2010 Scientific Committee meeting.

(9) AND (10) 2011 NORTH PACIFIC SIGHTING CRUISE AND ASSOCIATED MEETINGS

A new medium- to long-term research programme involving sighting surveys to provide annual information for cetacean stock management in the North Pacific is scheduled to commence in 2011. The cruise will last a total of about 60 days between July and August and the vessel *Kaiko Maru* will generously be provided by the Japanese Government. A two-day planning meeting for the 2011 cruise will be held in Tokyo. It will be preceded by a three-day workshop to develop the medium to long term objectives of the research programme and associated fieldwork.

(11) STATISTICAL CATCH-AT-AGE ESTIMATORS FOR ANTARCTIC MINKE WHALES

The Committee is trying to understand the reasons for the apparent large declines in abundance indicated by estimates produced from these surveys. Several of these reasons can be explored by population dynamics modelling. In 2005, Punt and Polacheck developed the statistical catch-at-age (SCAA) model, which has been refined over the last few years and is considered the most appropriate modelling framework for addressing these issues. Funding is requested for Committee's researchers to implement the recommendations so that in 2011 it will be in a position to apply the SCAA model to the most recent datasets.

Other Southern Hemisphere whale stocks

(12) SOUTHERN HEMISPHERE BLUE WHALE CATALOGUE PROJECT

Little is known about the present-day migration of blue whales, population structure and abundance or the level of interchange among populations. In 2008, the IWC supported the creation of a Southern Hemisphere blue whale catalogue and Centro de Conservacion Cetacea in Chile was tasked with developing a central web-based system by which Southern Hemisphere blue whale photo-id matching could take place. Matching will be conducted during the next two years through this platform by researchers from three Southern Hemisphere regions. Comparisons of blue whale photo-id and the significant number of individuals catalogued will be time consuming and researchers will not have enough free time to dedicate to the matching process. Therefore funding is required to ensure the matching process is completed. This will be a two-year project and a further request for funding (£11,200) will be submitted next year.

(13) MODELLING OF SOUTHERN HEMISPHERE HUMPBACK WHALE POPULATIONS

(1) Deliberations at the 2010 Annual Meeting have led to a number of proposed variants of stock-structure models for breeding stock B. Computer software needs to be developed to implement these models to take account of tag-recapture data.
(2) Simultaneous analysis of all 7 breeding stocks using the current age-aggregated model is desirable so that:
    (a) the catch allocation uncertainty is taken into account in a consistent and even-handed manner;
    (b) uncertainties in the boundaries for such allocations can be properly included in the analysis; and
    (c) likely similarities in intrinsic growth rate parameters for the different stocks can be properly factored into the analyses.

Development of this model has commenced but still needs further development. A contribution towards the salaries of researchers is requested to enable progress to be made with (1) and (2).

(14) ANTARCTIC HUMPBACK WHALE CATALOGUE

The Committee is already committed to funding this project, which represents only a partial cost of running the catalogue and is of great benefit to its in-depth assessment of Southern Hemisphere humpback whales. The funds are required to continue the cataloguing of submitted photographs and further develop and enhance the system for on-line access. The work will be carried out by Carlson and Allen.

Bycatch and other human-induced mortality

(15) FURTHER DEVELOPMENT AND MAINTENANCE OF THE IWC SHIP STRIKE DATABASE

Development of the IWC ship strike database has continued intersessionally. Funding is required for: (1) completing work on public summaries; (2) the development of a handbook; (3) data entry and validation; and (4) annual ongoing work by the data review group. The need for a global database of incidents involving collisions between vessels and whales has previously been recognised by the Committee, as well as other bodies such as the International Maritime Organization (IMO) and ACCOBAMS.

(16) DEVELOPMENT OF AN ONLINE SUBMISSION DATABASE FOR PROGRESS REPORTS

In 2009 the possibility of developing an online form/ database for submission of national Progress Reports was discussed as part of work on bycatches and small cetaceans, in addition to the general work of the Committee. Due to time constraints it was not possible to progress this further. A small group met this year to design an initial template and the Committee is now in the position to start trialling such a database. Funding is required for an expert to work with the IWC Secretariat to create this database and an initial version will be available at the next Annual Meeting.

Environment

(17) RISK ASSESSMENT MODELING TO DETERMINE THE IMPACT OF POLLUTANTS ON CETACEAN POPULATIONS

The report of the Phase II Intersessional IWC Pollution 2000+ Workshop (SC/62/Rep4) recommends that a number of modelling exercises be undertaken. This will involve the development and implementation of two demonstration projects, using the risk assessment framework (based on an individual based model approach). Funding is required to employ a post-doctoral research assistant to conduct this work under the direct supervision of Schwacke and Hall, with input and guidance from the Pollution 2000+ Steering Committee. This will be a two-year project and a further request for funding (£70,750) will be submitted next year.

(18) STATE OF THE CETACEAN ENVIRONMENT REPORT (SOCER)

The Committee regards SOCER to be a useful document that provides a 'snapshot' of environmental developments relevant to cetaceans that was requested by the Commission. Money is requested to support the production of this report.

Whalewatching

(19) DATA COMPILATION AND POWER ANALYSES FOR THE LAWE

The LaWE initiative aims to understand the possible effects of whalewatching on the demographic parameters of cetacean populations. In order to develop procedural mechanisms to centralise relevant data and to commence power analysis for key parameters, funding is required to employ a research assistant for 6 weeks.

Other

(20) INVITED PARTICIPANTS (IPs) FUND

The Committee **draws attention** to the essential contribution made to its work by the funded IPs. The IWC-funded IPs play an essential role in the Committee's work, including the critically important roles of Chairs and rapporteurs. They represent excellent value as they receive only travel and subsistence costs and thus donate their time, which is considerable. As was the case for previous meetings, where possible, effort will be made to accommodate scientists from developing countries.

25. WORKING METHODS OF THE COMMITTEE

25.1 Citation of Scientific Committee documents

SC/62/SCP1 was produced in response to the discussion last year about the Committee's policy with respect to the citation of Scientific Committee documents (IWC, 2010c, p.92). At that time the Committee had noted that *inter alia* its policy must ensure transparency with respect to advice provided by the Committee and to respect the rights of scientists to first publication of data.

The authors of SC/62/SCP1 had examined both the policy of the *Journal* and that of the Committee with respect to the question of including 'Not to be cited (or used) without the permission of the author(s)' at the top of a paper. They noted that there was some ambiguity in the present rules that required clarification and suggested that the ability to include a 'not to be cited....' restriction to a paper should be removed and replaced by a 'please inform authors when citing outside an IWC meeting' header.

There was considerable discussion of this proposal. The Committee, as before was concerned to:

(1) ensure transparency;
(2) respect rights to first publication; and
(3) avoid the possibility that authors may refuse to submit papers of value to the Committee's work.

Recognising the sensitivities involved and the need to find an appropriate balance amongst items (1)-(3) above, the Committee **agrees** that in future, all papers presented to the Scientific Committee contain the following header (this information will also be included in the Scientific Committee Handbook and when providing information on document submission to meetings and workshops):

> 'Papers submitted to the IWC Scientific Committee are produced to advance discussions within that Committee: they may be preliminary or exploratory. It is important that if you wish to cite this paper outside the context of an IWC meeting, you notify the author at least six weeks before it is cited to ensure that it has not been superseded or found to contain errors.'

The Scientific Committee List of Documents attempts to keep track of papers that have been presented to Scientific Committee meetings and can be found on the IWC website[7]. Authors who are aware of particular problems with any of their past papers are invited to inform the Secretariat who will keep an updated compilation.

25.2 Working papers, late papers and related issues

As a result of discussions during the meeting, the Committee **agrees** on the need to clarify certain issues with respect to working papers and primary papers that arrive late. The definitions and rules regarding these (and other categories of paper including 'For Info' papers) can be found in the Scientific Committee Handbook[8].

Primary papers must be submitted by the end of the first day of the Annual Meeting. Considerable flexibility has been shown by the Chair and Head of Science in the way they have dealt with papers for which a title has been submitted but which for one reason or another, arrive late. Formally, they can be called working papers because they have missed the deadline and then immediately be 'upgraded' to primary papers to minimise copying. Unfortunately, this flexibility is tending to be abused as a larger number of papers are being submitted past the deadline. For this reason, the Committee **agrees** that in future only in exceptional circumstances will late papers be accepted. In addition, Chairs will be very strict on the criteria for accepting working papers i.e. they must arise from discussions and be requested and/or be likely to expedite resolution of disagreements or stimulate debate within the meeting.

Notwithstanding the question of late papers, the Committee **agrees** that there may be circumstances in the future where it is appropriate for certain working papers to be 'elevated' to the status of a primary paper during the meeting. The Chair and Head of Science will apply the following two criteria:

---

[7] *http://www.iwcoffice.org/publications/pubmain.htm.*

[8] *http://www.iwcoffice.org/sci_com/handbook.htm.*

(1) the working paper has been presented and discussed within a sub-group or the plenary, such that an opportunity to comment on it has been given; and

(2) the text of the sub-group or plenary report would be significantly improved, streamlined or clarified by the ability to reference the paper as a primary document.

26. ELECTION OF OFFICERS

The Committee **agrees** that there was no need for elections this year.

27. PUBLICATIONS

Donovan reported on issues relating to the production of the *Journal*. Unfortunately, the year has been plagued by a series of problems with respect to getting the *Journal* published, due to internal problems at the printers that the IWC has used for many years. Sadly, after attempts to secure further investment, they are no longer trading but the Secretariat had very little notice in terms of finding an alternative. We have managed to find another company that we are using on a trial basis, and thanks to the page-setting abilities of Andrea Cooke, we managed to at least get the large *Supplement* out on time. We are now dealing with a different company and the *Journal* and Supplements should once again appear promptly. That being said, the Secretariat is in the process of examining a number of companies for ability and price. It is expected that the resultant backlog of papers will be reduced or eliminated in the coming year. In addition, the possibility of including electronic subscriptions is being investigated. The most efficient and cost effective way to digitise earlier reports is also being investigated. The Committee, as in previous years, **reiterates** the importance of the *Journal* to its work and encourages members to urge their institutes to subscribe.

28. OTHER BUSINESS

This is the final meeting for Nicky Grandy, Secretary of the Commission. The Scientific Committee rose in appreciation of her dedicated work in organising its meetings over the last decade. It noted the calm, efficient, good humoured way that she (and the team she ran) had assisted the Scientific Committee, even in the face of its sometimes unreasonable demands. On behalf of the Committee, its elder statesman, John Bannister, presented her with a specially painted card and a beautiful Moroccan rug, wishing her the very best for the future – she will be greatly missed.

29. ADOPTION OF REPORT

In closing the meeting, Palka thanked the Secretariat for carrying out its work in the usual efficient manner. The report was adopted at 17:20 on 11 June 2010. As is usual, final editing was carried out by the Convenors after the meeting.

Report of the

Scientific Committee

Tromsø, Norway, 30 May to 11 June 2011

Annex E: Standing Working Group on an Aboriginal Whaling Management Procedure (AWMP)

This report is **CONFIDENTIAL** until
the opening session of the Commission's Plenary
at **10.00am** on **Monday 11th July 2011**

International Whaling Commission, Tromsø and Jersey, 2011

Annex E

Report of the Standing Working Group on the Aboriginal Whaling Management Procedure (AWMP)

Members: Donovan (Convenor), Acquarone, Allison, Baker, Bickham, Borodin, Brandão, Brandon, Breiwick, Broker, Brownell, Butterworth, Childerhouse, Cipriano, Dupont, Fadeev, Givens, Gunnlaugsson, Heide-Jørgensen, Hiruma, Ilyashenko, Iñíguez, Jaramillo, Johnston, Kanda, Kitakado, Lang, Lockyer, Mate, Moore, J., Nukulina, Palka, Punt, Reeves, Roel, Rose, Schweder, Scordino, Suydam, Swindoll, Thomas, Tyurneva, Uoya, Walløe, Weller, Witting.

1. INTRODUCTORY ITEMS

1.1 Convenor's opening remarks

Donovan welcomed the participants to the meeting. He noted that given the logistics of the intersessional workshop, it had not been possible to dedicate sufficient time to consideration of Greenlandic issues related to future *SLA* development (SC/63/Rep2). Given that the focus of the pre-meeting was to provide time for that discussion to begin, he noted that that the relevant agenda items 2 and 3 would be completed during the normal SWG sessions.

1.2 Election of Chair

Donovan was elected chair.

1.3 Appointment of rapporteurs

Givens and Punt acted as rapporteurs, with assistance from the Chair.

1.4 Adoption of Agenda

The adopted agenda is given in Appendix 1.

1.5 Documents available

The new primary documents available to the SWG were SC/63/AWMP1-5 and SC/63/Rep2.

2. CONCLUSIONS ON THE SEX RATIO METHOD

Witting (2005 [SC/57/AWMP4]; 2006 [SC/58/AWMP3]) proposed that the abundance of West Greenland minke whales could be estimated using time series data on the sex ratio of past catches. Since then, the proposed method and subsequent improvements to estimate only the lower confidence bound on the abundance (starting with Witting and Schweder, 2007 [SC/59/AWMP6]) have been evaluated by the SWG to determine if they could provide reliable, accurate, and precise estimates at Annual Meetings and Workshops. Last year, the SWG agreed that despite considerable effort, it was still not possible to confirm whether a sex-ratio-based method was appropriate and effective. It agreed that it would no longer prioritize development of this technique unless a comprehensive final analysis could be endorsed at the 2011 Annual Meeting.

In response to the problems seen in the sex ratio method, SC/63/AWMP5 described a possible remedy involving transformation of a key parameter in the model. An illustrative example used a transformation which operates in a way that for population sizes much greater than are realistic, the impact of catches of females on abundance is damped. This leads to finite estimates of carrying capacity *K* even in circumstances where the trend over time in the proportion of whales in the catch that is male is decreasing (as is the case for West Greenland minke whales). The example was shown to produce positively biased estimates of the lower 5% confidence interval for current population size. However the degree to which this bias warrants concern is difficult to assess since the estimator is positively biased even in circumstances where the proportion of the catches that are male does not trend downwards over time.

The SWG thanked the authors of SC/63/AWMP5 for their efforts to resolve the problems. Although SWG members offered the authors a variety of technical suggestions and comments on the method, it was clear that exploratory work in SC/63/AWMP5 was not the comprehensive final analysis sought by the SWG. The most obvious limitation of the method was that estimation of abundances appeared to be strongly positively biased. This is problematic in relation to abundance estimation, but it was noted that the approach in SC/63/AWMP5 might still prove useful in a future *SLA* if, for example, the bias was corrected for, or the *SLA* was tuned to adapt suitably to the bias.

The SWG thanked Witting, Schweder, Brandão and Butterworth for their considerable effort over the last several years in developing a novel and scientifically interesting estimation approach for sex ratio data. Despite their outstanding contributions to the work of the SWG, no final solution had yet been developed to remedy the previously expressed concerns. The SWG also noted that the original motivation for the work, the need to obtain a satisfactory abundance estimate has been superseded by the aerial survey (Heide-Jørgensen *et al.,* 2010) that had resulted in an agreed abundance estimate (16,600; 95% CI:7,170-38,500) that was suitable for assessment. Discussion of how to proceed with the development of an operating model to evaluate candidate *SLA*s for this stock is provided under item 3.2.

3. CONSIDERATION OF WORK REQUIRED TO DEVELOP *SLA*S FOR ALL GREENLANDIC HUNTS BEFORE THE END OF THE INTERIM PERIOD

In Greenland, a multispecies hunt occurs and the expressed 'need' is for 670 tonnes of edible products from large whales for West Greenland; this involves catches of common minke, fin, humpback and bowhead whales. The flexibility among species is important to the hunters and satisfying 'subsistence need' to the extent possible is a critical component of management. Last year, the SWG noted that the development of a combined approach to calculate strike limits for more than one species has not been previously attempted (IWC, 2011).

The SWG **endorsed** the views of the intersessional Workshop that this matter should be deferred until single-species management approaches had been developed further. These would provide the necessary basis to extend to multi-species considerations, such as need being expressed on a species-combined rather than a species-specific basis.

For a number of reasons, primarily related to stock structure issues, the SWG noted that development of *SLA*s for Greenland aboriginal hunts (especially for common minke and fin whales) will be more complex that any implementation the SWG had previously considered. The Committee endorsed an interim safe approach to setting catch limits for the Greenland hunts in 2008 (IWC, 2009), noting that this should be considered valid for two five-year blocks i.e. the SWG target will be for agreed and validated *SLA*s, at least by species, for the 2017 Annual Meeting (assuming that the Commission sets 5-year block quotas in 2012 as scheduled). Given the complexity of the development process, this work is high priority and the SWG **emphasised** that it will be necessary to hold intersessional workshops (see item 10) to expedite progress.

3.1 and 3.2 Fin whales and common minke whales

At its 2011 intersessional workshop, the SWG noted that the first step toward *SLA* development for West Greenland fin whales and common minke whales will be to define the operating model(s) that are to be used to test the performance of candidate *SLA*s.

The SWG noted that both of these species have been the focus of RMP *Implementations* and *Implementation Reviews*, even though the focus has not been on Greenland. It is clearly essential that the operating models used to develop *SLA*s for the Greenland hunts are based on those used in the RMP *Implementations.* These should be based on the existing *Implementation Simulation Trial* framework for the North Atlantic common minke (IWC, 1994, 2005, 2009) and fin whales (IWC, 2010). Given the SWG's focus on Greenland, it is clear that the review of the RMP operating models and specifications will probably identify refinements and modifications to the existing trials structure to properly account for the West Greenland case, particularly with respect to stock structure; it is important that ultimately these discussions are held in collaboration with the sub-committee on the RMP to ensure consistency with operating models to the extent possible. In addition, the *SLA* development process will have to take into account catches made under the RMP.

As part of the conceptual discussions held within the SWG, Witting and Heide-Jørgensen produced some initial ideas on the better integration of the West Greenland situation with the existing RMP operating models. They agreed to develop these ideas further and present a paper to the proposed intersessional meeting.

3.3 Humpback whales

The Scientific Committee has previously agreed to provide management advice on the West Greenland feeding aggregation of humpback whales by treating this as an independent stock (IWC, 2008, p.21). The SWG welcomed new work presented this year on the development of a stock assessment model for these whales (SC/63/AWMP2).

SC/63/AWMP2 used recent abundance estimates, historical catches starting from 1664, and an age- and sex-structured population model to perform Bayesian assessments of West Greenland humpback whales. The historical catches included the West Greenland catches as a lower bound on the catch history, and the West Greenland plus 10% of the West Indies catches as an upper bound. Prior distributions for life history parameters had been constructed from studies on humpback whales in the North Atlantic to account for the uncertainty associated with the parameters. The abundance data included a fully-corrected West Greenland humpback abundance estimate of 3,270 (CV: 0.50) individuals in 2007 (Heide-Jørgensen *et al*., 2008), a time-series of relative abundance estimates from aerial surveys (Heide-Jørgensen *et al*., 2008), and a time-series of relative abundance estimates from mark-recapture analysis (Larsen and Hammond, 2004).

SC/63/AWMP2 examined whether the long-term dynamics (from 1664) is best described by density-regulated growth, with perturbed populations returning monotonically towards an equilibrium state, or by inertia dynamics, where populations typically return through damped cycles. There was substantial statistical support for inertia dynamics and rejection of density-regulated growth. It was estimated that the abundance declined from a population dynamic equilibrium of 2,900 (90% CI:1,800-5,900) individuals in 1664 to a minimum of 1,300 (90% CI:230-5,100) individuals in 1927. The depletion ratio for 2011 was estimated to be 1.4 (90% CI:0.68-3.1), and the model projected that the population will increase to 5,200 (90% CI:2,400-9,000) individuals in 2020 (assuming yearly post 2010 catches of 10).

The SWG noted that a key element of SC/63/AWMP2 was the comparison of three alternative dynamics models: exponential growth (E), density regulated (D), and inertia dynamics (I). Model E fitted the available abundance data well, but was not appropriate to use without modification over time spans longer than a few decades because it included no regulation of abundance or density feedback mechanism. Model D explicitly included density regulation, but did not fit the data well over the long time period that started in 1664. However, it could be made to fit the abundance and catch data over a shorter period of time. In other applications (e.g., for eastern Pacific gray whales), model misfit over similarly long time periods has been addressed by starting the model recently and estimating its status relative to carrying capacity at that time. Such an approach may be applicable to the West Greenland humpback case, too. Additional calculations during the meeting applied a density-regulated model over a short time-period starting in 1980, and this fitted the data as well as the exponential model. In this case, however, the data were not informative about an upper bound for the carrying capacity.

Model I led to a good fit to the abundance data when the model was started in 1664, but may be questionable for use as operating model because the inertia dynamics over long time periods will be quite sensitive to parameterization. This sensitivity could also render the parameterization of future projections (i.e., as an operating model to test *SLA*s) difficult.

SWG members offered several comments on these assessment methods. It was suggested that the prior distributions for the bias parameters should be changed to be uniform on a log scale because this would mean that the relative abundance indices would not provide information on absolute abundance. It was noted that only one of the abundance estimates used in the analysis was an estimate of absolute abundance, so the fitted abundance curve should pass right through that point. This result was not seen, but calculations during the meeting using log uniform priors on the abundance parameters and the bias in the relative surveys did achieve this result.

It was noted that models E, D, and I used 7, 8, and 9 parameters, respectively, to fit 9 data points. One member expressed concern about the very low number of degrees of freedom in these models because (i) posterior distributions for some of the parameters (survival and birth rates, and age of sexual maturity) could be misleading (see below), and (ii) in an over-parameterized model, nearly any predicted outcome can be achieved from a variety of parameter combinations. The SWG noted that when dynamics models are sex- and age-structured, it is common to find that the data provide information about only a few parameters (e.g., carrying capacity and MSYR or the inertia parameter) while the posterior distributions for the remaining parameters differ little from the priors because the abundance data do not provide much signal for these parameters. This was found in SC/63/AWMP2. In the present application, the data were also informative about the parameters specifying bias in the relative abundance estimates. For parameters about which the abundance data contain little information, incorporating prior distributions (as done in SC/63/AWMP2) can be interpreted as a strategy to incorporate additional uncertainty into the results. The priors on the life history parameters of SC/63/AWMP2 were based on studies of humpback whales in other areas of the North Atlantic than West Greenland.

Over-fitting can sometimes be identified using the correlation and strength of nonlinear relationships among posterior parameter estimates. A supplement to SC/63/AWMP2 listed the parameter correlation matrix for each model. Correlations ranged from zero to strong (~0.90), yet it is important to realize that correlations among parameter estimates can also reflect the underlying constraints established by the structure of the dynamics model. The SWG **agreed** to carefully monitor for signs of problems associated with over-fitting when it conditions operating models for *SLA* development and testing.

In conclusion, the SWG recognised that the development process of an *SLA* for Greenland humpback whales would focus on consideration of the West Greenland feeding aggregation as a management unit. This may allow less attention on the overall North Atlantic humpback whale stock structure and may also avoid attempting to incorporate the long time series of catch data and the attendant catch allocation problems noted during the comprehensive assessment (e.g. IWC, 2002; 2003).

3.4 Bowhead whales

Discussion within the Committee in recent years has focussed on stock structure and associated abundance estimates. The present working hypothesis is that bowhead whales in eastern Canada - West Greenland comprise a single stock; the alternative hypothesis is one of two stocks: one in Hudson Bay - Foxe Basin and another in Baffin Bay - Davis Strait.

SC/63/AWMP3 used recent abundance estimates, historical catches starting from 1719, and an age- and sex-structured population model to conduct Bayesian assessments of bowhead whales in eastern Canada - West Greenland. It also included a model for a Baffin Bay - Davis Strait stock, given the alternative two stock hypothesis. The historical catches were based on Higdon (2010), with a lower bound on the catch histories being given by the high and medium quality catch data, and an upper bound being given by all available data. An agreed abundance estimate of 6,340 (CV: 0.38) for 2002 (IWC, 2009a) was available to represent either the abundance of the entire eastern Canada - West Greenland population, or the Baffin Bay - Davis Strait stock. A time series of five estimated sighting rates covering the range from 1981 to 1998 for the Disko Bay area (Heide-Jørgensen *et al.*, 2007) was also used when fitting the model.

SC/63/AWMP3 examined whether the long-term dynamics (from 1719) are best described by density-regulated growth or by inertia dynamics. For eastern Canada - West Greenland bowhead whales there was substantial statistical support for inertia dynamics and for rejection of density-regulated growth. It was estimated that abundance declined from a population dynamic equilibrium of 30,000 (90% CI:24,000-35,000) individuals in 1719 to a maximal depletion of 1,700 (90% CI:510-4,900) individuals in 1888. The depletion ratio in 2011 was estimated to 0.29 (90% CI:0.15-0.58), and the population was projected to increase to 10,000 (90% CI:5,200-20,000) individuals in 2020 (assuming yearly post-2010 catches of 5). For the Baffin Bay - Davis Strait stock under the two stock hypothesis, it was estimated that abundance declined from a population dynamic equilibrium with 34,000 (90% CI:23,000-40,000) individuals in 1719 to a maximal depletion of 3,400 (90% CI:590-8,500) individuals in 1888. The depletion ratio in 2011 was estimated to 0.25 (90% CI:0.13-0.52), and the population was projected to increase to 9,100 (90% CI:4,500-18,000) individuals in 2020 (assuming yearly post 2010 catches of 3).

In discussion, it was noted that this approach was very similar to the method used for humpback whales discussed under Item 3.3. However, in the bowhead case, limitations of the available data presented greater problems and raised concern for SWG members.

Most importantly, the SWG noted that 5 of the 6 abundance estimates used as data were rough indices of relative abundance (as opposed to absolute abundance) pertaining to a small area and hence may be questionable as indices of total abundance. These estimates were based on a total of only 11 sightings from aerial surveys of the spring aggregation of bowhead whales in the Disko Bay area. Data on body length suggest that it is primarily large and mature bowhead whales without calves that occur in the Disko Bay area (Heide-Jørgensen *et al*., 2010), and it may be expected that the time series of sighting rates relate to a local age/sex aggregation. It was further noted that problems with over-parameterisation were more likely here than for West Greenland humpbacks. For these reasons, the SWG was sceptical that the available index data could be used to fit a dynamics model reliably.

It was noted that the posterior distribution for adult mortality appeared to be bounded above by approximately 1%, whereas analysis of the Bering-Chukchi-Beaufort Seas bowhead populations had supported values half as large and even smaller. The analysis did not include an explicit prior on adult mortality. Instead, values for adult mortality were calculated from sampled values from the priors on the other life history parameters and the prior on the population growth rate. Thus, it was not clear whether this result was an artifact of the prior distributions for the other parameters or driven by the data (through the likelihood function). If desired, the assessment could place a prior on the adult mortality rate rather than the growth rate, with the growth rate being calculated from the values of the other parameters. The SWG did not consider whether it was most desirable to control the growth rate or adult mortality using an explicit prior.

The analysis in SC/63/AWMP3 assumed a prior for the growth rate parameter that supported only positive values. However, Witting reported that negative values would have received some posterior probability had they been given some prior probability. During the meeting, a version of the analysis that fitted the mature component of the population to the sighting data from Disko Bay using a uniform prior from -0.07 to 0.07 on the growth rate of the exponential model was presented. The posterior estimate (3.8%, 90% CI: -2.7% - 6.1%) was less accurate, but with a point estimate rather similar to the estimate from the Bering-Chukchi-Beaufort Seas population of bowhead whales (3.4%, 95% CI: 1.7%-5%, Zeh and Punt, 2005).

The SWG recalled that a primary purpose for this bowhead assessment is the development of an *SLA*. In this context, a high degree of precision appears unnecessary. The agreed abundance estimate for 2002 is 6,340 (CV: 0.38; IWC, 2009a), yet the need envelope is probably likely to be around five strikes per year, to which probably less than five additional removals would be added to reflect takes by native communities in Canada, at least on present information (Annex F). Compared to the abundance estimate, this level of removals would seem to have only limited impact. The SWG noted that it might be therefore possible to establish a simple *SLA* because these circumstances suggested that the need to develop a more sophisticated approach appeared to be a low priority. Furthermore, a simple method would still be subject to an *Implementation Review* if the approach appeared inadequate or if the need envelope or level of Canadian takes increased. Development of a simple method would require the determination of a need envelope, and the Chair of the SWG was asked to discuss need envelopes with the hunters.

4. IMPLEMENTATION REVIEW OF GRAY WHALES WITH EMPHASIS ON THE PCFG

At the 2010 Annual meeting (IWC, 2011), it had been agreed that the information on stock structure and hunting presented, although some of it had not met the Data Availability Guideline requirements (IWC, 2004) for the 2010 review, warranted the development of trials as part of a new *Implementation Review* in 2011 to evaluate the performance of *SLA*s for hunting in the Pacific Northwest, with a primary focus on the PCFG (Pacific Coast Feeding Group). It also agreed that the 2010 *Implementation Review* had shown that the population as a whole was in a healthy state, but that over the next few years, further work should be undertaken to investigate the possibility of structure on the northern feeding grounds, especially in the region of the Chukotkan hunts.

4.1 Summary of intersessional Workshop

Donovan summarised the report of the intersessional workshop held in La Jolla, California from 28 March – 1 April 2011. With respect to gray whales, the focus of the workshop was preparing to complete an *Implementation Review* of eastern gray whales at the 2011 Annual Meeting, with the focus on the proposed Makah hunt and the PCFG. Most of the effort centred on reviewing the available information in the context of developing an operating model and trial structure such that conditioning and trial runs could be completed before and at the Annual Meeting.

The SWG received new and updated information on stock structure and movements (including information, some preliminary, on movements of gray whales between the western and eastern North Pacific), abundance and trends (including estimates for the PCFG and for the 'total'), catch data (including bycatches) and feeding ecology.

The Workshop agreed that the trials would consider three geographic regions. The north area is north of 52^0N (roughly northern Vancouver Island), the PCFG area is between 41°N and 52°N, and the 'south' area is south of 41°N. The trials will consider two stocks ('PCFG' and 'north'). Some PCFG whales will be found outside of the PCFG area at various times during the year. However, this is not problematic since the historical catches north of 52°N occurred well north of 52°N and future catches will either occur in the Bering Sea or in the Makah U&A[1].

The discussions of trial structure were greatly aided by the presentation of SC/M11/AWMP1 in which an age- and sex-structured operating model was presented that could form the basis of operating models for the *Implementation Review.* The *SLA* to be considered was provided by the Makah Tribal Council (details are presented in SC/63/Rep2, Annex D). Its implementation in the operating model is included in Appendix 3 to this report as part of the overall trial specifications, as are details of catches, bycatches, abundance, biological parameters including MSYR and performance statistics, including updates from the present meeting.

Unlike previous *Implementations*, the PCFG was for a 'small' population (previously referred to as a 'Type 3 Fishery'). Based on the work of Punt and Breiwick (2002), it was agreed that demographic uncertainty would be largely inconsequential even for a population of 200. However, it also agreed (1) that the lowest number of mature females during the 100-year projection period should be included in the standard set of summary statistics so that an evaluation of the potential for depensation could be made; and (2) the set of trials will include cases in which there is environmental variability in the form of mortality events.

The Workshop agreed to the following specifications for the base-case trials:

(1) Two stocks (PCFG, non-PCFG)

(2) Four spatio-temporal strata (south, north, PCFG [Dec-May], CPFG [June-Nov])

(3) Split of catch to stock

  (a) South: 1% PCFG; 99% non-PCFG

  (b) PCFG [Dec-May]: 20.3% PCFG; 79.7% non-PCFG

  (c) PCFG [Jun-Nov]; 100% PCFG

  (d) North: 0% PCFG

(4) The split of the catch to stock is deterministic in the past, but stochastic in the future.

(5) The probability of a PCFG whale being classified as non-PCFG is 0.

(6) The probability of a north whale being classified as PCFG is 0.01.

(7) 50% of struck animals are lost.

(8) Selectivity is to be 1+.

(9) All catches occur prior to May[2].

(10) $MSYL_{1+} = 0.6$; $MSYR_{1+}$=4.5%.

From this, the Workshop developed an initial set of *Evaluation* and *Robustness Trials* (SC/63/Rep2, Tables 4 and 5) and reviewed and modified the performance statistics from the 2004 *Implementation.* The revised set of statistics can be found in Appendix 3 to this report.

A number of intersessional tasks were set and progress with these is discussed under Item 4.3.

4.2 Review of information on the PCFG

SC/63/AWMP1 presented a review of published and gray literature on PCFG gray whales. The objective of the paper was to familiarize the AWMP SWG with the biology of the PCFG whales and to draw attention to important components of the PCFG as it relates to management. The first issue for management consideration is the range of the PCFG. The IWC currently defines PCFG whales as gray whales observed in multiple years between 1 June and 30 November between 41N and 52N (IWC, 2011). This definition is based on research that does not uniformly survey the potential range of PCFG gray whales; the northern and southern extents of the range are poorly sampled. Gosho *et al.* (2011) found that 17.5% of gray whales photographed during surveys at Kodiak Island, Alaska matched to whales in

---

[1] 'usual and accustomed fishing grounds' – NB although these include the Strait of Juan de Fuca the hunt will be prohibited there due to the large portion of PCFG whales photographed in that area. The hunt will be limited to 1 December - 30 May to minimise the likelihood of PCFG whales.

[2] This is assumption is conservative because it will lead to the highest assessed risk to the PCFG stock. In principle, it would be desirable to model to relative probability of strikes by month but no data are available to make any estimates. Sensitivity is explored to the assumption that all of the catches occur in April.

the Cascadia Research Collective catalogue of whales in the PCFG area. If Kodiak Island were included in the PCFG range then the population estimate for the PCFG would be biased low by 100-200 whales. The second issue for management consideration is immigration. Recently Frasier *et al.* (2011) and Lang *et al.* (2011) have found small but significant differences in mitochondrial DNA haplotype frequencies between PCFG whales and samples thought to be representative of the overall Eastern North Pacific (ENP) population and high genetic diversity in both PCFG and ENP whales. Lang *et al.* (2011) suggested that the high observed genetic diversity and low level mtDNA differentiation is consistent with the PCFG either being a recently founded group or a group exhibiting filopatry recruitment with low level recruitment. Photo-identification surveys show recruitment into the PCFG at rates thought to be greater than the potential calf production of the PCFG (Calambokidis *et al.* 2010; IWC 2011). The newest time series of abundance estimates for PCFG whales indicates that there was an average recruitment of 25.8 whales into the PCFG between 1999 and 2002, coinciding with the observed mortality event of ENP whales (IWC, 2011). Ethnographic records presented by Scordino suggest gray whales have been hunted off the coast of Washington in the 1 June through 30 November timeframe since at least the 1850s. Stable isotope findings are less conclusive, but may show that the PCFG has existed for the past 1500 years in which Makah whaling has been documented. Together, these results strongly suggest that some level of immigration is occurring to the PCFG. As a result, when setting up implementation trials, some degree of immigration from the ENP must be considered and there should be recognition of potential negative bias to population estimates of the PCFG.

Scordino also provided an overview of the Makah Tribe’s proposed hunt (Annex D of SC/63/Rep2). The SWG noted that unlike the *SLA*s for the BCB bowhead and the ENP gray whales, the *SLA*s to be evaluated for the hunt in the Makah U&A were not developed by the SWG, but are rather based on the proposed hunt and variants thereof developed by the Makah Tribe.

4.3 Progress with intersessional tasks

4.3.1 Finalise the specifications for the trials

4.3.1.1 PROVIDE UPDATED ABUNDANCE ESTIMATES AND THE ASSOCIATED VARIANCE-COVARIANCE MATRIX

Jeff Laake provided the updated abundance estimates for inclusion in the trials (see Annex H of SC/63/Rep2). The SWG thanked Laake for providing this information before the agreed deadline.

4.3.1.2 SPECIFY HOW TEMPORAL AUTOCORRELATION IN THE ABUNDANCE ESTIMATES WILL BE MODELLED

The inter-annual correlation between the PCFG abundance estimates is generally small (maximum 0.215 between the abundance estimates for 2007 and 2008). The SWG **agreed** that this level of correlation is sufficiently low that it is not necessary to take it into account in trials.

4.3.2 Refine the estimates of PCFG / north mixing based on the 2009 photo-ID data

Weller notified the SWG that the 2009 and 2010 photo-ID data were not available for use during the current meeting.

4.3.3 Coding and validation

4.3.3.1 TRIALS

The trials specified during the March 2011 AWMP Workshop focused on the performance of *SLA*s for the proposed hunt in the Makah Tribe’s U&A, because, except for the proposed Makah hunt and the associated possibility of a stock in the PCFG area, the *Implementation Review* for the ENP gray whales had been completed during the 2010 Annual Meeting. The trials developed during the Workshop considered a number of major hypotheses, including those related to: (a) MSYR, (b) levels of immigration, (c) the level of mixing between PCFG and northern whales when the Makah hunt is likely to take place, and (d) aspects of the hunt including struck and lost rates.

SC/63/AWMP4 showed how the trials specified during the March 2011 AWMP Workshop led to poor residual patterns for the fits to the revised abundance estimates for the PCFG. It provided a set of revised trials which include a pulse of immigration from the northern into the PCFG stock, in 1999 and 2000. In general, the operating models on which the revised trials are based are able to mimic the abundance data adequately. However, a subset of the trials (e.g. with high annual rates of immigration) are unable to mimic the abundance data well.

The SWG thanked Punt for conducting this intersessional work. The SWG noted that the abundance estimates exhibit a high rate of increase during the early years which is biologically implausible. Pulse immigration was one way to allow the operating model to mimic the abundance data. However, pulse immigration is not the only way to achieve consistency between the operating model and the data. Specifically, an alternative explanation is that the trend in abundance from 1998 to 2002 is not due to immigration, but is instead due to a change in survey bias. It was recognized that neither model adjustment was developed independently of the abundance data. Thus, it was not surprising that models including a change in survey bias or pulse immigration fit the abundance data better than models which have neither effect, and which exhibit a residual pattern as noted in SC/63/AWMP4. Regardless, the SWG recognized the need to explore a plausible range of hypotheses with respect to the biologically implausible rates of increase in the abundance estimates. The predicted abundance trajectories (historical and future) for the three types of model differ, reinforcing the need to include alternative scenarios for changes in underlying abundance. Witting noted that models based on inertial dynamics were unlikely to be able to mimic the change in abundance estimates better than the other models considered by the SWG due to the short time period of the phenomenon discussed above.

The SWG emphasized that the set of operating models used to test *SLA*s need to cover the plausible range. The SWG discussed the relative plausibility of a change in survey bias. It was noted that there is no direct evidence for such a change, such as marked changes in survey effort and its spatial distribution (although changes in survey effort have occurred) [Appendix 2]. Moreover, the trend in abundance for the more intensively surveyed area from Oregon to Northern British Columbia shows the same trend as the entire PCFG area. However, there may be reasons other than a simply change in effort for a change in survey bias. For example, consider the case when individual PCFG whales have very heterogeneous detection probabilities. This would cause a downward bias in estimated abundance. Over several years, the accumulated data might begin to dominate and average away any such bias, leading to the pattern used in the SWG's survey bias model (Fig. 1). Another possible contributor to the (artificial) appearance of survey bias is the approach used for the capture-recapture abundance estimation that an animal is defined as being part of the PCFG only if it is seen in at least two years in the PCFG area.

The SWG considered how to best move forward given the concerns with the trials structure established during the March 2011 workshop and with that in SC/63/AWMP4. Furthermore, although software which could be used to condition and run trials during the meeting was available, the programs have yet to be validated by the Secretariat.

In order to establish a workplan, the SWG identified four 'broad' base-case models which captured hypotheses for the trend in the abundance data for PCFG area:

(1) The 1998 abundance estimate is biased due to 'discovery' and 20 whales immigrated into the PCFG stock from the northern stock in each of 1999 and 2000 (hypothesis E).

(2) There has been no pulse immigration into the PCFG stock; rather the abundance estimates are subject to time-varying bias (Fig. 1a) (hypothesis A)

(3) There has been no pulse immigration into the PCFG stock and the abundance estimates are unbiased (hypothesis X).

(4) 10 whales immigrated into the PCFG stock from the northern stock in each of 1999 and 2000 and the abundance estimates are subject to time-varying bias (but not the extent as for hypothesis A; Fig. 1b) (hypothesis Y).

The SWG then identified a subset of the evaluation trials in SC/63/AWMP4 which cover a range of the factors which might impact eventual performance and could help the SWG select which trials to focus on (Table 1). The factors considered were: (a) $MSYR_{1+}$; (b) need in the Russian hunt; (c) the probability of harvesting a PCFG whale during an April hunt in the PCFG area; (d) the struck and lost rate in the PCFG hunt; (e) low-level (non-pulse) immigration into the PCFG stock from the northern stock; (f) episodic events; and (g) the sex-ratio of future catches in the PCFG area.

The SWG also selected a number of diagnostic plots and tables to help it understand the behaviour of the models and trials, in order to narrow down the SLA testing framework. Among the items considered were:

(1) Time-trajectories of 1+ population size (northern and PCFG stock) in absolute terms and relative to carrying capacity, along with the fits to the abundance estimates. This plot allows an evaluation of whether conditioning has been achieved satisfactorily.

(2) Histograms of the 100 parameter vectors for each trial. This plot allows an evaluation of whether and how conditioning has impacted the priors for these parameters.

(3) Individual time-trajectories of 1+ population size for the northern and PCFG stocks, individual time-trajectories of strikes for the northern and PCFG area, a summary (median and 95% intervals) for the depletion of the PCFG stock, and a summary (median and 95% intervals) for the time-trajectories of 1+ population size when (a) there are no future catches, (b) there are only incidental catches, and (c) there are incidental catches and catches due to hunts in the PCFG and northern area.

(4) Tables showing the statistics selected during the March 2011 Workshop.

The SWG noted that the time-trajectories of strikes for the PCFG area are uninformative, but that the 'ray plot' developed during the March 2011 Workshop was not more informative. The SWG requested that in thefuture, the number of strikes of PCFG-stock animals be added to the tabular summary. It was also not possible to condition all of the 'X' and 'Y' trials during the meeting and owing to very strong posterior correlations. Specifically, it was not possible during the meeting to obtain 100 unique parameter vectors for the trials in which $MSYR_{1+}$ is 4.5% for the northern stock and 1% for the PCFG stock without adjusting the priors.

The SWG noted that carrying capacity varied among the hypotheses (a wide range for the 'E', 'X' and 'Y' trials and a relatively narrow range for the 'A' trials). The SWG also noted that the results for both the northern and PCFG stocks differed between the various hypotheses even when the remaining specifications were the same (e.g. the final depletion for the northern stock for trials GA03 and GE03). The SWG emphasized the need to fully understand the results before drawing any final conclusions about the relative merits of the four operating models or any changes to the list of evaluation and robustness trials, with the exception that the SWG agreed to move the trial with $MSYR_{1+}$=2% and all future Makah hunting takes PCFG animals to the evaluation set (this is reflected in table 1).

The SWG established a Steering group (Donovan (Convenor), Allison, Brandon, Butterworth, Givens, Punt, Scordino) to further review the trials structure before the proposed intersessional workshop. The SWG **strongly recommended** that the abundance estimates for the PCFG be updated to include data for 2009 and 2010. A paper presenting all of the abundance estimates should be provided to the SWG.

4.3.3.2 PARAMETER VECTOR GENERATION

This issue will be considered during the next *Implementation Review*.

4.4 Review of results, conditioning and work plan

The SWG was unable to fully review the conditioning because the full set of trials have yet to be completed. Similarly, the SWG did not review the results of the trials.

The SWG **agreed** that its work plan for the 2011 Annual Meeting and associated interessional period would be as follows:

(1) Update the output from the control program to include the number of struck PCFG whales [Punt, June 30, 2011] (item 4.3.3)

(2) Validate the control program and the code for implementing the PCFG hunt (item 4.3.3).

(3) Refine the set of trials (Steering Group, item 4.3.3).

(4) Condition all of the trials and conduct all of the projections before the Workshop (item 4.3.3).

(5) Conduct a Workshop, probably in March 2012 with a focus on the completion of the *Implementation Review* (item 4), and an initial consideration of operating models for West Greenland fin whales (although progress on all species will be considered).

5. IMPLICATIONS OF NEW INFORMATION ON GRAY WHALE STOCK STRUCTURE

5.1 Summary of relevant BRG discussions

Kitakado summarised the discussions in the BRG sub-committee related to the implications of western gray whales being seen off the U.S. west coast: (1) there is now more uncertainty regarding Pacific gray whale stock structure; (2) there is no need to revise stock structure assumptions for Pacific gray whales at present; and (3) range-wide studies need to be undertaken to better understand the situation.

5.2 Conclusions with respect to *Implementation Review*

Given the information under Item 5.1, the SWG **agreed** that formally there was no need to modify the existing trials structure which had been designed to evaluate the *SLA*s for the northern and PCFG areas in the context of eastern gray whales. However, this structure does not incorporate conservation implications for western gray whales. Therefore, the SWG **stresses** that the new information on movements of gray whales described under Item 5.1 highlights the importance of further clarification of the stock structure of North Pacific gray whales. In particular, the matches of western gray whales with animals seen in the PCFG area and other areas along the west coast **emphasises** the need for efforts to estimate the probability of a western gray whale being taken in aboriginal hunts for Pacific gray whales. It **strongly endorses** the research programme developed by the BRG sub-committee that focuses on photo-identification, genetics and telemetry (see Annex F), incorporating both further analysis of existing data and collection of new data. The results of the research may require further trials for future *SLA* testing; this will certainly be a matter for the next *Implementation Review* if not before. The SWG will continue to monitor discussions within BRG and is willing to respond to any guidance or requests for further information from the Commission.

Final dates for the 2012 meeting are not yet, known but likely deadlines for the DAA process are:

Final datasets available (6 months): 30 November 2011.

Papers using novel methods (3 months): 28 February 2012.

Papers using standard methods (2 months): 31 March 2012.

Papers responding to those above (1 month): 30 April 2012.

6. ANNUAL REVIEW OF MANAGEMENT ADVICE

The SWG recognises the logistical difficulties in collecting samples in remote areas but in order to assist in its work, it **recommends** that biological information and material be collected from as many whales as possible.

6.1 Common minke whales off West Greenland

6.1.1 New information

In the 2010 season, 179 minke whales were landed in West Greenland and 7 were struck and lost (SC/63/ProgRepDenmark). Of the landed whales, there were 122 females, 53 males, and four whales of unreported sex. Witting noted that there are plans to tag minke whales in the coming years to establish correction factors to be applied to future surveys.

6.1.2 Management advice

In 2007, the Commission agreed that the number of common minke whales struck from this stock shall not exceed 200 in each of the years 2008-12, except that up to 15 strikes can be carried forward. In 2009, the Committee was for the first time ever able provide management advice for this stock based on a negatively biased estimate of abundance of 17,307 (95% CI 7,628 – 39,270) and the method for providing interim management advice which was confirmed by the Commission. Such advice can be used for up to two five-year blocks whilst *SLA*s are being developed (IWC, 2009b, p.16). Based on the application of the agreed approach, and the lower 5th percentile for the 2007 estimate of abundance (i.e. 8,918), the Committee repeats its advice of last year that an annual strike limit of 178 will not harm the stock.

6.2 Common minke whales off East Greenland

6.2.1 New information

Nine common minke whale were struck (and landed) off East Greenland in 2010 (no animals were struck and lost) (SC/63/ProgRepDenmark). Of the landed whales, there were two females, four males, and three whales of unreported sex. The SWG noted that catches of minke whales off East Greenland are believed to come from the large Central stock of minke whales.

6.2.2 Management advice

In 2007, the Commission agreed to an annual quota of 12 minke whales from the stock off East Greenland for 2008-2012, which the Committee stated was acceptable in 2007. The present strike limit represents a very small proportion of the Central Stock (see Table 1). The SWG agreed that the present strike limit would not harm the stock.

6.3 Fin whales off West Greenland

6.3.1 New information

A total of four fin whales (all females) were landed, and one struck and lost, in West Greenland during 2010 (SC/63/ProgRepDenmark). An acoustic study on fin whales in Davis Strait between Greenland and Canada found that call frequencies peaked in November–December, and continued until the area was covered by ice in January (Simon *et al*., 2010).

6.3.2 Management advice

In 2007, the Commission agreed to a quota (for the years 2008-2012) of 19 fin whales struck off West Greenland. The Committee agreed an approach for providing interim management advice in 2008 and this was confirmed by the Commission. It had agreed that such advice could be used for up to two five-year blocks whilst *SLA*s were being developed (IWC, 2009b). Based on the application of the agreed approach in 2008 (IWC 2009b), the SWG agreed that an annual strike limit of 9 whales will not harm the stock.

6.4 Humpback whales off West Greenland

6.4.1 New information

A total of nine (three males; five females; one unreported sex) humpback whales were landed (none were struck and lost) in West Greenland during 2010 (SC/63/ProgRepDenmark). Genetic samples were obtained from five of these five whales.

6.4.2 Management advice

In 2007, the Committee agreed an approach for providing interim management advice and this was confirmed by the Commission. It had agreed that such advice could be used for up to two five year blocks whilst *SLA*s were being developed (IWC, 2009b, p.16). Using this approach, as last year, the SWG agreed that an annual strike limit of 10 whales will not harm the stock.

6.5 Humpback whales off St Vincent and The Grenadines

6.5.1 New information

The SWG received no information on 2010-2011 catches by St Vincent and The Grenadines. The SWG **strongly recommended** that catch data, including the length of harvested animals, be provided to the Scientific Committee. It also **strongly recommended** that genetic samples by obtained for any harvested animals as well as fluke photographs, and that this information be submitted to appropriate catalogues and collections.

6.5.2 Management advice

In recent years, the Committee has agreed that the animals found off St. Vincent and The Grenadines are part of the large West Indies breeding population. The Commission adopted a total block catch limit of 20 for the period 2008-12. The SWG **agreed** that this block catch limit will not harm the stock.

7. ABORGINAL WHALING MANAGEMENT SCHEME

7.1 Draft guidelines for *Implementations* and *Implementation Reviews*

The SWG did not have time to discuss this Item at the meeting. Given this, the SWG **agreed** that the item would be referred to the intersessional workshop and the Chair agreed to circulate a draft proposal at least one month before the workshop.

7.2 Scientific aspects of an aboriginal whaling scheme
The SWG refers to the previous discussions of this matter and notes that the Commission is still considering the Committee's recommended text on this matter (IWC, 2002)

8. PLANNING FOR A BOWHEAD WHALE *IMPLEMENTATION REVIEW*

8.1 Summary of relevant BRG discussions
Kitakado reported that the BRG sub-committee had received some updates on genetic analyses and age determination of bowhead whales. It also welcomed information on dedicated ice-based abundance surveys (with visual and acoustic components) with independent observers in 2010 and 2011, and a concurrent 2011 aerial photo-identification survey. It noted that SC/63/BRG1 had presented a sophisticated method to estimate detection probabilities using the 2010 ice-based data. Work is continuing to develop a new abundance estimate but this is not expected to be completed before 2013.

8.2 Work plan
The purpose of an *Implementation Review* is to examine new information to see if the current situation is outside the parameter space tested in the existing trials. The SWG noted that no information had been presented at the present meeting to suggest that this was the case. It **agreed** that an *Implementation Review* should be scheduled for the 2012 Annual Meeting. In accordance with the Committee's DAA, the following deadlines apply:

Final dates for the 2012 meeting are not yet known but likely deadlines for the DAA process are:

Final datasets available (6 months): 30 November 2011.

Papers using novel methods (3 months): 28 February 2012.

Papers using standard methods (2 months): 31 March 2012.

Papers responding to those above (1 month): 30 April 2012.

The SWG recognised that it was unlikely that a new abundance estimate would be available for the *Review*. It noted that this is not a required component of an *Implementation Review*. Once an agreed abundance estimate is received it will be incorporated routinely into the *SLA* for the provision of management advice.

9. PROGRESS OF FOLLOW-UP WORK ON CONVERSION FACTORS FOR THE GREENLANDIC HUNT
For indigenous hunting of whales in West Greenland, need is expressed in terms of kg of edible product (across species), whereas for the development of *SLA*s the SWG approach is to express need in terms of numbers of strikes (per species). Based on the recommendations in the report of the Commission's Small Working Group on Conversion Factors for use in Greenland Hunts (Donovan *et al*., 2010), the Committee had requested Greenland to provide information on its sampling scheme and data validation protocols to the present meeting. The focus of the recommendations concerned the fin, humpback and bowhead whales for which provisional conversion factors ad been proposed; sufficient data had been available to develop a conversion factor for the common minke whale (Donovan *et al*., 2010).

The SWG received a response to this request (Appendix 4). It was informed that data had been obtained for a small number of humpback whales, fin whales and bowhead whales using a new protocol and with the assistance of wildlife officers. The Greenland Institute of Natural Resources is planning to continue its efforts this year, targeting humpback and bowhead whales, with the effort extending to fin and minke whales in later years. The Greenland Ministry of Fisheries indicated that data collection will have to run for 'quite some years before an appropriate sampling size is reached'.

The SWG welcomed the provision of a report and appreciated and encouraged this work, recognizing the logistical difficulty of collecting this kind of data. However, it noted that considerably more detail is needed for it to evaluate the proposed programme; it noted that the authors of the original report had offered to assist in the development of a programme and the SWG **urges** Greenland to take advantage of this offer and it **requests** that a detailed report be presented for consideration at the next meeting.

In particular, the report should provide:

(1) a description of the field protocols and sampling strategy, including effort and likely sample sizes;

(2) a description of analysis methods and models; and

(3) presentation from results thus far, including from preliminary analyses with the available data.

Such information will assist the SWG in addressing issues such as appropriate sample size.

10. WORK PLAN
Details of the work plan can be found under the relevant agenda items. The priority topics for next year will be:

(1) Continue work on the development of *SLA*s for the Greenlandic hunts with a focus on common minke whales and fin whales (Item 3).

(2) Complete the *Implementation Review* for eastern gray whales with a focus on the PCFG (Item 4).

(3) Complete an *Implementation Review* for BCB bowhead whales (Item 8).

(4) Develop guidelines for *Implementations* and *Implementation Reviews* (Item 7).

(5) Provide management advice for the appropriate subsistence hunts (Item 6).

(6) Review the Greenlandic programme to provide information on conversion factors (Item 9).

Essential components of achieving this work are:

(1) The holding of an intersessional Workshop, probably in March 2012 with a focus on:

(a) operating models for Greenland fin and minke *SLA* development based on RMP *Implementations* (if time is available, progress on humpback and bowhead whales will also be reviewed);

(b) gray whale *Implementation Review*; and

(c) draft of guidelines for *Implementation*.

(2) Continuation of the AWMP Developer's Fund.

11. ADOPTION OF REPORT

The report was adopted at 16:22 on 7 June 2011. The SWG thanked Donovan for his predictably excellent chairmanship. Donovan thanked the rapporteurs and particularly Punt for his unstinting dedication to undertaking the computing work and his almost superhuman ability to work without sleep.

DETAILS OF FACTORS

Factors	Other Levels (Reference levels shown bold and underlined)
$MSYR_{1+}$	2%, **4.5%**, 6%
Immigration rate (annual)	**0, 2**, 4, 6
Immigration rate (1999/2000)	10, **20**, 30
Proportion of PCFG whales in PCFG area, ϕ_{fut}	0, **0.203**, 1
Struck and lost are	0, **50%,** 100%
Northern need in final year (linear change from 150 in 2009)	**340**, 530
Historic survey bias	**None,** Increasing between 1967 to 2002 from 0.5→1 50% (PCFG only)
Survey CV	**BaseCase,** ½ CV_{est}
Future episodic events	**None**, 3 events occur between yrs 1-75 (with at least 2 in yrs 1-50) in which 20% of the animals die events occur every 5 years in 10% of the animals die
Time dependence in *K*	**Constant**, Halve linearly over 100yr
Time dependence in natural mortality, *M* *	**Constant,** Double linearly over 100yr
Timing of harvest	**April,** **May**
Parameter correlations	Yes, **No**
Probability of mismatching north whales, p_2	0, **0.01**, 0.01-0.05
Probability of mismatching PCFG whales, p_1	**0**, 0.5
Frequency of PCFG surveys	**Annual**, 5-year

AGENDA

1. Introductory items
    - 1.1 Convenor's opening remarks
    - 1.2 Arrangements for the meeting
    - 1.3 Election of Chair
    - 1.4 Appointment of rapporteurs
    - 1.5 Adoption of agenda
    - 1.6 Documents available
2. Conclusion on the sex ratio method (SC/63/AWMP5)
3. Consideration of work required to develop *SLA*s for all Greenland Hunts before the end of the interim period
    - 3.1 Common minke whales
        - 3.1.1 Comments from the intersessional workshop (SC/63/Rep2)
        - 3.1.2 Discussion and work plan
    - 3.2 Fin whales
        - 3.2.1 Comments from the intersessional workshop (SC/63/Rep2)
        - 3.2.2 Discussion and work plan
    - 3.3 Humpback whales (SC/63/AWMP2)
        - 3.3.1 Comments from the intersessional workshop (SC/63/Rep2)
        - 3.3.2 Discussion and work plan
    - 3.4 Bowhead whales (SC/63/AWMP3)
        - 3.4.1 Comments from the intersessional workshop (SC/63/Rep2)
        - 3.4.2 Discussion and work plan

4. implementation review of gray whales with emphasis on the PCFG
    - 4.1 Summary of intersessional workshop (SC/63/Rep2)
    - 4.2 Review of information on the PCFG (SC/63/AWMP1)
    - 4.2 Progress with intersessional tasks (SC/63/Rep2; SC/63/AWMP4)
        - 4.2.1 Finalise the specifications for the trials
        - 4.2.2 Refine the estimates of PCFG/north mixing based on the 2009 photo-ID data
        - 4.2.3 Coding and validation
        - 4.2.4 Conditioning
    - 4.3 Review of results, conclusions and workplan (NB see Item 5)

5. Implications of new information on gray whale stock STRUCTURE (with BRG)
    - 5.1 Summary of relevant BRG discussions
    - 5.2 Conclusions with respect to *Implementation Review*

6. Annual review of management advice
    - 6.1 Common minke whales off West Greenland
        - 6.1.1 New information (incl. catch data and agreed abundance estimates)
        - 6.1.2 Management advice
    - 6.2 Common minke whales off East Greenland
        - 6.2.1 New information (incl. catch data and agreed abundance estimates)
        - 6.2.2 Management advice

6.3 Fin whales off West Greenland
        - 6.3.1 New information (incl. catch data and agreed abundance estimates)
        - 6.3.2 Management advice
    - 6.4 Humpback whales off West Greenland
        - 6.4.1 New information (incl. catch data and agreed abundance estimates)
        - 6.4.2 Management advice
    - 6.5 Humpback whales off St Vincent and The Grenadines
        - 6.5.1 New information (incl. catch data and agreed abundance estimates)
        - 6.5.2 Management advice

7. Aboriginal Whaling Management Scheme
    - 7.1 Draft guidelines for Implementations and Implementation Reviews
    - 7.2 Scientific aspects of an aboriginal whaling scheme

8. Planning for a bowhead whale *Implementation Review* (with BRG)
    - 8.1 Summary of relevant BRG discussions
    - 8.2 Work plan

9. Progress on follow-up work on conversion factors for the Greenlandic hunt

10. Work plan

11. Adoption of Report

Appendix 2

ASSESSING POTENTIAL FOR SURVEY BIAS IN THE PCFG TIME SERIES OF ABUNDANCE

Brandon, Lang, Scordino, Weller

In discussion of SC/63/AWMP4, the question was posed if the apparent pulse of external recruitment during 1999-2002 might have been due to survey bias. Survey bias could be generated by differences in effort over time or due to differences in the availability of whales over time.

Effort - Based on examination of SC/62/BRG32 and our understanding of survey effort included in that study, there seems to be no dramatic trends in effort over time, although some inter-annual variation has occurred. However, we did find a shift in effort through time in the sub-area of Northern California (NCA)[3]. This shift can be seen in Table 7 of SC/62/ BRG32 that shows whales seen annually by sub-area. The apparent pulse of early effort in NCA coincided with the Humboldt State (HSU) research group's survey effort during 1998-2002 (with a gap in HSU effort until 2008).

To better understand this issue, Jeff Laake was contacted via e-mail and asked the following question: 'What percentage of the 'Recruited' animals during 1998-2002 (and 2008) entered your updated abundance estimates via photos from NCA?' His response is as follows:

> '… there was effort in NCA and S. Oregon even though we hadn't contracted HSU because CRC[4] sampled in that area (John C[5] can verify that). Also, there is likely quite a bit of shifting in gray whale distribution between NCA and SOR[6]. Secondly, the pattern in the population estimates is the same even if you restrict the estimates to OR-SVI[7] region as shown in the plot I put together for the meeting (see Annex F, SC/63/Rep2). I also went ahead and ran the abundance estimates excluding NCA and you can see that the pattern is the same for it'
>
> 'There was certainly a reduction in effort in some years (I believe it was in 2006 where NMML had no funding to provide) and there have also been shifts in whale distribution like in 2007 where whales went off in Oregon and were largely absent from SVI that typically produces the most sightings. However, I don't think this will affect the overall pattern greatly. The 'increase' is certainly influenced by discovery of whales that have been around and not seen, but using the sample of those seen prior to 1998 and not in 1998, this tapered off quickly with most added in 1999 and very few added past 2000'

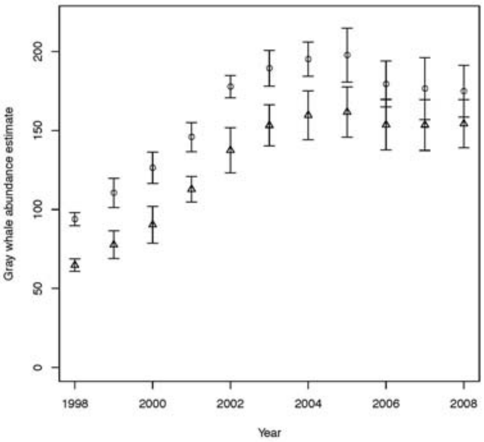

Fig. A, from Laake (*pers comm*). Plot of PCFG (41-52°)(circle) and OR-NBC[8] (triangle) abundance estimates from 1998-2008 with +/- 1 standard error bars. The OR-NBC abundance estimate excludes data from NCA.

Availability– If the availability of whales has shifted through time (for example, if many PCFG whales consistently fed offshore until 1999, then began to use inshore waters more consistently), this could lead to bias in the time series of abundance estimates. Given the data available, however, it is difficult to quantify this hypothesis, and thus to judge its plausibility.

Genetics - If survey bias is not present, the high number of new whales observed in some years of the study suggests external recruitment into the PCFG. Given the high haplotype diversity in the ENP gray whale population, it is likely that recruits would carry haplotypes not previously found in the PCFG. The addition of haplotypes found in single animals into the PCFG sample set would not have a large effect on frequency-based analyses, suggesting that some immigration into the PCFG could occur while maintaining genetic differentiation from the northern feeding group. As well, while photo-identification data may pick up a pulse of new recruits within a season, there would be some time lag

---

[3] The geographic area (41-52N) for the proposed abundance estimates is slightly different than those for abundance estimates calculated in SC/62/BRG32, but does include NCA at its southern extent (See Figure 1 of SC/62/BRG32).

[4] Cascadia Research Collective

[5] John Calambokidis, Cascadia Research Collective

[6] Southern Oregon

[7] Oregon – Southern Vancouver Island

[8] Northern British Colombia, which is at the northern extent of the proposed abundance estimates (see SC/62/BRG32, Fig. 1).

before the signature of that pulse is picked up in the genetics. This suggests that a recent and discrete pulse of new animals into the PCFG may not yet have had a large impact on estimates of genetic differentiation. However, it does not seem plausible that we would observe genetic differentiation between the PCFG and northern feeding whales if ~20 animals per year were recruited into the PCFG on a consistent basis.

To better assess the plausibility of these and other scenarios, we suggest that simulations (built on the TOSSM model) could be used in the future to assess the extent of external recruitment into the PCFG that could occur while maintaining genetic differentiation between the PCFG and northern feeding strata.

Appendix 3

GRAY WHALE TRIALS SPECIFICATIONS

This document outlines a set of trials to evaluate the performance of *SLA*s for hunting in the Pacific Northwest, with a primary focus on the PCFG (Pacific Coast Feeding Group). The operating model assumes the two groups (the ‘north’ group and the PCFG) are separate stocks.

A. The population dynamics model

The underlying population dynamics model is deterministic, age- and sex-structured, and based on a two-stock version of the Baleen II model (Punt, 1999).

A.1 Basic dynamics

Equation A1.1 provides the underlying 1+ dynamics.

$$\begin{aligned}
R^{s,m/f}_{t+1,a+1} &= (R^{s,m/f}_{t,a} + I^{s,m/f}_{t,a} - C^{s,m/f}_{t,a})\,\tilde{S}^s_t\,S_a + U^{s,m/f}_{t,a}\,\tilde{S}^s_t\,S_a\,\delta_{a+1} && 0 \le a \le x-2 \\
R^{s,m/f}_{t+1,x} &= (R^{s,m/f}_{t,x} + I^{s,m/f}_{t,x} - C^{s,m/f}_{t,x})\,\tilde{S}^s_t\,S_x + (R^{s,m/f}_{t,x-1} + I^{s,m/f}_{t,x-1} - C^{s,m/f}_{t,x-1})\,\tilde{S}^s_t S_{x-1} && \\
U^{s,m/f}_{t+1,a+1} &= U^{s,m/f}_{t,a}\,\tilde{S}^s_t\,S_a\,(1-\delta_{a+1}) && 0 \le a \le x-2
\end{aligned} \qquad (A1.1)$$

$R^{s,m/f}_{t,a}$	is the number of recruited males/females of age *a* in stock *s* at the start of year *t*;
$U^{s,m/f}_{t,a}$	is the number of unrecruited males/females of age *a* in stock *s* at the start of year *t*;
$C^{s,m/f}_{t,a}$	is the catch of males/females of age *a* from stock *s* during year *t* (whaling is assumed to take place in a pulse at the start of each year);
δ_a	is the fraction of unrecruited animals of age *a*-1 which recruit at age *a* (assumed to be independent of sex and stock);
S_a	is the annual survival rate of animals of age *a* in the absence of catastrophic mortality events (assumed to be the same for males and females):

$$S_a = \begin{cases} S_0 & \text{if } a = 0 \\ S_{1+} & \text{if } 1 < a \end{cases} \qquad (A1.2)$$

S_0	is the calf survival rate;
S_{1+}	is the survival rate for animals aged 1 and older;
$\tilde{S}^s_t$	is the amount of catastrophic mortality (represented in the form of a survival rate) for stock *s* during year *t* (catastrophic events are assumed to occur at the start of the year before mortality due to whaling and natural causes; in general $\tilde{S}^s_t$=1, i.e. there is no catastrophic mortality);
$I^{s,m/f}_{t,a}$	is the net migration of female/male animals of age *a* into stock *s* during year *t*; and
x	is the maximum (lumped) age-class (all animals in this and the *x*-1 class are assumed to be recruited and to have reached the age of first parturition). *x* is taken to be 15 for these trials.

Catastrophic mortality is assumed to be zero (i.e., $\tilde{S}^s_t = 1$) except for the north stock for 1999 and 2000 when it is assumed to be equal to the parameter $\tilde{S}$. This assumption reflects the large number of dead ENP gray whales observed stranded along the coasts of Oregon and Washington during 1999 and 2000 relative to annual numbers stranding there historically (Gulland *et al.*, 2005; Brownell *et al.*, 2007). The mortality event is assumed to have only impact the north stock because the abundance estimates for the PCFG stock increased when the mortality event occurred in contrast to those for the north stock which declined substantially.

Immigration only occurs from the north stock to the PCFG stock and only animals aged 1+ immigrate. The annual number of animals immigrating is given by $I_t = \bar{I}\, N_t^{\text{north},1+}/20000$ where $\bar{I}$ is the hypothesized recent average number of individuals recruiting into the PCFG from the north stock (i.e., 2, 4 or 6). The annual number of immigrants by age and sex is given by:

$$I_{t,a}^{s,m/f} = I_t \frac{N_{t,a}^{\text{north},m/\text{f}}}{\sum_{a=1}^{x}(N_{t,a}^{\text{north,m}} + N_{t,a}^{\text{north,f}})} \qquad \text{(A1.3)}$$

A.2 Births

The number of births to stock *s* at the start of year *t*+1, B_{t+1}^s, is given by:

$$B_{t+1}^s = b_{t+1}^s\, N_{t+1}^{s,f} \qquad \text{(A2.1)}$$

$N_t^{s,f}$ is the number of mature females in stock *s* at the start of year *t*:

$$N_t^{s,f} = \sum_{a=a_m}^{x} (R_{t,a}^{s,f} + U_{t,a}^{s,f}) \qquad \text{(A2.2)}$$

a_{m} is the age-at-maturity (the convention of referring to the mature population is used here, although this actually refers to animals that have reached the age of first parturition);

b_{t+1}^s is the probability of birth/calf survival for mature females:

$$b_{t+1}^s = b_{-\infty}\{1 + A^s(1-(D_{t+1}^s / D_{-\infty}^s)^{z^s})\} \qquad \text{(A2.3)}$$

$b_{-\infty}$ is the average number of live births per year per mature female in the pristine (pre-exploitation) population;

A^s is the resilience parameter for stock *s*;

z^s is the degree of compensation for stock *s*;

D_t^s is the size of the component of stock *s* in year *t* upon which the density-dependence is assumed to act;

and

$D_{-\infty}^s$ is the pristine size of the component of stock *s* upon which the density-dependence is assumed to act.

The number of female births, $B_t^{s,f}$, is computed from the total number of the births during year *t* according to the equation:

$$B_t^{s,f} = 0.5\, B_t^s \qquad \text{(A2.4)}$$

The numbers of recruited/unrecruited calves is given by:

$$\begin{aligned} R_t^{s,f} &= \pi_0\, B_t^{s,f} & R_t^{s,m} &= \pi_0\,(B_t^s - B_t^{s,f}) \\ U_t^{s,f} &= (1-\pi_0)\, B_t^{s,f} & U_t^{s,m} &= (1-\pi_0)(B_t^s - B_t^{s,f}) \end{aligned} \qquad \text{(A2.5)}$$

π_0 is the proportion of animals of age 0 which are recruited (0 for these trials).

For the trials $D_t^s = N_t^{s,1+}$ and $D_{-\infty}^s = K^{s,1+}$ because density-dependence is assumed to act on the 1+ component of the population and affects fecundity and infant survival. $N_t^{s,1+}$ and $K^{s,1+}$ are defined according to the equations:

$$N_t^{s,1+} = \sum_{a=1}^{x}(R_{t,a}^{s,f} + U_{t,a}^{s,f} + R_{t,a}^{s,m} + U_{t,a}^{s,m}) \qquad K^{s,1+} = \sum_{a=1}^{x}(R_{-\infty,a}^{s,f} + U_{-\infty,a}^{s,f} + R_{-\infty,a}^{s,m} + U_{-\infty,a}^{s,m}) \qquad \text{(A2.6)}$$

A.3 Catches

The historical (t<2010) catches by stratum (north, south, PCFG December – May, and PCFG June – November) are taken to be equal to the reported catches (Table 1). The historical catches are allocated to stocks in fixed proportions as follows:

(1) North area catches: all north animals;

(2) PCFG area catches in December – May: PCFG animals with probability ϕPCFG (base-case value 0.203, as determined by the photo-ID data);

(3) PCFG area catches in June – November: all PCFG animals; and

(4) South area catches: PCFG animals with probability ϕsouth (base-case value 0.01, as determined by relative abundance).

The future catches by stratum are incidental catches and the catches arising from application of the *SLA*s. Subsistence catches are only assumed to occur in the north and the PCFG area from December – May. The sex-ratio of future catches is assumed to be 50:50. The catches are allocated to stock as outlined above, except that the subsistence catches from the PCFG area in June – November are modelled individually. Thus, the catch from the PCFG area is allocated to the PCFG stock based on a Bernoulli trial with probability:

$$\frac{\sum_{m/f}\sum_{a'} R_{y,a'}^{PCFG,m/f}}{\delta \sum_{m/f}\sum_{a''} R_{y,a''}^{north,m/f} + \sum_{a''} R_{y,a''}^{PCFG,m/f}} \qquad \text{(A3.1)}$$

where δ is the relative probability of harvesting a PCFG versus a north animal had the sizes of the two populations been the same. δ is calculated from ϕ under the assumption that the number of PCFG animals is 200 and north animals is 20000, i.e:

$$\delta = (200/\phi - 200)/20000 \qquad \text{(A3.2)}$$

The incidental catches by stratum for the historical period are computed using the equation:

$$C_y^{1/s} = \begin{cases} 0.5\left\{p^I - \frac{p^I - 1}{69}[y - 1999]\right\}\bar{C}^I & \text{if } y \le 1999 \\ \bar{C}^I & \text{otherwise} \end{cases} \qquad \text{(A3.3)}$$

$C_y^{1/s}$ is the incidental catch of animals of sex s during year y;

$\bar{C}^I$ is the mean catch in the stratum (see Table 2).

The catches from the PCFG and north stocks are then allocated to age and size using the formula:

$$C_{t,a}^{s,m} = C_t^{s,m} R_{y,a}^{s,m} / \sum_{a''} R_{y,a''}^{s,m}; \quad C_{t,a}^{s,f} = C_t^{s,f} R_{y,a}^{s,f} / \sum_{a''} R_{y,a''}^{s,f}; \qquad \text{(A3.4)}$$

The probability of not identifying a PCFG whale as such, is p_2, (base-case value 0) while the probability of incorrectly identifying a north whale as a PCFG whale is, p_1,(base-case 0.01). If the survey frequency is not annually, p_2 is defined as:

$$p_{2,t} = 1 - \frac{\sum_{a \ge SF} (R_{t,a}^{\text{PCFG,m}} + R_{t,a}^{\text{PCFG,f}} + U_{t,a}^{\text{PCFG,m}} + U_{t,a}^{\text{PCFG,f}})}{\sum_{a \ge 1} (R_{t,a}^{\text{PCFG,m}} + R_{t,a}^{\text{PCFG,f}} + U_{t,a}^{\text{PCFG,m}} + U_{t,a}^{\text{PCFG,f}})} \qquad \text{(A3.5)}$$

where SF is the survey frequency for the PCFG area.

A.4 Recruitment

The proportion of animals of age a that would be recruited if the population was pristine is a knife-edged function of age at age 0, i.e.:

$$\pi_a = \begin{cases} 0 & \text{if } \ a = 0 \\ 1 & \text{otherwise} \end{cases} \qquad \text{(A4.1)}$$

The (expected) number of unrecruited animals of age a that survive to age a+1 is $U_{t,a}^{s,m/f} S_a$. The fraction of these that then recruit is:

$$\delta_{a+1} = \begin{cases} [\pi_{a+1} - \pi_a]/[1-\pi_a] & \text{if } 0 \le \alpha_a < 1 \\ 1 & \text{otherwise} \end{cases} \tag{A4.2}$$

A.5 Maturity

Maturity is assumed to be a knife-edged function of age at age a_m.

A.6 Initialising the population vector

The numbers at age in the pristine population are given by:

$$\begin{aligned} R^{s,m/f}_{-\infty,a} &= 0.5 \;\; N^s_{-\infty,0} \;\; \pi_a \prod_{a'=0}^{a-1} S_{a'} & \text{if} \quad 0 \le a < x \\ U^{s,m/f}_{-\infty,a} &= 0.5 \;\; N^s_{-\infty,0} \;\; (1-\pi_a) \prod_{a'=0}^{a-1} S_{a'} & \text{if} \quad 0 \le a < x \\ R^{s,m/f}_{-\infty,x} &= 0.5 \;\; N^s_{-\infty,0} \prod_{a'=0}^{x-1} \frac{S_{a'}}{(1-S_x)} & \text{if} \quad a = x \end{aligned} \tag{A6.1}$$

$R^{s,m/f}_{-\infty,a}$ is the number of animals of age *a* that would be recruited in the pristine population;

$U^{s,m/f}_{-\infty,a}$ is the number of animals of age *a* that would be unrecruited in the pristine population; and

$N^s_{-\infty,0}$ is the total number of animals of age 0 in the pristine population.

The value for $N^s_{-\infty,0}$ is determined from the value for the pre-exploitation size of the 1+ component of the population using the equation:

$$N^s_{-\infty,0} = K^{s,1+} / \left(\sum_{a=1}^{x-1} \left(\prod_{a'=0}^{a-1} S_{a'} \right) + \frac{1}{1-S_x} \prod_{a'=0}^{x-1} S_{a'} \right) \tag{A6.2}$$

It is well-known that it is not possible to make a simple density-dependent population dynamics model consistent with the abundance estimates for the eastern north Pacific stock of gray whales (Reilly, 1981; 1984; Cooke, 1986; Lankester and Beddington, 1986; Butterworth *et al.*, 2002). This is why recent assessments of this stock (e.g. Punt and Wade, in press) have been based on starting population projections from a more recent year (denoted as τ) than that in which the first recorded catch occurred. The trials are therefore based on the assumption that the age-structure at the start of τ=1930 is stable rather than that the population was at its pre-exploitation equilibrium size at the start of 1600, the first year for which catch estimates are available. The choice of 1930 for the first year of the simulation is motivated by the fact that the key assessment results are not sensitive to a choice for this year from 1930-1968 (Punt and Butterworth, 2002; Punt and Wade, in press). Note that even though the operating model ignores the catch data for 1600-1929, these catches are nevertheless provided to the *SLA* for the north area.

The determination of the age-structure at the start of 1930 involves specifying the effective 'rate of increase', γ, that applies to each age-class. There are two components contributing to γ, one relating to the overall population rate of increase (γ^+) and the other to the exploitation rate. Under the assumption of knife-edge recruitment to the fishery at age 1, only the γ^+ component (assumed to be zero following Punt and Butterworth, 2002) applies to ages *a* of age 0. The number of animals of age *a* at the start of τ=1930 relative to the number of calves at that time, $N^{s,*}_{\tau,a}$, is therefore given by the equation:

$$N^{s,*}_{\tau,a} = \begin{cases} 1 & \text{if } a = 0 \\ N^{s,*}_{\tau,a-1} \, S_{a-1} (1-\gamma^+) & \text{if } a \le 1 \\ N^{s,*}_{\tau,a-1} \, S_{a-1} \, (1-\gamma^s) & \text{if } 1 < a < x \\ N^{s,*}_{\tau,x-1} \, S_{x-1} (1-\gamma^s) / (1 - S_x \, (1-\gamma^s)) & \text{if } a = x \end{cases} \tag{A6.3}$$

B^s_τ is the number of calves in year τ (=1930) and is derived directly from equations A2.1 and A2.3 (for further details see Punt, 1999):

$$B^s_\tau = \left(1 - \left[1/(N^{s,f}_\tau b_{-\infty}) - 1\right] / A^s \right)^{1/z^s} \frac{D^s_{-\infty}}{D^{s,*}_\tau} \tag{A6.4}$$

$D^{s,*}_\tau$ is the number of animals in the density dependent component of the population relative to the number of births at that time (see equation A2.6).

The effective rate of increase, γ, is selected so that if the population dynamics model is projected from 1930 to 1968, the size of the 1+ component of the population (both stocks) in 1968 equals a pre-specified value, P_{1968}.

A.7 z and A

A^s, z^s and S_0, are obtained by solving the system of equations that relate *MSYL*, *MSYR*, S_0, S_{1+}, $f_{\max}$ $a_{\rm m}$, A^s and z^s, where $f_{\max}$ is the maximum theoretical pregnancy rate (Punt, 1999).

A.8 Conditioning

The method for conditioning the trials (i.e. selecting the 100 sets of values for the parameters $a_{\rm m}$, S_0, S_{1+}, $\tilde{S}$, K_{1+}^{N} , K_{1+}^{PCFG} A^N , A^{PCFG} , z^N , and z^{PCFG}) is based on a Bayesian assessment of the eastern North Pacific stock of gray whales (Punt and Butterworth, 2002; Wade, 2002). The algorithm for conducting the Bayesian assessment is as follows:

(a) Draw values for the parameters S_{1+}, $f_{\max}$, $a_{\rm m}$, K_{1+}^{N}, K_{1+}^{PCFG} , P_{1968}^{N} , P_{1968}^{PCFG} , $\tilde{S}$, CV_{add}^{N} (the additional variance for the estimate of 1+ abundance Carmel, California in 1968), CV_{add}^{PCFG} (the additional variance for the estimate of 1+ abundance from North California to Southeast Alaska in 1968 – had such a survey taken place) from the priors in Table 3. It is not necessary to draw values for $MSYR_{1+}$ and $MSYL_{1+}$ because the values for these quantities are pre-specified rather than being determined during the conditioning process.

(b) Solve the system of equations that relate $MSYL^s$, $MSYR^s$, S_0, S_{1+}, $f_{\max}$, $a_{\rm m}$, A^s and z^s to find values for S_0, A^s and z^s.

(c) Calculate the likelihood of the projection for each area, given by

$$-\ell{\rm n}L = 0.5\ell{\rm n}\,|\,\mathbf{V}+\Omega\,| + 0.5\sum_i\sum_j(\ell{\rm n}N_i^{\rm obs} - \ell{\rm n}\hat{P}_i^{1+})[(\mathbf{V}+\Omega)^{-1}]_{i,j}(\ell{\rm n}N_j^{\rm obs} - \ell{\rm n}\hat{P}_j^{1+}) \tag{A8.1}$$

$N_i^{\rm obs}$ is the $i^{\rm th}$ estimate of abundance[9] (Tables 4a, 4b),

$\hat{P}_i$ is the model-estimate corresponding to $N_i^{\rm obs}$,

$\mathbf{V}$ is the variance-covariance matrix for the abundance estimates, and

Ω is a diagonal matrix with elements given by $E(CV_{add,t}^2)$:

$$E(CV_{add,t}^2) = \eta(0.1 + 0.013P^* / \hat{P}_t) = CV_{add}^2\,\frac{0.1 + 0.013P^* / \hat{P}_t}{0.1 + 0.013P^* / \hat{P}_{1968}} \tag{A8.2}$$

(a) Steps (a) – (c) are repeated a large number (typically 1,000,000) of times.

(b) 100 sets of parameters vectors are selected randomly from those generated using steps (a) – (c), assigning a probability of selecting a particular vector proportional to its likelihood. The number of times steps (a) – (c) are repeated is chosen to ensure that each of the 100 parameter vectors are unique.

The expected value for the estimate of abundance of the north area is taken to the total abundance (PCFG and north stocks combined) while the abundance estimates for the PCFG area are assumed to pertain to the PCFG stock.

B. Data generation

B.1 Absolute Abundance Estimates

The historic (t<2010) abundance estimates (and their CVs) are provided to the *SLA* and are taken to be those in Tables 4a, 4c. Future estimates of absolute abundance (and their estimated CVs) are generated and provided to the *SLA* once every *F* years during the management period (starting in year 2011 where *F*=10 for the northern area and *F*=1 for the PCFG area). The CV of the abundance estimate (CV_{true}) may be different from the CV provided to the *SLA* (further details are provided below).

The survey estimate, $\hat{S}$, may be written as:

$$\hat{S} = B_A P Y\, w / \mu = B_A\, P^*\, \beta^2\, Y\, w \tag{B1.1}$$

B_A is the bias (the bias for the bulk of the simulations for the north area is 1 while the bias for PCFG area is generated from $\ell{\rm n}B_A \sim N(-0.335, 0.112)$ – this bias reflects the difference between the abundance estimates on which the ABL is based [which pertain to Oregon to Southern Vancouver Island] and the abundance of the entire stock];

P is the current total 1+ population size ($= N_t^{1+}$); (B1.2)

Y is a lognormal random variable: $Y = e^{\phi}$ where: $\phi \sim N[0;\sigma_\phi^2]$ and $\sigma_\phi^2 = \ell{\rm n}(1+\alpha^2)$ (B1.3)

w is a Poisson random variable, independent of Y, with $E(w) = {\rm var}(w) = \mu = (P\ /\ P^*)/\beta^2$; and (B1.4)

P^* is the reference population level (the pristine 1+ population, $= K^{1+}$).

---

[9] The shore-based abundance estimate for year *y*/*y*+1 is assumed to pertain to abundance at the start of year *y*+1.

Note that under the approximation $CV^2(ab) = CV^2(a) + CV^2(b)$,

$$E(\hat{S}) = B_A P_t \text{ and } CV^2_{true}(\hat{S}) = \alpha^2 + \beta^2 P^* / P \tag{B1.5}$$

[10]The steps used in the program to generate the abundance estimates and their CVs are given below.

The *SLA* is provided with estimates of CV_{est} (the estimation error associated with factors considered historically) for each future sightings estimate.

The estimate of $CV_{est,t}$ is given by:

$$\hat{C}V_{est,t} = \sqrt{\sigma_t^2 (\chi_n^2 / n)} \qquad \sigma_t^2 = \ell\text{n}(1 + E(CV^2_{est,t})) \tag{B1.6}$$

$E(CV^2_{est,t})$ is the sum of the squares of the actual CVs due to estimation error:

$$E(CV^2_{est,t}) = \theta^2 (a^2 + b^2 / w\beta^2) \tag{B1.7}$$

χ_n^2 is a random number from a χ^2 distribution with *n* (=19; the value assumed for the single stock trials for the RMP) degrees of freedom;

a^2, b^2 are constants and equal to 0.02 and 0.012 respectively;

The relationship between CV_{est} and CV_{true} is given by:

$$\eta = [E(CV^2_{true}) - E(CV^2_{est})] / (0.1 + 0.013 P^* / P) \tag{B1.8a}$$

where η is a constant known as the additional variance factor. The value of η is based on the population size and CVs for 1968 (for consistency with the way the CV for P_{1968} is generated in Table 3):

$$\eta = CV^2_{add} / (0.1 + 0.013 P^* / P_{1968}) \tag{B1.8b}$$

The values of α and β are then computed as:

$$\alpha^2 = \theta^2 a^2 + \eta\, 0.1\,, \qquad \beta^2 = \theta^2 b^2 + \eta\, 0.013 \tag{B1.9}$$

C. Need

The level of need in each year, Q_t, will be supplied to the *SLA*. The need is given by $Q_t = Q_{2010} + \frac{t - 2010}{100}(Q_{2110} - Q_{2010})$ where Q_{2010} (=150/7 for the north and PCFG areas respectively) is the need at the start of the first year in which the AWMP is applied and Q_{2110} is the value 100 years later. The level of need supplied.

D. Implementing the Makah harvest regime

Thus, the overall application of the Makah management regime is as follows:

(1) Compute the ABL (Allowable bycatch limit of PCFG whales)

(2) Strike an animal

(3) If the animal is struck-and lost in December-April[11]:

(a) If the total number of struck and lost animals is 3, stop the hunt.

(b) If the total number of struck animals equals the need of 7 stop the hunt.

(c) Go to step (2).

(4) If the animal is struck-and lost in May:

---

10 The steps used to generate estimates of abundance and their CVs are as follows (steps i) – iii) are part of the conditioning process).

(i) Read in CV_{est} (basecase value= 0.075 = value used to generate the 1968 abundance). Generate values of CV^2_{add} for 1968.

(ii) Set η using equation B1.8b and the value of CV_{add} generated in step i).

(iii) Set θ 2 using equation B1.7a and the values for CV_{est} from step (i) and $w\beta^2 = P / P^* = P_{1968} / P^*$. Set α2 and β 2 using equation B1.9.

(iv) Generate w (Poisson random variable – see equation B1.4) and ϕ (lognormal random variable – see equation B1.3).

(v) Set abundance estimate $\hat{S}$ using equation B1.1.

(vi) Set $E(CV^2_{est,t})$ using eqn B1.7a.

(vii) Generate $\hat{C}V_{est,t}$ from a χ_n^2 distribution using equation B1.6a.

[11] Whether a whale is struck and lost is determined from a Bernoulli trial with probability 0.5 (base-case).

(a) Add one to the number of whales counted towards the ABL

(b) If the ABL is reached; stop the hunt

(c) If the total number of struck and lost animals is 3, stop the hunt.

(d) If the total number of struck animals equals the need of 7; stop the hunt.

(e) Go to step (2).

(5) If the animal is landed and is matched against the catalogue[12]:

(a) Add one to the number of whales counted towards the ABL

(b) If the ABL is reached; stop the hunt

(c) If the total number of landed whales equals 5; stop the hunt

(d) If the total number of struck animals equals the need of 7; stop the hunt.

(e) If the number of landed whales for the current five-year block equals 20; stop the hunt

(f) Go to step (2).

(6) If the animal is landed and does not match any whale in the catalogue:

(a) If the total number of landed whales equals 5; stop the hunt

(b) If the total number of struck animals equals the need of 7; stop the hunt.

(c) If the number of landed whales for the current five-year block equals 20; stop the hunt

(d) Go to step (2).

E. Statistics

The risk- and recovery-related performance statistics are computed for the mature female and for the total (1+) population sizes (i.e. P_t is either the size of the mature female component of the population, N_t^f , or the size of the total (1+) population, N_t^{1+}). P_t^* is the population size in year t under a scenario of zero strikes in the northern and PCFG area (but allowing for incidental catches) over the years t≥2010 (defined as t=0 below), P_t^{**} is the population size in year t under a scenario of zero strikes in the PCFG area (but allowing for incidental catches and strikes in the north area) over the years t≥2010 (defined as t=0 below), and K_t^* is the population size in year t if there had never been any harvest.

The trials are based on a 100-year time horizon, but a final decision regarding the time horizon will depend inter alia on interactions between the Committee and the Commission regarding need envelopes and on the period over which recovery might occur. To allow for this, results are calculated for T=20 and 100.

Statistics marked in bold face have previously been considered the more important. Note that the statistic identification numbers have not been altered for reasons of consistency. Hence, there are gaps in the numbers where some statistics have been deleted.

E.1 Risk

D1. Final depletion: P_T / K . In trials with varying *K* this statistic is defined as P_T / K_t^* .

D2. Lowest depletion: $\min(P_t / K) : t = 0,1,...,T$. In trials with varying *K* this statistic is defined as $\min(P_t / K_t^*):\ t = 0,1,...,T$.

D6. Plots for simulations 1-100 of $\{ P_t : t = 0,1,..,T\}$, $\{ P_t^* : t = 0,1,..,T\}$, $\{ P_t^{**} : t = 0,1,..,T\}$

D7. Plots of $\{ P_{t[x]} : t = 0,1,..,T\}$ $\{ P_{t[x]}^* : t = 0,1,..,T\}$ and $\{ P_{t[x]}^{**} : t = 0,1,..,T\}$ where $P_{t[x]}$ is the *x*th percentile of the distribution of P_t. Results are presented for *x* = 5 and *x* = 50.

D8. Rescaled final population: P_T / P_T^* and P_T / P_T^{**}

D9. Minimum population level in terms of mature females, $\min(P_t):\ t = 0,1,...,T$

D10. Relative increase P_T / P_0

E.2 Need (for PCFG, statistics N1- N12 will be computed for the total number of strikes as well as the number of landed animals)

---

[12] PCFG whales are mismatched as north stock whales with probability p_1 while north stock whales are matched to the catalogue with probability p_2.

N1. Total need satisfaction: $\sum_{t=0}^{T-1} C_t / \sum_{t=0}^{T-1} Q_t$

N2. Length of shortfall = (negative of the greatest number of consecutive years in which $C_t < Q_t$) / T

N4. Fraction of years in which $C_t = Q_t$

N5. Proportion of block need satisfaction: $\Gamma/(T-h+1)$ where Γ is the number of blocks of h years in which the total catch equals the total need; h is 5 for these trials.

N7. Plot of $\{V_{t[x]} : t = 0, 1, T-1\}$ where $V_{t[x]}$ is the xth percentile of the distribution of $V_t = C_t / Q_t$ [catch for the PCFG area]

N8. Plots of V_t for simulations 1-100.

N9. Average need satisfaction: $\frac{1}{T} \sum_{t=0}^{T-1} \frac{C_t}{Q_t}$

N10. AAV (Average Annual Variation): $\sum_{t=-1}^{T-2} \left| C_{t+1} - C_t \right| / \sum_{t=-1}^{T-2} C_t$

N11. Anti-curvature: $\frac{1}{T-1} \sum_{t=0}^{T-2} \left| \frac{C_t - M_t}{\max(10, M_t)} \right|$ where $M_t = \left(C_{t+1} + C_{t-1}\right)/2$

N12. Mean downstep (or modified AAV): $\sum_{t=-1}^{T-2} \left| \min\left(C_{t+1} - C_t, 0\right) \right| / \sum_{t=-1}^{T-2} C_t$

N13. Average annual number of animals landed

N14. Average annual number of animals struck and lost.

N15. Ray Plot. For each simulation, make a line plot of cumulative absolute year-to-year quota changes versus time (x-axis). Superimpose all these rays.

GREENLANDIC RESPONSE TO ‘9.1 CONVERSION FACTORS FOR EDIBLE PRODUCTS FOR GREENLAND FISHERIES’ FROM THE IWC SCIENTIFIC COMMITTEE MEETING, 2010

Ministry of Fisheries, Hunting and Agriculture, Government of Greenland

The SWG requested Greenland to provide information on its sampling scheme and data validation protocols at the IWC SC meeting 2011 meeting.

Shortly after the 62nd Annual IWC meeting, a meeting between hunters, scientists, wildlife officers and managers concerning a revised sampling scheme resulted in a suggestion of using bins for the collection of the three types of edible products, weighing one and counting how many times it was filled with each product as a way of validating the total weight measurements.

This suggestion was implemented by including it in the executive order (nr. 11, 16 July 2010) regulating the hunt on large whales. Normally, it takes at least 3 months to prepare a new executive order due to the hearing process. Because of its importance, the Greenland Cabinet made a decision to implement the executive order with a shorter hearing process.

Furthermore an instruction on how to collect relevant data has been made to the wildlife officers following a hunt and a flensing situation on bowhead and humpback whales.

Focusing on the largest species, since the implementation of the extended sampling scheme 10 humpback whales (9 in 2010 and 1 in 2011), 2 fin whales (2010) and 1 bowhead whale (2011) have been caught in Greenland. Of these 13 catches, wildlife officers were able to follow the hunt of the bowhead whale and 2 humpback whale catches. During the last three hunting seasons all 7 bowhead whale caught in Greenland have been followed by wildlife officers and/or scientist/managers resulting in a working paper presented at IWC and a scientific paper under review. This covering has required a high level of effort and resources from the wildlife officers and the scientist/managers involved.

The Greenland Institute of Natural Resources are planning to have 2-3 persons collecting samples from this years hunt on humpback whales in Mid-Greenland (3 animals). During this field work an effort for estimating bin weight of the three types of edible products will also be prioritised. The plan is to extent this work to fin whales and minke whale.

The experience, especially on challenges of organising the practicalities so far shows that this revised data collection will have to run for quite some years before an appropriate sampling size is reached.

Assessment of stock structure among gray whales utilizing feeding grounds in the Eastern North Pacific

ABSTRACT

Although the majority of Eastern North Pacific (ENP) gray whales spend their summers feeding in the Bering, Beaufort, and Chukchi Seas, a small number of individuals, referred to as the Pacific Coast Feeding Group (PCFG), feed in waters between northern California and southeastern Alaska during summer and fall. Many individuals identified within this southern feeding area demonstrate intra- and inter-seasonal fidelity to the region, suggesting that structure could be present among ENP gray whales utilizing different areas for feeding. Little is known, however, about patterns of site fidelity of individuals feeding in northern waters. We utilized samples collected from individual gray whales within both southern (n=100) and northern (n=106) feeding areas to assess possible stock structure using both mtDNA control region sequences and 8 microsatellite markers. Significant mtDNA differentiation was found when the subset of samples representing individuals (n=71) sighted over two or more years within the seasonal range of the PCFG were compared to the combined set of samples collected from the northern feeding area(s) (F_{ST}=0.01, p=0.005; Fisher's exact test, p=0.008) as well as when the PCFG samples were compared to only those samples which were collected off Chukotka, Russia (n=71, F_{ST}=0.01, p=0.012; Fisher's exact test, p=0.030). No significant differences were found for any of the comparisons utilizing microsatellites. These results indicate that structure is present among gray whales utilizing different feeding areas and suggest that matrilineal fidelity plays a role in creating such structure. The lack of differentiation detected using nuclear markers (χ^2 test, p=0.636, PCFG versus northern; p=0.753, PCFG versus Chukotka) suggests that individuals from different feeding areas may interbreed. These results are important in evaluating the management of the ENP gray whale population, especially in light of the Makah Tribe's proposal to resume whaling in an area of the Washington coast utilized by both feeding and migrating whales. Although the proposed hunt is designed to target whales migrating to/from the northern feeding grounds, the possibility of taking a PCFG whale cannot be eliminated. Increasing our understanding of recruitment into this group is needed to assess potential impacts of a hunt.

INTRODUCTION

The current distribution of gray whales is limited to the eastern and western margins of the North Pacific (Rice & Wolman, 1971), where a small western population (~130 individuals, Cooke *et al.,* 2008) and a much larger eastern population (~19,000 individuals based on surveys in 2006/2007, Laake *et al.,* 2009) are recognized. Much of what is known about the western population is derived from photo-identification and genetic studies of individuals on the population's primary feeding ground, which is located in the coastal waters of northeastern Sakhalin Island, Russia (Weller *et al.,* 1999; Weller *et al.,* 2008; LeDuc *et al.,* 2002; Lang *et al.,* 2010). Photo-identification studies have documented seasonal site fidelity and annual return of individuals to this feeding area (Weller *et al.,* 1999). Reproductive females are known to utilize the Sakhalin feeding ground in years when they are accompanied by calves as well as when they are pregnant or resting, and the return of many individuals first identified as calves accompanying their mothers has been documented (Weller *et al.,* 2009). Genetic comparisons of samples collected from gray whales feeding off Sakhalin with samples collected from whales in the eastern North Pacific (ENP) have supported recognition of the two populations as distinct, with differentiation in both mtDNA haplotype and microsatellite allele frequencies (LeDuc *et al.,* 2002; Lang *et al.,* 2010).

Gray whales in the ENP population feed in waters between California and the Bering, Beaufort, and Chukchi Seas during summer and fall. Most of the population then migrates south along the coast of North America to overwinter in the lagoons and coastal waters of Baja Mexico. Three primary calving lagoons are utilized, with some females known to make repeated returns to specific lagoons (Jones, 1990). Genetic studies have demonstrated small but significant mtDNA differentiation between females (mothers with calves) utilizing two of the primary calving lagoons and females sampled in other areas (Goerlitz *et al.,* 2003). An additional study, utilizing both mtDNA and microsatellites with samples collected from all three of the primary calving lagoons, also identified small but significant departure from panmixia between two of the lagoons using nuclear data, although no significant differences were identified using mtDNA (Alter *et al.,* 2009).

Sub-structuring within the feeding range of the eastern population could also be present. Although little is known about fidelity of gray whales feeding north of the Aleutians, a small number of individuals, referred to as the Pacific Coast Feeding Group (PCFG; IWC, 2010), are known to show fidelity to more southern feeding grounds located in the coastal waters between northern California and southeastern Alaska (Gilmore, 1960; Pike, 1962; Hatler & Darling 1974; Darling, 1984; Calambokidis *et al.,* 2002, 2010). Within these waters, photo-identification research, which commenced in the early 1970s, has identified some whales that demonstrate consistent return to specific areas within this larger region, although movements between areas within the region also occur regularly (Hatler & Darling, 1974; Darling, 1984; Calambokidis *et al.,* 2002, 2010). In addition, photographic evidence has shown that some whales considered part of the PCFG move at least as far north as Kodiak Island, Alaska (Calambokidis *et al.,* 2010, Gosho *et al*., 2011). Recent estimates of the annual abundance of the PCFG suggest that at most a few hundred individuals utilize this feeding area (Calambokidis *et al.,* 2010).

Satellite tagging studies of 18 whales off the coast of Oregon and California have provided additional information on the movements of individual whales considered part of the PCFG (Mate *et al.,* 2010). Although the duration of tag attachment differed between individuals, movement patterns of the tagged animals were variable, with some individuals remaining in a relatively small area within the larger PCFG seasonal range and others traveling more widely. Only two of the eighteen whales moved north of Washington while tagged; one of these animals traveled at least as far north as southeastern Alaska (Mate *et al.*, 2010). All six of the individuals whose tags continued to transmit through the southbound migration utilized the wintering area within and adjacent to Laguna Ojo de Liebre. Although this lagoon is by far the most heavily used of the three major wintering lagoons, these results raised the possibility that PCFG whales may demonstrate philopatry to this particular wintering area (Mate *et al.,* 2010).

Concern for the PCFG of gray whales has stemmed in part from recent interest in the resumption of whaling by the Makah Tribe in northwest Washington, an area used by migrating whales as well as by whales considered part of the PCFG. The current proposal by the Makah Tribe includes time/area restrictions which will limit the hunt to between 1 December and 31 May and will not allow hunting in the Strait of Juan de Fuca east of Cape Flattery. The Makah Tribe also proposes to compare photographs of any whales harvested in the hunt to a photo-identification catalogue of known PCFG whales and to suspend the hunt for the year if the number of known PCFG gray whales struck is equal to the annual allowable bycatch level calculated for the PCFG (Makah Tribal Council, 2011). These restrictions are designed to reduce the probability of killing a PCFG whale and to focus the hunt on whales migrating to/from feeding areas north of the PCFG. Nevertheless, it is impossible to ensure that no PCFG whales would be killed. Evaluating whether such kills would, over time, have the potential to deplete the PCFG requires an understanding of how individuals are recruited into the group. If recruitment into the area is exclusively driven by calves learning the location of feeding grounds from their mothers (i.e., internally), then a PCFG individual that is removed would not be replaced by immigration. However, if recruitment is largely external, such that some whales stop to feed during the migration and then return to the PCFG area as their primary feeding destination in subsequent years, then it is likely that any takes from the PCFG would be offset by immigration into the group by whales that in previous years fed in northern areas.

Understanding recruitment into the PCFG is relevant to management under the Marine Mammal Protection Act (MMPA). The goal of the MMPA is to maintain population stocks as functioning elements of their ecosystem. The National Marine Fisheries Service considers stocks to be demographically independent units, such that the population dynamics of the affected group is more a consequence of births and deaths within the group (internal dynamics) rather than of immigration or emigration (external dynamics). Thus, the exchange of individuals between population stocks is not great enough to prevent the depletion of one of the populations as a result of increased mortality or lower birth rates (NMFS, 2005).

Previous genetic studies of the PCFG whales have focused on evaluating patterns of recruitment. Initial work utilizing a simulation-based approach indicated that if the PCFG originated from a single recent colonization event in the past 40 to 100 years, with no subsequent external recruitment into the group, detectable mtDNA genetic differentiation would be generated (Ramakrishnan & Taylor, 2000). Subsequent empirical analysis, however, failed to detect such a signal when comparing 16 samples collected from known PCFG whales utilizing Clayoquot Sound, British Columbia, with samples (n=41) collected from individuals presumably feeding in more northern areas (Steeves *et al.,* 2001). Additional genetic analysis utilizing an extended set of samples (n=45) collected from whales within the range of the PCFG indicated that the level of genetic diversity and the number of mtDNA haplotypes identified were inconsistent with measures, based on simulations, which would be expected if recruitment into the group were exclusively internal (Ramakrishnan *et al.,* 2001). However, both simulation-based studies focused on evaluating only the hypothesis of founding by a single and recent colonization event and did not evaluate alternative scenarios, such as limited dispersal of whales from other areas into the PCFG, which could have implications for management (Ramakrishnan and Taylor 2000, Ramakrishnan *et al.,* 2001). More recently, Frasier *et al.* (In press) have shown significant levels of mtDNA differentiation when comparing samples collected from 40 individuals considered part of the PCFG with published data generated from 104 samples collected from ENP gray whales, most of which stranded along the migratory route (LeDuc *et al.,* 2002). These results suggest that matrilineally directed fidelity may play a role in use of this area and led the authors to support recognition of the PCFG as a distinct management unit.

The lack of available samples collected from gray whales feeding in northern areas has limited previous genetic studies from directly addressing the potential for demographic independence among whales utilizing different feeding regions within the ENP. Here we use samples collected from various locations north of the Aleutians as well as samples collected from within the seasonal range of the PCFG. A high proportion of the samples collected north of the Aleutians were collected from individuals harvested off Chukotka, Russia, where between 111 and 134 whales per year have been taken during aboriginal whaling over the last decade (IWC, 2010). We also increased the number of samples collected from whales within the seasonal PCFG range and, for those samples linked to photographed individuals, were able to further refine our representation of the PCFG by incorporating sighting histories of known individuals in some comparisons.

The primary goal of this study was to evaluate whether multiple demographically independent units of gray whales exist on feeding grounds, with a special focus on comparing PCFG whales with whales utilizing northern feeding areas. Although other scenarios are possible, here we test three hypotheses using data from both mitochondrial and nuclear markers (n=8 microsatellite loci):

1. No population structure (e.g., panmixia) is present among gray whales utilizing feeding areas in the ENP; individuals move between feeding areas and exhibit random mating. This hypothesis would be supported by a finding of no nuclear or mitochondrial differentiation between samples collected in northern versus southern feeding areas.
2. Utilization of feeding areas is influenced by internal recruitment, with calves following their mothers to feeding grounds and returning in subsequent years. Mating is random with respect to feeding ground affiliation. This hypothesis would be supported by a finding of significant differences in mtDNA haplotype frequencies when comparing samples collected on northern versus southern feeding grounds, but no significant differences are expected in microsatellite allele frequencies between groups of samples from specific geographic areas (i.e., “strata”).
3. Utilization of feeding areas is influenced by matrilineal fidelity and mating is not random with respect to feeding ground affiliation. This hypothesis would be supported by a finding of significant differences in both mtDNA haplotype and microsatellite allele frequencies.

Support for the second hypothesis would indicate that groups of individuals feeding in northern and southern areas are demographically independent but not reproductively isolated, while support for the third hypothesis would provide support for both demographic independence and reproductive isolation.

METHODS

Sample Collection

A total of 277 samples were processed for this study. The majority of samples (n=185, including all samples collected between Northern California and British Columbia, Canada) were collected as biopsies from free-ranging individuals, with the remainder collected from individuals taken as part of the subsistence whaling (n= 75 samples from Chukotka) or from stranded individuals (n=17). Collection locations ranged from northern California to Barrow, Alaska and Chukotka, Russia (Figure 1).

For each of the biopsy samples collected, efforts were made to obtain a photograph of the biopsied whale. For whales biopsied between northern California and British Columbia, Canada, photographs were compared to photo-identification catalogues maintained by Cascadia Research Collective. This approach allowed sighting histories of individual individuals to be linked to samples and utilized (as described below) in the stratification of samples for comparisons.

Figure 1 shows that most of the PCFG samples utilized in this study came from the southern portion of the PCFG range. Although the original design of the study was to have both a Russian and a Barrow, Alaska strata, the sample size for the latter (n=14) was insufficient to characterize genetic frequencies from that area. We were therefore unable to directly address hypotheses about whether there are multiple demographically independent feeding units to the north of the Aleutian Islands.

Laboratory Processing

DNA extraction, PCR Amplification and Sequencing – DNA was extracted from samples using standard protocols. The 5' end of the hyper-variable mtDNA control region was amplified from extracted genomic DNA, using the polymerase chain reaction (PCR) and then sequenced using standard techniques (Saiki *et al.,* 1988; Palumbi *et al.,* 1991). DNA was amplified using a 25 ul reaction of 1ul DNA, 18.25 ul of water, 2.5 ul of buffer [10 mM Tris-HCl (pH 8.3), 50 mM KCl, 1.5 µl of 10 mM dNTP], 0.75 µl of each 10 µM primer, and 0.25 ul of Taq DNA polymerase. The PCR cycling profile consisted of 90°C for 2 min, followed by 35 cycles of 94°C for 50 sec, an annealing temperature of 60°C for 50 sec, and 72°C for 1 min, then a final extension of 72°C for 5 min. A 523 base pair region of the 5' end of the mtDNA control region was amplified using primers B (5’-TACCAAATGTATGAAACCTCAG - 3’; Rosel *et al.,* 1995) and TRO (5′- CCTCCCTAAGACTCAAGG-3′; developed at SWFSC). Both strands of the amplified DNA product were sequenced independently as mutual controls on the Applied Biosystems Inc. (ABI) model 3730 sequencer. All sequences were aligned using Sequencher v4.8

software (Gene Codes Corp., 2000). If discrepancies were found within the replication the sample was re-sequenced from extracted DNA. If the discrepancy was still not resolved, DNA was re-extracted from tissue and the sample was resequenced until the haplotype was confirmed. For a small number of samples (n=4), the mtDNA sequence contained an ambiguous base call which could not be resolved; these samples were excluded from the mtDNA analysis. In addition, if a sample was identified as having a mtDNA haplotype that was not found among any of the other samples, mtDNA amplification and sequencing was replicated to confirm the haplotype identity.

Nuclear DNA processing – Eight microsatellite loci isolated from other cetacean species were used to genotype the samples (Table 1). Extracted DNA was amplified using a 25 µl reaction of 1 µl of DNA, 18 µl of MilliQ water (Millipore, Bedford, MA), 2.5 µl of 10x PCR buffer (500 mM KCl, 100 mM Tris-HCl, pH 8.3, and 15 mM $MgCl_2$), 1.5 µl of 10 mM dNTP, 0.75 µl of each 10 µM primer, and 0.5 units of Taq DNA polymerase. The PCR cycling profile included 90 °C for 2.5 min, followed by 35 cycles of 94 °C for 45 sec, 1 min at the optimal annealing temperature (Table 1), and 72 °C for 1.5 min, then a final extension of 72 °C for 5 min. PCR products were assessed electrophoretically. Genotype data was generated on ABI's 3730 genetic analyzer and analyzed with ABI's Genemapper (version 4.0) software.

Sex determination - Samples were genetically sexed by amplification and Real-Time PCR (MX3000p, Stratagene Inc) of the zinc finger (ZFX and ZFY) genes. Sex was determined by the amplification pattern: males had two products and females had one (Morin *et al.,* 2005).

Quality Control – Quality control and sample tracking procedures, as detailed in Morin *et al.* 2010, were implemented for all laboratory processing by incorporating control samples (negative and positive) into all amplifications. In addition, a set of samples were randomly chosen to act as replicates for error tracking and error rate estimation. For these samples ("random replicates"), which represented ≥10% of all samples processed, the mtDNA sequence, sex, and microsatellite genotype were re-generated from DNA for each sample.

Analysis

Stratification of Samples – Two stratification hypotheses were tested in the analysis. The "Northern versus Southern" hypothesis assumed that individuals utilize each of these general regions in a relatively uniform manner such that sampling location within each stratum does not matter. The stratification used for the Northern-versus-Southern hypothesis included all samples described above (Figure 1). Those samples which were collected north of the Aleutian Island Chain were included in the "North" stratum, while all samples collected between northern California and southeastern Alaska (i.e. from within the described range of the PCFG) were included in the "South" stratum (Figure 1).

The second hypothesis is referred to as the "Fine-scale Feeding Aggregation" hypothesis. This hypothesis considers that there may be multiple feeding aggregations north of the Aleutians and hence sampling location within each stratum does matter. The only fine-scale area that was sampled adequately to capture genetic frequencies in the "North" stratum included the individuals hunted off Chukotka (Figure 2). The "Fine-scale Feeding Aggregation" hypothesis also used more stringent criteria than location and season to define individuals assigned to the PCFG stratum. The rationale for more stringent criteria is that photo-identification studies have indicated that whales utilizing the PCFG's seasonal range fall into two categories: 1) whales that return frequently and account for the majority of sightings, and 2) apparent stragglers from the migration that are sighted in only one year (Calambokidis *et al.,* 2010). The criteria for assigning samples to the PCFG stratum were intended to make this stratum representative of the first category of whales. Inclusion in the PCFG stratum for the "Fine-scale Feeding Aggregation" hypothesis relied on two criteria: 1) the sample was linked to a photographed animal with high or medium confidence, and 2) the photographed animal had been sighted two or more years within the season (June – November) and area representative of the PCFG.

Data Review – To avoid including duplicate samples, the Excel Microsatellite Toolkit (Park, 2001) was used to identify samples with identical genotypes, indicating that they may have been collected from the same animal. These sample pairs were then checked to see if they also shared the same mtDNA haplotype and sex, and, when possible, photo-identification records were used to confirm the genetic match. For all samples which shared identical mtDNA haplotypes, sexes, and genotypes, one sample from each pair was removed.

Genotyping Error Rate – For all plates of samples used to generate microsatellite genotypes, a random subset of samples, representing >10% of the samples on each plate, were assigned as replicates. Replicate and original genotypes were compared, and a per-allele error rate was calculated by determining the number of discrepant allele calls divided by the total number of allele calls compared across all loci.

Genetic Diversity – For the mtDNA, haplotypic diversity (h) and nucleotide diversity (π) were calculated using Arlequin 3.5.1.2 (Excoffier *et al.,* 2005). For the microsatellite data, the number of alleles per locus and observed and expected heterozygosities were calculated using custom R-code (eiaGenetics, available upon request[1]). Fstat (Goudet 1995) was used to calculate allelic richness for each stratum. Deviations from Hardy-Weinberg equilibrium (HWE) were assessed for each microsatellite locus using Genepop (version 4.0.11, Rousset 2008). Both the probability test (Guo & Thompson, 1992) and the test for heterozygote deficiency (Rousset and Raymond 1995) were conducted using the program defaults for the Markov chain parameters (10,000 dememorization steps, 20 batches, 5000 iterations/batch). Genepop was also used to test for linkage disequilibrium (LD) for each pair of loci. All tests were run for the combined dataset as well as for each stratum, and a sequential Bonferroni correction was applied across all tests for each stratum.

Genetic Structure – Pairwise estimates of genetic divergence were calculated using both F_{ST} and and Φ_{ST} (based on pairwise differences between sequences as the measure of genetic distance) for the mtDNA data as implemented in Arlequin 3.5.1.2 (Excoffier *et al.,* 2005). Statistical significance was assessed using 20,000 permutations. Fisher's exact test (Raymond & Rousset, 1995) was also used to test for mtDNA differentiation between strata using 100,000 replications to test for significance.

For the microsatellite data, F_{ST} (Weir &Cockerham, 1984), Jost's D (Jost, 2008), and a χ^2 test were used to assess genetic differentiation. These tests were implemented using custom code (eiaGenetics[1]) written in the statistical program language R (R Core Development Team, 2009). Statistical significance was determined from 10,000 permutations of each data set.

RESULTS

Data Review - Fifteen samples (including n = 11 samples collected from stranded whales) amplified at ≤5 microsatellite loci and were removed from the analysis. The remaining samples were genotyped for at least seven of the eight microsatellite loci. Fifty-six samples had microsatellite genotypes, mtDNA haplotypes, and sexes which matched at least one other sample in the dataset; these samples were removed from further analysis. No movements of animals between regions representing different strata were identified based on genetic matches (i.e., all samples sharing identical genetic profiles were part of the same stratum).

Genotyping Error Rate – Based on the samples randomly chosen for replication, a per-allele error rate of 0.16% was detected for the microsatellite data.

Genetic Diversity – Thirty-nine mtDNA haplotypes defined by 37 variable sites were identified from the 202 gray whale samples representing unique individuals (Table 2). Haplotype diversity (h) was high in all four strata ("Northern v. Southern" and "Fine-scale Feeding Aggregations") defined for the analysis (0.945 - 0.953). Nucleotide diversity (π) was also similar among the four defined strata (1.4 – 1.6%).

The frequency of each haplotype in the defined strata (including Barrow) is shown in Table 3. For the "Fine-scale Feeding Aggregations" strata, eighteen haplotypes were shared between Chukotka and the PCFG, with nine haplotypes found only in Chukotka and five haplotypes found only in the PCFG. For both Chukotka and the PCFG, many haplotypes were found in only one individual (n=12 haplotypes in Chukotka, n = 8 haplotypes in the PCFG).

The median-joining network shows the relationship among mtDNA haplotypes and their frequency in each stratum (Figure 4). MtDNA haplotypes from both Chukotka and the PCFG are dispersed throughout the network, and no phylogeographic pattern is apparent.

---

[1] Contact E. Archer @Eric.Archer@noaa.gov

A summary of microsatellite diversity for each locus is shown in Table 4. None of the tests for HWE were significant after the correction for multiple tests was applied. Significant linkage disequilibrium was found for only one pair of loci (EV14t and Gt023t) in the PCFG strata. No significant LD was found for these two loci in any of the other strata or for the combined dataset, so these loci were retained for the analysis.

Measures of genetic diversity for each stratum after averaging across loci are shown in Table 5. As in the comparisons of mtDNA diversity, nuclear diversity was similar across all strata.

Sex Ratio – A female bias was present among the samples, ranging from 1.3 – 1.5 females per male in each stratum (Table 6). This female bias is similar to that (1.47 females per male) described in Frasier *et al.* (In press) but contrasts with earlier studies (Steeves *et al.,* 2001; Ramakrishnan *et al.,* 2001). The male bias (1.7 males per female) described in Steeves *et al.* 2001 was based on a small sample size (n=16 samples). When the gender determination method utilized here was applied to the sample set used in the Ramakrishnan *et al.* 2001 study, only a slight male bias was identified (1.25 males/female). These results contrast with those presented in Ramakrishnan *et al.* (1.8 males/female) and indicates that an issue with the gender determination assay used at that time was responsible for falsely identifying some samples as males.

Genetic Structure – The results of the mtDNA comparisons are shown in Table 7. Low but statistically significant differences were detected when the PCFG stratum was compared with the North stratum (Φ_{ST} = 0.030, p= 0.0118; F_{ST}= 0.010, p=0.0052; Fisher's exact test p=0.0080) and with the Chukotka stratum (Φ_{ST} = 0.020, p=; F_{ST}= 0.012, p=0.0295; Fisher's exact test p = 0.0304). The F_{ST} comparisons for mtDNA were also significant when the North and South strata were compared (F_{ST}=0.007, p = 0.0272), although none of the other mtDNA comparisons involving the South stratum demonstrated significant differences. None of the comparisons across strata utilizing the microsatellite data were significant (Table 8), providing no evidence of nuclear structure among feeding areas.

DISCUSSION

The results presented here are consistent with the second hypothesis that was evaluated, indicating that utilization of at least some feeding areas is influenced by internal recruitment (e.g., matrilineal fidelity), but that individuals from different feeding grounds interbreed. The extent of differentiation, while significant, was low and was detected only in the mtDNA comparisons. Diversity within the PCFG strata was high and similar to that found among strata in the north.

The low level of mtDNA differentiation between strata, as well as the high diversity found in the PCFG, could be a reflection of relatively recent colonization (or re-colonization following depletion of the population by commercial whaling) of the PCFG area. If recruitment into the PCFG is driven exclusively by the return of individuals which followed their mothers to the area as calves, then over time those mtDNA haplotypes originally found only in males or non-reproducing females would be removed via genetic drift, while haplotypes found in females and their returning offspring would build to higher frequencies. By this process, genetic differences would develop between the PCFG and other feeding aggregations, and, given its small size, the PCFG would be expected to maintain low haplotypic diversity. However, if colonization of the PCFG area occurred relatively recently, strong mtDNA differences between the PCFG and individuals feeding further north may not have had time to develop, and the number and distribution of haplotypes in the PCFG may not yet have been affected by genetic drift.

The low level of mtDNA differentiation and high diversity is also consistent with a scenario in which the population structuring is largely driven by matrilineal fidelity (perhaps over longer time scales) but in which some low-level external recruitment also occurs. Some degree of external recruitment would slow the accumulation of genetic differences between the PCFG and northern individuals. As well, external recruits would likely carry haplotypes not previously found among PCFG individuals and would increase the number and diversity of haplotypes found.

These two explanations are not exclusive, and it is plausible that some combination of these scenarios (recent colonization and/or low-level external recruitment) may be occurring. The origin of the PCFG is unknown, and use of the area may date back to the "Little Ice Age" [ca. 1450-1850] when access to the Bering Sea feeding areas would have been limited by heavy ice and some whales may have started to use the PCFG range. Gray whales have been recorded feeding in the southern portion of the PCFG range as early as 1926, when a single gray whale, which was reported to have been feeding with four other whales, was taken by the Trinidad whaling station off the entrance to the Crescent City Harbor in July (Howell & Huey, 1930). The repeated return of individual whales to the area was first documented starting in the 1970s (Hatler & Darling, 1974; Darling, 1984). Photo-identification studies have identified some individuals that have consistently returned to the PCFG seasonal range over time, including some known reproductive females and their calves (Calambokidis *et al.,* 2010). However, "new" whales continue to appear annually and many are resighted in subsequent years (Calambokidis *et al.,* 2010). These new individuals may be internal recruits that were not sighted as calves, but could also be external recruits that return to the area following a successful feeding season. Even if some low-level external recruitment to the area is occurring, however, the differences in mtDNA haplotype frequencies observed in our comparisons indicate that matrilineal fidelity to the area does occur and is important in influencing population structure on the feeding grounds utilized by ENP gray whales.

Conception in gray whales is thought to primarily occur during a three week period between late November and early December (Nov 27 – Dec 13), although if no conception occurs during this first period, a second estrus may occur about 40 days later when whales are on or near their wintering grounds (Rice & Wolman, 1971). Rugh *et al.* (2001) estimate that the median (peak) sighting dates for the southbound migration are 12 December for Unimak Pass, Alaska, suggesting that many gray whales would be north of the PCFG seasonal range during the first mating period. In addition, of the eight individuals which had retained their satellite tags when they started the southbound migration, four (two males and two females) remained on the PCFG feeding ground after mid-December, with two staying until mid-January or later (Mate *et al.,* 2010). These findings raise the possibility that some segregation in breeding could occur based on feeding ground affiliation. However, while the results of the mtDNA comparisons indicate that matrilineal fidelity is generating structure among feeding areas utilized by ENP gray whales, the lack of differentiation found in the nuclear comparisons supports mixing of individuals from different feeding areas while breeding.

The genetic signal of matrilineal fidelity in the PCFG is less marked than that seen among gray whales feeding off Sakhalin Island in the western North Pacific (WNP). Although significant differences in F_{ST} and Φ_{ST} were observed in the mtDNA comparisons between the PCFG and the northern strata, the magnitude of differentiation is lower than that seen in the WNP versus ENP comparisons (F_{ST}=0.068, p≤0.001; Lang *et al.,* 2010). In addition, a pattern of matrilineal fidelity to the area is also reflected in the distribution of haplotypes among individuals in the western population, such that two haplotypes are found in very high frequencies (representing 36% and 31% of all sampled individuals, Lang *et al.,* 2010). This pattern would be expected if utilization of this area was driven in large part by the continued return over time of a small number of females and their offspring (and eventually their offspring's offspring), and examination of the haplotypes carried by individuals revealed that 16 of the 23 known reproductive females (between 1995 and 2007, Weller *et al.,* 2008) share one of these two common haplotypes (Lang, 2010). In the PCFG stratum, however, the three highest frequency haplotypes are found in only 10 to 13% of sampled individuals, which is consistent with more recent colonization of the PCFG area by a relatively large number of founders. In addition, genetic differentiation based on microsatellite allele frequencies was observed between the Sakhalin and ENP strata (F_{ST} = 0.009, p≤0.001; Exact test, p≤0.001), indicating that, unlike what has been suggested in the PCFG, some degree of reproductive isolation also occurs between these groups.

The results presented here are consistent with those presented in Frasier *et al*. (In press), which also found evidence of maternally driven structure when comparing samples collected from PCFG whales with samples from LeDuc *et al*. 2002, which were collected primarily from animals which stranded along the migratory route. The samples utilized in the Frasier *et al*. (In press) study were all collected from Clayoquot Sound, British Columbia. In contrast, the majority of samples representing the PCFG in this study were collected from animals in the waters off northern California, Oregon, and Washington, with only 11 samples collected from waters off British Columbia. Although some whales are known to move throughout the range of the PCFG, sightings of most whales are concentrated within subareas of the range (Calambokidis *et al*. 2010). This pattern is illustrated in Figure 7 of Calambokidis *et al.* (2010), which shows the distribution of latitudes of sightings for whales with 6 or more sightings after 1 June from 1998-2008. The patterns evident in this figure reveal that individual gray whales do not utilize the range of the PCFG randomly and indicate that, while there is likely overlap among the individuals sampled in Frasier *et al*. (In press) and the current study, neither represents random sampling across the range of the PCFG. To date, the photographs and/or genetic identities of sampled whales in the Frasier *et al*. (In press) study have not been compared with those used in the current study. In the future, such comparisons, along with the collection of additional samples from whales in the northern portion of the PCFG range, would be valuable in allowing sampling effort to be more evenly distributed throughout the range of the PCFG.

As aforementioned, the results presented here are consistent with the hypothesis that utilization of at least some feeding areas by ENP gray whales is influenced by internal recruitment. Within the PCFG, these findings are concordant with photo-identification records demonstrating site fidelity of individuals, including some known reproductive females and their calves, to the seasonal range (Calambokidis *et al.,* 2010). However, interpretation of the results is complicated by our lack of understanding of the potential for structuring within the northern feeding ground(s). If there is no structure on the feeding grounds north of the Aleutians, then the northern strata (both "north" and "Chukotka") can be considered representative of the genetic diversity of whales feeding throughout the northern feeding area. As such, the mtDNA differences observed here would be driven by fidelity of individuals to the PCFG seasonal range. However, if structuring is present among northern feeding areas, then the differences demonstrated here may be influenced by fidelity of individuals in either or both areas (Chukotka and PCFG). The collection of additional samples from northern feeding areas would be valuable in further elucidating the mechanisms creating the observed differences and in evaluating whether structuring is present among whales utilizing the northern feeding grounds.

Although the lack of nuclear differentiation found in our study indicates that gray whales from different feeding regions may be interbreeding, the significant differences in mtDNA haplotype frequencies that were identified in the study suggest that groups of gray whales utilizing different (northern versus southern) feeding regions are demographically independent. A similar pattern has been observed among humpback whales in the North Atlantic, where four feeding regions are present (Katona & Beard, 1990; Stevick *et al*., 2006). Within feeding regions, individuals demonstrate intra- and inter-seasonal site fidelity, with only low levels of interchange between regions (Stevick *et al*., 2006). Although most of the whales from these four feeding regions share a common mating ground in the West Indies (Katona & Beard, 1990; Clapham *et al.,* 1993; Palsbøll *et al.,* 1997; Stevick *et al.,* 1998), individuals utilizing the Gulf of Maine have been classified as a separate feeding stock, based on matrilineally-derived fidelity of individuals to this area and the assumption that, should this subpopulation be extirpated, repopulation by whales using adjacent areas would not occur on a management timescale (Waring *et al.,* 2000). It has been suggested that the timeframe for management should be, at most, decadal in scope (i.e., <100 years; Clapham *et al*., 2008).

Future Work - The low level of differentiation identified, as well as the high diversity found in the PCFG strata, may indicate relatively recent colonization of the PCFG but is also consistent with a scenario in which some low-level external recruitment into the PCFG may occur. Relatedness analysis, in which microsatellite genotypes are used to identify putative parent-offspring pairs, would provide insight into the proportion of internal versus external recruitment that is occurring. Such analysis would require genotyping additional microsatellite loci for sampled individuals and would benefit from the collection of additional samples from individuals within the PCFG.

As part of previous work exploring genetic differentiation between gray whales in the eastern and western North Pacific (Lang *et al.,* 2010), the genetic profiles of samples collected from individuals on the Sakhalin feeding ground (n=142) were compared to those generated from samples collected in the eastern North Pacific (n=136). Two individuals that were sampled off Sakhalin had matching genders, genotypes (n=13 loci), and mtDNA haplotypes to two individuals sampled off central California in 1995 (Lang, 2010). Although subject to caveats, these genetic matches may have represented movements of gray whales between the eastern and western North Pacific. Given that additional gray whale samples from feeding grounds in the ENP have been processed as part of this study, an expanded genetic comparison of all processed samples is currently underway to look for additional matches between the eastern and western populations.

ACKNOWLEDGEMENTS

Samples utilized in this project were collected under MMPA permit #14097 granted to the Southwest Fisheries Science Center and permit #540-1811 granted to John Calambokidis of Cascadia Research Collective. Samples collected in Russian waters were imported under CITES permit #1OUS77422319, held by the Southwest Fisheries Science Center. We thank Robin Abernathy, Billy Adams, Russ Andrews, Valentina Burkanov, Douglas Coleman, Dominick DeBari, Graeme Ellis, John Ford, Gary Friedrichsen, Brian Gisborne, Dawn Goley, Merrill Gosho, Ernie Grimes, Jeff Harris, Jason Herreman, Jeff Jacobsen, Barb Lagerquist, Rikki Manuel, Michael Murner, Carrie Newell, Sean Oliver, Nate Pamplin, Joe Scordino, Mikhail Shlemov, Tatiana Shulezhko, Debbie Steele, Rod Towell, Andrey Tretyakov, and Gina Ylitalo for their assistance with sample collection or contribution. Assistance in organizing sample collection efforts was provided by Paul Wade. All data for the analyses were generated in the SWFSC Genetics Laboratory, with assistance from Amanda Bowman and Jeremiah Minich. Gaby Serra-Valente and Nicky Beaulieu archived all samples. Eric Archer provided the R-code utilized for the microsatellite analysis, and Karen Martien provided help with analysis. Eric Archer, John Bickham, Karen Martien, Phil Morin, Wayne Perryman, and Dave Weller contributed to useful discussions on the analysis and interpretation of results. John Bickham, Bob Brownell, Donna Darm, Karen Martien, Steve Stone and Dave Weller provided helpful comments for improving the manuscript. Some of the work presented here was conducted as part of a National Research Council Postdoctoral Fellowship. Funding for the project was provided by the Northwest Regional Office of NOAA National Marine Fisheries and by a Species Recovery Grant for Tribes awarded to the Makah Tribe.

ABSTRACT: The eastern North Pacific gray whale *Eschrichtius robustus* was removed from the US Endangered Species List in 1994, and since then aboriginal groups in Washington (USA) and British Columbia (Canada) have discussed the resumption of traditional whaling. In particular, the Makah are pursuing legal permission to resume their hunt. Although the majority of whales in this population migrate to summer feeding grounds in the Bering, Chukchi, and Beaufort Seas, a small number of individuals (~200) spend the summers feeding in the waters ranging from northern California to southeast Alaska. The relationship of these 'southern feeding group' whales to the rest of the population is unknown. This information is key to making appropriate management decisions, because these whales inhabit the waters directly adjacent to the aboriginal communities interested in resuming whaling. We compared mitochondrial sequence data from 40 southern feeding group individuals to sequences from 105 individuals representing the larger population. We found significant differences in haplotype frequencies between the 2 groups, with an estimated long-term rate of exchange between the groups being <<1 %. Moreover, estimates of Θ ($N_e\mu$ for mtDNA data, i.e. the probability of a mutation occurring within the population in each generation) were significantly different between the 2 groups, indicating that the maternal lineages of the southern feeding group represent a distinct seasonal subpopulation. Combined, these data show that the southern feeding group of gray whales qualifies as a separate management unit, which should be considered when making conservation decisions.

KEY WORDS: Gray whale · *Eschrichtius robustus* · Whaling · Population structure · mtDNA · Management unit

INTRODUCTION

The eastern North Pacific gray whale *Eschrichtius robustus* represents one of the few populations that have been removed from the US Endangered Species List, with the classification changing from 'endangered' to 'recovered' in 1994. Commercial whaling targeting gray whales in the eastern Pacific began in ~1845 (Henderson 1984) and reduced the population from an estimated 12 000–15 000 ind. to as low as 1500–1900 ind. by 1900 (Henderson 1984, Reilly 1992, Butterworth et al. 2002). International protection began in 1937, when the United States and Norway ended their gray whale hunts, but it was not until 1951 that all modern whaling countries agreed to stop hunting gray whales (Reeves 1984). Systematic surveys from 1967 to 1998 showed that the population increased at an annual rate of ~2.6 %, reaching as many as 30 000 ind. (Shelden & Laake 2002, Rugh et al. 2005). Current estimates hover around 20 000 ind., and

---

*Email: timothy.frasier@smu.ca

there are even some suggestions that the population has reached carrying capacity (Moore et al. 2001, Wade 2002, Rugh et al. 2005, but see Alter et al. 2007 for an alternative perspective).

During the late fall and early winter, whales migrate to the lagoons of Baja California and the Gulf of California, which represent the winter calving grounds for this population (Swartz 1986, Findley & Vidal 2002, Swartz et al. 2006). During the spring, the majority of whales migrate to their northern feeding grounds in the Bering, Chukchi, and Beaufort Seas (Moore & Ljungblad 1984). However, a small subset of the population (~200 ind.) remains in more southerly feeding grounds ranging from northern California to southeast Alaska (Pike 1962, Hatler & Darling 1974, Darling 1984, Darling et al. 1998, Calambokidis et al. 2002, Swartz et al. 2006). These 2 subsets of the population will be referred to as the southern feeding group and the larger population, respectively.

Subdivision with respect to summer feeding ground use is common in baleen whales, and results from maternally directed site fidelity to different feeding grounds. For example, in humpback whales *Megaptera novaeangliae* and North Atlantic right whales *Eubalaena glacialis*, calves nurse for ~11 mo (and occasionally longer) and learn migration routes and the location of summer feeding grounds through cultural transmission from their mother (e.g. Baker et al. 1990, Malik et al. 1999). Thus, if there is differential use of feeding grounds by mothers, these preferences will be passed on to their offspring and result in substructuring with respect to summer feeding ground use. Gray whale calves nurse for a much shorter period of time (~6 mo; Swartz 1986). Although their length of lactation is still long enough to learn migratory routes and the location of summer feeding grounds, it is not yet clear whether gray whales show this maternally directed site fidelity. Because mitochondrial DNA (mtDNA) is maternally inherited, patterns of mtDNA diversity should reflect any maternally based patterns of movement and distribution. Therefore, analysis of mtDNA is ideal for testing hypotheses of maternally based site fidelity and subsequent population structure in baleen whales.

The relationship between the southern feeding group and the larger population is unknown. It is currently assumed that both of these groups use the same breeding ground, and therefore represent the same breeding population (e.g. Swartz et al. 2006). Given the known patterns in other baleen whale species, it seems likely that the southern feeding group and the larger population, and perhaps even smaller, as yet undefined subdivisions, result from maternally directed site fidelity to different feeding grounds by gray whale mothers. Photo-identification data are consistent with this hypothesis, showing that the majority of whales sighted in the southern feeding areas are re-sighted there in subsequent years, and therefore show the expected site fidelity (Darling 1984, Calambokidis et al. 2002, 2010). For example, Calambokidis et al. (2002) found that between 70 and 100% of the whales photo-identified off British Columbia had been sighted there in previous years. Moreover, the majority (63%) of calves first sighted in the southern feeding area with their mothers are resighted there in subsequent years, suggesting that this differential use of feeding grounds is indeed the result of maternally directed site fidelity (Calambokidis et al. 2010). This resighting rate is high, given the numerous factors that can reduce the resighting rates of calves, including: (1) mortality of individuals between their calf and subsequent year (as this age class has the highest mortality rate in many mammalian populations; Caughley 1966); and (2) changes in physical features that prevent re-identification (Calambokidis et al. 2010). However, preliminary genetic analyses of population structure based on mtDNA were inconclusive (Steeves et al. 2001).

Understanding the relationship between the southern feeding group and the rest of the population is of increasing importance due to the intention of some aboriginal communities to resume hunting gray whales. Several aboriginal groups traditionally hunted gray whales, but voluntarily stopped hunting as whale numbers decreased and/or were required to stop when the population received international protection (O'Leary 1984, Russell 2004). The exception was off Chukotka, Russia, where whaling was allowed to continue. In 1998, the Makah (in Washington, USA) resumed whaling and caught/killed a whale in 1999, but have been prevented from continuing since 2000 by litigation. Specifically, the Makah were given the right to hunt gray whales at traditional sites under the Treaty of Neah Bay in 1855. However, a final court ruling in 2004 determined that in order to resume their hunt, they must follow the necessary procedures for obtaining a waiver under the Marine Mammal Protection Act (MMPA). The Makah have applied for this waiver, and this request is still being processed. The outcome of the Makah application will have large implications for the resumption of whaling by other aboriginal communities in the area as well (Russell 2004).

The relationship of these 'southern feeding group' whales to the rest of the population is unknown. This information is key to making appropriate management decisions, because these whales inhabit the waters directly adjacent to the aboriginal communities interested in resuming whaling. The negative consequences of ignoring potential population structure when making management decisions, such as the extinction of unrecognized populations and/or species, are well known (e.g. Daugherty et al. 1990, Taylor 1997, Frankham et al. 2002). For the current gray whale situation, an understanding of population substructure in relation to known summer feeding ground use is required to infer how the whales in each feeding area, and the population as a whole, will respond to the removal of individuals through the proposed hunts. Therefore, if informed management decisions are to be made regarding resuming this hunt, it is first necessary to understand the relationship of this southern feeding group to the rest of the larger population. Here, we conducted analyses of the mitochondrial DNA of gray whales representing the southern feeding group, as well as the larger population, in order to better understand their relationship, and therefore inform management decisions.

MATERIALS AND METHODS

Sample collection. Skin samples were collected from whales representing the southern feeding group in Clayoquot Sound, British Columbia, from 1995 to 2006. Individuals of this group appear to move freely between specific feeding sites throughout this southern feeding range from northern California to southeast Alaska in summer (Calambokidis et al. 2002, 2010). Clayoquot Sound on central Vancouver Island is one such site (Darling 1984, Darling et al. 1998). Biopsy samples were collected using a crossbow and modified bolt (e.g. Lambertsen 1987, Palsbøll et al. 1991) or a pneumatic rifle biopsy system (Barrett-Lennard et al. 1996). The samples were collected in association with ongoing photo-identification research (e.g. Darling 1984), and the photo-identification data were used to ensure that individual whales were only represented once within the genetic data set. Moreover, the entire population migrates near this area on its northern and southern migrations. Therefore, samples were only used from whales sampled between 1 July and 15 November, i.e. the time period after which all northward migrants have passed and before which the first migrants start heading south (Darling 1984), to ensure that the sampled individuals actually represented the southern feeding group, as opposed to migratory animals. Tissue samples were stored in a 20% dimethyl sulfoxide (DMSO) solution (Seutin et al. 1991).

Genetic analysis. Approximately 40 mg from each sample was used for subsequent DNA extraction procedures. The skin was frozen in liquid nitrogen, ground to a fine powder, and transferred to a tube with 500 µl of lysis buffer (4 M urea, 0.2 M NaCl, 0.5% *n*-lauroylsarcosine, 10 mM 1,2-cyclohexanediaminetetraacetic acid, 100 mM Tris-HCl, pH 8.0). Samples were rotated in the lysis buffer at room temperature for ≥5 d, after which time they were subjected to 3 aliquots of Proteinase K, each at a concentration of 0.5 U mg^{-1} tissue. The addition of Proteinase K was as follows: after adding the first aliquot, samples were rotated at room temperature overnight; after adding the second aliquot, the samples were placed in a 65°C waterbath for 1 h, then transferred to a 37°C incubator for 1 h; after adding the third aliquot, the samples were rotated at room temperature overnight. Approximately 250 µl of the tissue/lysis buffer solution was subsequently extracted using Qiagen DNeasy Tissue Extraction Kits. DNA quantity was estimated using PicoGreen (Singer et al. 1997). Extracted samples included those previously analyzed by Steeves et al. (2001), which were re-extracted and analyzed here, along with the newly collected samples.

A 345 bp portion of the mitochondrial DNA control region was amplified using the primers t-PRO and Primer-2 from Yoshida et al. (2001). PCR cycling conditions consisted of: (1) an initial denaturation step of 5 min at 94°C; (2) 30 cycles of 94°C for 30 s, 57°C for 1 min, and 72°C for 1 min; and (3) a final extension step of 60°C for 45 min. Reactions were carried out in 20 µl volumes containing 1× PCR Buffer (20 mM Tris-HCl pH 8.0, 50 mM KCl), 0.05 U µl^{-1} *Taq* polymerase (Invitrogen), 1.5 mM $MgCl_2$, 0.2 mM each dNTP (Invitrogen), and 10 ng of DNA. After amplification, primers and unincorporated dNTPs were degraded using EXOSAP-IT (Dugan et al. 2002), and products were sequenced using the DYEnamic dye terminator kit (GE Healthcare). Products were size-separated and visualized on a MegaBACE 1000 (GE Healthcare). Sequences were edited using MEGA 4 (Kumar et al. 2008). Gender was determined for all individuals using the method described by Shaw et al. (2003).

Data analysis. To compare the data from southern feeding group whales to those of the larger population, we compared our mitochondrial sequence data to those reported by LeDuc et al. (2002). Their study reported mitochondrial sequences from 120 ind. representing eastern Pacific gray whales. The majority (>90%) of the samples were from stranded individuals found throughout their range, from southern California to the Chukotka Peninsula in Russia. The remaining samples were collected from subsistence takes, as biopsies of live whales, and from fisheries bycatch. Fifteen of the samples in LeDuc et al. (2002) were from southern feeding group whales. These were removed from the analyses, leaving 105 samples from the LeDuc et al. (2002) data set to compare with our data set of 40 ind. Because the vast majority of samples from the study by LeDuc et al. (2002) were from dead individuals (either stranded, as bycatch, or hunted), the chance of duplicate samples from the same individual being represented in their data is negligible. Given the number and geographic range of the sampled whales in the study by LeDuc et al. (2002), our rationale for choosing these for comparison was that these sequences would be a good representation of the larger population of eastern gray whales.

Sequences were aligned with CLUSTALX (Thompson et al. 1994). Alignments were conducted under a range of gap opening and extension penalties and compared by eye to establish the optimal alignment. The sequences were very similar, and all alignments were the same under the tested conditions. Haplotype and nucleotide diversity (π) (Nei 1987) were estimated using Arlequin ver. 3.5.1.2 (Excoffier et al. 2005). Variations between mtDNA sequences were recorded, and identical sequences were grouped into haplotypes. Final haplotype assignments were confirmed with FaBox ver. 1.35 (Villesen 2007). Population differentiation of the mtDNA sequences between the southern feeding group and the larger population was estimated using the analysis of molecular variance approach described by Excoffier et al. (1992) as implemented in the program Arlequin. The significance of the resulting estimates of F_{ST} and Φ_{ST} was tested using 1000 permutations. Relationships among haplotypes were visualized via a median-joining network using the program Network 4.5.1.6 (Fluxus Technology).

To gain insight into the nature of the observed population substructure, we estimated effective population sizes, migration rates, time since divergence, and growth rates for the 2 sample sets using the Isolation with Migration program (IM; Nielsen & Wakely 2001, Hey & Nielsen 2004, Hey et al. 2004). However, repeated trials with various parameter options suggested that there was not enough information in our data set to obtain accurate estimates for all of these values (data not shown). Instead, we focused on estimating just the effective population sizes and migration rates using the program MIGRATE (Beerli & Felsenstein 2001, Beerli 2006). The Bayesian inference approach was implemented, using a transition/transversion ratio of 11.22 and an α estimate of 0.09 for the gamma distribution of mutation rate heterogeneity among sites (both estimated using TREE-PUZZLE, Schmidt et al. 2002). We used the Metropolis-Hastings method of generating posterior distributions. The program was run with uniform prior distributions and 1 long chain. To ensure consistency between runs, MIGRATE was run 5 times with a burn-in of 100 000 steps, and a run length of 10 000 000 steps with data recorded every 500 steps. The likelihood ratio test option of MIGRATE was also used to test the hypothesis that the 2 sample sets have different effective population sizes. For the likelihood ratio test, 10 short chains and 1 long chain were run, with a burn-in of 50 000 steps. For the short and long chains, the run length was 10 000 000 steps with data recorded every 500 steps. Specifically, the hypothesis tested was $\Theta_{southern} = \Theta_{larger}$. Theta ($\Theta$) is a parameter that describes the genetic diversity within a population. The genetic variation existing within a single population is ultimately the result of mutations. The rate at which mutations are observed is a combination of the mutation rate (μ), which is how often mutations occur, and the effective population size (N_e), which represents how many 'opportunities' there are for mutations to occur in each generation. The product of these values represents the probability of a mutation occurring within the population in each generation, and this value is called Θ ($\Theta = N_e\mu$ for mitochondrial sequence data). With genetic data, we tend not to know the values of N_e and μ, but the data available are often the frequency of different DNA sequences and the number of mutations separating them. Thus, it is possible to estimate Θ from the data, and use that to make inferences of N_e and μ. Therefore, in this case we can assume that μ is the same for the southern feeding group and the larger population, and therefore comparisons of Θ estimates between the 2 groups directly correspond to comparisons of N_e.

RESULTS

DNA was extracted and mtDNA control regions sequenced from 40 gray whales representing the southern feeding group. Gender was determined for 37 of the 40 sampled whales, and resulted in 15 males and 22 females. This represents a slight female bias, which is contrary to previous studies, which obtained a slight male bias (Steeves et al. 2001). The sequencing protocol resulted in 336 bp of comparable sequence among individuals. Twenty-seven polymorphic sites were identified, which resulted in 18 haplotypes in the southern feeding group whales (Fig. 1). The sequences published in the study by LeDuc et al. (2002) (522 bp) were longer than those obtained here, and therefore all 336 bp from the southern feeding group sequences could be compared to those from the larger population. None of the variable sites or haplotypes identified in the southern feeding group were new; all were also represented by the sequences described by LeDuc et al. (2002) (Fig. 1). However, trimming the sequences of LeDuc et al. (2002) to the comparable 336 bp between the data sets did remove some variable sites that differentiated some of their haplotypes. Specifically, their haplotypes 'G' and 'O' were collapsed into 1 sequence (called 'G' in Fig. 1), haplotypes 'L', 'U,' and 'AD' were collapsed into sequence 'L,' and haplotypes 'AC' and 'AG' were collapsed into haplotype 'AC' (Fig. 1).

Although no haplotypes were found only in the southern feeding group samples, the distribution of

Fig. 1. *Eschrichtius robustus.* Variable sites characterizing haplotypes from both sample sets of gray whales. NFG, SFG, and TOT (top right) indicate the number of individuals from the northern feeding group (i.e. the larger population), the southern feeding group, and the total number of individuals with each haplotype, respectively

haplotypes was significantly different between the 2 groups, with values of 0.0125 for F_{ST} ($p = 0.0303$) and 0.0311 for Φ_{ST} ($p = 0.0254$). The median-joining network shows that although there is some differentiation between the haplotypes from the 2 feeding groups, for the most part the haplotypes from each are scattered throughout the network (Fig. 2). Haplotype diversity and π were estimated at 0.928 and 0.0199, respectively, for the southern feeding group. These values are very similar to estimates obtained for samples representative of the larger population, which were 0.95 and 0.016, respectively (LeDuc et al. 2002).

The results from the MIGRATE analyses are shown in Table 1. Estimates for each value are very similar across iterations, suggesting that the program was run long enough to reach convergence on the estimates. The estimates of Θ for the southern feeding group and the larger population are clearly different. This observation was confirmed by the likelihood ratio test, which rejected the hypothesis of $\Theta_{southern} = \Theta_{larger}$ ($p < 0.001$). The 95% confidence intervals for the migration rate estimates are extremely large, making them uninformative. This result is not surprising, however, because the approach implemented by MIGRATE is known to recover precise and accurate estimates of Θ even in situations where there is not enough information in the data to recover meaningful migration rate estimates (Beerli 2006).

Because the sample of haplotypes found in the southern feeding group represents a subset of the haplotypes found in the larger population (albeit at different frequencies), we conducted further analyses to ensure that our results were not simply due to the effect of sampling. For this assessment, we generated a new set of 40 sequences (representing a simulated southern feeding group data set) by randomly sampling the sequences of LeDuc et al. (2002), using R (R Development Core Team 2009). Thus, this process generated a simulated data set for the southern feeding group under the hypothesis that it represents a random subset of the larger population. This process

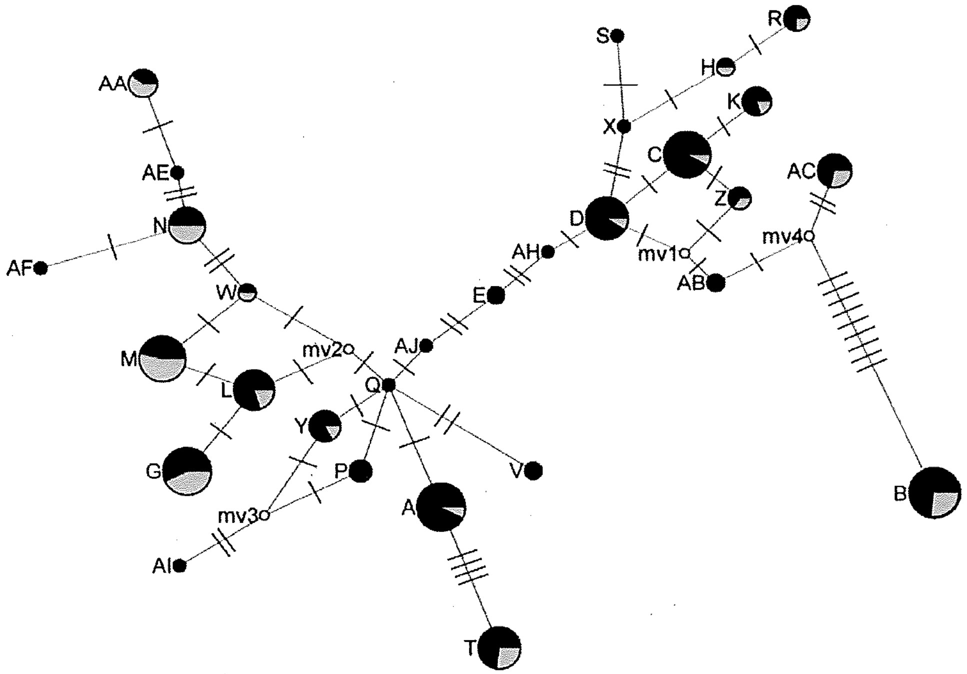

Fig. 2. *Eschrichtius robustus.* Median-joining network for the gray whale sequences. Transitional mutations are indicated with a line, with the number of lines showing the number of transitional mutations. Lengths of the lines connecting nodes are not proportional to the number of mutations. Sizes of the circles are proportional to the haplotype frequencies in the entire data set. Pie charts indicate the proportion of that haplotype found in the larger population (black) and southern feeding group (gray). 'mv' nodes represent inferred nodes that are missing from the data set

was repeated 10 times, generating 10 simulated data sets containing the data from LeDuc et al. (2002), as well as the simulated data for the southern feeding group. Analyses of F_{ST} and Φ_{ST} were conducted for each simulated data set using Arlequin, as were likelihood ratio tests for testing the hypothesis of $\Theta_{southern} = \Theta_{larger}$ using MIGRATE, under the same conditions as were used for the original data.

Table 1. *Eschrichtius robustus.* Results from the MIGRATE analysis. Included is the estimated mean for each parameter, as well as the 95% credibility intervals in parentheses (both obtained using the Bayesian approach in MIGRATE). M is the immigration rate m divided by the mutation rate μ. For mitochondrial DNA data, the number of immigrants per generation can be calculated by multiplying M by Θ. Included are the estimates for each of the 5 iterations of the program, as well as the average across all 5 iterations. Southern and larger indicate the southern feeding group of the eastern North Pacific gray whale population, and larger population, respectively

Iteration	Θ_{larger}	$\Theta_{southern}$	$M_{southern-larger}$	$M_{northern-southern}$
1	0.0430 (0.0220–0.0690)	0.0206 (0.00550–0.0380)	522 (205–860)	572 (250–920)
2	0.0462 (0.0235–0.0735)	0.0199 (0.00550–0.0385)	516 (190–865)	565 (245–960)
3	0.0437 (0.0205–0.0730)	0.0208 (0.00650–0.0385)	523 (195–870)	562 (210–920)
4	0.0421 (0.0165–0.0715)	0.0212 (0.00650–0.0425)	515 (190–865)	572 (240–950)
5	0.0430 (0.0200–0.0710)	0.0220 (0.00650–0.0445)	480 (175–810)	526 (195–875)
Avg	0.0436 (0.0205–0.0716)	0.0209 (0.00610–0.0404)	511 (191–854)	559 (228–925)

None of the simulated data sets showed significant signs of structuring based on F_{ST} or Φ_{ST}, and none showed significant differences in estimates of Θ (Table 2). Thus, the significant differentiation found for the real data set, based on all 3 of these analyses, suggests that the observed differentiation is indeed real, and not just an artifact of sampling.

DISCUSSION

The conservation and/or management of wildlife populations requires knowledge of how individuals are subdivided into separate entities that have relatively independent demographic processes, which are often referred to as 'management units' (MU). Such information is required to identify how each unit, and the popu-

Table 2. *Eschrichtius robustus*. Results from simulation tests under the hypothesis that the southern feeding group represents a random sample of the data set from LeDuc et al. (2002). Included are the F_{ST} and Φ_{ST} estimates, and associated p-values (in parentheses), from Arlequin, as well as p-values from likelihood ratio tests conducted in MIGRATE testing the hypothesis of $\Theta_{southern} = \Theta_{larger}$, where southern is the southern feeding group of the eastern North Pacific gray whale population, and larger is the larger population (not including the southern feeding group)

lation as a whole, will respond to exploitation and/or unintentional impacts. Moritz (1994) was the first to provide a working definition of MUs in a population genetics context, and defined them as

> ...populations with significant divergence of allele frequencies at nuclear or mitochondrial loci, regardless of the phylogenetic distinctiveness of the alleles. (p. 374)

While this definition has been widely applied in population genetics studies, it has recently been argued that MUs should be defined based on criteria demonstrating demographic isolation rather than simply rejecting the hypothesis of panmixia (Waples & Gaggiotti 2006, Palsbøll et al. 2007, Waples et al. 2008). This idea makes intuitive sense, because the true question for management is whether the units will respond differently to the pressures of concern (e.g. exploitation and/or unintentional mortality). However, there is a disconnect between inferring demographic independence and genetic estimates of differentiation because populations can be demographically independent even when long-term migration rates are high enough to result in relative genetic homogeneity (Waples & Gaggiotti 2006, Waples et al. 2008).

The data presented here show that the southern feeding group of gray whales represents a distinct MU under both of these criteria. The analysis showing statistically significant differentiation of mitochondrial haplotypes demonstrates qualification as an MU under the criteria of Moritz (1994). Moreover, the analysis showing that the effective sizes of both groups are different ($\Theta_{southern} \neq \Theta_{larger}$) shows that the maternal lineages of the southern feeding group represent a distinct seasonal subpopulation. Indeed, if they were not an independent unit but instead just represent different samples from the same mitochondrial 'population,' then estimates of Θ from the 2 data sets should converge on the same value. Thus, the southern feeding group qualifies as a separate MU under the criterion of Palsbøll et al. (2007). Combined, these data show that the southern feeding group requires separate management consideration with regards to resuming whaling.

Hastings (1993) showed that populations behave in a demographically independent manner when migration rates are less than ~10%. We have intentionally not converted Θ estimates to N_e estimates because this requires knowledge of the substitution rate (μ). Estimates of μ for the control region of baleen whale mtDNA vary by over an order of magnitude (e.g. Rooney et al. 2001). Moreover, μ, whatever its true value is, is undoubtedly the same for the southern feeding group and the larger population, and therefore comparing estimates of Θ is an appropriate and less controversial method for comparing N_e. Regardless, if we apply the μ estimate of 1.0×10^{-10} mutations $site^{-1}$ yr^{-1}, estimated by Alter & Palumbi (2009) for North Pacific gray whales, the resulting estimates of migration rates are << 1%. In this case, we are not dealing with migration rates between reproductive populations per se, but rather exchange rates between maternally based feeding groups. As with the haplotype frequency data, this result shows that the southern feeding group represents a distinct seasonal subpopulation.

Estimates of Θ represent long-term averages over the lifetime of the population; therefore, these genetic analyses provide information on an evolutionary time scale, whereas wildlife managers are generally more interested in the current state of a population (e.g. at the ecological time scale; Waples et al. 2008). To address this disconnect, we reiterate that photo-identification data of contemporary individuals also results in the same conclusion that the southern feeding group represents a distinct seasonal subpopulation based on maternally directed site fidelity. Photo-identification data show that the majority of whales sighted in the southern feeding areas are re-sighted there in subsequent years (Darling 1984, Calambokidis et al. 2002), and that the majority of calves first sighted in the southern feeding area with their mothers are re-sighted there as juveniles and adults (Calambokidis et al. 2010). Therefore, the combination of photo-identification and genetic data suggests distinct subdivision of the southern feeding group at both the evolutionary and contemporary (or ecological) time scales.

We reiterate that the southern feeding group likely mates with the rest of the population in the winter breeding grounds, and that the structuring we see is the result of maternally directed site fidelity to different feeding grounds. We used mtDNA (rather than nuclear markers) to test this hypothesis specifically for this reason, because such a pattern would be reflected in mtDNA and not nuclear DNA. This type of population substructure is common in whales (e.g. Hoelzel 1998), and has proven important for management. The rationale is that, because of this site fidelity, knowledge of specific feeding areas is only present within certain matrilines. Therefore, if whales are extirpated from a specific feeding ground, they will not be 'replaced' (or the area will not be re-populated) by others from the larger population because knowledge of that feeding area has been lost. Indeed, such localized extinctions and lack of subsequent re-population of areas (despite an increasing overall population size) is widely documented in whales (e.g. Northridge 2008). Thus, the combined genetic and photo-identification data showing that the southern feeding group represents a distinct maternally based seasonal subpopulation indicate that these whales require separate management consideration from the larger population.

Previous studies have suggested that the haplotype diversity in the southern feeding group is too high to have resulted from strict maternally directed site fidelity beginning with a few founders after the cessation of commercial whaling within the past century (Ramakrishnan et al. 2001). Under the hypothesis that this group was founded after the cessation of whaling, only a few closely related haplotypes should be represented within the southern feeding group, as opposed to the pattern seen in Fig. 2. In addition, the hypothesis of a founding event within the past century is not consistent with the known sighting information. Indeed, gray whales have been seen in the southern feeding grounds throughout their history, including in times of lowest abundance (Swartz et al. 2006, and references therein). Moreover, if a few individuals recently founded the southern feeding group, then the estimate of Θ_{southern} should be substantially smaller, as effective population size estimates are heavily influenced by bottlenecks.

Instead, what the sighting and genetic data suggest is that the southern feeding group of gray whales predates whaling. Under this hypothesis, the haplotype diversity is expected to be high, because those lineages that survived whaling would be a random sample from a much larger population. Substantial gaps would also be expected between existing haplotypes resulting from the removal of haplotypes by whaling. This pattern is exactly what is seen in Fig. 2. The similarity of haplotypes, and the degree of haplotype sharing between the southern feeding group and the larger population, both suggest some degree of migration between the 2 groups. However, although reliable estimates of migration rates could not be obtained here, the data clearly show that the rate of migration is low enough for the 2 groups to represent independent demographic entities. The southern feeding group therefore qualifies as a separate MU, and requires separate management consideration.

A larger sample set, and the analysis of more molecular markers (particularly nuclear markers), is obviously desirable for addressing topics such as this one. Moreover, it is possible that further structuring within each of these identified groups exists, but is as yet undetected. However, given the clarity of the results obtained and the implications that they have for the management of these whales, it seemed important to publish these data as soon as possible so that they could be available for informing management decisions. We are currently collecting more samples and collaborating with other scientists to increase the number and geographical representation of our sample set. Protocols for analyzing nuclear loci are also being developed. Combined, these efforts will allow for larger-scale analyses of this issue in the near future.

Acknowledgements. Funding for this work came from the Natural Sciences and Engineering Research Council of Canada (NSERC), a Canadian Research Chair grant to B.N.W., and the Pacific Wildlife Foundation through donations from Remote Passages and Jamie's Whaling Station, and a grant from Clayoquot Biosphere Trust in Tofino, BC. We acknowledge the earlier work on this subject by T. Steeves and the transfer of her samples to this data set. We also thank A. Lang for help identifying which southern feeding group samples were duplicated in the LeDuc et al. (2002) data set. We thank the members of the Aboriginal Whaling Management Procedure (AWMP) scientific committee of the International Whaling Commission (IWC), N. Rose, and 3 anonymous reviewers for comments and discussions that improved this manuscript.

Lack of nuclear differentiation suggests reproductive connectivity between the 'southern feeding group' and the larger population of eastern North Pacific gray whales, despite previous detection of mitochondrial differences

ABSTRACT

During winter, eastern North Pacific gray whales migrate south to calving grounds in the lagoons of Baja California, and in spring they migrate north to their summer feeding grounds in the Chukchi and Beaufort Seas. Although the majority of the population makes this migration, a small subset of the population known as the 'southern feeding group' ends their northward migration early, spending summers feeding in waters ranging from northern California to southern Alaska. Previous analyses based on photo-ID and mtDNA data indicate that this seasonal substructuring results from maternally-directed site fidelity to different feeding grounds, and that this site fidelity and feeding ground preference is passed from mothers to their offspring. It is currently assumed, but not known, that the individuals of the southern feeding group mate with the rest of the population, and therefore that the eastern North Pacific gray whale represents one interbreeding population. Testing this assumption and understanding how these whales are related to the rest of the population, is key to making appropriate management decisions, which are particularly relevant given the recent increase in potential removals, or threats in the area such as the proposed resumption of aboriginal whaling, and increased oil pipeline development and subsequent vessel traffic. This paper analyses 15 nuclear microsatellite loci in 59 individuals from the southern feeding group and 40 individuals from the calving lagoons (representative of the larger population) to test the hypothesis that the eastern North Pacific gray whale represents one interbreeding population. No indication of population substructuring was found based on these nuclear loci, suggesting that all sampled whales do indeed represent one interbreeding population. Combined, these data from mitochondrial and nuclear markers therefore suggest one interbreeding population that is seasonally subdivided based on maternally-directed site fidelity to different feeding areas.

INTRODUCTION

The eastern North Pacific gray whale (*Eschrichtius robustus*) was extensively hunted from the mid-1800s through the early 1900s, reducing the population to just a fraction of its estimated pre-exploitation population size (Butterworth *et al.*, 2002; Henderson, 1984; Reilly, 1992). However, since gaining international protection, the population has steadily increased to roughly 20,000 individuals (Laake *et al.*, 2012; Rugh *et al.*, 2005; Sheldon and Laake, 2002). This recovery resulted in the removal of this population from the US Endangered Species List in 1994, and some data suggest it has recovered to its pre-exploitation population size (Alter *et al.*, 2007; Moore *et al.*, 2001; Rugh *et al.*, 2005; Wade, 2002). Despite this recovery, the population is still faced with numerous threats throughout its range, particularly in the area encompassing the Pacific northwest of the USA and the Pacific southwest of Canada (roughly Northern California through southeast Alaska). Here, there are several proposed activities where informed management will be critical. These include the proposed resumption of gray whale hunts by some aboriginal groups, the development of new oil pipelines off the British Columbia coast and the subsequent increase in tanker traffic for shipping oil to Asia.

One of the primary topics of relevance to management is population structure: how individuals are divided in space and/or time such that some groups may be differentially affected by direct hunting or by non-intentional threats. If such structuring exists, then the different groups often require separate management/conservation consideration because the detrimental effects will not be spread evenly throughout the population, but instead will disproportionally affect the different groups (e.g. Hoelzel, 1998; Taylor, 2005; Wang, 2009). Such localised impacts on structured populations, if not considered, can nullify otherwise well-planned management/conservation initiatives. Indeed, there are several case studies where the effectiveness of conservation actions has been compromised because population structure was not taken into consideration (e.g. Daugherty *et al.*, 1990; Frankham *et al.*, 2002).

Previous studies have detected seasonal population substructuring in the eastern North Pacific gray whale in relation to summer feeding ground use (Frasier *et al.*, 2011). As with many other baleen whales, gray whales show a seasonal migration from low-latitude calving grounds in the winter to high-latitude feeding grounds in the summer. The winter calving grounds for this population are located in the lagoons of Baja California (Findley and Vidal, 2002; Swartz, 1986; Swartz *et al.*, 2006), whereas during the summer the majority of the population feeds in the Bering and Chukchi Seas (Moore and Ljungblad, 1984). However, there is a small

subset of the population—estimated at roughly 200 individuals (Calambokidis *et al.*, 2002) that spends the summer in lower-latitude feeding areas ranging from northern California to southeastern Alaska (Calambokidis *et al.*, 2002; Darling, 1984; Hatler and Darling, 1974; Pike, 1962; Swartz *et al.*, 2006). This group is often referred to as the 'southern feeding group', but is also referred to as the 'Pacific coastal feeding group' by the Scientific Committee of the International Whaling Commission (IWC, 2011; 2013a). Data from photo-ID and mitochondrial DNA (mtDNA) show that this seasonal population substructuring results from maternally-directed site fidelity to different feeding areas, and that this differential use of feeding areas is passed from mothers to offspring (Calambokidis *et al.*, 2002; Calambokidis *et al.*, 2010; Darling, 1984; Frasier *et al.*, 2011). This type of seasonal substructuring is common in baleen whales (e.g. Baker *et al.,* 1990; Malik *et al.,* 1999).

Despite this substructuring during the summer, it has always been assumed, but not known, that individuals from all feeding areas utilise the same mating area(s), and therefore represent one interbreeding population. Unfortunately, there is a lack of clarity regarding where fertilisation likely occurs, and hence where the mating grounds are. Sexual behaviour is frequently observed on the winter calving grounds (e.g. Swartz, 1986), and indeed these are often referred to as 'breeding grounds' (e.g. Alter *et al.*, 2009; Goerlitz *et al.*, 2003; Jones, 1990). However, the limited physiological data available actually suggest that fertilisation most often occurs during the southward migration, prior to arrival at the lagoons (Rice and Wolman, 1971). Thus, there is potential for differential feeding area use to also result in substructuring with respect to reproductive patterns.

There is also evidence that individuals show differential use of the calving grounds, with some females showing fidelity to particular lagoons (Jones, 1990; Goerlitz *et al.*, 2003; Alter *et al.*, 2009). Combined, there are enough questions regarding the timing and location of mating, as well as potential for differential habitat use of potential 'breeding' grounds, to warrant a full evaluation of the hypothesis of one interbreeding population. This paper uses data from nuclear microsatellite loci to compare genetic data from individuals of the southern feeding group to samples obtained from one of the calving lagoons (Laguna San Ignacio) used here as representatives of the larger population to test the hypothesis that individuals of the southern feeding group interbreed with individuals from the larger population. These data, in combination with previous information regarding structuring of mitochondrial haplotypes, can identify the degree of substructuring of the southern feeding group.

METHODS

Sample collection

Samples used for these analyses were collected over many years as part of other long-term research programmes on eastern North Pacific gray whales: off Vancouver Island, Canada by one of the authors (JDD); and off San Ignacio Bay, Mexico by another (JUR). Specifically, 86 samples from Vancouver Island (representing the southern feeding group, collected from 1996–2010) and 51 samples from San Ignacio Bay (representing the larger population, collected from 1996–1997) were analysed. All samples were collected using a crossbow and a modified bolt, as is common for collecting small skin samples from free-ranging large whales (Lambertsen, 1987; Palsbøll *et al.*, 1991). This method of sample collection has been extensively scrutinised, has proven to be safe, and does not have any short- or long-term impacts on the whales, other than an immediate startle response (Best *et al.*, 2005; Brown *et al.*, 1991). All sample collection procedures were conducted under permits obtained from the relevant governmental agencies. The timing of sample collection overlaps between the two sample sets, as is appropriate for comparison. The longer time for sample collection off Vancouver Island should not bias the results because the long life span and generation time of gray whales suggest that substantial genetic change within this putative population would take longer than the time interval sampled here. Thus, both sample sets should represent comparable genetic pools for analysis.

Genetic analyses

DNA was extracted from ~40mg of tissue from all samples using standard phenol:chloroform procedures as commonly used for whale skin (e.g. Wang *et al.*, 2008). The quantity of DNA obtained from each sample was estimated based on spectrophotometry using a NanoDrop 2000 (Thermo Scientific Inc.). The quality of DNA obtained (i.e. the amount of DNA degradation) was assessed based on electrophoresis through 2.0% agarose gels stained with SYBR Green I (Invitrogen). Sex was determined for each sample based on PCR amplification of a region on the X and Y chromosomes using the primers described in Gilson *et al.* (1998).

To identify useful microsatellite markers for this study, 23 loci were screened for amplification and variability in gray whales (Table 1). These loci were chosen because previous experience showed that they amplify well, and are highly variable, across a wide range of whale species. Specifically, loci were initially tested based on the amplification of two gray whale samples (one from the southern feeding group and one from the larger population) using annealing temperatures of 50, 55 and 60°C. The reactions contained 10ng of template DNA, 1X PCR Buffer (20 mM Tris pH 8.4, 50 mM KCl), 1.5 mM $MgCl_2$, 0.05 U/µl *Taq* DNA polymerase (Invitrogen), 0.2 mM each dNTP (Invitrogen), 0.3 µM each primer, and 0.1 mg/ml of bovine serum albumin (BSA) (Invitrogen). The cycling conditions were as follows: an initial denaturing step of 94°C for 5 minutes; 30 cycles of 94°C for 30 seconds, annealing temperature for 1 minute, and 72°C for 1 minute; followed by a final extension step of 60°C for 45 minutes. All PCR was conducted on Veriti® 96-well thermal cyclers (Applied Biosystems). PCR products were then size-separated and visualised via electrophoresis through 1.5% agarose gels stained with ethidium bromide. Loci that showed a clean PCR product (without amplification of multiple regions) were selected for further development.

For primer pairs that amplified well, the forward primer was re-ordered with one of four fluorescent tags (6FAM-Blue, VIC-Green, PET-Red, or NED-Yellow). Each locus was then screened for variation by amplifying 10 samples using the optimal conditions that had previously been

determined. PCR amplification was carried out using the same conditions as described for testing annealing temperatures. PCR products were de-salted via ethanol precipitation (Irwin *et al.*, 2003), and size-separated and visualised on an ABI 3500xl capillary-based genetic analyser (Applied Biosystems).

Based on these amplification data (i.e. peak height and allele ranges) multiplex reactions where multiple loci are amplified simultaneously in the same PCR were developed through testing the amplification of different combinations of loci. These tests resulted in combinations of loci that minimised the number of reactions that were needed to amplify the variable loci. These protocols were then used to genotype all individuals. Alleles were scored using the GeneMarker software (SoftGenetics). Each 96-well plate of samples contained 2 individuals as ‘standards’, meaning that these same two individuals were present on all plates, to ensure consistency in genotyping across plates. All samples were scored by two individuals in a double-blind fashion to identify any potential scoring errors (Morin *et al.*, 2010).

Statistical analyses

Once genotypes for each sample had been obtained, the program CERVUS (Marshall *et al.*, 1998) was used to identify any duplicate genotypes (i.e. individuals that had unknowingly been sampled more than once). Based on these data, duplicate individuals were removed. CERVUS was also used to obtain estimates of allele frequencies and to estimate the frequency of null alleles for each locus. Loci were tested for deviations from linkage and Hardy-Weinberg Equilibrium (HWE) using exact tests as implemented in the program GENEPOP (Rousset, 2008).

Population structure was assessed using ‘classical’ approaches based on estimating differentiation of allele frequencies between pre-defined groups of individuals and Bayesian techniques. Classical methods have the benefit of being far more powerful than available Bayesian methods but have the detriment of requiring pre-defined groups of individuals, which may or may not represent the real biological patterns (e.g. Waples and Gaggiotti, 2006). On the other hand, Bayesian methods allow for simultaneous assessment of the number of groups represented by the sampled individuals and the assignment of individuals to those groups (and therefore do not requiring pre-defined groupings) but suffer from lower power.

The classical assessment of population differentiation was conducted using the program GENEPOP. Here, individuals were categorised as representing either the southern feeding group or the larger population, based on sampling location. Specifically, samples collected off Vancouver Island were classified as the southern feeding group, while samples collected on the calving grounds off Baja California were classified as representing the larger population. Based on this division, estimates of F_{ST} were obtained and exact tests of population differentiation were conducted.

To assess the power to detect population structure using the methods implemented in GENEPOP (exact tests), the simulation program POWSIM (Ryman and Palm, 2006) was used. Specifically, conditions were simulated that would result in differing levels of differentiation (F_{ST} = 0.001, 0.0025, 0.005, 0.01, 0.025, and 0.05), given the characteristics of the loci. There are two biologically realistic scenarios that can result in the same F_{ST} value. First, two populations that are not completely isolated will eventually reach an equilibrium F_{ST} value dependent upon the migration rate between populations (N_m). Second, if two populations have recently become reproductively isolated, they will drift apart, with F_{ST} values increasing with increasing time since divergence. POWSIM obtains desired F_{ST} values under the latter scenario by generating a single simulated population and then splitting it into equally sized populations with complete isolation once the split occurs. In this way, different F_{ST} values are obtained based on the number of generations that have passed since the split. Thus, users obtain estimates of the power to detect different degrees of differentiation by selecting combinations of N_e and t that result in the desired F_{ST} value, where $F_{ST} = 1 - (1 - 1/2N_e)^t$ (e.g. Nei, 1987, p.359). Due to uncertainty regarding N_e for the two putative gray whale populations, power to detect the different F_{ST} values (0.001, 0.0025, 0.005 0.01, 0.02, 0.025, and 0.05) was estimated using N_e values spanning three orders of magnitude (500, 5,000, and 50,000) and using t values for each that would result in the appropriate F_{ST} value. Simulations for each scenario (N_e and F_{ST} value) were conducted 100 times and the proportion of iterations where significant differentiation was detected (using a critical α value of 0.05) was recorded.

Population structure was also assessed without making *a priori* assumptions about the nature of population structure (e.g. how many groups there are, and which individuals represent each group). These analyses were conducted in two different ways: using the programs STRUCTURE (Hubisz *et al.*, 2009; Pritchard *et al.*, 2000), and STRUCTURAMA (Huelsenbeck and Andolfatto, 2007). For the analyses in STRUCTURE, the number of groups, and the membership of individuals within those groups, were estimated based a run length of 1,000,000 Markov Chain Monte Carlo

(MCMC) steps, with 50,000 steps as the burn-in period. The program was run assuming that allele frequencies were correlated between groups, and allowing for admixture (i.e. allowing for individuals to have ancestry in more than one group). The program was run 16 times, testing for 1–4 populations (*K* = 1–4), with four iterations of each *K*. The average likelihood over the four iterations for each *K* was taken as the likelihood for that *K*.

The program STRUCTURAMA works in a similar manner as STRUCTURE but differs in how the user specifies the number of populations to be tested. With STRUCTURE, the user must explicitly specify the number of populations considered and then run the program independently for each hypothesised number, and subsequently compare the probabilities associated with each. With STRUCTURAMA the number of populations considered can be a random variable within the model (Pella and Masuda, 2006) and therefore the posterior probabilities associated with a range of values for the number of putative populations can be obtained within a single run, without requiring *a priori* specification by the user (Huelsenbeck and Andolfatto, 2007). STRUCTURAMA was run allowing the number of populations to be a random variable with a Dirichlet process prior. The alpha value (which determines the shape of Dirichlet prior, where smaller values result in individuals being distributed across fewer populations and larger values result in individuals being dispersed across more populations) was also treated as a random variable, following a gamma distribution. A shape parameter of 1.0001 and a scale parameter of 0.0001 were initially used, which result in a relatively flat distribution. However, to test the robustness of the subsequent posterior probabilities to the choice of shape and scale values, STRUCTURAMA was also run with the shape and scale values both set to 1, which results in an L-shaped distribution. Each scenario was run three times, to ensure consistency between runs under the same conditions. All analyses were run for 1,000,000 MCMC steps, with 10,000 steps used as the burn-in.

Finally, it has been argued that estimating migration rates between putative populations is more biologically meaningful than simply rejecting panmixia when trying to identify biologically independent 'units' for conservation (e.g. Palsbøll *et al.*, 2006). Estimating migration rates from genetic data is challenging, however, particularly when migration rates are high. This is because demographic independence can occur at migration rates that are high enough to genetically homogenise allele frequencies (e.g. Waples and Gaggiotti, 2006). Regardless, great progress has recently been made in the development of analytical techniques designed to address this issue and better infer biological processes from genetic data. For management, the parameter of interest is estimated contemporary migration rates. BayesAss has become the software commonly used for this purpose (Wilson and Rannala, 2003). However, the approach implemented therein is known to perform poorly when genetic differentiation is low (Faubet *et al.*, 2007). Our results suggest extremely low differentiation between the putative groups and perhaps none (see Results), therefore BayesAss was not appropriate for estimating migration rates for our data. Instead, the programs IMa and MIGRATE were used to jointly estimate migration rates in both directions, as well as effective population sizes of each putative population (Beerli, 2006; Beerli and Felsenstein, 1999; 2001; Hey and Nielsen, 2004).

RESULTS

The average yield of DNA from the extraction process was 2.80 nanograms (ng) of DNA per milligram (mg) of tissue for the samples from Vancouver Island, and 0.42 ng/mg for the samples from San Ignacio Bay. This lower yield from the San Ignacio Bay samples likely results from the fact that these samples were stored in ethanol rather than DMSO, and DNA degradation is known to occur at a higher rate in ethanol than DMSO (e.g. Michaud and Foran, 2011).

The tests of microsatellite amplification and variability resulted in the identification of 15 loci that amplify well in gray whales, and are also variable. Multiplex reaction development resulted in all 15 loci being amplified in 5 reactions (Table 2), which were subsequently used for genotyping all samples.

No genotypes differed between the duplicate scoring personnel, indicating that allele calls were consistent across scorers. Genotypes were considered to be 'full' if individuals were missing data from 3 or fewer loci (i.e. they had data for at least 12 of the 15 loci). Full microsatellite profiles were not obtained for 14 samples, resulting in 123 genotyped samples that were used for subsequent analyses. Analysis of the genotypes identified 24 duplicate sampling events (23 off Vancouver Island, 1 from Laguna San Ignacio). All re-sampling events were from the same location (i.e. there were no cases where one individual was sampled in one location and re-sampled at the other). These duplicates were removed from the data set, resulting in genotype data for 99 individuals (59 from off Vancouver Island, 40 from Laguna San Ignacio). The genotypes did not show any significant deviations from Hardy-Weinberg Equilibrium expectations when analysed independently for each putative population, or when the data were combined into one 'population' (Table 3). Out of the 105 pairwise comparisons for assessing linkage between loci (considering all individuals together), six (5.7%) had p-values <0.05. However, none of these were significant after Bonferroni correction (Hochberg, 1988).

Table 2

Amplification information. Included is the locus name, fluorescent label, and reaction number for all loci. The annealing temperature for all reactions is 55°C.

No loci had estimates of null allele frequencies greater than 0.05.

Sex could be determined for 86 of the 99 individuals, with 38 males and 48 females. The DNA was too degraded from the remaining 13 individuals to obtain reliable sex information. Within each region, the sex ratios were 33 females: 24 males and 15 females: 14 males for Vancouver Island and Laguna San Ignacio, respectively.

The 'classic' tests (based on hypothesis testing of pre-defined groupings) did not show any significant signs of genetic differentiation between the genotypes of the southern feeding group and the larger population. Specifically, the F_{ST} estimate was –0.0010, with a *P*-value estimate of 0.489. Simulation analysis showed that the power to detect structure, if it exists, was quite high. Specifically, given the sample sizes and the characteristics of the loci, we would expect to detect population structure over 70% of the time with an F_{ST} value as low as 0.005 (Fig. 1). The STRUCTURE analyses also did not detect any significant genetic differentiation within the data set, with one population (K = 1) having the highest probability (Table 4). Similar results were also obtained with STRUCTURAMA, with the scenario of the data representing one single population having a higher probability than scenarios with any other putative number of populations (Table 5).

Table 4

Results from STRUCTURE analysis. Shown is the estimated natural logarithm (*ln*) of the probability of the data with the number of populations (*K*) ranging from one to four, and performing four iterations of each *K*. The bold value indicates the average *K* with the highest probability.

	K			
Iteration	1	2	3	4

Table 5

Results from STRUCTURAMA analysis. Shown are the estimated posterior probabilities of the data representing 1–3 populations. The top panel shows these probabilities calculated with the alpha value for the Dirichlet process being a random variable following a gamma distribution with a shape parameter of 1.0001, and a scale parameter of 0.0001. The second panel shows these probabilities calculated when the shape and scale value parameters were both set to 1.

	Number of populations		
Iteration	1	2	3
gamma(1.0001,0.0001)			
1	0.96	0.04	0
2	0.96	0.04	0
3	0.96	0.04	0
gamma(1,1)			
1	0.97	0.03	0
2	0.97	0.03	0
3	0.97	0.03	0

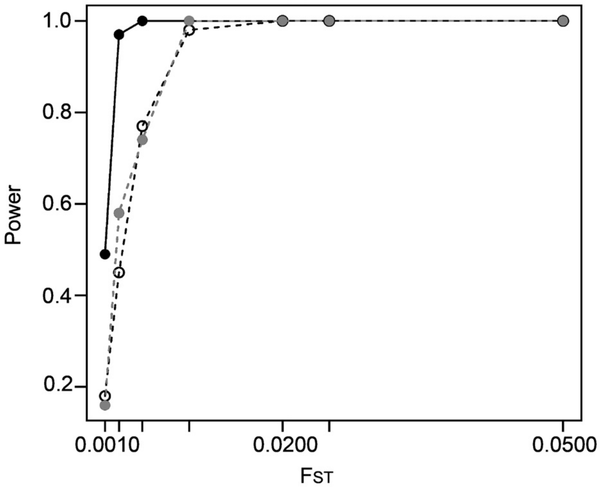

Fig. 1. Results from the POWSIM analyses. Shown is the power of the data (the proportion of simulations where population structure was detected (using a critical α value of 0.05)) under the different scenarios. The F_{ST} values tested were 0.05, 0.025, 0.02, 0.01, 0.005, 0.0025, and 0.001. These F_{ST} values were generated under three scenarios, N_e = 500, 5,000, and 50,000, with the time since divergence (t) varying to result in the desired F_{ST} values.

Despite testing a wide range of options with both IMa and MIGRATE, we were unable to get either program to converge on consistent estimates of migration rates. Our interpretation is that this inability is due to the lack of genetic differentiation of nuclear markers between the putative groups. This interpretation, as opposed to a lack of information in the data, seems appropriate particularly because we have previously obtained consistent estimates from these same programs and the same individuals but based on mitochondrial data, which showed significant structuring and limited migration consistent with maternally-directed site fidelity (Frasier *et al.*, 2011).

DISCUSSION

The differential recovery of DNA from tissue stored in different solutions merits consideration for future sample storage. Several studies have compared the ability of different solutions (primarily ethanol and DMSO) to preserve DNA over long periods of time (e.g. Michaud and Foran, 2011; Seutin *et al.*, 1991). All such studies indicate that DMSO solutions preserve DNA at a higher quality, and over a longer period of time. However, many researchers and museum staff still use ethanol for the long-term preservation of tissue. The differential yields of DNA obtained here add to the growing amount of data suggesting that DMSO is the desirable storage solution for long-term storage of tissue that may be used as a source of DNA.

The results of all analyses of population structure lead to the same conclusion: a lack of differentiation of nuclear genotypes. The 'classical' tests did not detect significant differences in allele frequencies between whales of the southern feeding group and those sampled in Laguna San Ignacio, and both Bayesian approaches indicated that the probability that all samples originated from one single population was substantially higher than any other alternatives. These data suggest that the whales of the southern feeding group do indeed freely interbreed with whales that utilise other summer feeding grounds. Thus, from these data, it appears that the eastern North Pacific gray whale represents one interbreeding population.

One caveat of our study is that samples representing the larger population were all collected from whales in one of the lagoons Laguna San Ignacio (but spanning several years). Gray whales are not evenly distributed throughout the three known lagoons in winter. Instead, photo-ID data suggest that females show some site fidelity to different lagoons (e.g. Jones, 1990) and genetic data also suggest some structuring (Goerlitz *et al.*, 2003; Alter *et al.*, 2009). However, the patterns and degree of structuring between lagoons remains unclear. For example, Alter *et al.* (2009) did not find significant structuring of mitochondrial haplotypes between the lagoons, but found slight but statistically significant differentiation of microsatellite alleles between Laguna San Ignacio and Bahia Magdalena. The authors attribute this pattern to either a high contemporary migration rate, or perhaps to stronger patterns of structuring being erased by whaling and only beginning to accumulate and leave a detectible genetic signature today.

Our justification for using samples from Laguna San Ignacio as representative of the larger population, are three-fold. First, based on numbers of single individuals and mother-calf pairs, Laguna San Ignacio represents the second most populated lagoon, with numbers of whales that are vastly larger than the estimated size of the southern feeding group (Jones and Swartz, 1984; Urban R *et al.*, 2003). Thus, Laguna San Ignacio is clearly used by a larger subset of the population than the southern feeding group. Second, although there are data suggesting that some females show fidelity to specific lagoons, there is also an abundance of data showing that some individuals move freely between lagoons, and that average residence times within the lagoon (for non-mother-calf pairs) are less than a week (Jones and Swartz, 1984; Urbán R *et al.*, 2003), suggesting that at least single whales move readily between lagoons. Moreover, some mothers are known to utilise different lagoons in different years (Swartz, 1986). Lastly, even if mothers do show fidelity to specific lagoons, this should not result in corresponding structuring of nuclear gene flow because fertilisation is thought to take place during the southward migration, prior to arrival at the lagoons (Rice and Wolman, 1971). Thus, although it would be ideal to have representative samples from all known lagoons, the available data provide no reason to doubt that the samples from Laguna San Ignacio are representative of the larger population.

These data based on nuclear markers add to previous photo-ID and mtDNA data to provide a more complete picture of the relationship between seasonal habitat use patterns and gene flow throughout the population. The photo-ID and mtDNA data indicate that, during the summer, whales of the southern feeding group represent a seasonal subpopulation, where this differential habitat use is driven by maternally-directed site fidelity to this feeding area that is then passed on to their offspring (Frasier *et al.*, 2011). However, the nuclear DNA data suggest that these whales breed with whales that show fidelity to other feeding grounds, and therefore are part of one interbreeding population. Thus, the combined picture is one of seasonal subdivision on summer feeding grounds, but with no such substructuring during the mating season, where all individuals in the eastern North Pacific represent one gene pool.

This result and interpretation is consistent with other data relating to known migration patterns and the timing of fertilisation. Briefly, it is thought that conceptions may occur in December, during the southern migration (Rice and Wolman, 1971). Whales that use the northern feeding grounds migrate through the areas occupied by the southern feeding group suggesting that whales from both known feeding grounds may migrate together the remainder of the way to the winter calving grounds (Darling, 1984). The peak time of migrants passing through the southern feeding area is mid-December to mid-January (Darling, 1984). Thus, the timing of fertilisation coincides with when whales from different feeding grounds become intermingled during their southern migration. This pattern indicates the strong potential for interbreeding regardless of any substructuring that may exist during the summer, or on the winter calving grounds.

Despite the presence of nuclear gene flow between whales from the southern feeding group and the rest of the population, this group still represents a separate management unit that warrants separate consideration with respect to the impacts of proposed threats, such as the resumption of traditional whaling and the impacts of oil distribution. This is the approach being used by the IWC Scientific Committee in examining the potential impacts of hunting (e.g. see IWC, 2013b). The presence of long-term site fidelity to this area that is passed on from mothers to offspring, indicates that these whales represent a seasonal subpopulation. Thus, detrimental impacts (e.g. 'takes') to these whales will not have a 'random' impact on the population at large, but will instead primarily impact these matrilines specifically. The resulting effect on this local subpopulation could be far greater than would be expected under the assumption of a single, unstructured population. Potential impacts could include the loss of knowledge of these feeding areas from this population, and localised extirpation. For example, if the whales that currently show this site fidelity are removed, then this information will be lost, and thus these whales will not likely be replaced by others from the larger population, resulting in localised extirpation. Indeed, the recognition of such seasonal subpopulations as separate management units is recommended, and common, for baleen whales (e.g. Dizon *et al.*, 1997).

ACKNOWLEDGEMENTS

This work was funded by the Canadian Wildlife Foundation, the Faculty of Graduate Studies and Research at Saint Mary's University, the Pacific Wildlife Foundation through donations from Remote Passages Marine Excursions, Jamie's Whaling Station and Ocean Outfitters in Tofino BC, and a grant from Clayoquot Biosphere Trust. We would like to thank Drs. Barbara Taylor and Phillip Morin for reviewing earlier drafts of this manuscript and providing valuable comments.

Fifth Rangewide Workshop on the Status of North Pacific Gray Whales

IWC

INTERNATIONAL
WHALING COMMISSION

Fifth Rangewide Workshop on the Status of North Pacific Gray Whales[1]

1. INTRODUCTORY ITEMS

1.1 Convenors' opening remarks

The Workshop was held at the Granite Canyon Laboratory (Big Sur, California) of the Southwest Fisheries Science Center from 28-31 March 2018. The list of participants is given as Annex A. Brownell welcomed the participants and explained the history of the facility, which has been used for almost five decades to census gray whales during their southbound migration. Donovan and Punt (co-convenors) noted that the primary tasks of the workshop were to review the results of the modelling work identified at the Fourth Workshop and SC67a, to examine the new proposed Makah Management Plan (submitted by the USA on gray whaling off Washington state and to update as possible (and develop a workplan for) updating the scientific components of the Conservation Management Plan (CMP) for western gray whales.

1.2 Election of Chair

Donovan and Punt were elected Chairs (Donovan chaired from the 28-30 March and Punt on 31 March).

1.3 Appointment of rapporteurs

Calambokidis, Cooke, Lang, Punt, Reeves, Scordino and Weller served as rapporteurs.

1.4 Adoption of Agenda

The Adopted agenda is given as Annex B.

1.5 Documents and data available

The documents available to the meeting are listed in Annex C. Annex D summarizes the terminology used to designate breeding stocks and feeding aggregations.

2. PROGRESS ON 'NON-MODELLING' RECOMMENDATIONS AND NEW DATA

2.1 Updated information from co-operative genetics studies

Bickham presented the results of a multi-authored study of SNPs using samples from approximately 50 whales feeding off Sakhalin Island ('western' gray whales) and approximately 100 whales from the Mexican wintering grounds (assumed 'eastern' gray whales); the full study was to be presented at SC67a. The methods used are described in DeWoody *et al.* (2017). Bickham stated that a finished version of the paper will be presented at the 2018 IWC SC meeting. The authors believe that the results will have implications for prioritising the various stock structure hypotheses being modelled in the Rangewide Review (see below).

Multiple duplicate biopsies were found within both the Sakhalin and Mexico sample sets, but none were shared between the two localities. SNP genotypes were also presented for two mitochondrial and two sex-linked loci (Zfx and Zfy). One of the sex-linked SNPs (ZFY_342) had an apparent fixed heterozygosity in the Mexican whales and thus only the second locus could be used for determining the sex of the whales. The Workshop noted that whilst there is no single explanation of this, one possibility is that there was a translocation (duplication) of the Y-linked SNP to the X or to an autosome.

Bickham also presented the results of the STRUCTURE analyses for the SNPs. In the cases with locality as a prior and without locality as a prior, $K = 2$ genomes (or populations) was the best solution; the plot with geography as a prior showed better differentiation with one predominating in the east (Mexico) and the other predominated in the west (Sakhalin). All eastern samples showed admixed ancestry (including some with predominantly the "western" genome) but the western samples showed a much higher proportion of admixture including individuals of nearly 'pure' eastern and western genomes. He also presented results for an analytical approach called Landscape and Ecological Associations (LEA)[2]. The LEA analysis also identified K = 2 genomes but with greater separation. In the Sakhalin sample set the western genome still predominated but there were both individuals with pure western and others with pure eastern genomes as well as admixed individuals. The more equal proportions

---

[1] Not all attendees have had a chance to comment on this final version although much of the report was agreed at the Workshop itself.

[2] http://membres-timc.imag.fr/Olivier.Francois/LEA/tutorial.htm

of western and eastern genomes in the Sakhalin samples was consistent with an Mxy estimate of genetic similarity (the Sakhalin sample set had a notably higher variance for genetic relatedness between paired samples than was observed in the Mexican sample set).

The authors of the working paper concluded that the Sakhalin population might be comprised of two types of individuals representing two breeding stocks (i.e., two different genomes), along with individuals of mixed ancestry (admixture). The proportions of the two genomes are vastly different in the two sample sets.

The Workshop **agreed** that incorporating photo-id data into the genetic results will greatly improve interpretation of stock structure and movements and **recommended** that the genetic dataset should be examined comparing whales seen only once off Sakhalin with those whales seen in multiple years.

Lang gave a brief update of her work on SNPs, using the next-generation sequencing approach ddRAD. She is analysing approximately 200 gray whales representing approximately equal sample sizes of PCFG (Pacific Coast Feeding Group), western gray whales, and Northern Feeding Group whales. She expects to present the results of at the 2019 gray whale *Implementation Review.*

The Workshop **welcomed** news from Bickham that a request to the government of Japan to obtain gray whale samples for genetics studies (including of the possible extant western breeding stock).

It was noted that the extent of mixing of gray whales in the past had probably fluctuated in response to changes in sea ice (glacial versus interglacial periods). Bickham responded that additional genome sequencing was planned and that the reconstruction of the historical demography of western and eastern gray whales is one goal of that study. Analyses may reveal associations with the climate cycles of the Pleistocene.

2.2 Updated information from photo-identification studies including consolidation of WGW catalogues

SC/MP/CMP/02 reviewed the results of long-term photo-identification studies conducted between 2002-2017 off northeast Sakhalin Island by the Joint Monitoring Program of two oil and gas companies[3]. The photo-identification catalogue resulting from this work contains 283 identified individual gray whales, including: (a) 175 whales that use the Sakhalin Island feeding area on a regular annual, (b) 27 occasionally-sighted whales (recorded at intervals greater than 3 years), and (c) 71 individuals that have been recorded only once. Forty-eight of the one-time visitors were recorded as calves, excluding the nine calves first identified in 2017. There are 29 identified mothers and 127 whales first identified as calves in the catalogue. Six mother-calf pairs were identified in 2017, along with three unpaired calves. Whale no. KOGW127 (aka “Agent”), was identified as a calf in 2005 and was first recorded as a mother in 2017 at the age of 12 years. Agent was satellite tagged in 2011 and her winter migration was tracked to the Gulf of Alaska before the transponder stopped working (Mate et al., 2015).

Drone-based photography was incorporated into the joint-programme field program in 2017. In most cases, the drone was used at an average distance of about 800 m from shore with a standard altitude of 8 meters. The range of the drone presently in use is 2.5 km from the shore. With the collection of aerial photographs from drones, a new body aspect (“back”) was added to the photo-identification catalogue. Also, a new supplemental catalogue of drone-collected video was created for 35 individuals.

The catalogues of the ENL-SEIC joint programme and the Russian Gray Whale Programme (previously the Russia-US programme) were last cross-matched using data available through 2011. At that time, the two Sakhalin photo-identification catalogues contained a total of 222 whales, of which 186 were common to both. Seventeen whales were found only in the Russian Gray Whale Programme catalogue and 19 only in the ENL-SEIC catalogue (IUCN, 2013). An updated catalogue comparison, under the auspices of the IWC, is being discussed as is the concept of a common shared catalogue and database.

In discussion, the Workshop **agreed** on the importance of the long-term nature of the research programmes being conducted off Sakhalin. The concept of a common catalogue and database was welcomed and several measures to ensure data compatibility were mentioned, including the important step to standardize reporting of effort and protocols used to designate calves versus yearlings. It was further mentioned that sighting histories of whales photo-identified off Kamchatka should be evaluated to determine patterns of annual occurrence. Finally, the availability of a shared catalogue and regular updating of such was highlighted with respect to the research component of the hunt management plan proposed for the Makah hunt.

2.3 Gray whales off Korea

SC/M18/CMP/04 reported the possible occurrence of a gray whale off Korea in 2015. Video footage of what appears to be a gray whale was uploaded on YouTube in 2015[4]. The whale was swimming near a port facility in

---

[3] Exxon Neftegas Limited (ENL) and Sakhalin Energy Investment Company (SEIC)

[4] https://www.youtube.com/watch?v=dJ4J7luGgcE

Samcheok, on the east coast of Korea. While the poor quality of the video prevented positive identification to species, some features of the whale suggest that it was a gray whale. Additional information is being sought to confirm the species identification. If this sighting was indeed of a gray whale, it would be the first record from Korea since 1977. The Workshop thanked D. Yasutaka Imai for alerting Kim to the existence of this video.

3. UPDATING SCIENTIFIC ASPECTS OF THE CMP

Donovan reported recent progress on the "Rangewide Review of the Status of North Pacific Gray Whales" and the 'Western Gray Whale Conservation Management Plan' (CMP). Since 2004, the IUCN and IWC have emphasized the need for a comprehensive international CMP to mitigate anthropogenic threats facing gray whales throughout their range in the western North Pacific. This CMP was initiated at an IUCN-convened international workshop in Tokyo in summer 2008 (IUCN 2009). A draft of the CMP was completed in 2010 (Brownell *et al.* 2010) and this was endorsed by both the IWC and IUCN. The first successes of the CMP included completion of a telemetry project conducted off Sakhalin and a Pacific-wide photo-identification catalogue comparison. The results of these projects showed that some of the whales sighted off Sakhalin in the summer migrate east, across the Pacific, reaching portions of the North American coast between British Columbia, Canada and the wintering lagoons off Baja California, Mexico. In light of this new information, the IWC has been engaged in the present rangewide review.

In support of the CMP initiative, in 2014 a 'Memorandum of Cooperation Concerning Conservation Measures for the Western Gray Whale Population' (the MoC), was signed by Japan, Russian Federation and the USA. In 2016, the memorandum was signed by Mexico and the Republic of Korea and Prof. Hidehiro Kato of the Tokyo University of Marine Science and Technology was appointed as coordinator of the memorandum. It is hoped that in time the other remaining range states will also sign the memorandum.

3.1 Review of existing sections

The Workshop noted that the work to complete the computing specifications, especially taking into account the new Makah Management Plan, meant that there was insufficient time to update the CMP sections, also recognising that this could best be completed after the modelling results became available, ideally at SC67b. Attention was drawn to the updated seasonal maps[5] and participants were asked to send any comments or suggestion for modification to Donovan and Reeves.

The Workshop **recommended** that the Scientific Committee considers establishing a small drafting group comprised of at least the national co-ordinators of the MoC, Reeves (IUCN) and Donovan be convened to meet intersessionally (e.g. at IUCN headquarters) to provide an updated version of the plan after SC67b.

3.2 Consideration of future stakeholder workshop

An important component of the CMP effort is the need for a stakeholder workshop (tentatively forecast to occur in 2019) that helps to finalize the CMP and develops a strategy for its implementation (IWC, 2017b). The workshop, which would be co-sponsored by IWC, IUCN and the signatories to the Memorandum of Cooperation, should be broad-based and include representatives of national and local governments, industry (e.g. oil and gas, fishing, shipping and tourism), IGOs and NGOs. Objectives of this meeting should include: (1) review and updating of the CMP taking into account any new scientific results from the rangewide workshops, (2) establish a stakeholder Steering Group to monitor CMP implementation, (3) arrange for a coordinator of the CMP and (4) establish a work plan and consider funding mechanisms to implement the actions of the plan. The IWC has a Voluntary Fund for Conservation, to which donations can be specifically directed towards the gray whale CMP and related work. It is expected, however, that after the first year of CMP implementation, range states will contribute the necessary funds to advance the conservation actions listed in the plan. The Workshop welcomed the support offered by IUCN with respect to organising the stakeholder workshop.

4 UPDATE ON MODELLING FRAMEWORK AND RUNS

4.1 Progress of modelling since SC67a including validation

4.1.1 General progress, including validation

Punt informed the Workshop that code implementing the specifications agreed at the 4th Rangewide Workshop and modified during SC67a had been written and used to condition the reference trials based on stock hypotheses 3a, 3e and 5a, along with the sensitivity tests that implement stock hypotheses 3b and 6b.

---

[5] https://iwc.int/western-gray-whale-cmp

Brandon summarized progress on validating the code implementing the operating model and the conditioning process. SC/M18/CMP/03 provides an update on code validation, including a brief overview of the code and input files, and a list of verification steps taken to date. The main focus of the validation process has been on the FORTRAN procedures necessary for the conditioning phase. Conditioning the operating model is the first and most computationally expensive phase of the Rangewide modelling effort because this code involves the bulk of calls to numerical methods to estimate parameters given model fits to the data. To this end, the conditioning code has been checked against the mathematical and statistical model specifications, to ensure that the procedures as implemented are consistent with the specifications (see Annex D for the specifications of the Rangewide model). Likewise, diagnostic output from the code has been checked against expected values. No errors in the coding were identified.

4.1.2 Modelling related to the proposed Makah management plan

Punt informed the Workshop that code implementing the Makah Management Plan (Annex X) had been developed and initial results presented to the March 2018 AWMP meeting. However, Brandon has yet to validate this code. The code implementing the Makah Management Plan needs to be validated prior to SC67b.

During the Workshop, the Makah Management Plan was clarified/updated as shown below.

(1) It was clarified that the hunt will be stopped if the PCFG 10-yr strike limit less number of PCFG-designated animals drops below 1 or if the PCFG 10-yr female strike limit less number of PCFG-designated females drops below 1. The initial implementation only stopped the hunt only when these differences were less or equal to zero.
(2) It was agreed to incorporate an ‘unknown identity’ component for landed whales because it may not be possible to obtain a useable photograph of landed as well as struck and lost whales (although at a lower probability).
(3) It was agreed to allowing for the fact that the amount that unidentified whales count towards the PCFG 10-year strike limit will be updated based on available data rather than always being assumed to be 0.4. The error associated with the estimate of the proportion of PCFG whales in even-year hunts needs to be accounted for (see Item 4.4.1).

4.2 Review of stock hypotheses

The Workshop reviewed how the three baseline stock hypotheses (3a, 3e and 5a) and the two stock hypotheses considered as tests of sensitivity (3b and 6b) had been implemented, noting that some of the ‘limited’ movements (light arrows in Annex E) had been omitted from the baseline hypotheses, but would be considered in tests of sensitivity (e.g. the PCFG in sub-area BSCS). The omission of the associated links was due to lack of mixing data to allow the links to be modelled. It was also noted that that there are no data (abundance estimates, mixing proportions, catches) for some of the sub-area (e.g. the OS sub-area), which implies that the results will be identical no matter how such regions are treated in the modelling.

The Workshop noted that the current implementation of hypothesis 5a did not include the WBS in the SKNK sub-area. This is because there was currently no basis to specify a mixing proportion for WBS vs WFG animals in the sub-area. Cooke provided abundance estimates by breeding stock / feeding group (see Item 4.3.1), which means that it is no longer necessary to specify mixing proportions for the SKNK sub-area.

The Workshop **agreed** that stock hypotheses 3a and 5a would form the references for the analyses as they appear to be most plausible, while trials would also be conducted for stock hypotheses 3b, 3c, 3e and 6b. Annex E shows the final stock hypotheses considered in the trials graphically, while Annex D, Table 2 shows the resulting mixing matrices. The γ values in Annex D, Table 2 indicate parameters that are estimated during the model fitting process.

4.2.1 Plausibility of stock hypothesis 6b

SC/M18/CMP/01 aimed to reopen discussion on the plausibility of the stock hypotheses previously considered as high priority for modelling, with special emphasis on stock hypothesis 6b. Stock hypothesis 6b assumes that the WBS has no fidelity to wintering ground and uses both wintering grounds in both Asia and Mexico. SC/M18/CMP/01 argued that this hypothesis was elevated to high priority due to discussions regarding the movements of humpback whales and the social aggregating hypothesis of Clapham and Zerbini (2015). This hypothesis involves humpback whales learning of new wintering grounds, likely through hearing other humpback whales, and temporarily immigrating. SC/M18/CMP/01 argued that this hypothesis does not apply well to gray whales because they are much quieter than humpback whales and there is a large distance between the distribution of WBS and eastern breeding stock whales (as portrayed by hypothesis 6b) preventing communication between whales. Furthermore, humpback whales and gray whales have very different breeding behaviour, with humpback whales aggregating on modified leks (Clapham and Zerbini 2015). There does not appear to be a functional benefit for WGW to justify shifting their migration to go to wintering grounds in Mexico instead of Asia given the extra 4,000 km of travel required (Villegas-Amtmann *et al*., 2015). Furthermore, it does not appear likely that the WBS used both wintering grounds without fidelity prior to commercial whaling given that whaling occurred off Japan and Korea during a period when the whales using the Mexican wintering grounds were depleted. Bickham et al. (2013) has also presented arguments based on genetics on why hypothesis 6b has low plausibility. SC/M18/CMP/01 also suggested that hypothesis 3e has low plausibility because it assumes that WBS whales occur in their historical feeding range but do not use the Piltun Lagoon area of Sakhalin Island, which has proved to be an important feeding area since the mid-1980s. It is more likely that if the WBS exists, that this breeding stock would spend at least some time feeding near Piltun Lagoon. SC/M18/CMP/01 concluded the trials based on stock hypotheses other than 3a and 5a should be sensitivity tests.

In discussion, it was noted that gray whales that feed off Sakhalin and traditionally used wintering grounds in the western North Pacific could be driven to occasionally use migratory routes and wintering areas in the Eastern North Pacific. While the Rangewide model does not explicitly account for breeding so does not incorporate information on when or where whales breed, this hypothesis could provide an explanation for the observations of Sakhalin whales in the eastern North Pacific. There is evidence showing that whales from the same feeding groups migrate together; both Sakhalin and PCFG whales have been photographically identified in the same groups and in localized areas while on migratory routes (Weller et al. 2012, Calambokidis and Perez 2017). This could provide a mechanism by which whales that feed together, but have traditionally used different wintering areas, could learn new migratory routes.

Although the possibility that gray whales use multiple wintering grounds could not be ruled out, the Workshop **agreed** that stock hypotheses 6b would be considered as a sensitivity test. It was also **agreed** that stock hypothesis 3e would be considered a sensitivity test.

4.3 Confirm final data sets

4.3.1 Removals (direct and incidental)

IWC (2018) referenced records of gray whale deaths from entanglement/entrapment, ship strike, and unknown causes in Japan from 1982 until the present (Nakamura *et al.*, 2017). A small group (Scordino, Reeves, Brownell) met to confirm and update what had been stated previously on removals in Japan (and elsewhere), recalling that the adult that ‘died off Hokkaido in 1996’ was killed deliberately (Brownell, 1999).

The Workshop **endorsed** the conclusions of the small group as summarised below.

(1) Of the six gray whales reported as beached in Japan between 1990 and 2016 but with cause of death undetermined, some proportion should be assumed to have died from either entanglement/entrapment or ship strike. The under-reporting factor (usually x4 but with sensitivities of x10 and x20; Annex D, tables 8 and 9) used in the model to convert observed mortality to true mortality in the case of bycatch and ship strike would account for this.

(2) There was no reason to believe there had been any change in fishing effort (e.g. set net fishing) in Japan between 1930 and 1982. Therefore, the removal rate from 1982 to the present should be extended back to 1930 for modelling purposes.

(3) Finally, with respect to commercial set gillnet fishing in California prior to 1981, as noted last year (IWC, 2018), a seabass fishery operated in northern Mexico and southern California prior to the 1980s (e.g. landing 412,000 pounds of black seabass and 873,000 pounds of white seabass in 1953; Marine Fisheries Branch, 1956). In fact, this fishery was active and overall fishing effort ‘fairly constant’ from before 1930 until the early 1980s (Vojkovich and Reed, 1983). There was no observer effort in this fishery before 1981, nor was an official stranding record of cetaceans maintained in California before that time. However, a coordinated reporting system for stranding was established in the early 1960s under the auspices of the American Society of Mammalogists, and stranded gray whales were regularly reported. For example, 24 dead gray whales were reported as stranded in California between 1960 and 1968, of which seven were confirmed or suspected of having been either entangled in fishing gear or struck by a ship; Brownell, 1971). A gray whale that stranded at Ocean Beach, California, on 19 February 1953 was missing its flukes and bore ‘several gashes’ on the body – all suggestive of an entanglement death (Robert Orr, pers. comm. to R. Brownell, April 1964).

At last year’s workshop, it was assumed that set gillnet fishing effort for halibut in California declined linearly from 1982 to no effort in 1975. To model the effect of this assumption, it was decided to assign all records of gray whales recorded as injured or killed in halibut or other set gillnet fisheries to a single fishery and modelled separately from all other California fisheries. It was also decided to examine both a low case that assigned no deaths to set gillnet fisheries and a high case that considered all bycatch reports related to gillnet, set gillnet, net, and halibut fisheries in California as if they came from a single fishery (IWC, 2018). A recently found publication (Bureau of Commercial Fisheries, 1936) reported that both set gillnets and trammel nets were used in the 1930s in California for halibut and white seabass fishing. Based on this new information, the Workshop **agreed** to drop the assumption that fishing effort declined linearly to zero from 1982 to 1975 and therefore there was no reason to evaluate high and low scenarios as a way of accounting for bycatch in California prior to 1975.

Set gillnetting effort off California changed markedly in 1991 due to regulations passed in November 1990 intended to eliminate gillnet fishing within 3 n.miles of the mainland and within 1 n.mile of any offshore island in southern California by 1994 (Barlow *et al.*, 1994). To address this, a second set gillnet fishery was added to the model starting in 1991 and the set gillnet fishery described in the preceding paragraph was modelled as having ended in 1990.

Table 1

Abundance estimates (1+) for the WFG feeding aggregation and the western breeding stock

Year	Group	Hypothesis	Estimate	SD	CV
1995	WFG	3a/3c/3e/6b	75.1	3.8	0.051
1995	WBS	3b	25.8	7.3	0.282
1995	WFG	3b	75.5	3.3	0.043
1995	WBS	3e	30.0*	15.0	0.500
1995	WBS	5a	26.6	6.9	0.259
1995	WFG	5a	47.8	7.7	0.160
1995	WBS+WFG	5a	74.4	3.9	0.052
1995	WBS/(WBS+WFG)	5a	0.358	0.093	0.259
2015	WFG	3a/3c/3e/6b	199.8	5.4	0.027
2015	WBS	3b	63.8	15.8	0.248
2015	WFG	3b	198.9	5.7	0.029
2015	WBS	3e	30.0*	15.0	0.500
2015	WBS	5a	64.4	14.0	0.218
2015	WFG	5a	135.6	14.1	0.104
2015	WBS+WFG	5a	200.0	5.7	0.029
2015	WBS/(WBS+WFG)	5a	0.322	0.069	0.200

* Guestimate because the WBS cannot be distinguished given the available information.

4.3.2 Abundance estimates

There were no updates to the estimates of abundance for the PCFG or the ENP stock. New abundance estimates for western gray whales had been presented to the last WGWAP meeting (Cooke *et al*., 2017), which will also be presented to the SC67b. Estimates for the WFG were extracted at the Workshop that would correspond to the stock structure hypotheses listed in Annex E (table 1). The larger estimates for the WFG correspond to the hypothesis that all whales visiting SE Kamchatka and/or Sakhalin belong to the WFG, while the smaller ones correspond with the hypothesis that only whales that visit Sakhalin belong to the WFG (regardless of whether these individuals also visit Kamchatka).

For the hypotheses where a proportion of the WFG belongs to the western breeding stock (WBS), this proportion is highly uncertain (and could be zero) even though the estimate for the total WFG is reasonably precise. The estimates of the numbers of WFG animals in each of the two breeding stocks are, therefore, highly negatively correlated. In these cases, the multi-stock model uses as inputs the estimate of the total WFG and the estimated proportion of this that belongs to the WBS.

Table 2

Mixing proportions for use in the trials

Sub-area	Season	Stock / Feeding aggregation	Mixing proportion
EJPJ	All	WBS/NFG	0.33
SEA	Feeding	PCFG	0.57[1]
SEA	Migration	PCFG	0.1[2]
SEA	Migration	WGW	0.002[3]
BCNC	Feeding	PCFG	0.93
BCNC	Feeding	WGW	0
BCNC	Migration	PCFG	0.28
BCNC	Migration	WGW	0.002
CA	Feeding	PCFG	0.60
CA	Feeding	WGW	0
CA	Migration	PCFG	0.1
CA	Migration	WGW	0.002[3]

1: Not used in the conditioning as no bycatch is recorded for the SEA sub-area during the feeding season.

2: Assumed value owing to lack of data to estimate mixing proportions.

3: Set to the value calculated for BCNC by Moore and Weller 2013)

4.3.3 Mixing proportions

Table 2 lists the updated mixing proportions. The mixing proportion for the EJPJ sub-area is unchanged from that specified at the 4th Rangewide Workshop because none of whales encountered recently in this sub-area had adequate photographs to allow for matching (Table 3).

Table 3

Updated information on matches between whales encountered off Japan and those photographed off Sakhalin (D. Weller, SWFSC).

Date	Location and source	Conclusion
April 2016	Shizuoka, beached	no useable photos/no match
February 2017	Kanagawa, sighting	poor quality video only/no match
April 2017	Chiba, sighting	poor quality video only/no match
March 2017	Aogashima, sighting	no useable photos/no match
February 2018	Aogashima, sighting	no useable photos/no match

New mixing proportions were calculated for PCFG whales by sub-area for the winter/spring (migrating) and summer/fall (feeding) seasons (Table 4). The sub-regions of the BCNC region used for the analysis were northern Oregon, southern Washington, and northern Washington because they were thought to have the least chance of bias in calculated mixing proportions. Updated data through 2015 based on matches to the PCFG catalogue were used. There was considerable discussion about how to calculate the mixing rate for the Oregon-Washington outer coast area due to a dramatic change in proportion of PCFG whales in northern Washington from surveys in early April 2015. Those surveys identified a large number of whales in a previously poorly sampled area that had very few PCFG whales. Identifications in spring 2015 (heavily influenced by these April surveys) reduced the overall proportion of PCFG whales based on pooled proportions through 2015 to 24% (it had been 36% based on data through 2014). To provide a value less influenced by these two days of surveys, the proportions of PCFG whales were averaged over sub-region and month to compute an overall average of 28% (an average of the eight values presented in Table 4.

Table 4

Proportion of PCFG whales by region and month for cells with >10 IDs; complete through 2015 for OR-WA Jan to May (no Dec data)

Region	Jan	Feb	Mar	April	May
NWA	0.09		0.09	0.10	0.41
SWA			0.38	0.21	0.33
NOR					0.63

Mean of above cells for OR to WA: **Unweighted = 28%**, Pooled = 24%
Mean of above for just N WA: Unweighted = 17%, Pooled = 20%

The Workshop **agreed to** adopt 28% for the proportion of PCFG whales in the BCNC sub-area during the migrating season for the bulk of the trials, and that sensitivity would be evaluated to 17%. This value is obtained by restricting the analysis of mixing rates of PCFG whales during the winter/spring to just northern Washington where the hunt would occur (based on the unweighted average of the 4 months where there were at least 10 photo-IDs, table 4). Pooling all 622 photo-IDs for December to May would result in a rate of 20%, although this approach weights values towards periods with more photo-IDs.

Considering some of the uncertainty around the estimate for the portion of PCFG whales present in the spring off the Washington-Oregon coast and the variation by location, month, and year, the Workshop **agreed** the current best estimate of 28% to be +-20% (8-48%) for the true PCFG mixing rate. The rationale for the choice is that very different results would be obtained in different areas such as 1) the recently sampled zone north of Tatoosh Island in the early spring where migrating whales appear to gather in some years where recent efforts revealed almost no PCFG whales, compared to 2) areas along the Northern Washington Coast or for example in Barkley Sound that are feeding areas for PCFG whales and where their proportion compared to migrating whales would be highest.

4.4. Confirm final trial structure and conditioning

4.4.1 Changes to the trials specifications, including stock structure

Annex D lists the specifications for the model that will form the basis for drawing final conclusions regarding the implications of alternative stock structure hypotheses and of the implementation of the Makah management plan. The specifications (see also Annex D and Table 5 and 6) reflect changes to how the stock hypotheses are implemented as well as how the abundance estimates for the western Pacific are used in conditioning. The Workshop also agreed that the following additional changes will be made the trials specifications:

(1) the base-case survival rate for animals aged 1 and older would be assumed to be 0.98, which reflects the estimates obtained by Cooke (ref) and Punt and Wade (2012); the values used in previous trials was 0.95;

(2) the SET1 and SET2 fleets (set gillnets off California in the feeding and migration seasons) would be split between 1990 and 1991 given the changes in regulations in the associated fisheries that appear to have changed bycatch rates;
(3) the survey plan for the California counts were updated to reflect the current plan (two surveys in every five-year block); and
(4) the periods used to calculate average bycatch rates to infer bycatch prior to the establish of monitoring networks into the future as generally but the earliest and most recent five years, but a longer period is specification for sub-areas (e.g. EJPJ and SI) with limited data (Annex D, table 3)

Evaluation of the Makah Management Plan requires specification of the probability of photographing a landed or struck and lost whale, as well as the probability of correctly deciding that such a whale is from the PCFG or the WFG. In addition, it is necessary to specify the probability of striking and losing a whale and assigning a sex to an animal for which a match has been made. These probabilities are specified as follows:

(1) *Probability of obtaining a photograph of sufficient quality to allow it to be matched to the catalogue*. For struck and lost whales, this probability is estimated to be a 0.6 for winter/spring and 0.8 for summer/fall (due less favourable light and weather in winter/spring compared to summer/fall). For landed whales, it is estimated to be 0.9 for all seasons.
(2) *Probability of struck and lost*. The review of the Makah whale *SLA* concluded in 2013 was based on a value for this probability of 0.5, which was informed by two strikes that occurred during the Makah 1999 hunt in which one strike resulted in a landing and the other contacted the whale but did not penetrate the skin. The Workshop agreed to retain the assumption of a 50% struck and lost rate for hunts during the winter and spring. It was decided that hunts occurring during the summer and fall were much less likely to have struck and lost due to better weather conditions and more predictive movement behaviours of whales in the normal feeding depths of PCFG whales. The Workshop therefore agreed that the struck and lost rate for summer and fall hunts would be 0.1 and that sensitivity would be explored to a value of 0.5.
(3) *False positive rate for PCFG (i.e. probability of a non-PCFG being identified as from the PCFG given a good quality photograph*). The probability that a non-PCFG whale might be falsely identified as a PCFG whale is estimated to be 0.05. Normally, there is a near 100% confidence for matches that are identified to Cascadia's PCFG catalogue because these are double checked and photographs of poorer quality where there is some ambiguity are treated as Poor Quality and not used. The value of 0.05 is based on the assumption that a slightly different set of circumstances would exist for comparison of a whale struck or landed because there would be pressure to try to match regardless of the quality of the photograph and it would be hard to justify not reporting as a match something where there was a relatively high degree of confidence (i.e. 95% confident of the match to a PCFG whale).
(4) *False negative rate for PCFG* (i.e. *i.e. probability of a PCFG whale not being identified as such given a good quality photograph*). This probability is estimated to be 0.25 for a hunt in the winter/spring, and zero for a hunt in summer since all struck whales are assumed to be of the PCFG. This value of 0.25 accounts for several factors, including whales only seen in fewer in two years in the PCFG because of a combination of being young, not being photographed, and the one year lag in available catalogue. In addition, there could be a matcher error in missing a match due to things like changed markings.
(5) *False positive rate for WFG (i.e. probability of a non-WFG being identified as from the WFG given a good quality photograph*). This probability is estimated to be 0.01 based on the WFG catalogue being smaller and more well-known. Also, it is suspected that the matcher would likely only declare a match when there was a high level of confidence given the infrequent rate of these matches.
(6) *False negative rate for WFG* (i.e. *i.e. probability of a WFG whale not being identified as such given a good quality photograph*). On the assumption that calves and lactating mothers will not be hunted, the proportion of huntable WFG whales that would not be known as WFG whales if taken during the spring northward migration was estimated using the population model fit to the Sakhalin and Kamchatka photo-id data. An animal that has been seen off Sakhalin is assumed to be a WFG animal if seen or taken in the eastern North Pacific. An animal seen off eastern Kamchatka but not Sakhalin is not assumed to be a WFG animal, because it might be an NFG animal. The estimated proportion, averaged across the posterior distribution of the population trajectory, was 4-5% depending on the hypothesis. These estimates used data through 2011 only, that being the last season for which the catalogues were cross-matched. If only a single catalogue were used, the rate would be higher. The values used in the trials are: stock hypotheses 3a, 3c, 3e, and 6b: 0.041; stock hypothesis 3b: 0.040; stock hypothesis 5a: 0.049.
(7) *Probability of not assigning a sex to a struck and lost animal that has been identified to the PCFG.*
    a. This probability is estimated at 19% for the feeding season based on 81% of encounters of PCFG whales from June-Nov through 2015 for the Oregon and Washington outer coast having known sex. For those with known sex in this sample 58% were female and 42% male, but this could be

biased by some directed sampling toward females so the sex ratio should be treated as 50:50 in the management plan.

b. This probability is estimated at 27% for the migrating season based on 73% of encounters of PCFG whales from Dec-May through 2015 for the Oregon and Washington outer coast having known sex. For those with known sex in this sample 46% were female and 54% were male. This male-biased sex ratio is in the opposite direction of the bias from intentionally sampling females, which suggests males are actually more abundant and available in the spring off the Oregon and Washington outer coast likely as a result of females with calves migrating later and being less available in spring. Given the bias for trying to sample known females, it is likely that the sex ratio in spring is likely closer to 60:40 male:female. If hunters avoid taking mothers with calves it would further reduce the chances of taking a female.

Estimates of the proportion of PCFG whales used in the Makah management plan for assigning a struck unidentified whale in the winter/spring hunt are subject to uncertainty due to for example shifting proportions based on sampling differences and these should be considered subject to a bias (which depends on trials) that ranges from -0.1 to 0.1.

Table 5

Factors considered in the model scenarios. The bold values are the base-levels and the values in standard font form the basis for sensitivity analyses.

Factor	Levels
Model fitting related	
Stock hypothesis	**3a,** 3b, 3c, 3e, **5a,** 6b
MSYR_{1+} (western)	As for WFG
MSYR_{1+} (north)	**4.5%**, 5.5%, Estimated (common); estimate (separately)
MSYR_{1+} (WFG)	**4.5%** Estimated (common); estimate (separately)
MSYR_{1+} (PCFG)	2%, **4.5%**, 5.5%, Estimated (common); estimate (separately)
Mixing rate (migration season in BCBC	**0.28**, 0.17, 1.00
Immigration into the PCFG	0, 1, **2**, 4
Bycatches and ship strikes	Numbers dead + M/SI, **dead x 4**; dead x 10; dead x 20
Pulse migrations into the PCFG	10, **20**, 30
Projection-related	
Additional catch off Sakhalin (mature female)	0, 1
Catastrophic events	**None**, once in years 0 – 49, and once in years 50-99
Northern need in final year (from 150 in 2014)	**340**
Struck and lost rate	**(0.1; odd-years; 0.5 even years),** 0.5 all years
Future effort	**Constant**, Increase by 100% over 100 years
Probability of a photo (struck and lost whales)	**0.8; odd-years; 0.6 even years**
Probability of a photo (landed whales)	**0.9**
Probability of false positive rate PCFG	**0.05**, 0.1
Probability of false negative rate PCFG	**0.25**
Probability of false positive rate WFG	**0.01**
Probability of false negative rate WFG	**0.041 (stock hypotheses 3a, 3c, 3e, 6b);** 0.040 (stock hypothesis 3b); **0.049 (stock hypothesis 5a)**
Probability of a sex assignment given a PCFG match	**0.81**

4.4.2 Base-case trials and sensitivity tests

The 4th Rangewide workshop specified a series of trials. However, it had not been possible to implement all of these trials during the intersessional period. The Workshop reviewed the set of trials and made the following changes (trial numbers relate to revised numbering system):

(1) stock hypothesis 3e is now treated as a sensitivity test as it is a variant of stock hypothesis 5a (with no WBS animals in the SI sub-area);

(2) a new sensitivity test (18C) based on stock hypothesis 3c has been added as agreed at the 4th Rangewide workshop (IWC, 2018);

(3) the sensitivity test exploring a higher proportion of WBS whales in sub-area SI (3B) involves increasing the estimates of abundance for the WBS by 50% and correspondingly reducing the estimates of abundance for the WFG;

(4) the trials involving PCFG whales in the BSCS sub-area (12A/B) are based on assuming that all PCFG whales are in the BSCS sub-area. The assumption will be conservative given that most PCFG whales are located elsewhere when the aboriginal hunt off Chukotka occurs;

(5) the trials involving WFG whales in the BSCS sub-area (13A/B) are based on assuming that all WFG whales are in the BSCS sub-area. The assumption will be conservative given that most WFG whales are located elsewhere when the aboriginal hunt off Chukotka occurs;

(6) the trials exploring the sensitivity of how the California set gillnet catches were modelled (trials 14 and 15 in Table 8 of IWC (2018)) were dropped as the approach for modelling the SET1 and SET2 fleets was modified (see Item 4.3.1);

(7) the trials with MSYR estimated and a higher pulse were dropped as these trials are unlikely to be informative (trials 14A/B and 8A/B examine these factors individually);

(8) variants of trials 5A/B and 16A/B (trials 18A/B and 19A/B) that have net immigration of 1 to the PCFG were added because the assumption of zero immigration into the PCFG is unlikely given the results of Lang and Martien (2012);

(9) trials 7A/B and 16A/B exclude the PCFG abundance estimates for 1998-2002 as a low pulse would not allow the model to mimic these data – this change in model specifications mimics the adoption in the trials used to evaluate the *SLA* for a Makah hunt by IWC (2013) of a time-varying survey bias;

(10) trials 22A/B have been added to examine the future consequences of a catastrophic events in the NFG – these events occurs randomly once in the first 50 years and randomly once in the second 50 years, with a magnitude equivalent to that of the mortality event in 1999/2000; and

(11) trials 23A/B and 24A/B have been added to explore sensitivity to the struck and lost rate for a Makah hunt in the feeding season, and the false negative rate for a Makah hunt in summer.

Table 6

Final trial specifications

Trial	Description/stock hypothesis	PCFG or WFG in BSCS	MSYR$_{1+}$			PCFG		Bycatch	Condition?

4.4.3 Conditioning statistics

The Workshop reviewed the diagnostic plots for evaluating the conditioning developed for the trials specified at the 4th Rangewide Workshop. The Workshop **agreed** that the following plots should be produced for each trial and provided to the Intersessional Steering Group for review:

(1) The estimates of absolute abundance (with 90% sampling intervals) and the median, 50% and 90% intervals for the time-trajectory of the model estimates of 1+ population size.
(2) The time-trajectory of the model estimates of the number of mature females.
(3) The distributions (median, 50% and 90% intervals) for the generated mixing proportions and those for the model-predicted mixing proportions.
(4) The distribution for the net immigration rate from the NFG to the PCFG and the target value (black vertical bar).
(5) The estimates of average bycatch over the period for which reporting is considered adequate [Annex D, table 3] (with 90% sampling intervals) and the median, 50% and 90% intervals for the model-estimate of the average bycatch over the period.
(6) The distributions (median, 50% and 90% intervals) for the generated survival rates for PCFG whales and those for the model-predicted survival rates for PCFG whales.
(7) The time-trajectories of removals, including the recorded removals (adjusted for under-reporting) and the bycatch inferred for the years for which reporting is not considered adequate.

4.4.4 Projection scenarios

Previous projections for the Sakhalin population (J. Cooke in Reeves *et al.*, 2005) considered a scenario in which there is future bycatch of 1.5 mature females off Japan based on inferences from bycatch at that time. The Workshop noted that observed bycatch off Japan has declined since then. The Workshop **agreed** that a projection scenario with 1 mature female taken each year in the EJPJ sub-area should to be conducted.

In addition, the Workshop **agreed** that, if possible, projections should be conducted for the current Makah *SLA*, although it was recognised this may not be feasible to achieve before 67b.

The Workshop noted that care needs to be taken to compare the results from the previous *Implementation Review* with those based on the Rangewide review because the population structure hypotheses have changed and the Rangewide review has more fully accounted for bycatch and its uncertainty.

4.4.5 Performance statistics

4.4.5.1 TIME-TRAJECTORIES OF POPULATIONS

The results of the model fits and the projections will be summarized by time-trajectories of 1+ numbers of breeding stock / feeding group and by sub-area

4.4.5.2 MAKAH MANAGEMENT PLAN

The results of the projections to evaluate the performance of the Makah management plan will be based on the standard statistics used by the Committee to evaluate the performance of Strike Limit Algorithms

(1) D1. Final depletion of 1+ and mature female numbers by breeding stock / feeding group (median, lower 5th and upper 5th percentiles)
(2) D8. Rescaled final depletion: P_T/P_0 (1+ and mature female numbers by breeding stock / feeding group; median, lower 5th and upper 5th percentiles) where P_0 is number of 1+ / mature female animals had there been no future Makah hunts.
(3) D10. Relative increase. The ratio of the 1+ and mature population size after 10 and 100 years to that at the start of the projection period by breeding stock / feeding group (median, lower 5th and upper 5th percentiles)
(4) N9. Need satisfaction. The proportion of the total number of requested strikes that were taken over the first 10 years and the entire 100-year period (median, lower 5th and upper 5th percentiles).

Results are provided for both 10 and 100 years for the D10 and N9 statistics because (a) the Makah management plan current only operates for 10 years, and (b) previous evaluations of the performance of management procedures (RMP and AWMP) have considered performance over 100 years. Population-related statistics should be also be provided for the case there is no future Makah hunt (only bycatch and hunting off Chukotka).

5. WORKPLAN

Before / during 67b

(1) Update the code for the operating model (Punt)
(2) Validate any changes to the historical (conditioning) component of the operating model (Brandon)
(3) Conduct conditioning and distribution of conditioning diagnostics to the Steering Group (Punt)
(4) Review of the conditioning results (Steering Group)
(5) Code the revised Makah management plan and the associated testing code (Punt)
(6) Validate the revised Makah management plan and the associated testing code (Brandon)
(7) Conduct the projections and assemble the projection results (Punt)

After 67b

(1) Complete drafting of the CMP.

6. ADOPTION OF REPORT

The co-chairs thanked Brownell and his colleagues for the excellent and historic facilities provided at the laboratory in the beautiful setting of Granite Canyon (complete with gray whales migrating by). The report was adopted by email.

Agenda

1. Introductory items
    - 1.1 Convenor's opening remarks
    - 1.2 Election of Chair
    - 1.3 Appointment of rapporteurs
    - 1.4 Adoption of Agenda
    - 1.5 Documents and data available
2. Progress on 'non-modelling' recommendations and new data
    - 2.1 Updated information from the co-operative genetics studies
    - 2.2 Updated information from photo-identification studies including consolidation of WGW catalogues
    - 2.3 Gray whales off Korea
3. Updating scientific aspects of the CMP
    - 3.1 Review of existing sections
    - 3.2 Consideration of future stakeholder workshop
    - 3.3
4. Update on modelling framework and runs
    - 4.1 Progress on modelling since SC/66b, including validation
        - 4.1.1 General progress, including validation
        - 4.1.2 Modelling related to the proposal Mkah management plan
    - 4.2 Review of stock hypothesis
    - 4.3 Confirm final data sets
        - 4.3.1 Removals (direct and incidental)
        - 4.3.2 Abundance estimates
        - 4.3.3 Mixing proportions
    - 4.4 Confirm final trial structure and conditioning
        - 4.4.1 Changes to the trial specifications, including stock structure
        - 4.4.2 Base-case trials and sensitivity tests
        - 4.4.3 Conditioning statistics
        - 4.4.4 Projection scenarios
        - 4.4.5 Performance statistics
5. Work plan
6. Adoption of Report

Annex D

Terminology Used with Respect to Stock Structure Hypotheses

Breeding stocks. There are up to two extant breeding stocks: Western (WBS) and Eastern (EBS).

*Feeding groups or aggregations**. There are up to three feeding groups or aggregations. There is dispersal between the PCFG and North Feeding Group (NFG), but the Western Feeding Group (WFG) is demographically independent of the other two feeding groups (i.e. there is no permanent movement of animals from the NFG or PCFG to the WFG).

	Feeding groups or aggregations	Abbreviation	Definition (may vary with hypothesis)
1	Western Feeding Group	WFG	Animals that feed regularly (define?) off Sakhalin Island* according to photo-identification data
2	Pacific Coast Feeding Group	PCFG	Animals that feed regularly (define?) in the PCFG area according to photo-identification data
3	North Feeding Group	NFG	Animals found in other feeding areas (and for which there is relatively little information including photo-ID)

* May need revising with regard to Southern Kamchatka animals given Justin's paper.

Sub-areas. The model includes 11 geographical sub-areas that are used to explain the movements of gray whales (breeding stocks and feeding groups) in the North Pacific and two 'latent sub-areas' used to link model predictions to observed indices of abundance.

	Sub-area	Abbreviation
1	Vietnam-South China Sea	VSC
2	Korea and western side of the Sea of Japan	KWJ
3	Eastern side of the Sea of Japan and the Pacific coast of Japan	EJPJ
4	Northeastern Sakhalin Island	SI
5	Southern Kamchatka and Northern Kuril Islands*	SKNK
6	Areas of the Okhotsk Sea not otherwise specified	OS
7	Northern Bering and Chukchi Sea	BSCS
8	Southeast Alaska	SEA
9	British Columbia to Northern California	BCNC
10	California	CA
11	Mexico	M
12	Latent sub-area	Calif-3
13	Latent sub-area	BC-BCA-3

* New at this workshop – replaces the old East Kamchatka and Kuril Islands to recognise the information from telemetry and photo-ID.

Annex E

Specifications of the rangewide model

A. Basic concepts and stock structure

The aim of the projections is to explore the population consequences of various scenarios regarding anthropogenic removals of gray whales, with a view to informing future conservation and management. The model distinguishes 'breeding stocks' and 'feeding aggregations'. Breeding stocks are demographically and genetically independent whereas feeding aggregations may be linked through dispersal of individuals[6], though perhaps at very low rates for some combinations of feeding aggregations. Each breeding stock / feeding aggregation is found in a set of sub-areas, each of which may have catches (commercial, aboriginal or incidental), proportions of breeding stock / feeding aggregation mixing[7] in those sub-areas, observed bycatch rates[8], estimates of survival rates, and indices of relative or absolute abundance. Removals may be specified to sets of months during the year for some sub-areas if the various feeding aggregations are not equally vulnerable to catches throughout the year for those sub-areas. The trials capture uncertainty regarding stock structure and MSYR, as well as uncertainty regarding bycatch and immigration.

The region concerned, the North Pacific, is divided into 11 sub-areas (Fig. 1). The model also includes several 'latent' sub-areas used to link model predictions to observed indices of abundance. These are denoted, WFG, WBS, WST, CA-3 and BCNC-3. There are up to two extant *breeding stocks* (Western and Eastern). The Eastern breeding stock consists of up to three *feeding aggregations* depending on the stock structure hypothesis: Western Feeding Group (WFG), Pacific Coast Feeding Group (PCFG) and North Feeding Group (NFG). There is dispersal between the PCFG and the NFG, but the WFG is demographically independent of the other two feeding aggregations (i.e. there is no *permanent* movement of animals from the NFG or PCFG to the WFG or vice-versa).

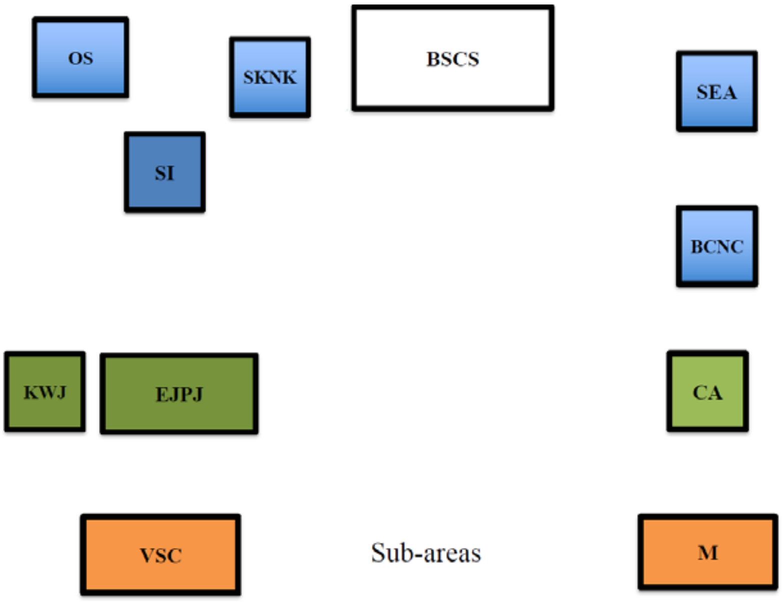

Fig. 1. The sub-areas in the model.

The trials consider five stock structure hypotheses

(1) *Hypothesis 3a.* Although two breeding stocks (Western and Eastern) may once have existed, the Western breeding stock is assumed to have been extirpated. Whales show matrilineal fidelity to feeding grounds, and the Eastern breeding stock includes three feeding aggregations: PCFG, NFG, and WFG.

---

[6] The term 'dispersal' is used here in the sense of 'effective dispersal', and refers to permanent movement of individuals among feeding aggregations. Such individuals become part of the feeding aggregation to which they move and contribute to future reproduction.

[7] Mixing is defined here as two feeding aggregations that overlap at some time on the feeding grounds, but do not exchange individuals.

[8] Bycatch is understood to include mortality or 'serious' injury from entanglement or entrapment in fishing gear (or debris) and ship strikes.

(2) *Hypothesis 3b*. Identical to hypothesis 3a, except that NFG whales do not feed off SKNK. In addition, a Western breeding stock exists that overwinters in VSC and feeds in the OS (but not SI) and SKNK. Thus, SKNK is used by both the WFG whales and the whales of the Western breeding stock.

(3) *Hypothesis 3c*. Identical to 3a, except that on occasion whales migrating between the Sakhalin feeding region and Mexico travel through the BSCS sub-area

(4) *Hypothesis 3e*. Identical to hypothesis 3a, except that the Western breeding stock is extant and feeds off both coasts of Japan and Korea and in the northern Okhotsk Sea west of the Kamchatka Peninsula. All of the whales feeding off Sakhalin overwinter in the eastern North Pacific

(5) *Hypothesis 5a*. Identical to hypothesis 3e except that the whales feeding off Sakhalin include both whales that are part of the extant Western breeding stock and remain in the western North Pacific year-round, and whales that are part of the Eastern breeding stock and migrate between Sakhalin and the eastern North Pacific

(6) *Hypothesis 6b*. This hypothesis assumes that the WFG does not exist, but that whales feeding in the SI sub-area represent an extant Western breeding stock that utilizes two wintering grounds (VSC and M). This hypothesis differs from hypothesis 5a, in that 1) all removals off China and Japan are assumed to be Western breeding stock animals, and 2) the abundance estimates for Sakhalin are assumed to relate only to the Western breeding stock.

B. Basic dynamics

The population dynamics are based on the standard age- and sex-structured model, which has formed the basis for the evaluation of *Strike Limit Algorithms* for eastern North Pacific gray whales, i.e.:

$$\begin{aligned}
N^{m/f,i,j}_{t+1,0} &= 0.5B^{i,j}_{t+1} && a=0 \\
N^{m/f,i,j}_{t+1,a} &= (N^{m/f,i,j}_{t,a-1} + I^{m/f,i,j}_{t,a-1} - C^{m/f,i,j}_{t,a-1})\,S_{a-1}\,\tilde{S}^{i,j}_{t} && 1 \le a \le x-1 \\
N^{m/f,i,j}_{t+1,x} &= ((N^{m/f,i,j}_{t,x} + I^{m/f,i,j}_{t,\mathrm{x}} - C^{m/f,i,j}_{t,x})S_x + (N^{m/f,i,j}_{t,x-1} + I^{m/f,i,j}_{t,\mathrm{x}-1} - C^{m/f,i,j}_{t,x-1})\,S_{x-1})\,\tilde{S}^{i,j}_{t} && a=x
\end{aligned} \tag{B.1}$$

where $N^{m/f,i,f}_{t,a}$ is the number of males / females of age *a* in feeding aggregation *j* of breeding stock *i* at the start of year *t*; $C^{m/f,i,f}_{t,a}$ is the number of anthropogenic removals of males / females of age *a* in feeding aggregation *j* of breeding stock *i* during year *t* (whaling/incidental catches are assumed to take place in a pulse at the start of each year); S_a is the annual survival rate of animals of age *a* in the absence of catastrophic mortality events (assumed to be the same for males and females):

$$S_a = \begin{cases} S_0 & \text{if } a=0 \\ S_{1+} & \text{if } 1<a \end{cases} \tag{B.2}$$

S_0 is the calf survival rate; S_{1+} is the survival rate for animals aged 1 and older; $\tilde{S}^{i,j}_t$ is the amount of catastrophic mortality (represented in the form of a survival rate) for feeding aggregation *j* of breeding stock *i* during year *t* (catastrophic events are assumed to occur at the end of the year after mortality due to anthropogenic removals, whaling and non-catastrophic natural causes and dispersal; in general $\tilde{S}^{i,j}_t=1$, i.e. there is no catastrophic mortality); $B^{i,j}_{t+1}$ is the number of births to feeding aggregation *j* of breeding stock *i* during year *t*; $I^{s,m/f}_{t,a}$ is the net dispersal of female/male animals of age *a* into feeding aggregation *j* of breeding stock *i* during year *t*; and *x* is the maximum (lumped) age-class (all animals in this and the *x*-1 class are assumed to be recruited and to have reached the age of first parturition). *x* is taken to be 15.

C. Births and density-dependence

Density-dependence is assumed to be a function of numbers of animals aged 1 and older by feeding ground relative to the carrying capacity by feeding ground. The density-dependence component for feeding aggregation *j* of breeding stock *i* is the sum of the density-dependence components by feeding aggregation weighted by the proportion of animals from feeding aggregation *j* of breeding stock *i* that are found on each feeding ground, i.e.:

$$F(i,j,t) = \sum_A \psi^{A,i,j}\left(X^{A,i,j}(N^{1+,A}_t / K^{1+,A})^z\right) / \sum_A \psi^{A,i,j} X^{A,i,j} \tag{C.1}$$

where z is the degree of compensation; $\psi^{A,i,j}$ indicates whether sub-area A impacts density-dependence for feeding aggregation j of breeding stock i, N_t^{1+A} is the number of 1+ animals on feeding ground A at the start of year t:

$$N_t^{1+,A} = \sum_i \sum_j X^{A,i,j} \sum_{a=1}^{x} (N_{t,a}^{m,i,j} + N_{t,a}^{f,i,j}) \tag{C.2}$$

K^{1+A} is the carrying capacity for feeding ground A:

$$K^{1+,A} = \sum_i \sum_j X^{A,i,j} \sum_{a=1}^{x} (N_{-\infty,a}^{m,i,j} + N_{-\infty,a}^{f,i,j}) \tag{C.3}$$

$X^{A,i,j}$ is the proportion of animals of feeding aggregation j of breeding stock i that are found in feeding ground A[9] (Tables 1 and 2).

The number of births at the start of year t for feeding aggregation j of breeding stock i, $B_t^{i,j}$, is given by:

$$B_t^{i,j} = b_t^{i,j}\, N_t^{f,i,j} \tag{C.4}$$

where $N_t^{f,i,j}$ is the number of mature females in feeding aggregation j of breeding stock i at the start of year t:

$$N_t^{f,i,j} = \sum_{a=a_m}^{x} N_{t,a}^{f} \tag{C.5}$$

a_m is the age-at-maturity (the convention of referring to the mature population is used here, although this actually refers to females that have reached the age of first parturition); $b_t^{i,j}$ is the probability of birth/calf survival for mature females:

$$b_t^{i,j} = \max(0, b_K\{1 + A^{i,j}(1 - F(I, j, t))\}) \tag{C.6}$$

b_K is the average number of live births per year per mature female at carrying capacity; and $A^{i,j}$ is the resilience parameter for feeding aggregation j of breeding stock i.

D. **Immigration (dispersal)**

The numbers dispersing into feeding aggregation j of breeding stock i, include contributions from pulse migration as well as diffusive dispersal:

$$I_{t,a}^{s,j,i} = I_{t,a}^{1,s,j,a} - I_{t,a}^{2,s,j,a} \tag{D.1a}$$

$$I_{t,a}^{1,s,j,i} = \sum_{k \neq j} \delta^{k,j,i} N_{t,a}^{s,i,k} \left(\frac{N_t^{f,i,k}}{N_{-\infty}^{f,i,k}}\right)^{\tilde{\lambda}} + \sum_{k \neq j} \Omega_y^{k,j,i} \frac{N_{t,a}^{s,i,k}}{\sum_{a=1}^{x} (N_{t,a}^{m,i,k} + N_{t,a}^{f,i,k})} \tag{D.1b}$$

$$I_{t,a}^{2,s,j,i} = \sum_{k \neq j} \delta^{j,k,i} N_{t,a}^{s,i,j} \left(\frac{N_t^{f,i,j}}{N_{-\infty}^{f,i,j}}\right)^{\tilde{\lambda}} + \sum_{k \neq j} \Omega_y^{j,k,i} \frac{N_{t,a}^{s,i,j}}{\sum_{a=1}^{x} (N_{t,a}^{m,i,j} + N_{t,a}^{f,i,j})} \tag{D.1c}$$

---

[9] It is usually the case that $\sum X^{A,i,j} = 1$. However, for gray whales, this is not necessarily the case because removals can take place in the various sub-areas at different times. What is then important is the relative values of the $X^{A,i,j}$ among feeding aggregations for a given feeding ground.

where $\delta^{k,j,i}$ is the rate of dispersal from feeding aggregation *k* to feeding aggregation *j* of breeding stock *i*; λ is a factor to allow for density-dependence in the dispersal rate (set to 2); and $\Omega_y^{k,j,i}$ is the number of animals that disperse in year *y* from feeding aggregation *k* to feeding aggregation *j* of breeding stock *i* in a pulse.

E. **Anthropogenic removals**

The catch by feeding aggregation, sex and age is the sum of the catch over fleet (see Table 3 for fleet definitions), i.e.:

$$C_{t,a}^{m/f,i,j} = \sum_k C_t^{m/f,k} \frac{\alpha_a^k X^{A_k,i,j} N_{t,a}^{m/f,i,j}}{\sum_{i,j,a} \alpha_a^k X^{A_k,i,j} N_{t,a}^{m/f,i,j}} \qquad \text{(E.1)}$$

where $C_t^{m/f,k}$ is the catch of males/females by fleet *k* during year *t*; A_k is the sub-area in which fleet *k* operates; and α_a^k is the relative vulnerability of animals of age *a* to harvest by fleet *k*. The values for the catches by fleet and sex are either pre-specified (Table 4[10]) or computed using Equation E.2. for the years for which actual estimates are not available:

$$C_{t,a}^{m/f,k} = \lambda^k E_t^k \sum_{i,j,a,m/f} \alpha_a^k X^{A,i,j} N_{t,a}^{m/f,i,j} \qquad \text{(E.2)}$$

where E_t^k is a measure of the effort by fleet *k* during year *t* (Table 5) and λ^k is the catchability coefficient for fleet *k*.

F. **Initializing the parameter vector**

The numbers at age in the pristine population are given by:

$$\begin{aligned} N_{-\infty,a}^{m/f,i,j} &= 0.5\, N_{-\infty,0}^{i,j} \prod_{a'=0}^{a-1} S_{a'} && \text{if } a < x \\ N_{-\infty,x}^{m/f,i,j} &= 0.5\, N_{-\infty,0}^{i,j} \prod_{a'=0}^{x-1} S_{a'} / (1 - S_x) && \text{if } a = x \end{aligned} \qquad \text{(F.1)}$$

The value for $N_{-\infty,0}^{i,j}$ is determined from the value for the pre-exploitation size of the 1+ component of feeding aggregation *j* of breeding stock *i* using the equation:

$$N_{-\infty,0}^{m,i,j} = K^{1+,i,j} / \left(\sum_{a=1}^{x-1} \left(\prod_{a'=0}^{a-1} S_{a'} \right) + \frac{1}{1-S_x} \prod_{a'=0}^{x-1} S_{a'} \right) \qquad \text{(F.2)}$$

where $K^{1+,i,j}$ is the carrying capacity (in terms of the 1+ population size size) for feeding aggregation *j* of breeding stock *i*:

$$K_t^{1+,i,j} = \sum_{a=1}^{x} (N_{-\infty,a}^{m,i,j} + N_{-\infty,a}^{f,i,j}) \qquad \text{(F.3)}$$

$N_{-\infty,a}^{m/f,i,j}$ is the number of animals of age *a* that would be in feeding aggregation *j* of breeding stock *i* in the pristine population.

The model is based on the assumption that the age-structure at the start of year τ is stable rather than that the population was at its pre-exploitation equilibrium size at some much earlier year. The determination of the age-structure at the start of year τ involves specifying the effective 'rate of increase', γ, that applies to each age-class. There are two components contributing to γ, one relating to the overall population rate of increase (γ^+) and the other to the exploitation rate due to all forms of anthropogenic removal. Under the assumption of knife-edge recruitment to the fishery at age a_r, only the γ^+ component (assumed to be zero following Punt and Butterworth

---

[10] The bycatches for 2016 are set equal to those for 2015 as data on bycatch for 2016 are not finalized at present.

[2002]) applies to ages *a* of a_r or less. The number of animals of age *a* at the start of year τ relative to the number of calves at that time, $N^*_{\tau,a}$, is therefore given by the equation:

$$N^*_{\tau,a} = \begin{cases} 1 & \text{if } a = 0 \\ N^*_{\tau,a-1}\, S_{a-1} & \text{if } a \le a_r \\ N^*_{\tau,a-1}\, S_{a-1}\,(1-\gamma) & \text{if } a_r < a < x \\ N^*_{\tau,x-1}\, S_{x-1}(1-\gamma)\,/\,(1-S_x\,(1-\gamma)) & \text{if } a = x \end{cases} \tag{F.4}$$

where B_τ is the number of calves in year τ and is derived directly from equations C.1 and C.6.

$$B_\tau = \left(1-\left[1/(N^f_\tau b_K)-1\right]/A\right)^{1/z} \frac{K^{1+}}{N^{1+,*}_\tau} \tag{F.5}$$

The effective rate of increase, γ, is selected so that if the population dynamics model is projected from year τ to a year Ψ, the size of the 1+ component of the population in a reference year Ψ equals a value, P_Ψ.

G. **Conditioning**

The parameters of the model are: (a) the carrying capacity of each stock, (b) the population size for each stock at the start of 1930 (expressed relative to carrying capacity), (c) MSYR by stock, (d) annual survival under 'normal' conditions, (e) maturity as a function of age, (f) the impact of the mortality event in the eastern Pacific in 1999 and 2000, (g) selectivity, (h) the rate of dispersal between the NFG and the PCFG, (i) the parameters of the mixing matrices, (j) the catchability coefficients that determine bycatch by fleet (Eqn E.2), and (k) the extent of additional variation for each abundance index. Some of these parameters are pre-specified:

(1) MSYR (except for trials 14, 15, and 17);
(2) Annual survival under 'normal' conditions (base-case 0.98);
(3) Maturity as a function of age (a logistic function of age, with an age-at-50%-first-parturition of 8 years and a minimum age-age-at-first parturition of 3 years); and
(4) Selectivity (Table 3).

Under the assumption that the estimates of abundance for a sub-area (Table 6) are log-normally distributed, the negative of the logarithm of the likelihood function is given by:

$$-\ell nL = \ell n\sqrt{\text{Det}[V]} + 0.5\sum_k (\ell\,\text{n}\,\underline{N}^{A,obs} - \ell\,\text{n}\,\underline{N}^{A})[V^{-1}](\ell\,\text{n}\,\underline{N}^{A,obs} - \ell\,\text{n}\,\underline{N}^{A})^T \tag{G.1}$$

where $N^{A,\text{obs}}_t$ is the survey estimate of abundance for sub-area *A* during year *t*; and V is the sum of the variance-covariance matrix for the abundance estimates plus an additional variance term (assumed to be independent of year). Note that the abundance estimates for the western areas (Table 6a) depend on the stock hypothesis under consideration.

The data on the proportion of each stock (Tables 6a and 7) in each sub-area are modelled under the assumption that the proportions are normally distributed, i.e.:

$$-\ell nL = \sum_i \sum_A \sum_t \tfrac{1}{2(\tau^{i,A}_t)^2}(p^{i,A}_t - p^{i,A,\text{obs}}_t)^2 \tag{G.2}$$

where $p^{i,A}_t$ is the model-estimate of the proportion of the animals in sub-area *A* that are from feeding aggregation *i* of the Eastern breeding stock*;* $p^{i,A,\text{obs}}_t$ is the observed proportion of animals in in sub-area *A* that are from feeding aggregation *i* of the Eastern breeding stock; and $\tau^{i,A}_t$ is the standard error of $p^{i,A,\text{obs}}_t$.

The (non-zero) bycatches by sub-area for the first five years for which data are available are assumed to be log-normally distributed, and the model is fitted to the average bycatch by sub-area over a pre-specified set of years (the years for which detection and reporting of entanglements, ship strikes, and strandings in general was relatively good; Table 3), i.e.:

$$-\ell\text{n}L = \sum_A \tfrac{1}{2\sigma_{BC}^2}\left(\ell\text{n}C^{I,A,\text{obs}} - \ell\text{n}\hat{\bar{C}}^{I,A}\right)^2 \tag{G.3}$$

where $C^{I,A,\text{obs}}$ is the observed average annual bycatch from sub-area *A* over the pre-specified period, $\hat{\bar{C}}^{I,A}$ is the average over this period of the model-estimate of the bycatch from sub-area *A*, and σ_{BC} is the standard error of the logarithms of the observed bycatches.

A penalty is imposed on the average number of animals moving permanently from the NFG into the PCFG between 2001 and 2008, i.e.:

$$-\ell nL = \tfrac{1}{2\sigma_I^2}\left(\tilde{I} - \frac{\delta^{\text{m/f,north,}West\text{st}}}{8}\sum_{t=2001}^{2008}\sum_{s=m/f}\sum_{a=1}^{x} I_{t,a}^{s,\text{East,north}}\right)^2 \tag{G.4}$$

where $\tilde{I}$ is the pre-specified average number of immigrants into the PCFG from the NFG, and σ_I is a weighting factor.

The estimates of survival for PCFG whales (Calambokidis *et al.*, 2017) are assumed to be normally distributed, i.e.:

$$-\ell\text{n}L = \tfrac{1}{2\sigma_{S,1}^2}(S^{\text{obs},1} - \hat{S}^1)^2 + \tfrac{1}{2\sigma_{S,2}^2}(S^{\text{obs},2} - \hat{S}^2)^2 \tag{G.5}$$

where $S^{\text{obs},1} = 0.917$, $\sigma_{L,1} = 0.0142$, $S^{\text{obs},2} = 0.967$, $\sigma_{L,2} = 0.0066$, $\hat{S}_1$ is the estimate of post-first-year survival for whales that entered in 1998 or earlier, and $\hat{S}_2$ is the estimate of post-first-year survival for whales that entered in 1999 or later.

H. **Quantifying uncertainty using bootstrap**

A bootstrap procedure is used to quantify uncertainty for a given model specification. Each bootstrap replicate involves:

(1) Generating pseudo time-series of abundance estimates based on the assumption that the abundance estimates are log-normally distributed with means and variance-covariance matrices given by the observed abundance estimates and the reported variance-covariance matrices.
(2) Generating pseudo mixing proportions from beta distributions with means and CVs given by the observed means and CVs.
(3) Generating pseudo bycatch rates by sub-area from log-normal distributions with means of $C^{I,A,\text{obs}}$ and a log standard error of σ_{BC}.
(4) Generating a pseudo immigration rate from the NFG into the PCFG based on a normal distribution (truncated at zero) with mean $\tilde{I}$ and standard error σ_I.
(5) Generating pseudo survival rates from normal distributions.

I. Generation of Data

The actual historical estimates of absolute abundance (and their associated CVs) provided to the *Strike Limit Algorithms* are listed in Table 6. The future estimates of abundance for sub-areas WFG, WST, BCNC-3 and CA-3 (say sub-area *K*) are generated using the formula:

$$\hat{P} = PYw / P^{*}\beta^2 Yw \tag{I.1}$$

where *Y* is a lognormal random variable Y=e$^{\varepsilon}$ where $\varepsilon \sim N(0;\sigma_\varepsilon^2)$ and $\sigma_\varepsilon^2 = \ell n(1+\alpha^2)$; *w* is a Poisson random variable with $E(w) = \text{var}(w) = \mu = (P/P^{*})/\beta^2$, *Y* and *w* are independent; *P* is the current total (1+) population size in survey area *K*:

$$P = P_t^K = \sum_i\sum_j\sum_g\sum_{a\geq 1} N_{t,a}^{g,i,j} \tag{I.2}$$

P^* is the reference population level, and is equal to the total (1+) population size in the survey area prior to the commencement of exploitation in the sub-area for which an abundance estimate is to be generated. For consistency with the first-stage screening trials for a single stock (IWC, 1991, 1994), the ratio $\alpha^2 : \beta^2 = 0.12 : 0.025$, so that $CV^2(\hat{P}) = \tau(0.12 + 0.025P^* / P)$. If $\overline{CV}$ is the target CV then $\tau = \overline{CV}^2 / (0.12 + 0.025P_{\text{ref}} / P^*)$ where P_{ref} is the population size in a reference year.

An estimate of the *CV* is generated for each estimate of abundance:

$$CV(\hat{P})^2_{\text{est}} = \sigma^2 \chi^2 / n \tag{I.3}$$

where $\sigma^2 = \ell n(1 + \alpha^2 + \beta^2 P^* / \hat{P})$, and χ is a random number from a Chi-square distribution with *n* degrees of freedom (where *n*=10 as used for NP minke trials; IWC, 2004).

J. Trials

The factors included in the trials are listed in Table 8 and the trials in Table 9.

K. Management options

The strike limits for the BSCS sub-area are based on the Gray Whale *SLA* (IWC, 2005). The strike limits for the BCNC sub-area based on the Makah Management Plan (Appendix 1) although sensitivity is explored using variant 1 agreed to in 2012 (IWC, 2013; Appendix 2).

Removals due to bycatch are based on the scenarios regarding future trends in effort. Table 8 lists the factors considered in the projections.

L. Output Statistics

The population-size statistics are produced for each breeding stock / feeding aggregation, while the removal-related statistics are for each sub-area.

I.1 Risk

D1. Final depletion: P_T/K (1+ and mature female numbers by breeding stock / feeding group (median, lower 5th and upper 5th percentiles)).

D2. Lowest depletion: $\min(P_t / K) : t = 0,1,...,T$.

D3. Plots of $\{P_{t[x]} : t = 0,1,..,T\}$ where $P_{t[x]}$ is the *x*th percentile of the distribution of P_i . Results are presented for x = 5, 50, and 95.

D8. Rescaled final depletion: P_T/P_0 (1+ and mature female numbers by breeding stock / feeding group; median, lower 5th and upper 5th percentiles) where P_0 is number of 1+ / mature female animals had there been no future Makah hunts.

D10. Relative increase. The ratio of the 1+ and mature population size after 10 and 100 years to that at the start of the projection period by breeding stock / feeding group (median, lower 5th and upper 5th percentiles)

I.2 Removal-related

N9. Need satisfaction. The proportion of the total number of requested strikes that were taken over the first 10 years and the entire 100-year period (median, lower 5th and upper 5th percentiles).

R1. Plots of strikes by year for simulations 1-100.

R2. Plots of landed whales by year for simulations 1-100.

R3. Plots of incidental catches by year for simulations 1-100 (median, lower 5th and upper 5th percentiles by year).

Table 4a

Non-bycatch removals. The BSCS ‘fleet’ represents the aboriginal catches, the two WAUA ‘fleets’ represent Makah hunting in the Makah usual and accustomed area, and the CA migration ‘fleet’ is the scientific catches off California.

2015	WBS	5a	64.4	14.0	0.218
2015	WFG	5a	135.6	14.1	0.104
2015	WBS+WFG	5a	200.0	5.7	0.029
2015	WBS/(WBS+WFG)	5a	0.322	0.069	0.200

* Guestimate because the WBS cannot be distinguished given the available information.

Table 6b
Estimates of absolute abundance (with associated standard errors) for the eastern North Pacific stock of gray whales based on shore counts (source: 1967/78-2006/07: Laake *et al*, 2012; 2006/07-2015/16: Durban *et al*, 2013, 2017). These estimates are assumed to pertain to the total number of gray whales.

Table 7

Data on mixing proportions (definite and likely matches / non-matches only) to be used when conditioning the models.

Sub-area	Season	Stock / Feeding aggregation	Mixing proportion (assumed SD)
EJPJ	All	WBS/NFG	0.33 (0.1)
SEA	Feeding	PCFG	0.57[1] (0.1)
SEA	Feeding	WFG	0
SEA	Migration	PCFG	0.1[2] (0.1)
SEA	Migration	WFG	0.002[3] (0.05)
BCNC	Feeding	PCFG	0.93 (0.1)
BCNC	Feeding	WFG	0
BCNC	Migration	PCFG	0.28 (0.1)
BCNC	Migration	WFG	0.002 (0.05)
CA	Feeding	PCFG	0.60 (0.1)
CA	Feeding	WFG	0
CA	Migration	PCFG	0.1 (0.05)
CA	Migration	WFG	0.002[3] (0.05)

1: Not used in the conditioning except for the sensitivity test based when the bycatch is based on M/SI as no dead bycatch is recorded for the SEA sub-area during the feeding season.

2: Assumed value owing to lack of data to estimate mixing proportions.

3: Set to the value calculated for BCNC by Moore and Weller (2013)

Table 8

Factors considered in the model scenarios. The bold values are the base-levels and the values in standard font form the basis for sensitivity analyses.

Factor	Levels
Model fitting related	
Stock hypothesis	**3a,** 3b, 3c, 3e, **5a,** 6b
$MSYR_{1+}$ (western)	As for WFG
$MSYR_{1+}$ (north)	**4.5%**, 5.5%, Estimated (common); estimate (separately)

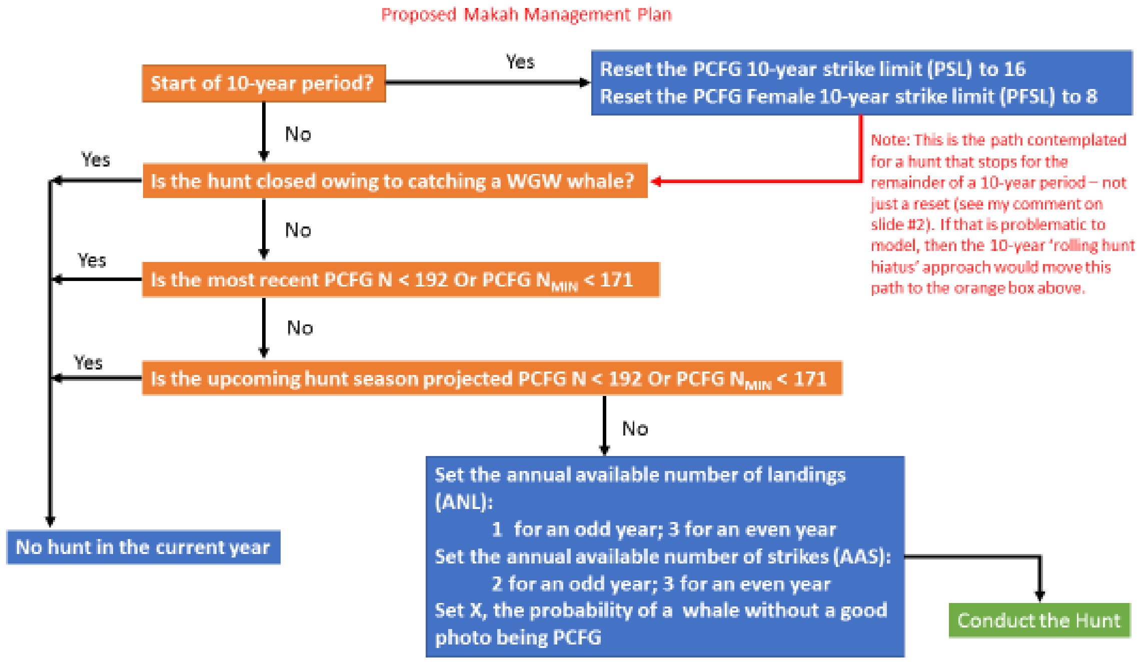
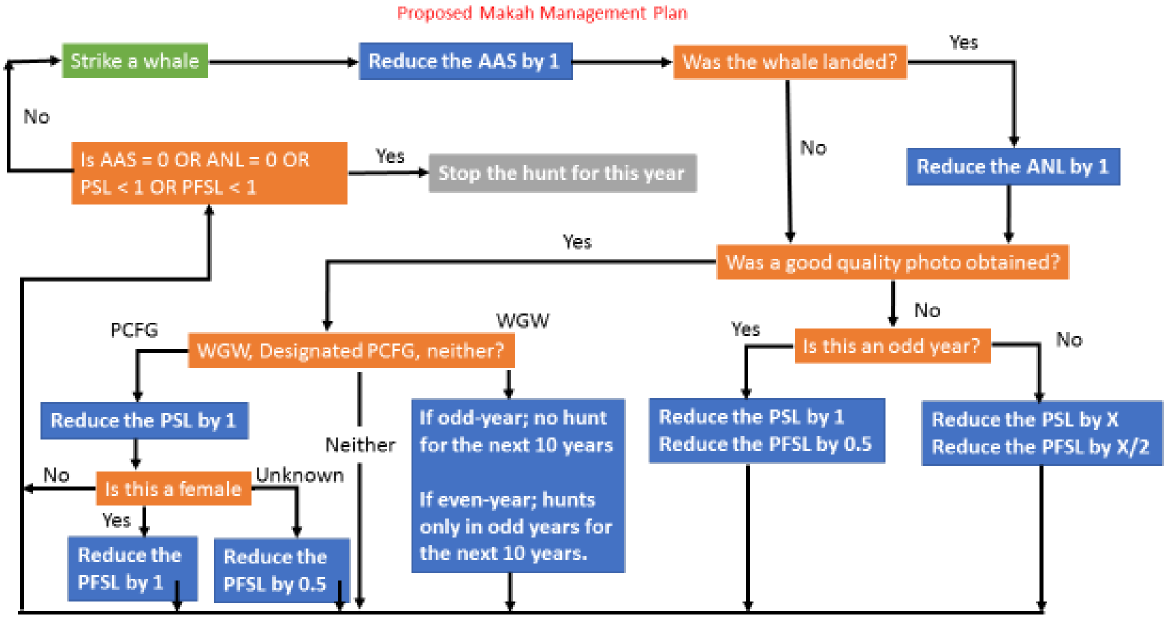
Appendix 1

OUTLINE OF THE MAKAH MANAGEMENT PLAN AND ITS IMPLEMENTATION IN TRIALS





Appendix 2
THE ‘RESEARCH WITH VARIANT’ (SLA VARIANT 1) OPTION (IWC, 2013).

This option operates as follows:

(1) Update the ABL (Allowable Bycatch Limit of PCFG whales) if this is the start of a new 6-year block as:

$$ABL = N_{MIN} * 0.5 * R_{MAX} * F_R$$

Where:

N_{MIN} is the log-normal 20th percentile of the most recent abundance estimate for the Oregon to Southern Vancouver (OR-SVI) sub-area of the PCFG. The abundance estimates for use in the ABL formula are generated as specified in Section I, except for allowance is made for a bias which differs among simulations but is constant over time between the estimates for OR-V and those for the PCFG, i.e. $\ell n B_A \sim N(-0.335, 0.112^2)$ (IWC, 2012).

R_{MAX} is equal to 0.04;

F_R is equal to 1.0.

(2) Strike an animal
(3) If the total number of struck animals equals the need of 7 stop the hunt.
(4) If the animal is struck-and lost:
  a. if the total number of struck and lost animals is 3, stop the hunt.
  b. go to step (2).
(5) If the animal is landed and is matched against the PCFG catalogue:
  a. add one to the number of whales counted towards the ABL
  b. if the ABL is reached; stop the hunt
  c. if the total number of landed whales equals 5; stop the hunt
  d. if the number of landed whales for the current six-year block equals 24; stop the hunt
  e. go to step (2).
(6) If the animal is landed and does not match any whale in the PCFG catalogue:
  a. if the total number of landed whales equals 5; stop the hunt
  b. if the number of landed whales for the current six-year block equals 24; stop the hunt
  c. go to step (2).

ABSTRACT

Counts of southbound migrating whales off California form the basis of abundance estimation for the eastern North Pacific stock of gray whales (*Eschrichtius robustus*). Previous assessments (1967–2007) have estimated detection probability (p) from the detection-non detection of pods by two independent observers. However, tracking distinct pods in the field can be difficult for single observers; resulting in biased estimates of pod sizes that needed correcting, and matching observations of the same pod by both observers involved key assumptions. Due to these limitations, a new observation approach has been adopted wherein a paired team of observers work together and use a computerised mapping application to better track and enumerate distinct pods and tally the number of whales passing during watch periods. This approach has produced consistent counts over four recently monitored migrations (2006/7, 2007/8, 2009/10 and 2010/11), with an apparent increase in p compared to the previous method. To evaluate p and estimate abundance in these four years, counts from two independent stations of paired observers operating simultaneously were compared using a hierarchical Bayesian '*N*-mixture' model to jointly estimate p and abundance without the challenge of matching pods between stations. The baseline detectability p_o was estimated as 0.80 (95% Highest Posterior Density Interval [HPDI] = 0.75–0.85), which varied with observation conditions, observer effects and changes in whale abundance during the migration. Abundance changes were described using Bayesian model selection between a parametric model for a normally distributed common migration trend and a semi-parametric model that estimated the time trends independently for each year; the resultant migration curve was a weighted compromise between models, allowing for key departures from the common trend. The summed estimates of migration abundance ranged from 17,820 (95% HPDI = 16,150–19,920) in 2007/08 to 21,210 (95% HPDI = 19,420–23,230) in 2009/10, consistent with previous estimates and indicative of a stable population.

KEYWORDS: ABUNDANCE ESTIMATE; MIGRATION; MODELLING; GRAY WHALE; SURVEY – SHORE BASED; PACIFIC OCEAN; NORTHERN HEMISPHERE

INTRODUCTION

The eastern North Pacific stock of gray whales migrates annually along the west coast of North America from high latitude feeding grounds to winter breeding grounds in the lagoons and adjacent ocean areas off Baja California, Mexico (Rugh *et al.*, 2001). This nearshore migration pattern has enabled repeated abundance estimates from shore-based counts off Granite Canyon, central California. In 23 years, between 1967 and 2007, counts of the number of observed pods travelling southbound have been rescaled using estimates of pods undetected during watch periods, pods passing outside watch periods, and night travel rate (Buckland and Breiwick, 2002; Buckland *et al.*, 1993; Hobbs *et al.*, 2004; Laake *et al.*, 2012; Laake *et al.*, 1994; Rugh *et al.*, 2005). Population models based on these estimates indicate that gray whales have increased substantially in population size, recovering from whaling operations in the 19th and 20th centuries, and are now close to carrying capacity and likely pre-exploitation levels (Punt and Wade, 2012). The most recent population estimate from abundance counts in 2006/07 was approximately 19,000 whales (Laake *et al.*, 2012).

To facilitate continued population monitoring, the abundance estimation approach has seen continual evolution throughout this time series to more realistically estimate detection probability (p) to link observed counts to true abundance; this paper describes the latest modification. Notably, previous assessments have estimated p from the detection and non-detection of pods by independent observers using an analytical mark-recapture approach. However, tracking distinct pods in the field is difficult (Rugh *et al*. 2008), particularly for a single observer using just hand-recorded entries onto a paper data form. As a result, matching observations of the same pod by both observers involved key (and untestable) assumptions and limited observations of a given pod required corrections for bias in pod size estimation (Rugh *et al*. 2008; Laake *et al*., 2012). Due to these limitations, a new observation approach has been developed wherein a paired team of observers work together and use a computerised mapping application to help better track distinct pods and tally the number of whales passing during watch periods (Durban *et al.*, 2010). This approach has a number of advantages, including open communication between observers, enabling observers to search for whales continually without the distraction of looking down to record data, and easier separation and tracking of distinct pods due to the precise computerised data recording and visualisation. As a result, this approach enables more repeated observations of each pod, leading to larger (and presumably less biased) estimates of pod size (Durban *et al*., 2010) and has produced consistent counts over four recently monitored migrations (2006/07, 2007/08, 2009/10 and 2010/11), with an apparent increase in p compared to the previous method (Durban *et al*., 2011).

To evaluate p for this new approach, watch period counts from two independent stations of paired observers operating simultaneously were compared during two of the four years (2009/10 and 2010/11), using a hierarchical Bayesian '*N*-mixture' model (Royle, 2004) to jointly estimate the probability of detection and abundance in all four years, without the challenge of matching pods between stations.

This ‘*N*-mixture’ approach has been successfully used to estimate abundance and detectability from replicate count data for a range of wildlife species where it has not been possible to match repeat sightings of individuals (e.g. Chelgren *et al.*, 2011; Joseph *et al.*, 2009; Kery *et al.*, 2005). The untility of this approach to extend the time series of abundance estimates for eastern North Pacific gray whales is demonstrated in this paper.

METHODS

Data samples

Counts of gray whales were conducted from shore-based watch stations at Granite Canyon, California, during the 2006/07, 2007/08, 2009/10 and 2010/11 southbound migrations (see Table 1). Counts were made by rotating teams of observer pairs using naked eye aided by 7×50 binoculars; the primary observer in the pair kept continual visual watch while the secondary observer served as a data recorder but also kept watch and assisted with tracking already identified pods whenever possible. Each observer had one 90 minute shift as primary observer, followed by a second 90 minute shift as secondary observer and then a 90 minute break. Sightings were entered into a real-time data logging PC program, which had a mapping screen to help track repeated sightings of the same pod. The map projected the likely movement tracks (and error ellipses) of the pods using predicted swimming speeds (1.44–1.95 ms^{-1}), allowing re-sightings and new sightings to be queried. Up to six lots of 1.5 hour watch periods were used to cover daylight hours from 07:30 to 16:30 local time, during which the observers recorded passing whales and environmental conditions, specifically visibility (subjectively categorised from 1–6 for excellent to unusable) and sea state (Beaufort scale). To control for weather conditions and for consistency with previous abundance estimations, only counts during watch periods with acceptable weather conditions throughout their entire duration were used, specifically visibility code <5 (excellent to fair) and Beaufort Scale <5.

Estimating detection probability

The ‘*N*-mixture’ approach was used (Royle, 2004) to simultaneously estimate detection probability p_{ijt} and abundance N_{jt} for each watch period *j* in each year *t*, based on the total aggregated counts n_{ijt} of passing whales recorded by each of $i = 1{:}2$ watch stations in each period. The observed counts n_{ijt} were modelled as a binomial outcome conditional on the unknown true number of whales passing N_{jt} and the detection probability p_{ijt} with hierarchical models assumed to describe variability in both *N* and *p* (e.g. Chelgren *et al.*, 2011). The power to estimate detectability was achieved by comparing gray whale counts from two independent stations of paired observers operating simultaneously during two years (2009/10 and 2010/11) from watch stations that were positioned 35m apart at the same elevation (22.5m) above sea level. In 2009/10 counts were compared from the two watch stations operating simultaneously during 70 lots of 1.5 hour watch periods with acceptable weather conditions, covering 20 different days of the migration; in 2010/11 simultaneous counts were available from 94 watch periods over 24 different days (see Table 1). However, detectability was extrapolated for all monitored watch periods in each of the four years based on the fitted model for detectability. In order to accomplish this, the counts for the south watch station were treated as zero-inflated binomial outcomes, with the binomial probability specified as a function $u_{ijt}\, p_{ijt}$ where $u = 1$ or 0 to indicate whether or not count data were actually collected from that station, thus ensuring that structural zero counts from periods without a second watch did not contribute to the likelihood for estimation of *p* or *N*.

Consistent with Laake *et al.* (2012), the model for detectability incorporated fixed effects β for visibility (VS) and Beaufort Scale (BF), as well as random effects associated with each observer *o* in 1:OB observers. These were modelled as additive effects on a general intercept so that the direction and magnitude of the estimated effects away from zero (no effect) could be assessed. The selection for the inclusion of these effects using Bayesian model selection with stochastic binary indicator variables *g* to switch each of the three possible effects either in or out of the model depending on their relevance to the observed data (Kuo and Mallick, 1998):

$$\text{logit}\,(p_{ijt}) = \text{logit}(p_{\text{o}}) + g^{bf}\beta^{bf}\,\text{BF}_{jt} + g^{vs}\beta^{vs}\,\text{VS}_{\text{jt}} + g^{ob}\boldsymbol{\beta}^{\boldsymbol{ob}}_{\boldsymbol{ijt=o}}$$

where the intercept p_{o} was the base detection probability in the absence of covariate effects, assigned a Uniform(0,1) prior distribution, and $\text{logit}(p_{\text{o}}) = \ln(p_{\text{o}}/1–p_{\text{o}})$. Centred around this base detectability, each of the fixed effects β^{bf} and β^{vs} was assigned a Normal prior distribution with mean zero and large standard deviation of 10; this prior value was smaller than the corresponding posterior estimates of standard deviation, and as such this was vague prior distribution that allowed any non-zero effects to emerge if supported. The random effect for each observer was drawn from a Normal distribution with mean zero and standard deviation σ^{ob}~Uniform(0,10). Each of the binary indicator variables, *g*, was assigned a Bernoulli(0.5) distribution to specify equal probability of inclusion or not of the effect in the model.

Table 1

The number of whales recorded during the southbound gray whale surveys from 2006/07 to 2010/11. Data are the total counts, hours and distinct days for watches during acceptable observation conditions.

	North Station			South Station		
Migration	Dates	Whales	Hours (days)	Dates	Whales	Hours (days)
2006/07	02/01–03/02	2,691	204 (34)	–	–	–
2007/08	02/01–09/02	2,079	202.5 (34)	–	–	–
2009/10	30/12–19/02	2,034	246 (43)	11/01–06/02	1,551	105 (20)
2010/11	03/01–18/02	2,885	265 (45)	10/01–04/02	1,754	141 (24)

Fitting migration curves

The *N*-mixture approach also accounted for variation in *p* relative to changes in *N* (latent watch period abundances) during the migration. So, some power to estimate detectability was achieved by assuming a model for changes in watch period abundance over the course of the migration. A Poisson distribution $N_{jt} \sim \text{Poisson}(\lambda_{jt})$ was adopted as a hierarchical prior for the distribution of abundances, and a model was specified for the Poisson mean λ in terms of the number of whales passing each day (*d*), with an offset for the effort duration of each watch period, E_{jt} in decimal days (e.g. Laake *et al.*, 2012):

$$\log(\lambda_{jt}) = \log(E_{jt}) + \text{model}_{d(j)t}$$

$$\text{model}_{dt} = z_{dt}\text{Common}_{dt} + (1\text{–}z_{dt})\ \text{Specific}_{dt}$$

Days were specified as $d = 0$ to D_t. In all four years *t* we used $D_t = 90$, where days were counted from 12:00am on 1 December, and we added an abundance of 0 whales passing for day 0 and D_t to anchor the fitted model when we assumed whales did not pass (following Buckland *et al.,* 1993). Estimates from the remaining days were derived from a mixture (or compromise) of two competing models (‘Common’ and ‘Specific’, e.g. Li *et al*., 2012) describing changes in abundance across each annual migration. The model contributing each daily estimate was indicated using stochastic binary indicator variables z_{dt}, each assigned a non-informative Bernoulli(0.5) prior distribution. As such, each z_{dt} indicated the probability of a daily estimate conforming to the common trend, allowing flexibility for departures from this trend that may only exist on certain days in certain years to be identified and modelled (rather than assuming all counts from an entire year conform to or depart from a common trend, which would be represented by z_t). The total number of whales passing during each migration was then estimated by summing the expected value from the model-averaged number of whales passing each day from time 0 to D_t (e.g. Laake *et al*., 2012). These estimates were then rescaled to account for the differential passage rate at night (Perryman *et al*., 1999), based on the nine hour day multiplicative correction factor of Rugh *et al.* (2005). Specifically, we applied a constant night time correction factor that was assumed to be a Normally distributed fixed effect with mean of 1.0875 and standard deviation of 0.037.

For the ‘Common model’, we assumed a typical trend in abundance throughout each annual migration (e.g. Buckland *et al.*, 1993), with abundance changes assumed Normally distributed around a migration mid-point, with a Normal distribution specified as a quadratic function of days, on the log scale:

$$\text{Common}_{dt} = a_t + b_t d_t + c_t d_t^2$$

where the mid-point of the migration curve for each year *t* was derived by $-b_t/2a_t$. This assumed common migration curve allowed information to be ‘borrowed’ across years when needed, specifying association across years to strengthen inference about migration curves in years with relatively sparse counts. However, we specified each of the curve parameters a_t, b_t and c_t to be drawn from hierarchical Normal distributions with means μ^a, μ^b, $\mu^c \sim$ N(0, 10) and standard deviations σ^a, σ^b, σ^c ~Uniform(0,10); hyper-parameters that were common across years, rather than assuming that the parameters themselves were constant. This random effects formulation allowed the timing, level and extent of the Normal migration curve to vary annually around the general pattern, if supported by the data.

Although it is likely that there is a typical pattern to the migration, it was acknowledged that abrupt departures may occur at any time in any particular year. To incorporate unusual patterns, the selection of an alternative ‘Specific’ migration model was allowed; a semi-parametric model that estimated the time trends independently for each year (e.g. Laake *et al.*, 2012). A method in which the shape of the relationship of abundance across days was determined by the data was adopted without making any prior assumptions about its form, by using penalised splines (Ruppert, 2002). Following Crainiceanu *et al.* (2005) a linear (on the log scale) penalised spline was used to describe this relationship:

$$\text{Specific}_{dt} = S_{0t} + S_{1t}d_t + \Sigma_{k=1}^{m}\ \lambda_{kt}\ (d_t - \kappa_{kt})$$

Where S_{0t}, S_{1t}, ${}_{1t}, \ldots, {}_{kt}$ were regression coefficients to be estimated separately for each year and $\kappa_{1t} < \kappa_{2t} < \ldots < \kappa_{kt}$ were fixed knots. We used $m = 15$ knots, a relatively large number to ensure the desired flexibility, and let κ_{kt} be the sample quantile of ’s corresponding to probability $k/(m + 1)$. To avoid overfitting, the λ’s were penalised by assuming that these coefficients were Normally distributed random variables with mean 0 and standard deviation ~Uniform(0,10). The parameters S_{0t}, S_{1t} were modeled as fixed effects with Normal(0, 10) prior distributions.

Bayesian inference using MCMC

The multi-level model was fit using Markov Chain Monte Carlo (MCMC) sampling using the WinBUGS software (Lunn *et al.*, 2000). Inference was based on 15,000 repeated draws from the posterior distribution of each model parameter conditional on the observed data, following 5,000 iterations that were discarded as burn-in. Convergence of parameters within these initial 5,000 iterations was determined based on Gelman-Rubin statistics below 1.05 (Brooks and Gelman, 1998) calculated from three independent chains begun from over-dispersed starting values. To gauge the adequacy of the model for each annual set of count data, Bayesian P-values were computed (Gelman *et al.*, 1996) by using the same MCMC sampler to predict a distribution for each watch-period count from the posterior estimates of model parameters and comparing the total predicted and observed counts. For each year, there was good agreement between the model predictions and observed counts, with Bayesian P-values ranging from 0.45 to 0.53; values close to 0.5 would indicate that the data was consistent with replications under the model, with the distribution of the predicted count symmetrically overlapping the observed count (Gelman *et al.*, 1996).

The MCMC sampling approach allowed uncertainty to be propagated across levels of the model. Notably, estimates of parameter values across MCMC iterations were used to estimate the probability of inclusion of covariate effects in the model for detectability, given by the posterior probability $p(g = 1)$ of each indicator variable *g*. Fitting and selection of the two competing migration models was achieved within the same MCMC run using the ‘cut’ function in WinBUGS to ensure that estimation of the two models was not affected by the selection of the model indicator (e.g. Li *et al.*, 2012). The posterior probability of conforming to the common trend model was then calculated by the relative frequency that each model was selected by the indicator z_{dt} in the overarching mixture model, and inference about abundance on each day was based on a weighted compromise between the competing models by sampling across the posterior distribution of z_{dt}.

RESULTS

The base detectability was estimated as $p_o = 0.80$ (95% Highest Posterior Density Interval [HPDI] = 0.75–0.85), which was modified by observation conditions and observer effects (see Table 2). The posterior distribution for the effect of sea state β^{bf}, measured using the Beaufort scale, largely overlapped with zero and there was therefore low support for including this effect in the model with $p(g^{bf} = 1) = 0.004$. In contrast, there was a relatively strong negative effect of visibility on detectability (higher visibility code = lower visibility = lower detectability), with the entire distribution for β^{vs} falling below zero [$p(g^{vs} = 1) = 1$]. There was also support for inclusion of observer effects [$p(g^{bs} = 1) = 1$], with both positive and negative effects reflecting relatively high and low counts by different observers. A total of 35 different observers were used over 4 years between North and South stations; 15/35 counted in multiple years (2 years = 7, 3 years = 4, 4 years = 4). The Posterior medians for observers' effects ranged from –0.59 to 0.80, but only five observer effects (all positive) had posterior distributions that did not include zero.

Detectability also varied with changes in whale abundance during the migration, as shown by the extent of extrapolation from the daily summed counts (effort adjusted) to the estimated daily abundances (Fig. 1). Detectability declined with increasing abundance, with a greater proportion of whales estimated to be missed as more whales passed during busy watch periods. In general, changes in abundance during the migrations were adequately described by a Normal curve over time, but there was greater uncertainty in the tails of the distribution resulting from generally sparse coverage. The Normal trend was useful for comparing migration timing: the median of the curve midpoints was 53.5 days since December 01 (23–24 January), ranging between 49–57 days. However, there were some notable deviations from the Normal trend, with estimates from the year-specific non-parametric trend model being favoured for some days in each of the four years. In particular, there was a high probability in favour of the Specific model [$p(z = 0) > 0.75$] on 9 days in 2006/07, 9 days in 2007/08, 16 days in 2009/10 and 11 days in 2010/11, representing key departures from the Normal migration trend. The summed (model-averaged) estimates of migration abundance ranged from a posterior median of 17,820 (95% HPD = 16,150–19,920) in 2007/08 to 21,210 (95% HPDI = 19,420–23,230) in 2009/10, consistent with previous estimates (Fig. 2). These new estimates were also relatively precise with coefficients of variation (CV = Posterior Standard Deviation/Posterior Median) ranging from 0.04 to 0.06 (median = 0.05), but nonetheless the 95% HDPI's of all four estimates overlapped.

DISCUSSION

The new counting method adopted here was intended to reduce reliance on the ability of single observers acting independently to record and track distinct whale groups. By adopting teams of paired observers working together, with the benefit of a real-time computerised tracking and

Table 2

Parameters of models for detectability, *p*. All estimates are presented as the 2.5%, 50%, 97.5% highest density posterior probability intervals, plus the probability of inclusion in a model (if tested), given by the posterior probability $p(g = 1)$ of each indicator variable *g*. Observers are arbitrarily numbered, differently for each year.

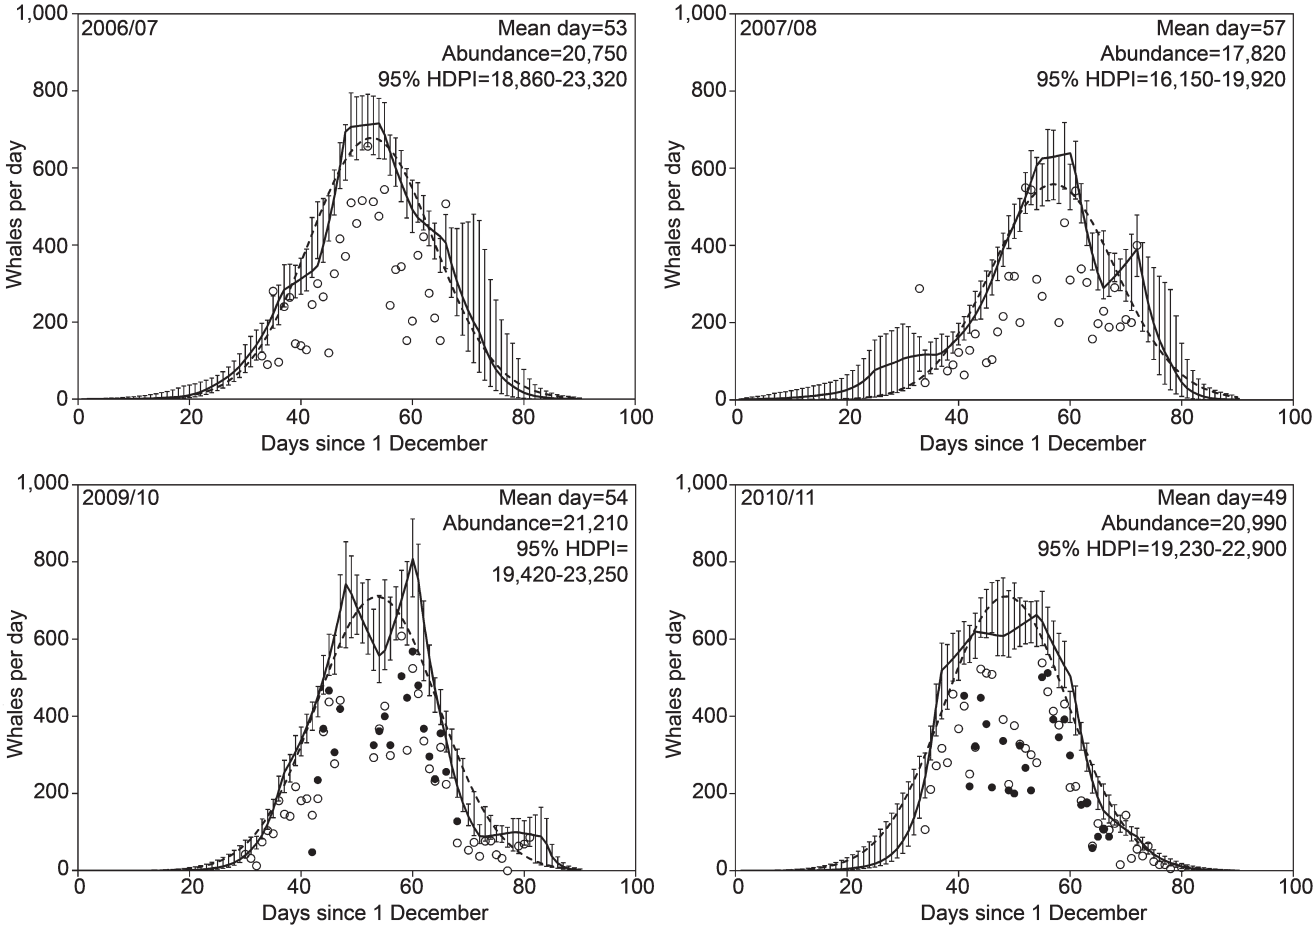

Fig. 1. Observed whale passage rates expressed as total counts per day/ proportion of day observed (circles) and fitted migrations models (lines) for the four southbound gray whale migration counts from 2006/07 to 2010/11. Solid circles represent counts from a second watch station, when operating. The broken line represents the median estimates from a hierarchical Normal model for migration and the solid line represents a semi-parametric model of penalised splines; the abundance estimate for each day (95% highest posterior density interval shown by vertical lines) is a model averaged compromise between the migration models, and these were summed to estimate the overall abundance for the migrations.

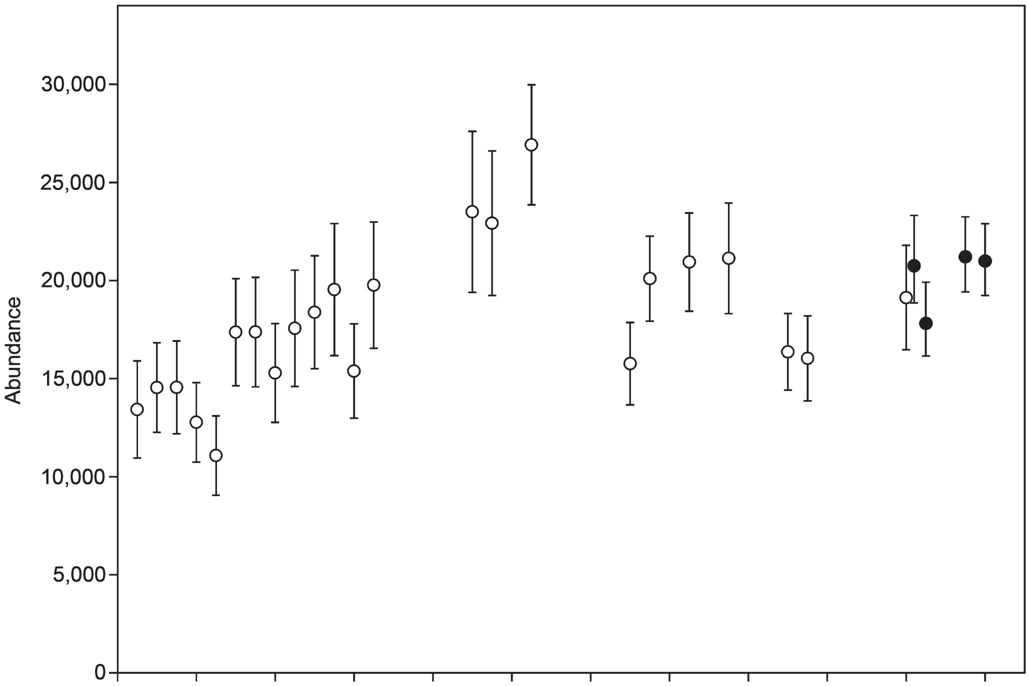

Fig. 2. Gray whale abundance estimates for each of 23 southbound migrations with an end year between 1967 and 2007 (open circles, with 95% confidence intervals; from Laake *et al.,* 2012) together with the four recent migrations reported here (closed circles show posterior medians, lines are 95% highest posterior density intervals).

visualisation tool, this approach has proved successful in increasing detection probability (Durban *et al.*, 2011) and also reducing variability in detections due to observer effects. Although still present, the magnitude of observer effects estimated from the new counts (see Table 2) was generally not as great as those apparent with the traditional counting approach (see Laake *et al.*, 2012, table 7).

Furthermore, our method for estimating detectability departed from the mark-recapture approach of matching detections and non-detections of specific pods by independent observers. Instead, inference was based on total watch period counts that were not sensitive to differential lumping and splitting of pods by observers, and avoided the assumptions required to match observed pods between pairs of observers. As an alternative to the mark-recapture analytic approach, we have shown how tallied watch period counts from two observer pairs counting simultaneously can lead to similar inference when analysed using with the *N*-mixture approach (Royle, 2004).

The *N*-mixture approach is conceptually simple: multiple observations of watch period counts, *n*, from the different observer teams represented different samples from an unknown binomial distribution with total population size *N* and detection probability *p*. A binomial likelihood function could then be easily used to estimate *N* and *p* from the sample of *n*'s. Although there were only a maximum of two samples of *N* during any specific watch period, a large sample of *n*'s was built up across many watch periods, allowing the estimation of the parameters. Layered on top of this core estimation process were both a trend model for true daily abundance through time based on the migration pattern and a model for how detection varied according to environmental conditions and different observers. Specifically, a hierarchical model fit to the replicate count samples allowed us to link detectability to key covariates, as in previous gray whale assessments (e.g. Laake *et al.*, 2012), and also extrapolate detectability based on these covariate relationships for watch periods without replicate counts. Similarly, by assuming a common underlying model for the migration pattern, this approach notably accounted for variation in *p* relative to changes in abundance *N* during the migration. Furthermore, this joint modelling of data from multiple years allowed the borrowing of strength across years to better parameterise the migration during years with sparse data.

Previously, two contrasting approaches have been used to model changes in abundance over the course of the annual gray whale migration: either by assuming a parametric model to determine the shape of the migration curve (Buckland *et al.*, 1993) or by fitting a non-parametric smoother to allow the data to determine the trend in abundance over time (Laake *et al.*, 2012). Here we drew on elements of both these approaches in a flexible framework using Bayesian model selection between a parametric model for a common migration trend and a semi-parametric model that estimated the time trends independently for each year; the resultant migration curve was a weighted compromise between models, allowing for key departures from the common trend.

The abundance estimates produced for 2006/07, 2007/08, 2009/10 and 2010/11 were internally consistent, consistent with previous estimates and indicative of a stable population (Fig. 2). The 95% HDPI's of all four estimates overlapped, and there was substantial overlap between the 95% HDPI from the 2006/7 estimate with the 95% confidence intervals of the estimate for the same migration produced using the previous counting and estimation approach (Laake *et al.* 2012). Further, our estimates are very similar to the predictions of Punt and Wade (2012) based on assessment models for the full time series; their baseline model prediction for 2009/10 had 90% posterior density intervals ranging from 17,726 to 23,247; the posterior distribution for our 2009/10 estimate was centered within these intervals at 21,210 (95% HPDI = 19,420–23,250). It is noteworthy that the estimates produced using our approach were relatively precise with CVs ranging from 0.04 to 0.06 (median = 0.05) in contrast to CVs ranging from 0.06 to 0.09 (median = 0.08) for the 23 previous estimates.

This consistency provides a level of confidence in our approach and resultant estimates, but nonetheless there are limitations to address. Our approach makes a number of important modelling assumptions, both in terms of distributional forms and model structure. It was assumed that the detectability relationships described by modelling repeated counts during two years were also applicable in the remaining two years with no replicate counts. We also assumed observer effects remained constant, although in reality this may change with experience. Additionally, the definition of what constituted the common migration trend was dependent on the joint modelling of just four years of data, and precise inference about the shape of the migration curve relies on count data being collected from throughout the migration time span. During at least 3/4 of the years reported here, count data were sparse (or non-existent) during the tails of the migration, resulting in uncertainty over the shape of the abundance curve. While this uncertainty was propagated into inference about overall abundance in our Bayesian inference using MCMC sampling, the resulting imprecision will ultimately constrain power to detect between-year changes in migration patterns and abundance. Data collected during further migrations will be incorporated into this hierarchical model and therefore used to refine parameter estimates; this will benefit from replicate counting experiments, repeated when possible. As the time series grows, specific goodness-of-fit tests should be adopted to investigate aspects of model structure and suggested changes as necessary.

There are also practical considerations as well as modelling assumptions. Previous work has shown that the new counting approach produces estimates of pod size that are typically larger (and presumably less biased) than the traditional counting approach (Durban *et al.*, 2010), likely because the computerised tracking software facilitates more repeated observations of the same groups. In fact, it has been assumed that estimates of pod size using this observation approach are effectively unbiased and have not been rescaled to tally watch period counts. This is an assumption that remains to be tested, but suitable calibration experiments are difficult to design and implement, particularly due to the inherently subjective differences between observers in lumping and splitting whales to define groups. Similarly, although observer effects have been accommodated in the model for detectability, it is clear that too many observers

(35 in total) counted too infrequently to allow precise parameterisation of their relative effects on detectability in many cases. This will have resulted in further imprecision.

Although there may be field protocols that could be adapted to address these limitations within the current approach, further modernisation of the observation process is recommended. Specifically, more accurate information could be gleaned from observations recorded with high-definition video files to allow subsequent review and re-review, rather than relying on instantaneous assessment by visual observers. The use of infra-red sensors would further allow for 24 hour monitoring (e.g. Perryman *et al*., 1999) and provide greater coverage of the entire migration during acceptable weather conditions; automated blow detectors (e.g. Santhaseelan *et al*., 2012) can be developed to eliminate observer effects and standardise detectability to provide counts with minimal (and quantifiable) bias. These extensions would further serve to build a more robust and automated observation model to combine with the flexible abundance model for the migration process described in this paper.

ACKNOWLEDGEMENTS

The observers are thanked for their participation in the field work. Also appreciation is given for the advice from Steve Reilly, Bill Perrin, Jeff Breiwick, Dave Rugh, Rod Hobbs and Jeff Laake. Thanks also to Paul Wade, Andre Punt and Jeff Laake for providing valuable comments on an earlier version of this manuscript.

REGIONAL VARIABILITY IN FOOD AVAILABILITY FOR ARCTIC MARINE MAMMALS

Bodil A. Bluhm[1] and Rolf Gradinger

University of Alaska Fairbanks, School of Fisheries and Ocean Sciences, Institute of Marine Science,
245 O'Neill Building, Fairbanks, Alaska 99775 USA

Abstract. This review provides an overview of prey preferences of seven core Arctic marine mammal species (AMM) and four non-core species on a pan-Arctic scale with regional examples. Arctic marine mammal species exploit prey resources close to the sea ice, in the water column, and at the sea floor, including lipid-rich pelagic and benthic crustaceans and pelagic and ice-associated schooling fishes such as capelin and Arctic cod. Prey preferred by individual species range from cephalopods and benthic bivalves to Greenland halibut. A few AMM are very prey-, habitat-, and/or depth-specific (e.g., walrus, polar bear), while others are rather opportunistic and, therefore, likely less vulnerable to change (e.g., beluga, bearded seal). In the second section, we review prey distribution patterns and current biomass hotspots in the three major physical realms (sea ice, water column, and seafloor), highlighting relations to environmental parameters such as advection patterns and the sea ice regime. The third part of the contribution presents examples of documented changes in AMM prey distribution and biomass and, subsequently, suggests three potential scenarios of large-scale biotic change, based on published observations and predictions of environmental change. These scenarios discuss (1) increased pelagic primary and, hence, secondary production, particularly in the central Arctic, during open-water conditions in the summer (based on surplus nutrients currently unutilized); (2) reduced benthic and pelagic biomass in coastal/shelf areas (due to increased river runoff and, hence, changed salinity and turbidity conditions); and (3) increased pelagic grazing and recycling in open-water conditions at the expense of the current tight benthic–pelagic coupling in part of the ice-covered shelf regions (due to increased pelagic consumption vs. vertical flux). Should those scenarios hold true, pelagic-feeding and generalist AMM might be advantaged, while the range for benthic shelf-feeding, ice-dependent AMM such as walrus would decrease. New pelagic feeding grounds may open up to AMM and subarctic marine mammal species in the High Arctic basins while nearshore waters might provide less abundant food in the future.

Key words: Arctic; benthos; climate change; food availability; marine mammal; plankton; prey; sea ice; seal; whale.

Introduction

The physical and chemical settings of Arctic seas provide the framework for the structure of marine food webs, which support Arctic marine mammals (AMM) as top consumers. Unique features specific to the Arctic influencing habitat suitability and prey availability include the seasonal and permanent sea ice cover, the extreme seasonal variability of light and primary production and their consequences, the interannual and decadal climate variations, and the polar amplification of recent climate change (Walsh 2008). The focus area of this paper includes the deep central Arctic Basin, consisting of two major sub-basins (the Eurasian Basin and the Amerasian Basin) and the surrounding shallow continental shelves, occupying approximately 53% of the Arctic Ocean. The shelves vary in width, with narrow extents along part of the Beaufort Sea and Canadian Archipelago coastlines and wide shelves everywhere else. The shelves are the locations at which currently most of the annual ice formation and melt occurs and where AMM spend most of their time. Freshwater runoff from major river systems influences the Arctic hydrography and chemistry, contributing sediment, organic material, and inorganic nutrients to the shelves. Annual sea ice dominates on the shelves while unique multiyear sea ice covers the Arctic deep-sea basins (Wadhams 2000). The complex bathymetric and hydrographic structure of the Arctic basins and shelves influence their use by AMM as summarized by Laidre et al. (2008).

Large parts of the Arctic, in particular the shelves, are inhabited by AMM for at least part of the year (Laidre et al. 2008, Moore and Huntington 2008). During their feeding periods, AMM require energy hot spots to forage efficiently (e.g., Piatt and Methven 1992) and to build up reserves to sustain their metabolism and potentially produce a calf or pup during fasting periods. Caloric density at AMM feeding sites, therefore, appears

to be at least as important as prey species choice per se (Darling et al. 1998). Some migratory AMM specifically select subarctic or Arctic latitudes for their foraging period (Laidre et al. 2008). Feeding can occur throughout the year (e.g., male polar bear), primarily in the summer (e.g., gray whale; Nerini 1984), or primarily outside the summer (e.g., narwhal; Laidre and Heide-Jørgensen 2005). Whatever the selected site or time period, AMM foraging areas are selected because of certain, typically high, levels of primary and/or secondary production at the trophic levels of phytoplankton through fishes (e.g., Bradstreet and Cross 1982, Piatt and Mathven 1992).

This review aims at providing an overview of AMM prey preferences and prey distribution patterns and current biomass hotspots, organized by the three major physical realms: sea ice, water column, and seafloor. Examples of observed changes in AMM prey distribution and biomass are presented and potential biotic change scenarios suggested, based on published observations and predictions of environmental change. We propose these scenarios to provide insights into possible linkages between environmental changes and effects and caution the reader that settings on local or regional scales might have different effects than those described. This paper tightly links to Walsh (2008), which describes the climatic conditions by which AMM prey species are framed, and Laidre et al. (2008), which reviews habitat utilization of AMM species and quantifies their sensitivity to climate-induced habitat change.

Prey Preferences

Here we summarize the main prey items at different Arctic foraging sites for seven Arctic core and four subarctic (non-core) AMMs (Moore and Huntington 2008), while acknowledging bias introduced by differences in digestion rates of different prey. The information is presented, albeit admittedly incomplete, in short paragraphs organized by core and non-core AMM species and in the form of two tables, one on major prey by species (Table 1) and one on energy content of major prey items (Table 2). We will use the term Arctic cod for *Boreogadus saida* (see Plate 1) and polar cod for *Arctogadus glacialis*, according to the fish name list used by the American Fisheries Society.

Core Arctic marine mammals

Bowhead whale (Balaena mysticetus).—Most information on bowhead whale feeding ecology comes from the Alaskan and Canadian Arctic. Bowhead whales primarily feed on zooplankton, mostly crustaceans such as copepods, euphausids, and hyperiid amphipods (Lowry et al. 2004), all of which have especially high lipid and therefore caloric content (Percy and Fife 1980; Table 2). Feeding behavior may be consistent within size cohorts and diving abilities of age classes (Finley 2000). Juvenile bowheads tend to feed on large swarming zooplankton such as mysids or euphausids or on the very small copepods *Pseudocalanus* and *Limnocalanus*, while adults prefer large *Calanus glacialis* and *C. hyperboreus* in offshore areas (Lowry et al. 2004). Less common food items such as mysids, fish, and isopods were more frequent in smaller whales in the Alaskan Beaufort Sea, although this difference was not statistically significant compared to bigger whales ($n = 32$). No differences between size classes or sexes were found in a large sample of bowhead whale stomachs in the Alaskan Beaufort Sea ($n = 242$; Lowry et al. 2004). On occasion, bowheads may feed on benthic prey, as indicated by mud plumes and stomach contents. Epibenthic prey includes mysids and cumaceans.

In the Alaskan Beaufort Sea, a large fraction of whales feed throughout the fall with regional differences regarding the major prey, such as a higher fraction of copepods in fall-hunted animals from Kaktovik, whereas fall-hunted whales from Barrow consumed more euphausids and hyperiid amphipods (Lowry et al. 2004). A substantial sample size covering 1969–2000 indicates that feeding during the spring migration is opportunistic, but may be more common than previously appreciated. Major feeding areas are known from the western and eastern Beaufort and Chukchi Seas (Lowry et al. 2004) and off Baffin Island (Finley 1990), where whales primarily fed on copepods. Stable isotope studies suggest that the Chukchi-Beaufort Sea stock may also be feeding in the Bering Sea and that habitat selection patterns were consistent over a three-year period (Hoekstra et al. 2002). Little is known about the foraging grounds of the Svalbard and Okhotsk bowhead stocks (Shelden and Rugh 1995).

Beluga (Delphinapterus leucas).—The North Atlantic Marine Mammal Commission (NAMMCO 2004) recently summarized beluga prey spectrum findings from various foraging grounds. *Boreogadus saida* dominated beluga whale diet in Greenland, the Canadian High Arctic, Russian waters, and waters around Svalbard. *Arctogadus glacialis* and whitefish (Coregonidae) were similarly common in the Upernavik area in Greenland and in Russian waters, respectively. Other items found in stomachs in Greenland-caught belugas included squid beaks, redfish (*Sebastes marinus*), Greenland halibut (*Reinhardtius hippoglossoides*), and the decapod *Pandalus borealis*. Belugas preyed largely upon salmon in the Okhotsk Sea (Sobolevskii 1983) and on saffron cod and other fishes as well as shrimps and octopus in Norton and Kotzebue Sounds (Seaman et al. 1982). In the St. Lawrence River and Hudson Bay, stomach contents were dominated by capelin, but also included sand lance, Atlantic cod, tomcod, and benthic invertebrates such as crustaceans and polychaetes (NAMMCO 2004).

Ice type and distribution may influence beluga feeding patterns (Seaman et al. 1982), but prey species distribution also appears to affect seasonal movement patterns. Spring prey in migrating belugas in the Chukchi Sea was dominated by Arctic cod, shrimps, and octopus, while summer foods in the coastal northern Bering and southern Chukchi Seas included saffron cod, sculpins, herring, smelt, capelin, salmon, and char (Seaman et al. 1982). However, foraging occurred to a large extent in the wintering grounds rather than at the shallow estuarine summer sites in belugas off west Greenland (NAMMCO 2004). Shallow murky areas with relatively warm temperatures and mollusk, crustacean, and fish bottom fauna are generally often occupied by females and their young.

Narwhal (Monodon monoceros).—Studies of narwhal stomach contents in the Canadian Arctic, off west Greenland, and in Russian waters revealed that Arctic and polar cod, squid, in particular *Gonatus fabricii*, and Greenland halibut were the primary prey items of narwhals during the summer (e.g., Finley and Gibb 1982, $n = 73$; Laidre and Heide-Jørgensen 2005, $n = 121$). Less prevalent were redfish, snail fish, and crustaceans (Baffin Island; Finley and Gibb 1982). Fall and winter prey were dominated by Greenland halibut and squid (Laidre and Heide-Jørgensen 2005). The deep-water fishes indicate the deep-diving capability of narwhals. Laidre and Heide-Jørgensen (2005) reported that stomachs taken off west Greenland contained considerably more and fresher food during the winter than stomachs sampled in the summer. Similarly, Finley and Gibb (1982) observed little feeding during later summer in the Canadian Arctic fjords and suggest that summering areas may not primarily be inhabited based on their prey availability.

Walrus (Odobenus rosmarus).—Walrus primarily feed on benthic bivalves, but stomachs of some walrus also included a variety of other benthic invertebrates from all major phyla and over 60 genera (e.g., Fay et al. 1984). Food items other than clams were suggested to only be consumed opportunistically while clams were preferred, although later digestion experiments indicated that differential digestion probably exaggerates the importance of bivalves in walrus' diet to some extent (Sheffield et al. 2001). In the Bering Sea, the clams *Mya truncata*, *Serripes groenlandicus* (see Plate 1), and *Macoma* spp. dominated stomach contents as well as benthic communities in which feeding pits and furrows of walrus were studied (Oliver et al. 1983). In the Foxe Basin, Northwest Territories, stomach contents were also dominated by the clam *Mya truncata*, and the same species was dominant in Atlantic walrus feces around Svalbard (e.g., Fisher and Steward 1997). *Mya truncata*, *Hiatella arctica*, and *Serripes groenlandicus* were dominant prey in Young Sound, east Greenland (Born et al. 2003). Other bivalves, holothurians, and polychaetes contributed most of the remaining share in the Canadian study (Fisher and Steward 1997). Occasionally, ringed seals, bearded seals, seabirds, and squid have been reported from walrus stomachs.

For east Greenland waters, a male 1200-kg walrus consumed on average 2576 kJ per dive (53.2 bivalves), and consumption in Alaskan waters was estimated at 6 bivalves/minute (Oliver et al. 1983). Some authors found that probably all soft parts of the bivalves were consumed, while others suggested that primarily the exposed tissue parts such as foot and siphon are taken (Sheffield et al. 2001).

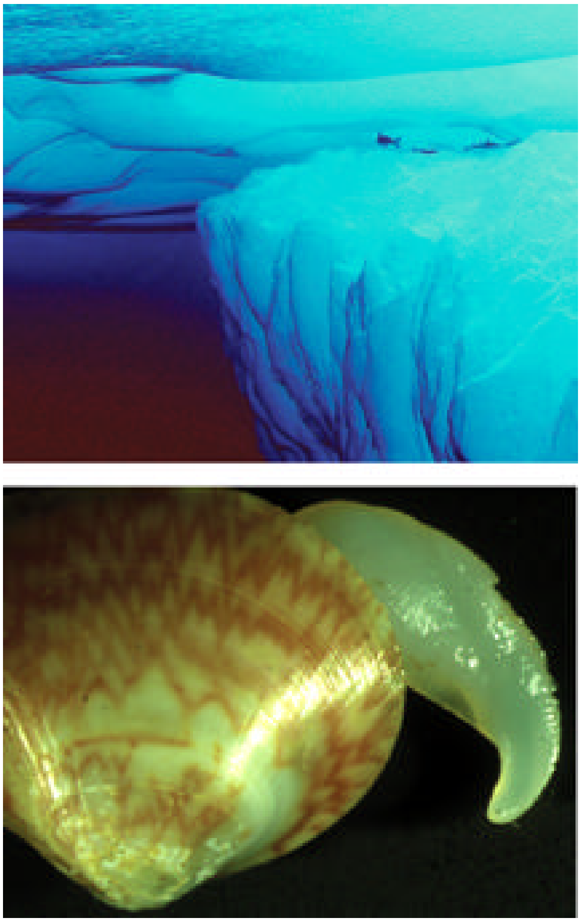

PLATE 1. Common prey organisms of Arctic marine mammals: (top) Arctic cod, *Boreogadus saida*, and (bottom) an example of benthic clam species, *Serripes groenlandicus*. Photo credits: cod, Katrin Iken; clam, B. Bluhm.

Bearded seal (Erignathus barbatus).—Bearded seals have been characterized as foraging generalists that prey on pelagic and demersal fishes as well as a wide range of infaunal and epifaunal invertebrates. The relative contribution of prey species varied between and within geographic areas and seasons (Antonelis et al. 1994). In a Bering Sea study, bearded seals primarily fed at the seafloor, where they consumed bivalves, crabs, and shimps, but few fishes, similar to findings from a southern Chukchi Sea study (Lowry et al. 1980*b*). Other invertebrates from seals taken around Svalbard include shrimps and whelks (Hjelset et al. 1999). In contrast, near St. Matthew Island, in the Bering Sea, 78 bearded seal stomachs were dominated by fishes, especially capelin, cod species, and eelpouts (Antonelis et al. 1994); snow crab, clams, snails, and amphipods were prevalent among the invertebrates in that study. Fish

TABLE 1. Primary prey and feeding areas of Arctic marine mammals.

Species and major feeding area	Feeding habits	Primary prey items	Trophic level	Reference
Core Arctic marine mammals				
Bowhead whale				
Chukchi and Beaufort Seas	shallow, pelagic, (hyperbenthic)	copepods, euphausids, mysids	3.2†	Lowry et al. (2004)

Notes: Information in parentheses in the "Feeding habits" column indicates less common feeding habits. Information without parentheses indicates common feeding habits. Trophic level values are taken from Pauly et al. (1998) (indicated by a dagger) and Hobson et al. (2002) (indicated by a double dagger). Abbreviations are: su, summer; wi, winter.

were also major prey items for bearded seals in the Kara and Barents Seas, in the Canadian High Arctic, and in the Svalbard area (Hjelset et al. 1999). Like other researchers, these investigators expressed uncertainty about the degree of selective feeding because of sampling biases.

Diets were similar between genders in two Bering Sea studies (Lowry et al. 1980*b*, Antonelis et al. 1994). Contradictory results were published about age class-specific prey selection: Lowry et al. (1980*b*) found that young bearded seals preyed upon shrimps, crabs, and fish while adults preferred clams; no age-specific differences were found in the mainly fish-eating bearded seals near St. Matthew Island (Antonelis et al. 1994).

Ringed seal (Phoca hispida).—Studies from various Arctic areas showed considerable regional and seasonal variability in ringed seal primary prey. In Northwest and East Greenland *Boreogadus saida* and *Arctogadus glacialis* were the most dominant prey items, while seals in central West Greenland mainly preyed upon pelagic amphipods (*Parathemisto* spp.), capelin, redfish, and squid, while capelin was the most important prey item in southwest Greenland (Siegstad et al. 1998). In the northern Bering and southern Chucki Seas (U.S. sector),

TABLE 2. Energy value of major Arctic marine mammal prey items.

Species	Phylum or order	Energy content	Realm	Area	Reference
Aglantha digitale†	Cnidaria	4.7–5.0 kcal/mg AFDM	pelagic	Frobisher Bay, Canada	Percy and Fife (1980)

Notes: The Frobisher Bay samples were collected from late July to mid-September. Abbreviations are: AFDM, ash-free dry mass; DM, dry mass; WM, wet mass.

† Other abundant species rarely preyed upon, given for comparison.

saffron cod dominated stomach contents in spring/summer, while the shrimps *Pandalus* spp., *Eualus* spp., *Lebbeus polaris*, and *Crangon septemspinosa* dominated in the north-central Bering, the hyperiid amphipod *Parathemisto libellula* in the central Beaufort Sea, and the euphausid *Thysanoessa* spp. in the Barrow area (Lowry et al. 1980*a*; total number of stomachs = 299). Similar prey taxa were preferred in Svalbard: Arctic cod, shrimps (*Pandalus borealis*), euphausids (*Thysanoessa inermis*), and amphipods (*Themisto libellula*) (Weslawski et al. 1994). A seasonal shift towards a dominance of Arctic cod was observed in the northern Bering, Chukchi, and Beaufort Seas in the winter, similar to findings from the Kara Sea and Novaya Zemlya (Lowry et al. 1980*a*). In other areas, saffron cod, smelt, and herring dominated the winter diet (Sea of Okhotsk), whereas no seasonality was found in yet other areas, where euphausids, amphipods, shrimps, mysids, Arctic cod, and other fishes were consumed throughout the year (e.g., northern Labrador and southwest Baffin). Age-specific differences in diet were found in some areas and included a smaller fraction of cod in pups than in adults in the northeast Bering and southeast Chukchi Seas and a decline of crustacean consumption with age in the Canadian Arctic. Based on energetic value and amounts consumed, Lowry et al. (1980*a*) concluded that species occurring in high densities or swarms were of particular importance for ringed seals.

Polar bear (Ursus maritimus).—Polar bears prey primarily on ringed seals, bearded seals, and harp seals (e.g., Derocher et al. [2002]). Based on 135 observations in Svalbard and the western Barents Sea, ringed seals were the dominant prey numerically (63%), while bearded seals contributed the highest biomass (55%). Prey composition was suggested to depend on the area a bear roamed for prey, with more ringed seals taken by near-shore bears on land-fast ice and more bearded and harp seals taken by off-shore bears (Mauritzen et al. 2003). Occasional opportunistic prey items include other marine mammals such as beluga whales, walrus, and narwhals as well as marine birds and even reindeer (references in Derocher et al. [2002]). Polar bears also opportunistically scavenge, for example in Barrow Alaska, where bears take advantage of subsistence-harvested bowhead whale carcasses (C. George, *personal communication*).

Non-core species

Gray whale (Eschrichtius robustus).—Throughout their feeding grounds in the northern Bering and Chukchi Seas and offshore Kodiak and Vancouver Islands, eastern North Pacific gray whales prey on a variety of invertebrates, ranging from benthic amphipods, polychaetes, cumaceans, and bivalves to pelagic mysids, herring eggs, and crab larvae (e.g., Nerini 1984, Darling et al. 1998). Dietary analysis indicated that ampeliscid amphipods, tube-building benthic crustaceans, are, or were, the primary prey item of gray whales in some northern feeding grounds, in particular the Chirikov Basin in the northern Bering Sea. Pelagic feeding has so far been reported less frequently from the northern feeding areas than from Vancouver Island (Darling et al. 1998), although some evidence for pelagic feeding is emerging. Overall, the taxonomic composition of the available prey per se may be less relevant than the energy density in gray whale feeding sites (Darling et al. 1998). Some authors attributed recent mortality events of gray whales to limited food supply in the northern feeding grounds, but other factors such as disease may also have played a role.

Spotted or Largha seal (Phoca largha).—The prey spectrum of spotted seals in the Bering Sea is dominated by pelagic fishes, but also includes invertebrates such as shrimp, crabs, and octopus (Sobolevskii 1996, Lowry et al. 2000). Spring foods included walleye pollock and zoarcids in the central Bering Sea and capelin, pollock, and herring in the southeast Bering Sea; Arctic cod was important prey in the northern Bering Sea, while octopus played an important role in the Gulf of Anadyr and Karaginsky Bay. In the fall, herring, saffron cod, and salmon were dominant prey (Lowry et al. 2000). In the Chukchi Sea, 41 spotted seals stomachs primarily contained herring (Lowry et al. 1980*b*), but saffron cod, smelt, Arctic cod, and capelin were also found in seals from the Chukchi Sea (Sobolevskii 1996). Spotted seals mostly utilized small to medium sized fishes as prey (Lowry et al. 1980*b*), e.g., two Bering Sea spotted seals primarily ate pollock with a mean fork length of 10.9 cm. In the Russian sector of the Bering Sea, young seals heavily depended upon crustaceans and octopus in the summer (Sobolevskii 1996).

Ribbon seal (Phoca fasciata).—Little has been published on the feeding ecology of ribbon seals. Walleye pollock and Arctic cod otoliths dominated digestive tracts of 61 ribbon seals from the south-central and northern Bering Sea, respectively (Frost and Lowry 1980). From concurrent trawls, these authors concluded that ribbon seals selected against sculpins and capelin in the central and northern Bering and preferred large Arctic cod to small ones. While pollock of all sizes were preyed upon in this study, ribbon seals primarily ate small pollock (mean 11.2 cm fork length) in a later study from the Bering Sea (Frost and Lowry 1986).

Harp seal (Phoca groenlandica).—The North Atlantic-wide-distributed harp seal preys on both pelagic and demersal fishes and pelagic invertebrates. Stomach contents of 369 harp seals in coastal waters of northern Norway were dominated by a variety of near-bottom fishes such as gadoids and energy-rich pelagic shoaling fish such as Atlantic herring and capelin (Haug et al. 1991). Shrimps and squid were present in stomachs, but less prevalent. Dominant prey species varied between years, areas, and age classes; for example, saithe was eaten by older seals off northern Norway, while Norway pout was consumed by younger seals. In the Barents Sea, the pelagic amphipod *Parathemisto libellula* dominated the diets of 22 harp seals by abundance and mass, and the shrimp *Pandalus borealis*, euphausids *Thysanoessa* spp., and fishes contributed the remaining 25% (Nilssen et al. 1991). In the Greenland Sea, pelagic amphipods (*Parathemisto*), the squid *Gonatus fabricii*, Arctic cod, and capelin combined constituted 63–99% of the observed diet biomass with the amphipod dominating in the summer (Haug et al. 2004). Arctic cod and capelin were the major prey species off eastern Newfoundland, while capelin and Atlantic cod were most important in the Gulf of St. Lawrence (Stenson et al. 1997).

Conclusion

In summary, AMM exploit a wide range of pelagic and benthic invertebrate and vertebrate food resources, ranging from small copepods to large fishes and other mammals. Some AMM or at least some populations are very prey-, habitat-, and/or depth-specific (e.g., walrus, polar bear) while others are more opportunistic (e.g., beluga, bearded seal). It is apparent that prey occurring in high densities and/or with high caloric values are preferred. The distribution and biomass of the various prey items is ultimately linked to the productivity of the Arctic marine food webs, which varies on temporal and regional scales.

Arctic Marine Food Webs

The occurrence of marine mammals in the Arctic is patchy due to variations in both physical and biological (prey) characteristics. The differences in water depth, ice cover, and hydrography (Walsh 2008) cause considerable differences in the rate of primary production and food web structure between different Arctic shelves and in particular between the shelves and the Arctic deep sea. Consequently, prey availability and use of that prey will largely depend on the physical settings of the habitat of any given AMM species (Laidre et al. 2008, Walsh 2008). Below we outline the general biological characteristics of the three major physical realms (sea ice, pelagic, and benthic) in the Arctic Seas and discuss their current relevance for the nutrition of Arctic marine mammals. This information will also be used as a platform to discuss the impacts of ongoing and future environmental changes in the Arctic marine environment on AMM.

Sea ice communities and food web

Sea ice, formed by freezing of seawater, is a key component in structuring polar environments in general (Gradinger 2002, Sakshaug 2004). In addition to its important role as a platform for marine mammals (Laidre et al. 2008) and birds, sea ice serves as a habitat for a unique, highly specialized community of bacteria, algae, protozoans, and metazoans, which contribute to the biogeochemical cycles of polar seas (Horner 1985, Gradinger 2002).

Two major types of Arctic sea ice can be distinguished, depending on location and ice age (Wadhams 2000). Fast ice is attached to land and forms ice sheets in coastal areas, where it may grow either annually or for several years. Pack ice consists of separate ice floes of varying sizes (ranging from a centimeter to a kilometer in scale), drifting on the surface of the ocean with wind and currents. The sea ice cover in the Arctic shows distinct seasonal patterns driven by the yearly melt and ice formation cycle, with maximum ice extent in March (average 15.7×10^6 km^2) and minimum extent in September (average 9.3×10^6 km^2; period 1979–1987) (Wadhams 2000). Most of the annual sea ice formation occurs on the shelves, while the central Arctic Ocean remains ice-covered by multiyear pack ice even in summer. The accumulation of snow is not well studied but a thickness of ~40 cm may accumulate over winter and starts to melt (depending on latitude) in May/June (Gradinger 2002).

On average, ice thickness increases from areas with mainly first-year ice (e.g., Russian Arctic: thickness <2 m) to areas with multiyear ice cover (central Arctic) to a maximum north of Greenland (thickness 7–8 m) (Wadhams 2000). Recent observations indicate a substantial reduction in the ice thickness by 0.5–1.5 m in various parts of the Arctic, parallel to a loss of ice extent by ~2–3% per decade (ACIA 2004).

The biology related to sea ice is largely controlled by its physical and chemical properties (e.g., Gradinger 2002), mainly light availability and nutrient supplies. The biota is found inside the sea ice in pockets and channels of brine between the ice crystals or is attached to the underside of the fast and pack ice. So far, more than 200 diatom species (mainly pennate taxa) and more than 70 species of flagellates are described from Arctic sea ice (Horner 1985). Ice algae contribute 4–26% to total primary production in seasonally ice-covered waters and more than 50% in the permanently ice-covered central Arctic (Gosselin et al. 1997, Sakshaug 2004; Fig. 1). Overall, absolute production rates of organic carbon were below 10 g C/yr. The organic matter produced within the sea ice serves as the base for the sympagic (ice-associated) food web including protozoans and metazoans, e.g., ciliates, rotifers, copepods, copepod nauplii, nematodes, turbellarians, and, in fast ice, larvae of benthic polychaetes and gastropods (Horner 1985). Meiofauna abundances decrease from the nearshore fast ice (up to 350 000 animals/m^2) to the deep-sea basin by about three orders of magnitude (Gradinger and Bluhm 2005, Gradinger et al. 2005). Although a variety of ice meiofauna and meroplanktic larvae consume ice algae, only a minor fraction (<10%) of the ice algal production is consumed by sea ice metazoans (Gradinger et al. 2005).

Gammaridean amphipods, the dominant macrofaunal taxon in the Arctic under-ice habitat, are the best-studied consumers of ice algal production in all parts of the Arctic (e.g., Gradinger and Bluhm 2004). Several

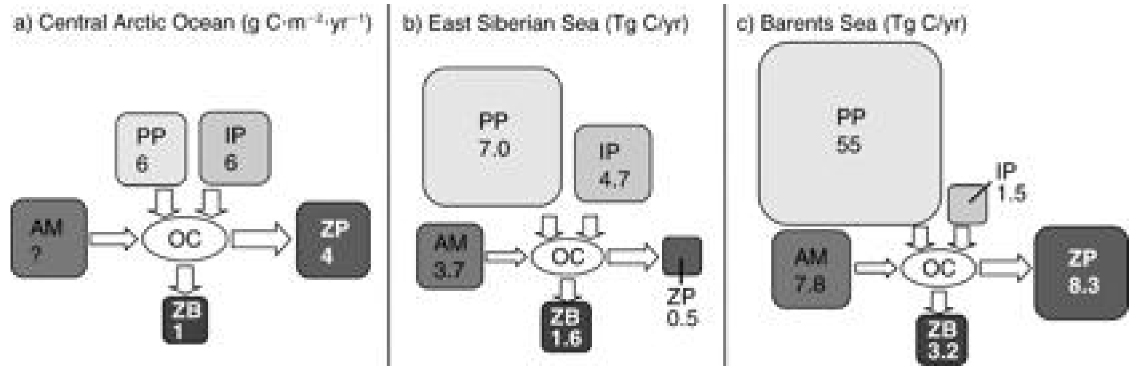

FIG. 1. Yearly production estimates for phytoplankton (PP), ice algae (IP), allochthonous material (AM), zooplankton (ZP), and zoobenthos (ZB) contributing to the organic-carbon pool (OC) for three different Arctic regions: (a) central Arctic Ocean (from Gosselin et al. 1997 [PP, IP], Klages et al. 2004 [ZB], and Mumm et al. 1998 [ZP]), (b) East Siberian Sea (Petrova et al. 2004), and (c) Barents Sea (Vetrov and Romankevich 2004). Units used correspond to those in the original data sources. This schematic depicts only rough estimates to emphasize the different sizes of the boxes in each region.

species of amphipods (e.g., *Gammarus wilkiztkii*, *Apherusa glacialis*, *Onisimus* spp.) are endemic to the multiyear sea ice cover and exploit the ice cover year-round, while benthic species such as *Onisimus litoralis* are common in nearshore seasonal ice regimes (Bradstreet and Cross 1982). Under-ice amphipods occur in abundances of 1–1000 individuals/m^2 in coastal areas and with, on average, 1–40 individuals/m^2 in offshore pack ice (Gradinger and Bluhm 2004). These under-ice amphipods are an important food source for Arctic diving birds and Arctic cod (*Boreogadus saida*) (Bradstreet and Cross 1982) and thereby provide the link from the food web within the sea ice to the more accessible open water below.

Arctic cod are frequently observed in close association with fast ice and pack ice year-round, and use the ice both for protection against potential predators and as a feeding habitat, ingesting under-amphipods and zooplankton (Gradinger and Bluhm 2004). In ice-free areas or conditions, Arctic cod is a pelagic species, but may also be found near the bottom in shallow shelves. Arctic cod can occur in small groups in protected seawater wedges within the offshore pack ice or form dense swarms of several million fish. This northernmost distributed gadid is the crucial link between the sea ice food web and AMM, in particular ringed seals, ribbon seals, and narwhals (e.g., Siegstad et al. 1998; Table 1) in that it "concentrates mg-sized particles into energy packets large enough to be eaten efficiently by seals, whales and birds" (Welch et al. 1992:351). In Lancaster Sound, Canada, alone, AMM and birds consume ~148 000 Mg/yr (metric tons per year) of Arctic cod (Welch et al. 1992).

Pelagic communities and food web

Much like those occurring in the ice, biological processes in the water column are mainly controlled by abiotic forcing. Seasonal fluctuation of light and ice melting and formation regularly alter growth conditions for phytoplankton. In early spring, increasing light and ice melt enhance water column stability; as a result phytoplankton blooms form in the marginal ice zones (MIZ) before algal growth occurs in the adjacent open ocean. These substantial MIZ algal blooms, which move across the shelves with the sea ice retreat, make up 50% of the total primary production in Arctic waters (Sakshaug 2004).

Total primary production rates in the Arctic can exceed values of >100 g C·m^{-2}·yr^{-1} on the shelves of the Barents, Chukchi, and Bering Seas (Sakshaug 2004). The highest production values are encountered on the Bering Shelf, where values are close to 5 g C·m^{-2}·d^{-1} or >500 g C·m^{-2}·yr^{-1} and are among the highest in the world's oceans. These very high rates reflect the high nutrient concentrations that allow the buildup of substantial phytoplankton biomass while Arctic shelves with lower nutrient availability (e.g., northern Barents Sea, East Siberian Sea, Kara Sea) exhibit much lower production values (15–70 g C/m^2; Sakshaug 2004). Primary production rates in the central Arctic Basin are one order of magnitude (<20 g C·m^{-2}·yr^{-1}) lower than on the shelves (Gosselin et al. 1997, Sakshaug 2004; Fig. 1). Within the ice pack, enhanced primary production rates were found in polynyas around Greenland, where yearly primary production estimates range between 20 and 50 g C/m^2.

In certain areas, the microbial food web plays an important role in the Arctic, based on locally very high concentrations of dissolved organic carbon (e.g., Sherr and Sherr 2003). From the perspective of AMM however, larger size classes, mainly herbivorous mesozooplankton, such as copepods and euphausiids, and fish are the most significant prey items within the water column. For example, the adults of some of the biomass-dominating marine Arctic copepod species, such as *Calanus glacialis* and *C. hyperboreus*, reach sizes larger than 1 mm. The Arctic pelagic herbivores adapted their life cycles to deal with the seasonally pulsed food supply (Hagen and Auel 2001). The storage of large amounts of lipids in form of either waxesters or triglycerids for either winter survival or spring reproduction (Hagen and Auel 2001) makes these copepods a rich food source for higher trophic levels from fish to AMM, among those in particular the bowhead whale (Tables 1 and 2). These copepods contribute the largest fraction to Arctic mesozooplankton biomass (Mumm et al. 1998). Besides copepods, typical Arctic zooplankton includes amphipods, chaetognaths, larvaceans, hydro- and scyphomedusae, and pelagic snails (Hopcroft et al. 2005). The biomass of Arctic mesozooplankton can exceed the phytoplankton biomass and shows a steep decline north of approximately 83° N from values of 8 g dry mass/m^2 in the Greenland Sea to ~1 g dry mass/m^2 in the High Arctic Nansen and Makarov Basins (Mumm et al. 1998). Similar latitudinal trends are obvious for the zooplankton productivity, as exemplified in Fig. 1.

Several of the dominant zooplankton taxa are linked in their occurrence to the Arctic hydrographical regime. The lipid-rich calanoid copepod species *Calanus glacialis* is endemic to polar waters, while *C. finmarchicus* is found in the Atlantic domain and, e.g., *Neocalanus cristatus* in the Pacific domain (Hopcroft et al. 2005). Similarly, the herbivorous euphausiid *Thysanoessa inermis* is abundant in the sectors influenced by Atlantic water and *T. longicauda* and *T. raschii* in Bering Sea water. Fluctuations or long-term changes in the large-scale hydrographical regimes will consequently alter the species spectra in the inflow shelves, which carry Atlantic and Pacific species, respectively. On a smaller scale, regional hydrographical processes, specifically freshwater runoff and consequent salinity changes, influence zooplankton composition and biomass, in particular on the shelves with large rivers (e.g., Deubel et al. 2003). For example, decreasing total zooplankton abundance and increasing contribution of smaller freshwater taxa were observed along a decreasing salinity gradient in the Lena River delta.

The food spectrum of copepods and euphausiids includes phytoplankton and microzooplankton but varies from species to species with actual ingestion rates frequently relating to the abundance of the prey (Hagen and Auel 2001). Depending on the availability of food and the abundance of mesozooplankton, their yearly grazing rates range between 1 and >18 g C/m^2 (Sakshaug 2004) and zooplankton production shows similar variability (Fig. 1). Increased primary productivity rates in specific regions such as marginal ice zones can sustain high densitites of mesozooplankton, which attract higher trophic levels such as plankton feeding birds and baleen whales (Bradstreet and Cross 1982).

Major AMM nekton prey include capelin, herring, walleye pollock, and squid (Table 1). In the southeastern Bering Sea walleye pollock is the single most abundant fish, and variations in its stock, therefore, percolate through the whole food web (Wepestad et al. 2000). Fish stock size is highly variable and, along with distribution, may be influenced by temperature. Walleye pollock, for example, currently a subarctic species, is dispersed across the Bering Sea shelf and even north of Bering Strait in warm but not in cold years and spends most time above 2°C, while Arctic cod inhabits areas of consistently colder waters (Wyllie-Echeverria and Wooster 1998). In the Atlantic sector of the Arctic, the distribution of forage fishes such as herring and capelin is influenced by climatic conditions in any given year (e.g., Loeng 1989). For example, capelin, a very energy-dense fish relative to walleye pollock (Table 2), was distributed more easterly and northerly in warm than in cold years in the Barents Sea. Adult capelin fed in both Atlantic and Arctic water masses in the Barents Sea with a preference for temperatures between −1°C and +2°C. Feeding area and growth were related, probably a function of temperature, with warmer temperatures and faster growth in southern areas. In the northwest Atlantic, the large capelin schools formed during the spawning season also make up a significant contribution of the diet of commercial fishes, marine mammals, and seabirds. Less is known about the pelagic fishes of the High Arctic shelves and Arctic deep sea. In a three-year study in the Beaufort Sea, Arctic cod (more on this species in *Sea ice communities and food web*), capelin, and liparids dominated epipelagic catches in coastal waters, with the 0+ age class being most abundant (Jarvela and Thorsteinson 1999). During approximately 15 pelagic dives of a remotely operated vehicle across the Canada Basin, few pelagic fishes were observed (R. Hopcroft, *personal communication*).

Among the squids, *Gonatus fabricii* is the most abundant species in Arctic and subarctic waters of the North Atlantic, where *Gonatus* predators apparently take advantage of aggregations of inactive females at their spawning sites (e.g., Bjørke 2001). While *Gonatus* juveniles inhabit the upper water column, the short-lived adults roam depths >400 m, where they are preyed upon by narwhals (Laidre and Heide-Jørgensen 2005), belugas, and other deep-diving mammals such as sperm whales, northern bottlenose whales, and long-finned pilot whales (Bjørke 2001). In the Bering Sea, where *Berrytheuthis magister* is the predominant squid species, squid are preyed upon by some mammals such as northern fur seals (Arkhipin et al. 1995).

Arctic benthic communities and food web

Major environmental determinants of Arctic benthic community structure include food supply, which largely originates in the surface waters and is highly seasonal in the Arctic, substrate type and grain size, salinity, temperature, and, in shallow water, ice scouring (Klages et al. 2004, Piepenburg 2005). Densities of sedimenting particles and their nutritional values range vastly from the nutrient-rich waters of the northern Bering, Chukchi, and Barents Seas to the oligotrophic deep waters of the Arctic Basins (Klages et al. 2004). Settling food particles add to the soft sediments predominating the Arctic and the grain size of these sediments, along with above-listed factors, determines faunal community composition (Grebmeier et al. 2006*a*). Exceptions to the soft bottoms in the Arctic are local accumulations of boulders, nearshore coastal regions, canyons, and High Arctic islands and Arctic fjords. In near-shore areas, benthic biomass and diversity intermittently decline due to ice scour, resulting in a patchwork of different successional stages (Piepenburg 2005). In addition, nearshore areas are under the influence of freshwater runoff, in particular the Laptev, Kara, and Beaufort Seas (Jørgensen et al. 1999, Deubel et al. 2003). Low numbers of euryhaline and brackish-water benthic species, some particularly well-adapted to high sedimentation rates (e.g., *Portlandia arctica*), dominated the shelf regions in estuaries (Deubel et al. 2003), where benthic biomass can be lower than under fully marine conditions (Jørgensen et al. 1999).

Arctic marine mammals prey on benthic species from the size classes macrofauna (mostly infaunal; >1 mm) to megafauna (large enough to be seen on seafloor images; mostly epifaunal). Benthic bacteria and meiofauna (<1 mm) are therefore excluded from this review. Arctic macrofauna is dominated, like most soft-bottom fauna in the world's oceans, by polychaetes, bivalve mollusks, and crustaceans, in particular amphipods, both on the Arctic shelves and in the central deep sea (e.g., Klages et al. 2004, Grebmeier et al. 2006*a*). Important macrofauna AMM prey species include bivalves taken by walrus, *Macoma* spp. and *Mya truncata*, and benthic amphipods utilized by gray whales and bearded seals (Table 1). Enhanced primary production at frontal systems, polynyas, and along the ice edge result in enriched benthic biomass with high water column productivity related to high benthic infaunal biomass in tightly coupled systems such as the Bering/Chukchi Seas. Benthic biomass is particularly high in the northern Bering Sea (~24 g C/m^2), the southern Chukchi Sea (~40–50 g C/m^2), and in the Gulf of Anadyr (~30 g C/m^2; Grebmeier et al. 2006*a*). In contrast, benthic infauna communities are depleted in biomass on the less productive Alaskan Beaufort Sea shelf (~4 g C/m^2) and in the eastern Chukchi Sea under influence of the nutrient-poor Alaska Coastal Current water (<10 g C/m^2; Grebmeier et al. 2006*a*). On the river-influenced Russian interior shelves, strong gradients of estuarine to fully marine conditions result in benthic biomass gradients (Deubel et al. 2003).

Arctic epibenthic communities include taxa with long life spans (several years to decades) and often slow growth rates such as echinoderms, crabs, and demersal fishes. These communities account for >25% of the overall benthic community respiration and, due to their often large size, contribute significantly to overall benthic biomass despite their patchy occurrence (Piepenburg 2005). At most locations studied, ophiuroids dominated the epibenthic megafauna with locally several hundred individuals per square meter. Other conspicuous epibenthic faunal elements, in varying abundances, included sea urchins, sponges, sea cucumbers, sea stars, crabs, and bryozoans (Piepenburg 2005). With the exception of crabs, shrimps, and molluscs, heavily calcified taxa tend to have little nutritional value (Table 2) and are rarely found on the AMM prey list. Several epifaunal organism groups are highly mobile and play an important role in the redistribution of pelagic carbon partitioned to the benthos and in organic carbon mineralization (Piepenburg 2005).

Benthic or demersal fishes preyed upon by AMM include mostly gadids, redfishes, and Greenland halibut (Table 1). Off Greenland, the demersal fish assemblage is dominated by Atlantic cod, golden and deep sea redfish, American plaice, Atlantic wolfish, and starry skate, although all underwent dramatic declines in abundance, biomass, and/or individual fish size from 1982 to 1996 (Rätz 1999). Greenland halibut, a major prey species of narwhals in Baffin Bay (Laidre and Heide-Jørgensen 2005), ranked 12th in average catch statistics off Greenland from 1982 to 1996 (Rätz 1999). Common and commercially fished demersal fishes in the eastern Bering Sea include Pacific cod, Greenland halibut (or turbot), yellowfin sole, arrowtooth flounder, and other flatfishes (Witherell 2000), a group which in that area does not seem to be among the preferred AMM prey items (Table 1). In High Arctic regions, benthic marine fishes have been poorly studied. Nevertheless, local subsistence fishing has a long tradition along the Arctic coasts and Barrow's native population, for example, is reporting more salmon catches in recent years (C. George, *personal communication*). In the northeastern Chukchi Sea, gadids made up 69–83% of the fishes in trawls in 1990 and 1991; cottids, pleuronectids, and zoarcids contributed much of the remaining catches (Barber et al. 1997). Two species of sculpin were dominant in the southern and northwestern Chukchi Sea in 2004, followed by Bering flounder and Arctic cod (C. W. Mecklenburg, B. A. Sheiko, D. L. Stein, N. V. Chernova, and B. A. Holladay, *unpublished manuscript*). Gadids and sculpins were dominant in a few bottom trawls in the Chirikov Basin in 2003 (R. Highsmith, C. O. Coyle, B. A. Bluhm, and B. Konar, *unpublished data*). The potential distribution and stock size changes in a warming Arctic climate may prompt more interest in Arctic fishes in the future.

Cryo-pelagic–benthic coupling

Coupling processes and interdependencies between ecosystem components are of great significance in the Arctic and are, therefore, stressed again here. The sea ice and pelagic and benthic realms are inherently linked through sedimentation of particles, animal migrations, life cycles, and direct food web interactions. The quantity and quality of particles produced in the sea ice or water column and settling out to the sea floor depend on nutrient availability and overall primary production in the water column, water stratification and mixed layer, midwater grazing rates, and bacterial degradation (Klages et al. 2004). If primary production is high in regions of high nutrient availability and zooplankton grazing is simultaneously low, coupling between the ice and/or pelagic and the benthic systems is tight, resulting in high benthic biomass (Grebmeier et al. 2006*a*). In a latitudinal comparison of energy flow partitioning, the benthic system received more energy in Arctic vs. temperate and tropical systems, although there are significant differences within the Arctic. A prime example for tight pelagic–benthic coupling can be found in the northern Bering and southern Chukchi Seas (Grebmeier et al. 2006*a*). Sediment trap measurements in the 1980s indicate that total particulate organic carbon (POC) flux in the northern Bering Sea is extremely high (253–654 mg $C{\cdot}m^{-2}{\cdot}d^{-1}$) and low C/N ratios of organic material in the sediment traps (4.9–7.4) indicate that fresh organic matter is reaching the benthic community. The latter utilizes the carbon directly and efficiently as indicated by a match of the mean vertical carbon flux (501 mg $C{\cdot}m^{-2}{\cdot}d^{-1}$) and the estimated organic carbon utilization at the seafloor (464 mg $C{\cdot}m^{-2}{\cdot}d^{-1}$; Grebmeier et al. 2006*a*). The high carbon flux is driven by high primary production, which was estimated at 250–300 g C/m^2 for the summer months or $\sim$2 g $C{\cdot}m^{-2}{\cdot}d^{-1}$. Those high production areas serve as feeding grounds for the bottom-feeding Pacific walrus, California gray whale, diving birds, and surface-feeding seabirds associated with feeding mammals (e.g., Oliver et al. 1983). In recent years, evidence is accumulating that change is underway, with less tight pelagic–benthic coupling and locally changing benthic biomass (Grebmeier et al. 2006*b*; see *Recent changes and fluctuations in Arctic marine food webs*).

RECENT CHANGES AND FLUCTUATIONS IN ARCTIC MARINE FOOD WEBS

The described characteristics of the ice, pelagic, and benthic realms provide a diverse spectrum of feeding habitats and prey communities for AMM. Variability and changes in environmental conditions (Walsh 2008) likely have different consequences for different trophic levels and species within them (Laidre et al. 2008). The growing concern about the potential impact of Arctic warming on the marine ecosystem stimulated major new large-scale biological climate studies and is one of the topics of the ongoing International Polar Year (IPY) 2007–2008. While Arctic systems have been described as well adapted or resilient to some degree of climate variation because of the frequent natural disturbances (Piepenburg 2005), the magnitude of change expected in this century makes the Arctic system vulnerable to climate change (ACIA 2004). It should be noted, however, that large changes are not necessarily (only) driven by climate. Arctic ecosystems are also impacted by high loads of pollutants and human exploitation (including harvest of fish and AMM), which have caused changes in Arctic food webs (e.g., AMAP 2003). The difficulty in documenting solid causal relationships between climate and biological populations lies in several factors, most importantly, the scarcity of long-term time series. Also, the best studied (sub-)arctic regions, the southern Bering and Barents Seas, are those that have undergone major climate variability, but are at the same time the most heavily exploited Arctic areas in terms of historic whaling, past and present fisheries, and/or oil and gas exploration.

Here we present examples of documented changes, attributed to climate variability or change, in subarctic and Arctic biological communities on a range of trophic levels. Examples will have a focus on subarctic regions, as biological investigations in the High Arctic have been too rare for analyses of interdecadal variabilities. Our current understanding of the High Arctic provides evidence for the close linkages between environment and marine food webs, but long-term time series are largely missing. Sporadic observations from the Central Arctic indicate substantial changes might be occurring already with the loss of sea ice and its attributed flora and fauna (Melnikov et al. 2001). Even today in the era of Arctic warming (ACIA 2004), no unified pan-Arctic long-term monitoring plan has been implemented to follow changes in the High Arctic marine food web composition and biomass. National programs, however, are underway, and so are efforts attempting to connect those in the framework of the IPY.

Pacific (sub-)arctic

A growing body of evidence suggests that regime shifts and long-term climate changes in the Bering and Chukchi Seas are coincident with alterations in biological regimes (Schumacher et al. 2003, Grebmeier et al. 2006*b*). Regime shifts are dynamic and can oscillate. The co-occurring biological changes can serve as model scenario indicators for effects of long-term climate change. The best understood example for climate-driven variability is the Bering Seas regime shift complex. The regime shift in 1997 had various effects on sea surface temperature, the extent of sea ice, and wind forcing of ocean currents in the Bering Sea. Since then, several coccolithophorid blooms have occurred in the Bering Sea and were intermittently thought to replace the previously occurring summer flagellate community (Schuhmacher et al. 2003). As a result, profound effects on consumer abundance and feeding types and on biogeochemical cycling were observed. As an example, zooplankton communities in the Bering Sea changed from crustacean-dominated communities to an increase in gelatinous plankton, which has since decreased again. The prey items of the dominant jellyfish species in the late 1990s and early 2000s, *Chrysaora melanaster*, includes euphausids, copepods, and amphipods, as well as juvenile pollock and, hence, overlaps with that of some Arctic marine mammals.

Shifts in fish and benthic community composition also occurred in recent decades (Hamazaki et al. 2005). In the heavily fished southeastern Bering Sea, flatfish and general groundfish biomass was higher in 1980–2000 than in 1960–1980. Catch per unit effort of total benthic epifauna (in particular crabs and sea stars) and fish (in particular flatfishes) increased from 1976 to 2002 in Norton Sound and from 1976 to 1998 in Kotzebue Sound. In contrast, a decrease in benthic infauna biomass and sediment oxygen uptake was observed south of St. Lawrence Island on the Bering Sea shelf (Grebmeier et al. 2006*b*). Here, the changes in the bivalve population composition by the late 1980s affected benthic predators, such as the spectacled eider, that heavily use this feeding ground. Between 1986 and 1988, ampeliscid amphipod biomass and production in the Chirikov Basin (northern Bering Sea) declined by ~20%, and by 2002–2003 production had further declined to ~50% of the highest value in 1986 (Coyle et al., *in press*). It is not fully resolved to what extent climate or whale predation is responsible for this decline. Indications for climate-related shifts in Arctic community composition are also evident from benthic studies in this region: Recent sampling in the Chukchi Sea suggests northern range extensions of some mobile epifauna species with climate warming as the suspected cause (B. Sirenko, B. A. Bluhm, and K. Iken, *unpublished manuscript*).

Arctic marine mammals have been used to understand long-term trends in ecosystem productivity in this region. The $\delta^{13}C$ stable isotope ratios in bowhead whale baleens support the hypothesis that the productivity of the Bering Sea declined by ~30–40% over the time period 1966–1997 (Schell 2000). Besides food web changes, ranges of AMMs might have changed as recent acoustic and visual observations documented temporally extended stays of gray whales in the Chukchi Sea all the way up to Barrow, potentially a consequence of warming trends (Moore et al. 2006).

Atlantic (sub-)Arctic

The variable inflow of comparatively warm North Atlantic water into the Barents Sea drives the variability of environmental conditions and of fish larval and zooplankton biomass in this area (e.g., Dalpadado et al. 2003). The North Atlantic Oscillation is thought to have an effect on the distribution and biomass of North Atlantic zooplankton. Over the last two decades the Barents Sea zooplankton biomass has undergone large changes with overall higher plankton biomass in relatively warm years such as 1994 than in cold years such as 1986. The biomass of the dominant copepod species, *Calanus finmarchicus*, was tightly linked to the supply of Atlantic water into the Barents Sea. With warming North Atlantic waters and stronger inflow into the Arctic, "warm-year" conditions may become prevalent in the future and extend northward. Zooplankton stock and growth fluctuations affect pelagic planktivorous fish such as capelin and herring, prey items of ringed seals and other AMM (Siegstad et al. 1998). More directly, a climate-related shift from large lipid-rich Arctic copepod species (Table 2) to smaller North Atlantic taxa might reduce the nutritional quality of the food present in areas affected by warming.

Similar linkages between warming and climate-related changes in benthic invertebrate and fish biomass and composition have already been observed in the Barents Sea half a century ago. Warming in the Barents Sea in the first half of the 20th century resulted in the restoration of the cod stock on Bear Island Bank after the species' practical absence for about four decades (Blacker 1957). Blacker also observed that several Atlantic indicator species had a northward range extension from 75° N to 78° N since 1878, apparently as a consequence of increased inflow of warm North Atlantic water. By 1978–1981, Dyer et al. (1984) noted that the same indicator species had further increased their temperature ranges in the same study region. In addition Arctic and Atlantic species overlapped more extensively in their ranges in the 1970s relative to the 1950s. Kiyko and Pogrebov (1997:330), in their analysis of pollution effects, observed decreases in polychaete biomass in the Barents and Kara Seas in the early 1990s relative to the 1920–1930s as well as a "redistribution of some organism groups." Although these authors interpret these changes as sampling effects and "natural population fluctuations," an analysis of these range changes in relation to climatic conditions still needs to be done.

Potential future scenarios for Arctic marine food webs

The Arctic Ocean will be, and to some extent already is, exposed to tremendous changes in the environmental boundary conditions, including loss of summer sea ice, increasing temperatures, and alterations in the precipitation and river runoff patterns (ACIA 2004, Walsh 2008). Detailed biological consequences of such changes on a species level are difficult to predict, as biological systems might react in unprecedented ways as learned from the described shifts between crustaceans and jellyfish in the Bering Sea. Here we describe three scenarios that, therefore, should be considered as thought experiments, providing inspiration to discuss possible effects on the Arctic marine food web and their implications for AMM and to pose related hypotheses. The underlying assumptions for the scenarios are based on published results from the literature described in the sections before; the scenarios themselves are, from our perspective, likely but not prognostic, each taking into account a particular set of parameters. We restricted ourselves to alterations outlined within the ACIA (2004) framework that assumes only slight modifications of the current Arctic Ocean hydrography; we excluded major alterations such as a potential loss of the Arctic halocline (Walsh 2008) and its subsequent impacts.

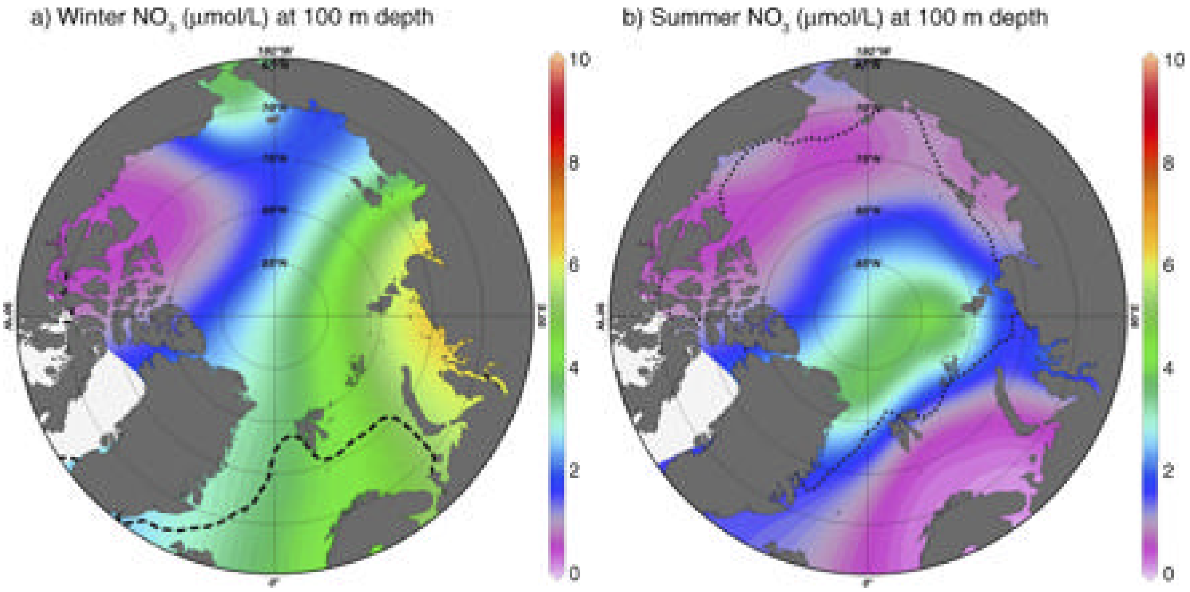

FIG. 2. (a) Winter and (b) summer nitrate concentration in the Arctic seas based on Colony and Timokhov (2001). Note that the data for winter are sparse (for details, see Colony and Timokhov [2001]). The dashed line indicates the long-term mean ice extent (concentration >50%) for (a) March and (b) September. The nutrient reservoir over the Central Arctic in the summer (blue and green areas) could support additional new primary production in an ice-free Arctic Ocean.

Changes in sea ice cover and resulting primary production.—The loss of summer sea ice cover will have immediate consequences for ice-dependent AMM. Examples include reduced reproductive success and survival chances of polar bears and the loss of insulation from snow and interruption of nursing in ringed seals due to early breakup (Kelly 2001, Laidre et al. 2008). The loss of the ice-based food web and the associated food sources such as amphipods and Arctic cod (Gradinger and Bluhm 2004) would additionally negatively impact the ice seals. For the Pacific walrus, the retreat of spring sea ice beyond the Arctic shelves into the deep basins will make ice no longer a resting and reproduction environment that is within the reach of their benthic prey (depth limit approximately 100 m; Kelly 2001).

On a broader ecosystem scale, the loss of sea ice will likely change the amount and characteristics of primary production in the Arctic seas. Several researchers (e.g., Anderson and Kaltin 2001) have proposed that the increased summer ice melt will increase the overall extent of marginal ice zones and lead to increased primary productivity in these regions. Increased primary productivity would supply more food for pelagic and benthic consumers, while the low productivity zone of the multiyear sea ice (MYI) would shrink. Also, ice retreat off the shelves may result in upwelling of nutrients or prey from the basins (Carmack et al. 2004). Based on the inorganic carbon availability, Anderson and Kaltin (2001) proposed an increase of up to 50 g C/m^2 integrated over the upper 100 m of the water column across the Arctic, mainly as a result of ice loss. Ultimately, however, nutrient availability, mainly nitrogen and phosphorous, determines the total amount of primary productivity possible in any given ocean.

Hence, we estimated the potential for increased primary productivity in the Arctic based on nutrient concentration data from the "Hydrochemical Atlas of the Arctic Ocean" (Colony and Timokhov 2001), which summarizes hydrographical and chemical data from drift ice stations and ship-based expeditions from 1948 to 2000. We selected nitrate concentration data from within the euphotic zone (10-m depth) to address the question of whether the removal of sea ice, and thus the increase in solar radiation in the water column, could indeed support an increase in primary production or whether the current nutrient resources are already completely consumed by phytoplankton growth. The large-scale nutrient regime in winter (Fig. 2a) shows three major features: (1) the oligotrophic Beaufort Gyre in the Canadian Basin, (2) the higher nutrient concentrations in the Transpolar Drift regime, and (3) the inflow of nutrients through the Bering Strait, the North Atlantic, and rivers on the Arctic shelves. The summer distribution (Fig. 2b), in contrast, shows a reduction of nitrate in the region south of approximately 80° N as a consequence of phytoplankton blooms in the dynamic marginal ice zones. North of 80° N, an area that currently overlaps with the MYI zone (Walsh 2008), summer nutrient concentrations remain higher, i.e., they are not completely utilized by phytoplankton. Based on the provided gridded data set, we calculated a mean nitrate summer concentration of 3.2 μmol NO_3 north of 80° N and of 0.8 μmol NO_3 between 70° and 80° N.

Assuming a typical phytoplankton C/N ratio of 7, the mean summer concentration of approximately 3.2 µmol NO_3 in the central Arctic would allow for an additional new production of 270 mg C/m^3 or 13 g C/m^2 (assuming a relatively shallow 50-m euphotic zone as typical for marginal ice zones, e.g., Sakshaug 2004) (Fig. 2b). This estimate is within the same order of magnitude as the current production estimates for the central Arctic Ocean (Gosselin et al. 1997), which according to our scenario would, hence, roughly be doubled. Similarly noteworthy is that the current nutrient regime would not allow for a substantial change in total primary productivity in the coastal and shelf regions using our assumptions.

In reality, total primary production will also depend on seasonal stratification, river runoff (see *Increased river runoff changes nearshore biological communities*), etc. Ice receding from the shelves could facilitate upwelling along the shelf breaks (Carmack et al. 2004), which in turn may support higher primary production on the shelves than suggested in our scenario that assumed constant nutrient concentrations. Nevertheless, we consider it reasonable to assume a primary production increase in the central Arctic Transpolar Drift system. Currently little of the Transpolar Drift system and the area north of 80° N is utilized by AMM (Laidre et al. 2008), but this might change under the outlined scenario. The fate of the above-described increased production at very high latitudes will depend on the food web structure. Currently, subarctic and Arctic pelagic and benthic communities (including AMMs) successfully exploit the seasonal ice systems of the Arctic shelves. Increased primary production in the Central Arctic might lead to higher biomass of zooplankton and/or benthos, depending on the reworking and sedimentation patterns. The great water depths in the Central Arctic will make remineralization of the majority of the production in the water column very likely, similar to current conditions in the Central Arctic (Fig. 1). From the perspective of AMM, benthic feeders such as gray whale and walrus will remain unable to exploit the Arctic basins because they are well beyond their diving depths. Pelagic feeders such as bowhead, fin, minke, and blue whales, in contrast, might be able to use the increased productivity. The question of whether jellyfish rather than (or in addition to) crustaceous zooplankton would increase in relative importance in subarctic and Arctic food webs, as documented in the Bering Sea and elsewhere, is open. Jellyfish and other gelatinous zooplankton are an integral part of the current High Arctic food web (Hopcroft et al. 2005) but have low caloric value for higher trophic levels (Table 2). Their increase would likely not lead to better feeding conditions for AMMs.

Increased river runoff changes nearshore biological communities.—A second scenario revolves around the potential effects of the observed and predicted increase in river runoff in the Arctic (ACIA 2004). Total freshwater inflow into the Arctic Ocean is on the order of 4523 km^3/yr (R-ArcticNet, *available online*)[2] and increased by ~7% from 1936 to 1999, with the potential for further increase with Arctic warming (ACIA 2004).

Increased freshwater discharge acts on biological communities through three major pathways (besides addition of organic dissolved matter): (1) nutrient transport, (2) turbidity, and (3) inflow of low salinity water (Pivovarov et al. 2003). All three effects can act on the levels of species richness, community composition, productivity, and biomass, and although these effects are tightly coupled, we will evaluate their current significance separately for clarity of the argument.

1) Arctic river runoffs differ in the amount of inorganic nutrients, both macro- and micronutrients. The injected macronutrients are consumed by phytoplankton within the river estuaries, as exemplified for both the Kara and the Beaufort Seas (e.g., Pivovarov et al. 2003). Additional nutrient input to the nearshore waters through either higher freshwater input (through changes in the hydrological cycle) or higher nutrient concentrations in the freshwater (through changes in the terrestrial environment; ACIA 2004) could increase the current productivity in coastal and estuarine areas, but this might be counteracted by the impact of decreased salinities and increased turbidity.

2) Increased river runoff, with its high levels of suspended inorganic material, will increase nearshore sedimentation and turbidity, which reduces light transmission for algae and can clog filtration apparatuses of filter-feeding animals (Thrush et al. 2004). Certain Arctic cumacean and bivalve species, e.g., *Portlandia arctica*, can endure high sedimentation rates (Syvitski et al. 1989) while many other species cannot. High turbidity reduces the capability of visual predators to find prey. Increased land use in the Arctic over the next decades due to resource exploitation and climate change has the potential to further increase the sediment load and impact the marine food web.

3) Increased freshwater discharge would likely result in larger areas inhabited by euryhaline and brackish-water species relative to marine species compared to the current situation. In general, species richness is related to salinity, with high numbers of species in fully marine and true freshwater conditions and the lowest number of species around 5–7 practical salinity units (PSU; Remane 1958; Fig. 3). Brackish-water species occur at a salinity range from close to 0 to ~20 PSU, but are not very numerous.

The structuring effect of freshwater runoff, with all features combined, on the biomass, productivity, and community composition of Arctic phytoplankton, zooplankton, and benthic taxa is reasonably well documented and outlined here, although some results are

---

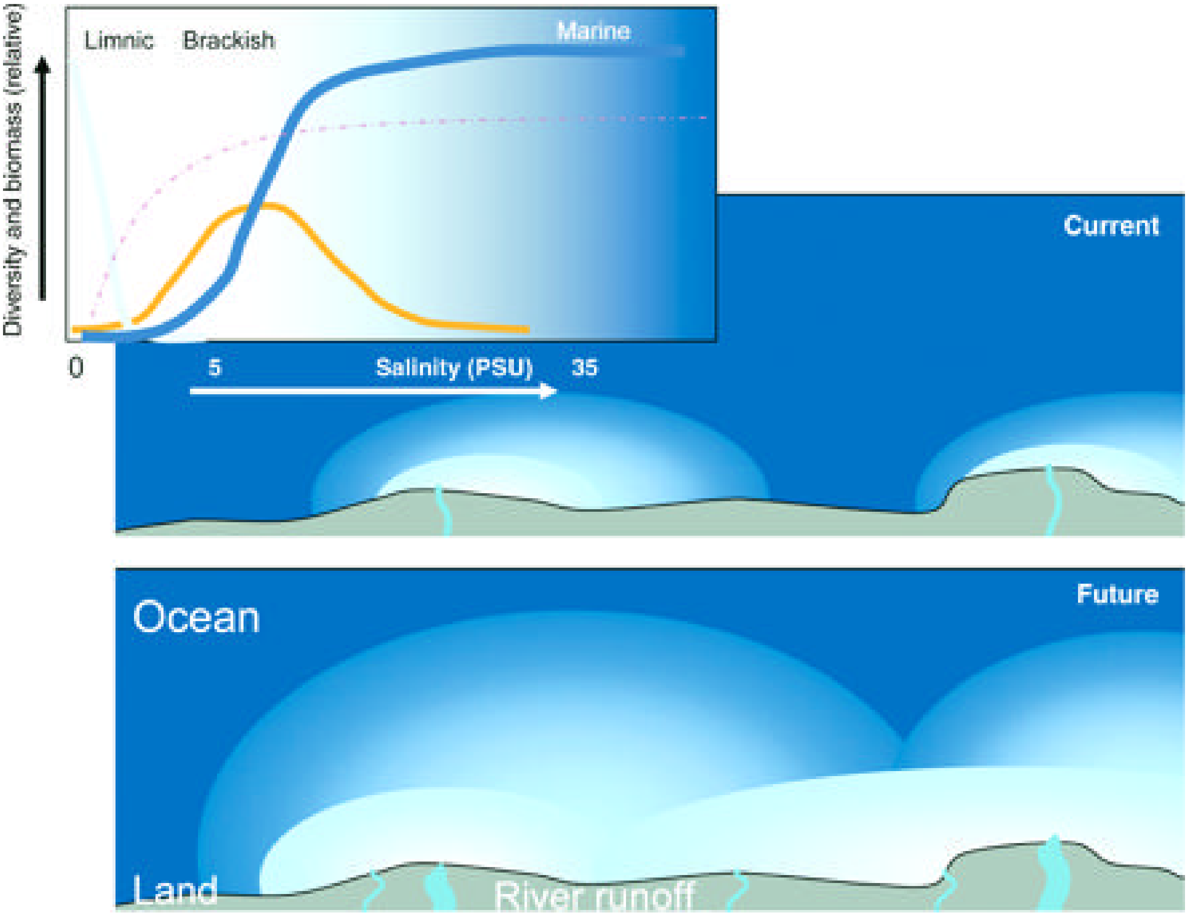

Fig. 3. Schematic representation of surface water salinity gradients in Arctic estuaries. Increased river runoff will decrease salinity over a broader area (indicated by light blue colors) in the nearshore Arctic Seas. This might lead to decreased diversity and biomass of the pelagic and benthic prey taxa of Arctic marine mammals. The relationship between water salinity and species diversity for freshwater (light blue line), brackish-water (orange line), and marine species (dark blue line), and biomass (pink line) is based on Remane (1953). For details see *Potential future scenarios…: Increased river run-off…*.

conflicting (Parsons et al. 1988, Deubel et al. 2003, Udalov et al. 2005).

In the pelagic realm, freshwater taxa currently dominate in the river mouths of the large Siberian rivers, and highest biomass was associated with the marine realm, where large copepods (*Calanus glacialis*) dominated the zooplankton (Deubel et al. 2003). In the near-mouth zone of an estuary in the White Sea, the concentration of suspended matter was higher than in the intermediate and marine zones, and the highest phytoplankton concentrations were observed in the marine zone, whereas the lowest occurred in the near-mouth zone (Dolotov et al. 2002). Similarly, minimum algal biomass (0.3 µg chlorophyll *a*/L) occurred close to the mouth of the estuary of Chesterfield Inlet in the Canadian Arctic, and maximum biomass (1.9 µg chlorophyll *a*/L) was observed near the estuary head (Roff et al. 1979). In the MacKenzie River estuary, the planktonic community near the river mouth experienced high dissolved organic carbon pools, high bacterial activity, and high amphipod biomass, while the more productive offshore community consisted of copepods, medusae, and ctenophores (Parsons et al. 1988).

Benthic infaunal species richness, biomass, and Shannon-Wiener diversity increased with salinity in the Kara Sea (e.g., Deubel et al. 2003). Arctic estuaries are dominated by few benthic species, as is typical for areas with large fluctuations in environmental conditions, such as the euryhaline polychaetes *Prionospio cirrifera* and *Marenzelleria arctica*, the cumacean *Diastylis* cf. *glabra*, and the bivalve *Portlandia* cf. *arctica* (Denisenko et al. 1999, Jørgensen et al. 1999). The biomass of micro- and macrozoobenthos also decreased with salinity in a White Sea estuary, whereas that of the meiozoobenthos increased in association with dramatic community composition changes: At salinity values <10 PSU, the proportion of nematodes dropped from 86% to 50% by abundance, while ostracods increased to up to 45% of the total abundance of meiobenthos (Udalov et al. 2005). Nematode and harpacticoid densities and biomass dropped dramatically below salinities of 3 PSU. These studies suggest that diversity and biomass in Arctic

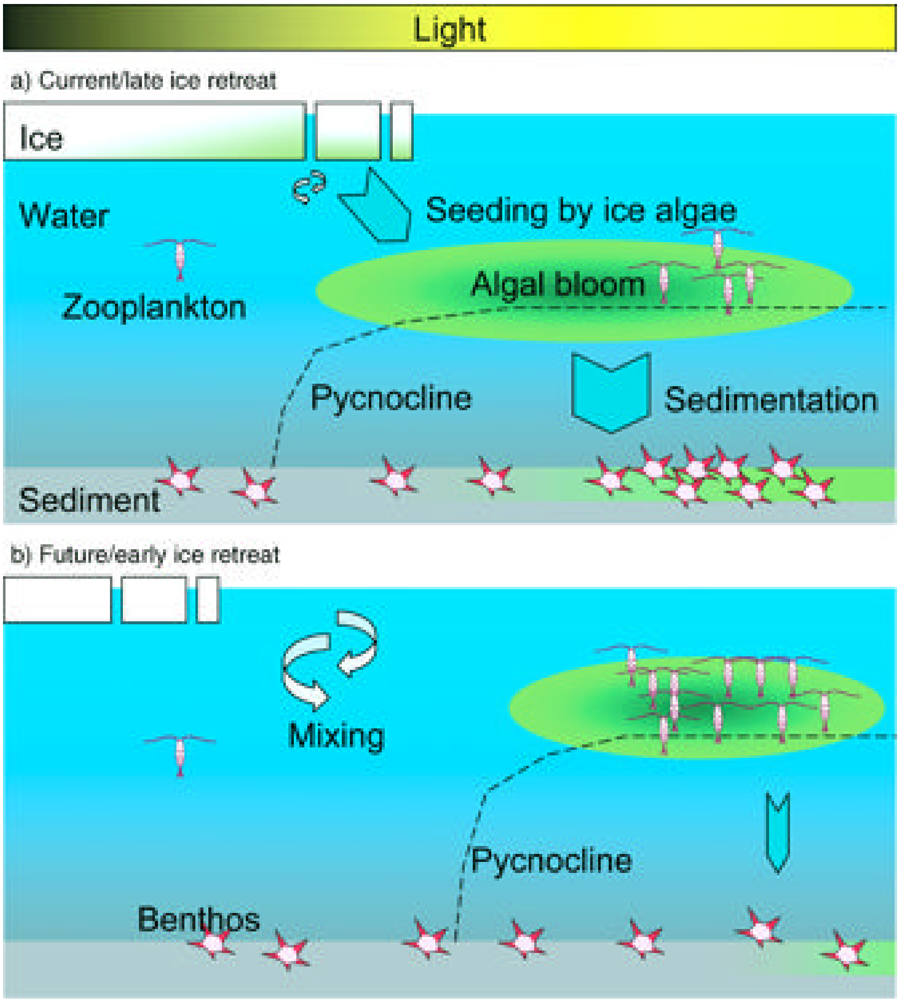

FIG. 4. Schematic representation of seasonal cycle of marine production in current/late ice retreat (a) and future/early ice retreat conditions (b). Early ice retreat allows for stronger wind mixing and causes later formation of the seasonal pycnocline. The delayed phytoplankton bloom is consumed by zooplankton, while, under current conditions on several Arctic shelves, it largely sinks directly to the sea floor, sustaining high benthic biomass.

estuaries often, but not always, covary along a salinity gradient with increasing biomass from the freshwater to the marine conditions and a diversity minimum at salinities of ~5 PSU (Fig. 3).

Applying the described relationships to the future situation for AMM, increased river runoff may be more likely to cause reduced rather than constant or increased benthic biomass and diversity, which would put benthic-feeding AMM at a disadvantage in the nearshore freshwater to brackish-water areas. Some studies suggest that reduced biomass may also be the trend in a fresher future pelagic realm. The total biological changes associated with the salinity gradient might cause AMM to prefer areas further offshore than they currently occupy, which could be harmful for the subsistence hunting activities of coastal Arctic communities.

Changes in cryo-pelagic–benthic coupling.—The extent of cryo-pelagic–benthic coupling varies in the Arctic, from regimes in which most of the primary production is consumed by pelagic zooplankton to regions with substantial flux to the seafloor and resulting high benthic biomass and production (Fig. 1; Piepenburg 2005, Grebmeier et al. 2006*a*). Two conceptual primary production scenarios have been suggested that relate to ice cover and may, therefore, have predictive value. In years of abundant sea ice (and, thereby, cold surface waters), herbivorous zooplankton is less abundant early in the season and has little grazing impact on the ice algal and marginal ice zone blooms (e.g., Carroll and Carroll 2003). As a result, primary production occurring in these well-stratified conditions is largely exported to the benthic community and can support a biomass-rich benthic community and benthic-dominated food web including bottom-feeding mammals and birds (Grebmeier et al. 2006*a*). In years or areas with less ice, in contrast, an open water and later-occurring phytoplankton bloom dominates over sea ice-related blooms. With zooplankton further along in their life cycles at this time and water temperatures slightly warmer, these phytoplankton blooms may be efficiently grazed by abundant zooplankton (Carroll and Carroll 2003; Fig. 4), which in turn are capable of supporting pelagic larval and juvenile fishes. The increased pelagic carbon utilization and recycling would result in a reduced flux of more refractory carbon to the seafloor.

These two contrasting scenarios imply that the ongoing trend of declining sea ice, earlier ice melt, and increased water temperatures in the Arctic (ACIA 2004) would make the pelagic food web-dominated scenario both more common and occur over a geographically larger area. The increased consumption of pelagic primary production by pelagic herbivores enhancing planktivorous fish abundance would increase the prey concentrations for pelagic-feeding AMM such as bowhead whales. Reduced carbon input to the benthic environment could have the reverse effect for benthic-feeding AMM such as walrus. Arctic marine mammal species currently flexible in their feeding mode and capable of utilizing both pelagic and benthic prey, e.g., bearded seals, may be less affected by the proposed alterations of the food web structure. In the extreme case of all benthic-feeding AMM species switching to pelagic feeding, if so capable, resource competition might be intensified.

Closing Remarks

Two if not all three of the suggested scenarios, although somewhat hypothetical at this point, propose higher pelagic rather than benthic prey availability to AMM in the future. Should these assumptions hold true, some AMM populations would need to adjust their feeding habits and/or location and timing of migrations for populations to maintain their current population levels. Several AMM (Table 1) are apparently capable of feeding in the pelagic and benthic realms within the same or in different geographic areas, e.g., bearded seals and gray whales. Other species, such as the walrus, may be less capable of changing to a different feeding mode and/or location and may hence be more vulnerable to changing conditions (Laidre et al. 2008). Besides changing food availability, the capability of shifting prey items and realms will ultimately depend on the trophic plasticity of AMM species with respect to their functional morphology, enzymatic and diving physiology, and foraging behavioral spectrum.

Our compilation shows that, for certain areas and species, sufficient information is now available on major prey selection patterns to produce pan-Arctic resource selection functions and preferred habitat models for AMM. Such approaches are underway for cetaceans on a worldwide scale and for selected vertebrate species on regional scales. These modeling efforts should be linked to historic data sets as currently compiled for cetaceans by the History of Marine Animal Population project and others in order to address effects of environmental change and human impact on a stronger data basis.

It should be noted that the various effects of environmental changes will occur simultaneously, which may provoke unpredicted and unprecedented developments. As pointed out previously, other changes that are not directly related to Arctic warming also influence AMM, but are not included in this paper. In our view, only holistic ecosystem monitoring approaches, combining ocean-observing systems and AMM and prey distribution and biomass surveys with modeling efforts, will provide the tools to detect, predict, and evaluate changes in the next decades.

Acknowledgments

We are grateful for fruitful discussion of an earlier manuscript draft with Sue Moore, NOAA Seattle, and Michael Castellini, University of Alaska–Fairbanks. We appreciate the valuable comments by Brendan Kelly, University of Alaska–Southeast, and an anonymous reviewer. We thank the Marine Mammal Commission, especially John Reynolds and Tim Ragen, for supporting the project that resulted in the Special Issue of which this article is a part.

METHODS AND COUNT DATA

This paper presents updated counts and abundance estimates for gray whales (*Eschrichtius robustus*) migrating southbound off the central California coast between December and February 2014/15 and 2015/16. Counting and analytical methods followed those described by Durban *et al*. (2015) for four previous abundance estimates between 2006/7 and 2011/12. Counts were made from a shore-based watch station at Granite Canyon, California, by teams of observer pairs rotating from a larger pool. A total of 16 observers were used over the two years, 10 in 2014/15 and 12 in 2015/16; six observers counted in both years. Only five of these 16 observers were not involved in the previous independent counting experiments when the detection models were parameterized; in these cases, observer effects were predicted (with uncertainty) from the hierarchical model for observer effects (Durban *et al*. 2015).

Data were the total counts of whales from each 1.5-hour watch period that had acceptable weather conditions (see Durban *et al*. 2015). These comprised 179 watch periods in 2014/15 and 151 in 2015/16, totaling 269 and 226 hours of watch effort over 39 and 37 days, respectively (Table 1). The result was 2978 and 2666 whales counted in each of these years, the former representing the highest count since our new watch protocol was started in 2006/2007 (Durban et al. 2015).

Table 1: The number of whales recorded during the southbound gray whale surveys in 2014/15 and 2015/16. Data are the total counts of whales, hours and distinct days for watches during acceptable observation conditions.

Migration	Dates	Hours	Days	Whales
2014/2015	30-Dec-14 to 13-Feb-15	269	39	2978
2015/2016	30-Dec-15 to 12-Feb-16	227	37	2666

ABUNDANCE ESTIMATES AND DISCUSSION

Bayesian Markov Chain Monte Carlo (MCMC) sampling was used to simultaneously rescale counts for detectability and also smooth to abundance changes over the course of each migration (Durban *et al*. 2015). These abundance changes were described using Bayesian model selection between a parametric model for a Normally distributed migration trend that borrowed strength across years and a semi-parametric model that estimated the time trends independently for each year; the resultant migration curve was a weighted compromise between models, allowing for key departures from the common trend. The total number of whales passing during each migration was then estimated by summing the expected value (along with associated uncertainty, see error bars in Fig 1) from the model-averaged number of whales passing each day from time 0 (01 December) to 90 days, and these estimates were then rescaled to account for the differential passage rate at night (see Durban et al. 2015).

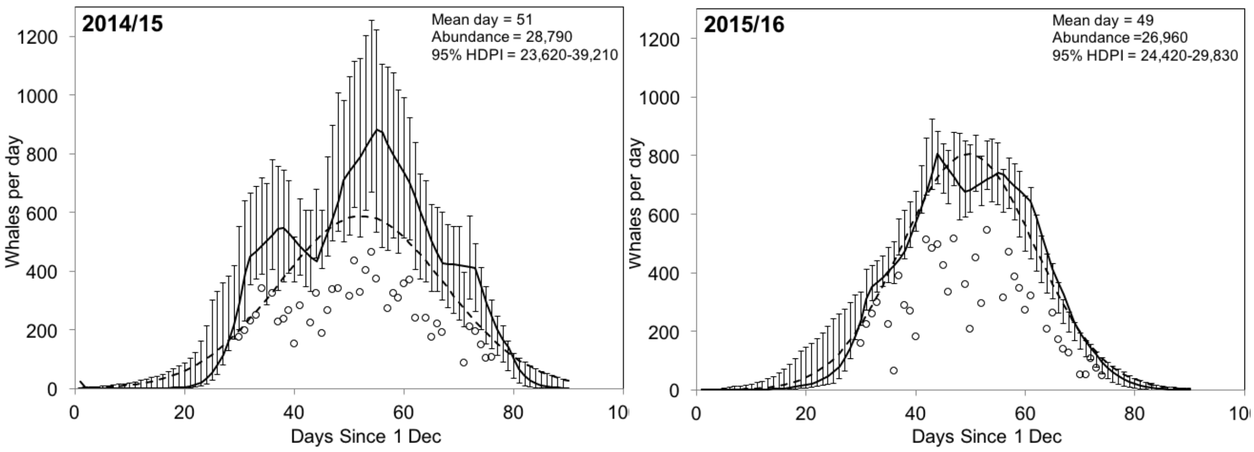

Figure 1. Observed whale passage rates expressed as total counts per day / proportion of day observed (circles) and fitted migrations models (lines) for two gray whale migration counts in 2014/15 and 2015/16. The broken line represents the median estimates from a hierarchical Normal model for migration and the solid line represents a semi-parametric model of penalized splines (see Durban et al. 2015). The abundance estimate for each day (95% highest posterior density interval shown by vertical lines) is a model averaged compromise between the migration models, and these were summed to estimate the overall abundance for the migrations.

To sample the full extent of the uncertainty associated with model parameters, inference was based on each 10th iteration of the MCMC sampler to generate a sample of 30,000 iterations following a burn-in of 10,000. There was consistency between the model predictions and observed counts for both years, with Bayesian P-values of 0.49 and 0.54, respectively; values close to 0.5 would indicate that the data were consistent with replications under the model such that the distribution of the predicted count would symmetrically overlap the observed count (Gelman *et al*. 1996). However, daily and total abundance in 2014/15 were subject to considerable uncertainty, as shown by the large error bars associated with each of the daily estimates (Figure 1) and the large coefficient of variation (CV = posterior standard deviation / posterior median; $CV^{2015} = 0.13$). This is likely explained in part by the results of model fitting, as significant departures from the Normal migration model (probability of Normal model <0.25) were estimated in 18/90 days in 2014/2015 compared to only 9/90 days in 2015/16. These departures, and the uncertainty associated with estimating an independent migration curve, constrained estimation of a precise migration curve. In contrast the $CV^{2016} = 0.05$ was consistent with previous estimates using this counting approach and model (CV = 0.04-0.06 for four previous estimates since 2006/2007), and this estimate was therefore more useful for interpreting in the context of the abundance time series. Differences in the CVs from the two years demonstrated the value of completing two counts and abundance estimates in back-to-back years, which provided a measure of redundancy.

The 2015/16 estimate of 26,960 (95% highest posterior density interval = 24,420-29,830) represented a 22% (5970 whales) increase in the five years since the 2010/11 estimate of 20,990. This is consistent with high estimates of calf production (Perryman *et al*. SC/67a), with a total of >6000 calves estimated during this period, including four of the highest years of calf production (>1000 calves per year) since our calf counts began in 1994. This increase in gray whale abundance also supports inference that gray whales have been experiencing a period of favorable feeding conditions in the Arctic due to a combination of expanding ice-free habitat (Moore 2016), increased primary production (Arrigo and Dijken 2015) and increased flow of nutrient-rich waters through the Bering Strait (Woodgate et al. 2012).

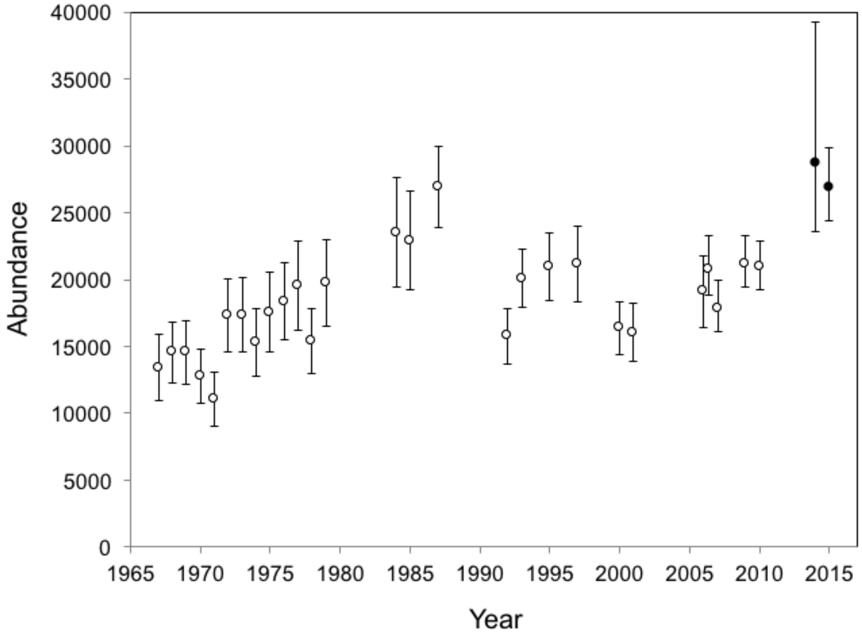

Figure 2: Gray whale abundance estimates for southbound migrations with an end year between 1967 and 2011 (open circles, with 95% confidence intervals; from Laake *et al.,* 2012 and Durban et al. 2015) together with the two recent migrations reported here for 2015 and 2016.

Report of the Scientific Committee

Bled, Slovenia, 24 April-6 May 2018

**This report is presented as it was at SC/67b.
There may be further editorial changes (e.g. updated references, tables, figures)
made before publication.**

**International Whaling Commission
Bled, Slovenia, 2018**

Report of the Scientific Committee
Bled, Slovenia, 24 April - 6 May 2018

The meeting (SC/67b) was held at the Rikli Balance Hotel, Bled, Slovenia, from 24 April-06 May 2018 and was chaired by Caterina Fortuna. The next meeting of the Commission (IWC/67) will take place 4-14 September 2018. The list of participants is given as Annex A (about one-third of the Contracting Governments were represented by delegates).

1. INTRODUCTORY ITEMS

1.1 Chair's welcome and opening remarks

Fortuna welcomed the participants to the meeting. Although the meeting was not officially hosted by the Slovenian Government, she thanked it for welcoming them back and noted how pleased the Scientific Committee was to be once again in such a beautiful place. She thanked the IWC Secretariat staff for their hard work during the intersessional period, particularly Mark Tandy for organising the meeting under time pressure Stella Duff and Andrea Cooke for their assistance with meeting documents and Greg Donovan for all his support intersessionally. She thanked Sava Hotels for providing the meeting facilities and her Slovenian colleagues for helping meeting arrangements run smoothly. Fortuna also thanked the vice-Chair Robert Suydam, the Convenors (including those of intersessional groups) and Committee members for all their hard work since the last meeting.

Rebecca Lent, the new IWC Executive Secretary, welcomed participants to the meeting She noted this was her first IWC meeting, but already knew of its excellent global reputation and looked forward to attending many sessions. She noted her pleasure at joining the IWC at such an exciting time, with a busy year of meetings and several new initiatives. Two new coordinators have joined the Secretariat as part of the IWC work programmes endorsed by the Commission in 2016: Marguerite Tarzia as bycatch coordinator; and Karen Stockin as strandings coordinator. They will lead the Commission's work in these areas and will provide valuable input into the Scientific Committee's work.

Lent noted that the external "The IWC review – final report" (https://archive.iwc.int/?r=6890) undertaken as part of the IWC's Governance Review has recently become available and she noted that the Commission would welcome comments on it from the Scientific Committee, and that in particular, the Commission's Operational Effectiveness Working Group will take into consideration the comments from the Scientific Committee in making its recommendations to the Finance and Administration Committee; that Committee will then make recommendations to the Commission, which will determine the next steps in the governance review. Budget Management has become more challenging in recent years and there is much work to do to make sure the workplan of the Commission and all its subsidiary bodies is affordable going forward and into the long term. Finally, she thanked Scientific Committee members for their scientific input over the next two weeks and wished everyone a successful meeting.

The Committee was saddened to learn of the death of four scientists connected with the Scientific Committee:

(1) Greg Kaufman, a member of the Committee since 2006 and an active member of the sub-committee on whale watching and the Whale watching Working Group of the Conservation Committee;

(2) Doug Coughran, who although he did not attend Scientific Committee meetings, was a participant in numerous IWC workshops on entanglement and stranding response and was a charter member of both the IWC's entanglement and stranding expert (advisory) groups;

(3) Dale Rice, who although he has not attended IWC meetings in recent years, first represented the USA on the Scientific Committee as far back as 1960; and

(4) John Reynolds, who although not a member of the Scientific Committee, was a mentor to many Committee members.

The Committee paused in silence and respect for these scientists who had contributed directly and indirectly to the Committee's work and to whale conservation and management. Short obituaries can be found in Annex AA.

1.2 Appointment of rapporteurs

Donovan was appointed rapporteur with assistance from various members of the Committee as appropriate. Chairs of sub-committees and Working Groups appointed rapporteurs for their individual meetings.

1.3 Meeting procedures and time schedule

The Committee agreed to the meeting procedures and time schedule outlined by the Chair.

1.4 Establishment of sub-committees and Working Groups

The following pre-meetings were held:

1. the Standing Working Group on Environmental Concerns held a pre-meeting on 'Cumulative Effects' from 22-23 April; and
2. the sub-committee on Whale Watching held a pre-meeting on the IWC's 'Five Year Strategic Plan for Whale Watching' from 22-23 April.

Several sub-committees and Working Groups were established. Their reports were either made Annexes (see below) or subsumed into this report.

Annex D – Sub-Committee on the Revised Management Procedure;

Annex E – Standing Working Group on an Aboriginal Whaling Management Procedure;

Annex F – Sub-Committee on In-Depth Assessments;

Annex G – Sub-Committee on Other Northern Hemisphere Whale Stocks

Annex H – Sub-Committee on Other Southern Hemisphere Whale Stocks;

Annex I – Working Group on Stock Definition and DNA testing;

Annex J – Sub-Committee on Non-Deliberate Human-Induced Mortality of Cetaceans;

Annex K – Sub-Committee on Environmental Concerns;

Annex L – Standing Working Group on Ecosystem Modelling;

Annex M – Sub-Committee on Small Cetaceans;

Annex N – Sub-Committee on Whale Watching;

Annex O – Sub-Committee on Conservation Management Plans;

Annex P – Revised 'Annex P';

Annex Q – Standing Working Group on Abundance Estimates, Stock Status and International Cruises;

Annex R – *Ad hoc* working Group on Sanctuaries;

Annex S – *Ad hoc* Working Group on Photo-ID;

Annex T – Ad hoc Group on Global databases and repositories

Annex U – Statements on Special Permit discussions

Annex V – IWC-SORP – Southern Ocean Research Partnership

Annex W – Updated Rules of Procedure

Annex X – Comments on the 'Governance Review'

Annex Y – Intersessional groups

Annex Z – Minority Statements on the Agenda

1.5 Computing arrangements

Donovan outlined the computing and printing facilities available for delegate use.

2. ADOPTION OF AGENDA

The adopted Agenda is given as Annex B. Statements on the Agenda are given as Annex Z.

3. REVIEW OF AVAILABLE DATA, DOCUMENTS AND REPORTS

3.1 Documents submitted

The documents available are listed in Annex C. As agreed at the 2012 Annual Meeting, primary papers were only available at the meeting in electronic format (IWC, 2013a, pp 78-79).

3.2 National Progress Reports on research

The National Progress Reports have their origin in Article VIII, Paragraph 3 of the Convention. All member nations are urged by the Commission to provide Progress Reports to the Scientific Committee following the most recent guidelines developed by the Scientific Committee and adopted by the Commission. The report is intended to provide (1) a concise summary of information available in member countries and (2) advice on where to find more detailed information if required. In addition, the IWC holds several specialist databases (including, catches, sightings, ship strikes, images – see Item 23).

As agreed at the 2013 Annual Meeting (IWC, 2014), all National Progress Reports were submitted electronically through the IWC National Progress Reports data portal. Encouragingly, 18 countries (Argentina, Australia, Brazil, Croatia, Denmark, France, Germany, Iceland, Italy, Japan, Korea, Mexico, New Zealand, Netherlands, Norway, Spain, UK and USA) submitted reports this year compared to 12 last year. Information was provided on bycatch, entanglement, ship strikes, direct and indirect takes, sampling, sightings and tracking studies.

Nearly all the recommendations identified by the Committee in 2017 (IWC, 2018c) have been implemented although further guidance is required on the appropriate level of aggregation for some records (e.g. strandings) to simplify and accelerate data entry without losing valuable resolution.

Although data entry this year was hampered due to problems with the IWC server, this generic issue has already been resolved by the IWC Secretariat. Several suggestions for improvements, including the removal of default values, can be See Annex T for full details.

Attention: C, CG, S, SC

Despite the technical issues of the portal, the eighteen Progress Reports submitted to SC67b was an improvement on the twelve submitted to SC67a. Nevertheless, this represents a small proportion of IWC member nations. The Committee ***reiterates*** *that National Progress Reports are required under the Convention and they represent a useful tool and* ***recommends*** *that Contracting Governments to submit them annually through the IWC data portal (http://portal.iwc.int).*

National Progress Reports include records of reported bycatch and ship strikes. The Committee ***agrees*** *that the data collected in these reports are not intended to replace in-depth studies and they should be considered and used with great caution. However, it also* ***agrees*** *the reports have value because much of these data would not otherwise be available and the reporting process can assist in supporting national compilation of cetacean data.*

To address in part several of the issues and challenges described above the Committee ***agrees*** *to:*

(1) develop a strategy with the Scientific Committee Chair and Secretariat to raise awareness of National Progress Reports and promote reporting by member nations;
(2) produce a short summary explaining the utility of National Progress Reports and suggest including this text in the circular to member nations calling for data submission;
(3) request the Secretariat to issue the first call for data submission in February and repeat the call a few weeks prior to the start of the SC meeting;
(4) develop text acknowledging the likely limitations of the reported data (subsequently this text will be included in all reports and data downloads;
(5) further explore approaches (using R markdown) to produce PDF- formatted national reports.
This work will be conducted by the GDR Steering Group intersessionally (see Annex Y).

3.3 Data collection, storage and manipulation

3.3.1 Catch data and other statistical material

Table 1 lists data received by the Secretariat since the 2017 meeting.

Table 1
List of data and programs received by the IWC Secretariat since the 2017 meeting.

Date	From	IWC ref.	Details
18/05/2017	St Vincent&G: J. Cruickshank-Howard	E128 Cat2016	Information from St Vincent and the Grenadines aboriginal hunt 2016-17

18/04/2018	Iceland: G. Vikingsson	E130 Cat2017	Individual records of minke whales caught by Iceland 2017 [there was no fin whale catch]
18/04/2018	Norway: N. Øien	E130 Cat2017	Individual minke records from the Norwegian 2017 commercial catch. Access restricted (specified 14-11-00).
19/04/2018	USA: R. Suydam	E130 Cat2017	Individual records from USA Alaska aboriginal bowhead hunt 2017
20/04/2018	Japan: H.Morita	E130 Cat2017	Individual data for Japan's catch in 2017 in the N. Pacific (JARPN II) & 2017/8 in the Antarctic. (pdf format)

3.3.2 Progress of data coding projects and computing tasks

On behalf of Allison, Donovan reported that the 2017 catches and Japan coastal records in 1943-44 (data from NMML Seattle) have been added to the database. The changes agreed at the 2017 meeting, in particular to split out the catches taken *en route* to and from the Antarctic whaling grounds, have been implemented. Work on computing tasks with respect to work on the AWMP, RMP and in-depth assessments is reported under the relevant agenda items.

4. COOPERATION WITH OTHER ORGANISATIONS

Attention: C-A

The Committee ***stresses*** *the value of cooperation with other organisations when addressing the range of issues affecting cetacean conservation and management. In addition to the summaries below, co-operation is also discussed where relevant elsewhere in the agenda.*

4.1 African States Bordering the Atlantic Ocean (ATLAFCO)

There was no meeting of the Ministerial Conference of ATLAFCO during the intersessional period.

4.2 Arctic Council

4.2.1 PAME (Protection of the Arctic Marine Environment)

The PAME II-2017 meeting was held in Helsinki, Finland from 18-20 September 2017. No IWC observer attended the meeting. The Committee agrees that if possible an IWC observer should attend the next meeting of PAME.

4.3 Convention on Biological Diversity (CBD)

There was no meeting of the Conference of Parties during the intersessional period. The next meeting will take place 10-22 November 2018. The Committee agrees that if possible an IWC observer should attend the next meeting of CBD.

4.4 Convention for the Conservation of Antarctic Marine Living Resources (CCAMLR)

The 36th Meeting of the CCAMLR Scientific Committee was held 16 - 20 Oct 2017 October 2016 in Hobart, Australia. Although no IWC observer attended the meeting, co-operation with CCAMLR remains an important component of the IWC's work and is discussed further under Item 16.1.

4.5 Convention on the Conservation of Migratory Species (CMS)

4.5.1 Scientific Council

The Second Meeting of the Sessional Committee of the Scientific Council was held 10- 13 July 2017 in Bonn, Germany. No IWC observer attended the meeting.

4.5.2 Conference of Parties

The Conference of Parties met 23-28 October 2017 in Manila, Philippines. No IWC observer attended the meeting.

4.5.3 Agreement on Small Cetaceans of the Baltic and North Seas (ASCOBANS)

The report of the observer to ASCOBANS is given as SC/67b/COMM01E. The following key activities have occurred since the last IWC Scientific Committee meeting:

(1) first Joint Meeting of the 13th Meeting of the Jastarnia Group (Baltic Sea harbour porpoises) and the 6th Meeting of the North Sea Group;
(2) best-practice workshop on 'Fostering Inter-regional Cooperation on Underwater Noise Monitoring and Impact Assessments in waters around Europe, within the context of the European Marine Strategy Framework Directive';
(3) 23rd Meeting of the Advisory Committee; and
(4) 14th Meeting of the Jastarnia Group.

The key ongoing ASCOBANS activities are:

(1) work on the three harbour porpoise Action Plans (Baltic, Belt and North Seas)- in place since February 2018;
(2) web-accessed database on marine mammal stranding and necropsy in preparation (ZSL/IOZ leading), 2018-2020;
(3) preparation of an action plan for common dolphins; and
(4) implementing a change in the national reporting cycle from annual (on all topics) to a four-year cycle (selected topics each year) - the intention is that all the key ASCOBANS working groups and meetings align their agendas to home in on these issues in the respective years of reporting (e.g. covering 2017 in 2018).

The Action Points at the last Advisory Committee meeting included:

(1) preparing a discussion on prey depletion and changes in prey quality on the agenda of the 24th Meeting of the Advisory Committee;
(2) co-organisation of a workshop with ACCOBAMS on strandings and marine debris (the report has been made to the Scientific Committee);
(3) future focuses will include the white-beaked dolphin and the white-sided dolphin.
(4) a draft Action Plan for the Common Dolphin is due to be presented at the 24th Advisory Committee Meeting.

The Committee thanked Simmonds for his report and **agrees** that he should represent the Committee as an observer at the next ASCOBANS meeting.

4.5.4 Agreement on the Conservation of Cetaceans of the Black Sea, Mediterranean Sea and Contiguous Atlantic Area (ACCOBAMS)

MEETING OF PARTIES

There was no Meeting of the Parties (MoP) to ACCOBAMS during the intersessional period. Donovan will represent the Committee as an observer at the next ACCOBAMS MoP.

SCIENTIFIC COMMITTEE

There was no meeting of the ACCOBAMS Scientific Committee during the intersessional period. Donovan will represent the Committee at the next ACCOBAMS Scientific Committee meeting.

4.6 Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES)

No relevant meetings of CITES have taken place during the intersessional period.

4.7 Food and Agriculture Organisation of the United Nations (FAO)

There was no meeting of The Committee on Fisheries (COFI) during the intersessional period. The next meeting will take place in Rome, Italy 9-13 July 2018.

4.8 Inter-American Tropical Tuna Commission (IATTC)

The 92nd meeting of the Inter-American Tropical Tuna Commission (IATTC) was held in Mexico City, Mexico 24-28 July 2017. No observer attended IATTC meetings in the intersessional period.

4.8.1 Agreement on the International Dolphin Conservation Program (AIDCP)

No observer attended IADCP meetings in the intersessional period.

4.9 International Committee on Marine Mammal Protected Areas (ICMMPA)

There was no meeting of ICMMPA task force during the intersessional period. The 5th International Conference will be held from 8- 12 April 2019 in Greece. It will evaluate progress in meeting the ICMMPA's long-standing goal of bringing the MMPA community closer together. A primary goal is to focus on the challenges ahead towards achieving effective place-based protection and management for marine mammals. It will build on previous initiatives to advance our understanding of science, management, and effective biodiversity conservation in protected areas. It will also provide updates on plans for the worldwide Important Marine Mammal Area (IMMA) initiative (*marinemammalhabitat.org*). Rojas-Bracho will represent the Committee at this meeting.

4.10 International Council for the Exploration of the Sea (ICES)

The report of the IWC observer documenting the 2017 activities of ICES is given as SC/67b/COMM01A. The ICES Working Group on Marine Mammal Ecology (WGMME) reported on recent information on status of, and threats to, marine mammal populations and briefly reviewed current knowledge of effects of plastics and underwater noise. Criteria for assessment of abundance trends in offshore cetaceans in the context of the Marine Strategy Framework Directive (MSFD) were reviewed, modifying the proposed indicator (previously based solely on the rate of decline) to make specific reference to baseline values. The group also considered the outcomes of the 2016 SCANS III survey[1]. All three SCANS surveys have arisen from individual projects. WGMME recommended that the surveys be co-organised and coordinated by Member States as part of their routine monitoring and that the frequency is increased to once every six years to match the MSFD reporting cycle.

A Workshop on Predator-prey Interactions between Grey Seals and other marine mammals (WKPIGS) focused on predatory behaviour of grey seals towards other grey seals, harbour seals and harbour porpoises in European waters. The workshop aimed to consolidate pathological indicators of grey seal predation events, collate data on the prevalence and distribution and discuss methods to aid in detection of predation events and potential population level consequences of reported incidences. Cases of predation on harbour porpoises peaked in spring months. Reported incidence has increased over the last decade although it is not known if this represents a true increase in prevalence, an increase in seal numbers or an increase in effort/reporting.

Highlights from the 2017 ICES Working Group on Bycatch of Protected Species (WGBYC) included: review of ongoing bycatch mitigation research projects; presentations on interdisciplinary bycatch monitoring programs in the US Northwest Atlantic northeast region; collaborations with other ICES working groups; positive advancements on WGBYC database development working jointly with the ICES Data Centre; and progress on summarising bycatch for the Baltic Sea and Bay of Biscay/Iberia fisheries overviews.

Four cetacean species were reported as bycatch from the 2015 member state reports (common dolphins, white-beaked dolphin, bottlenose dolphin, and harbour porpoise). The WGBYC continues to highlight the inconsistent submission and content of annual reports provided by some member states and the shortcomings to accurately reflect the full magnitude of cetacean bycatch in European fisheries. WGBYC is preparing for the transition away from regular member state reports as the primary source of data on bycatch of cetaceans over to data coming through the ICES regional database.

---

[1] https://synergy.st-andrews.ac.uk/scans3/

The 2017 ICES Annual Science Conference (ASC) had no sessions devoted entirely to marine mammals. Nevertheless, some sessions had marine mammals included as an integral part - the most relevant sessions were: ‘microbes to mammals: metabarcoding of the marine pelagic assemblage’ and ‘from iconic to overlooked species: how (electronic) tags improve our understanding of marine ecosystems and their inhabitants’.

More information is available from the ICES website *www.ices.dk.*

The Committee thanked Haug for his report and **agrees** that he should represent the Committee as an observer at the next ICES meeting.

4.11 International Maritime Organisation (IMO)

The report of the observer is given as SC/67b/COMM01D. At IWC66, the Commission endorsed recommendations of the IWC Conservation and Scientific Committees for continued engagement with the IMO, including submission of a paper to the IMO Marine Environment Protection Committee (MEPC) providing an update of recent information related to the extent and impacts of underwater noise from shipping. This paper was written by an intersessional group appointed at SC67a and submitted to the IMO MEPC 72 meeting 9-13 April 2018 (MEPC 72/Inf.9).

The ship strike section of the IWC website now contains a list of the measures that have been put in place globally through IMO or national regulations, to reduce ship strike risks to whales. These include Traffic Separation Schemes, Areas to be Avoided, Recommended Routes, voluntary and mandatory speed restrictions. New measures relevant to ship strikes include three recommendatory areas to be avoided (ATBA) encompassing King Island, Nunivak Island, and St. Lawrence Island in the Bering Sea proposed by the United States (NCSR 5/3/8). The proposal noted that King Island is a biologically important site to the gray whale, while St. Lawrence Island’s ATBA would provide protection to bowhead whales, gray whales, and humpback whales. These areas were recommended for adoption (with a reduced size for the St. Lawrence ATBA) by the IMO Navigation, Communications and Search and Rescue sub-committee NCSR 5 in February 2018.

Members of the IWC Scientific Committee have attended IMO meetings in order to discuss how best to provide information on populations of marine mammals relevant to the marine mammal avoidance provisions of the IMO Polar Code. This is discussed further under Item 14.3.

The Committee thanked Ferris and Leaper for their report and **agrees** that they should represent the Committee at the next IMO meeting.

4.12 International Union for the Conservation of Nature (IUCN)

The report of the observers to IUCN is given as SC/67b/COMM01G. The IUCN Marine Mammal Protected Areas Task Force (*https://www.marinemammalhabitat.org*) held its 3rd regional workshop in Malaysia in March 2018 to identify, describe and map candidate areas for inclusion in the Important Marine Mammal Area (IMMA) e-Atlas (*marinemammalhabitat.org/imma-eatlas*). The 46 candidate IMMAs proposed by the workshop are currently undergoing independent review.

Cetaceans entries on the Red List are in the process of being updated. The first batch of updates covering 19 taxa was published on *redlist.org* in December 2017 and is summarised at *iucn-csg.org/index.php/page/3*. Most of the remaining mysticete species assessments and some subpopulation assessments, as well as around 10 more new assessments of small and medium-sized odontocetes, have been submitted for publication in the next Red List update in June 2018. Most of the remaining taxa are in the pipeline for publication in late 2018.

IUCN continues to convene the Western Gray Whale Advisory Panel (WGWAP), which provides advice to Sakhalin Energy Investment Company (SEIC) and other parties, especially on the mitigation of industrial and other impacts on the gray whales that feed each summer off Sakhalin Island, Russia. Details of the Panel’s recent work are given in Annex O, Appendix 3.

Regular news items on activities by members of the IUCN SSC Cetacean Specialist Group are posted on the CSG website, *www.iucn-csg.org*.

4.13 North Atlantic Marine Mammal Commission (NAMMCO)

Scientific Committee

The report of the IWC observer at the 24th meeting of the NAMMCO Scientific Committee (NAMMCO-SC) is given as SC/67b/COMM01B. The NAMMCO-SC discussed a current joint project, ‘Exploring marine mammal consumption relative to fisheries removal in the Nordic and the Barents Seas’. Preliminary results suggest that marine mammal consume around 15 million tons ± 50% of prey per year, predominantly targeting low and mid trophic level species (zooplankton and small pelagic fish). Fisheries remove around 4.3 million tons per year, targeting mid and top trophic levels (small pelagic fish and larger demersal and pelagic fish).

The NAMMCO By-Catch Working Group (BYCWG) met in May 2017. Methods used for collection of data and by-catch estimation were reviewed, and both the WG and the SC recommended methodological improvements to be implemented both in the data collection and the analysis before the bycatch estimates could be endorsed. Greenland is an atypical case because marine mammals that are caught, either directly or indirectly, are assumed to be reported as direct catch (with large whales being the exception where bycatch is reported as such). The primary concern is to ensure that any bycatch is included in the total number of removals to be used in population assessments.

The NAMMCO SC noted and appreciated that the IWC *Implementation Reviews* for North Atlantic fin whales and North Atlantic common minke whales are completed. The NAMMCO SC provided advice on sustainable catch levels fro these species in Icelandic waters (from 2018-2025) based upon application of the RMP. The NAMMCO SC also recommended that the *SLAs* that are developed in the IWC SC be used for advice for large whales in Greenland and provided advice on strike limits for West Greenland humpback whales for the 2019-24.

The NAMMCO SC received the results from an updated global review of monodontids and provided updated assessments and advice for white whales and narwhals in Greenland and Canada. It also received a new abundance estimate for bottlenose whales from the Faroese component of the 2007 T-NASS survey that was analysed together with data on deep diving species from the SCANS-II and CODA surveys. Sightings were mainly from the Faroese survey block.

Increased research on harbour porpoises in Norway is being driven by the concerns regarding bycatch. Bycaught harbour porpoises were collected in 2016 and 2017 by Norway for biological sampling, and a food-web model is being developed for the Vestfjord area close to Lofoten to study the role of the species in this area. An abundance estimate is now available from the SCANS-III survey which was extended from 62°N to include Vestfjorden, an area with high bycatch. Preliminary investigations using this new abundance estimate suggest that bycatch levels are within PBR.

NAMMCO's whale sighting surveys in the Northeast Atlantic in 2015 (NASS2015) included an intensive survey with the purpose of estimating the abundance of pilot whales around the Faroe Isles, an aerial survey of the coastal waters in East Greenland and a ship-based survey around Jan Mayen following methods developed for the Norwegian minke whale surveys. The next NASS survey should be in 2022-23. The NAMMCO SC strongly recommended that an attempt be made to conduct again a trans-Atlantic coordinated survey and charged the NAMMCO Secretariat to explore what are the present plans and how much flexibility they encompass.

Council
The report of the IWC observer at the 26th Annual Council meeting of NAMMCO held in Tromsø, Norway 7-8 March 2018 is given as SC/67b/COMM01C. Relevant items discussed at the Council meeting include the following:

> (1) A newly established working group on bycatch, entanglements and live strandings has started its work and will gather information on the matter from other organisations and develop recommendations for NAMMCO. The focus is animal welfare associated to non-hunting related activities, and how NAMMCO can best contribute to addressing significant adverse impacts of by-catch, entanglement and live strandings on marine mammals; and
>
> (2) The report of the Global Review of Monodontids (white whales and narwhals) reviewed the conservation status, threats, and data gaps for all stocks globally. The last review was in 1999.

The Committee thanked Moronuki for his report.

4.14 North Pacific Marine Science Organisation (PICES)

The report of the IWC observer at 2017 annual meeting of PICES is given as SC/67b/COMM01F.

The marine birds and mammals section (S-MBM) focussed on 'seasonal and climatic influences on prey consumption by marine birds, mammals and predatory fishes' Presentations were made on (1) significance of seasonal changes in prey consumption on energy budgets and ecosystem dynamics; (2) effects of changes in water temperature and other climatic variables on food requirements; (3) relationships between dietary shifts and population trends; (4) limits of plasticity in prey selection; and (5) how prey consumption of birds, mammals and predatory fishes is affected by the recent extreme climatic events. Overall, the collection of presented studies in this session contributed to the efforts of the S-MBM to estimate prey consumption of birds and mammals. They provided new methods to estimate prey consumption of marine mammals and gave insights into the existing databases of diets and population estimates that can be used to further this effort.

For 2018, the S-MBM will focus on 'diets, consumption and abundance of marine birds and mammals in the North Pacific'. Since the 2016 workshop, work on the agreed upon databases to estimate prey consumption has been initiated and will continue to be added to over the coming 12 months in anticipation of the 2018 workshop, when invited experts will review the compiled information. This process should result in near-complete databases of diets, abundances and energy requirements of marine birds and mammals in the North Pacific.

The 2018 annual meeting of the PICES will be held in Yokohama, Japan 25 October-4 November 2018. The Committee thanked Tamura for attending on its behalf and **agrees** that he should represent the Committee as an observer at the next PICES meeting.

4.15 Protocol on Specially Protected Areas and Wildlife (SPAW) of the Cartagena Convention for the Wider Caribbean

No observer attended SPAW meetings in the intersessional period.

4.16 Pacific Region Environment Programme (SPREP)
No observer attended SPREP meetings in the intersessional period.

5. GENERAL ASSESSMENT ISSUES WITH A FOCUS ON THOSE RELATED TO THE REVISED MANAGEMENT PROCEDURE (RMP)

Several assessment topics apply not only to the Revised Management Procedure (RMP), but to the work of the Scientific Committee as whole. This item focuses on general assessment issues, such as: (1) the relationship between MSYR_{mat} and MSYR_{1+}; (2) implications of RMP and AWMP simulation trials for consideration of 'status'; and (3) matters of relevance to special permits that involve RMP considerations including effects of catches upon stocks.

5.1 Evaluate the energetics-based model and the relationship between MSYR_{1+} and MSYR_{mat}
MSYR is a key parameter in the *Implementation Simulation Trials* used to evaluate the conservation and catch performance of alternative RMP variants for specific species and regions. In recent years, the Committee has been reviewing progress on an individual based energetics model (IBEM) to provide insights into the relationship between MSYR_{1+} and MSYR_{mat}. Two papers on the IBEM were reviewed by the Committee in SC/67b.

SC/67b/EM07 outlined enhancements to the IBEM since the last meeting. This included the ability to explicitly model the effects of feeding while on migration, which can have effects on the yield curve as well as MSYR and MSYL. The Committee discussed (Annex D, Item 2.1) several ways in which this model can potentially enhance understanding of the relationship between biological processes and MSYR.

SC/67/RMP01 reported on trials using the IBEM within the standard RMP testing framework. The results were consistent with the behaviour of the RMP *CLA* observed in less complex population models and will also provide a point of comparison for the emulator model for the IBEM currently under development. The Committee has previously agreed that a fully-developed emulator model could form the basis for future *Implementation Simulation Trials*.

Attention: SC

The Committee ***agrees*** *that work continue to develop an emulator model; assess whether it is possible to represent the trajectories from the IBEM using an emulator model; compare the yield curves from the IBEM with those from the emulator model; and develop guidelines for how to use an emulator model as the basis for a multi-stock, multi-area population dynamics model and how such a model could be conditioned given available data.*

5.2 Implications of ISTs for consideration of species' and populations' status
Last year, the Committee recommended that a set of *Implementation Simulation Trials* should be summarised using three statistics to provide information on status (IWC, 2018d). The Committee was advised that intersessional tasks toward that goal could not be completed prior to SC/67b due to computing workloads.

Attention: SC

The Committee ***agrees*** *that Allison should modify the control programs used for* Implementation Simulation Trials *to report the three measures of status agreed last year (IWC, 2018d). The RMP sub-committee, in conjunction with the Working Group on ASI, will review outcomes of the analyses at SC/68a. Punt and Donovan will develop draft updates to the Guidelines for* Implementations *and* Implementation Reviews *to reflect decisions on evaluation status of stocks for consideration at SC68a.*

5.3 General consideration of how to evaluate the effect of special permit catches on stocks and levels of information needed to show improved management performance
5.3.1 General issues
The Committee developed general guidelines on the levels of information needed to show improved management improvement, for proposals that identify this as an objective (Annex D; appendix 2). The guidelines are intended to assist proponents in proposal preparation and to facilitate the review process. It was stressed that these were guidelines not requirements. Proponents might request the establishment of an Advisory Group to provide comment on intersessional work, but this is not mandatory. An Advisory Group may most benefit nations which have not previously developed proposals or may be lacking analysts familiar with the modelling approaches commonly applied at the IWC.

Attention: SC

The Committee ***agrees*** *that the general guidelines on the levels of information needed to show improved management improvement, for proposals that identify this as an objective (Annex D; appendix 2), should be included as an Appendix to the Scientific Committee handbook.*

5.3.2 Specific issues
SC/67b/RMP03 provided draft specifications for RMP/IST type simulations to evaluate management procedures based on modified *CLA*s that use information on recruitment inferred from age data from Antarctic minke whales. This work originally arose from discussions of NEWREP-A and Recommendation 1 of the Panel Review of that proposal (and see Item 19). The Committee noted that SC/67b/RMP03 was a work-in-progress, and that several features of the operating models would need to be extended before final conclusions could be drawn. The author of SC/67b/RMP03 plans to continue this work and received several suggestions from the Committee to carry those efforts forward (Annex D, Item 2.3).

5.4 Work plan 2019-20
Details of work to be undertaken both before and during the 2019 Annual Meeting are given in Table 2.

Table 2

Work plan for general assessment matters with a focus on the RMP

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Item 5.1: Conduct work to evaluate the energetics-based model and hence the relationship between MSYR1+ and MSYRmat	(a) Continue to assess whether it is possible to represent the trajectories from the IBEM using the emulator model (Annex Y); (b) Compare the yield curves from the IBEM with those from the emulator model (Annex Y); and (c) Develop guidelines for how to use an emulator model as the basis for a multi-stock, multi-area population dynamics model and how such a model could be conditioned given available data (Annex Y).	Continue to work to evaluate the energetics-based model and hence the relationship between MSYR_{1+} and MSYR_{mat}	Conduct follow-up analyses	Continue to work to evaluate the energetics-based model and hence the relationship between MSYR1+ and MSYRmat
Item 5.2: Implications of ISTs, for consideration of status	(a) Modify the control programs used for *Implementation Simulation Trials* to report the three measures of status (Allison) (b) Draft updates to the Guidelines for *Implementations* and *Implementation Reviews* to reflect decisions on evaluation status of stocks (Punt and Donovan)	Review the results of the projections Review the draft guidelines		
Item 5.3: levels of information needed to show improved management performance		Review progress implementing the suggested changes to the specifications of the model in SC/67b/RMP03 and any results.		

6. RMP – *IMPLEMENTATION*-RELATED MATTERS (RMP)
This agenda item includes the details of ongoing *Implementation Reviews* and preparation for new *Implementation Reviews*. For discussions related to the stock structure and abundance of these stocks, see also Items 11 and 12.

6.1 Completion of the *Implementation Review* of western North Pacific Bryde's whales
6.1.1 Report of the intersessional Workshop
The second intersessional Workshop on western North Pacific Bryde's whales was held in Tokyo from 14-16 February 2018 (SC/67b/Rep02). The objective was to facilitate completion of the *Implementation Review*. Much of the Workshop focussed on completing the final trial specifications, especially confirming the mixing matrices, updating the abundance estimates for the new sub-areas and confirming future sighting survey plans and whaling options. The Workshop reviewed preliminary conditioning results and agreed that they were satisfactory. It developed a workplan to try to ensure completion of the *Review* at SC/67b.

The Committee noted that the intersessional workshop had led to considerable progress towards completing the *Implementation Review*. It thanked Donovan for chairing the meeting, the Government of Japan for providing excellent facilities and all the participants for their contributions to the development of trial specifications and workplan.

The code and specifications for *Implementation Simulation Trials* were updated following the intersessional Workshop.

Attention: SC

The Committee ***agrees*** *to the updated trial specifications for the* Implementation Review *of western North Pacific Bryde's whales. These specifications are provided in Annex D, Appendix 3. It also* ***agrees*** *that conditioning has been achieved satisfactorily.*

6.1.2 Conclusions and recommendations

Once the trial specifications and conditioning had been agreed, the next step was to conduct projections under alternative RMP variants and survey plans. There was insufficient time during the meeting to complete all of the required projections and to check the associated calculations. Consequently, the remaining work will be completed intersessionally and reviewed and summarised by a Steering Group (Annex Y). This will occur well before SC/68a so that Japan has sufficient time to consider the results (e.g. with regard to its preferred survey options), prior to final conclusions being drawn. The Committee expects that this work can be completed before the end of 2018, but if complications arise conducting the projections, an extra day should be added to the 'First Intersessional Workshop for the western North Pacific minke whales' (see Item 6.2) to address outstanding issues.

Attention: SC

The Committee ***agrees*** *that the* Implementation Review *of western North Pacific Bryde's whales will be completed at SC/68a. Outstanding tasks will be completed intersessionally and the results reviewed and summarised by a Steering Group (Annex Y). This will occur well prior to SC/68a, and if complications arise then an extra day should be added to the First Intersessional Workshop for the western North Pacific minke whales (see Item 6.2) to address those issues.*

6.2 Start of the *Implementation Review* of western North Pacific common minke whales

6.2.1 Report of the intersessional Workshop

Donovan summarised the report of the preparatory Workshop for the Western North Pacific common minke whale *Implementation Review* (SC/67b/Rep05). Last year, the Committee recognised that the most difficult aspect of the last *Implementation Review* had been selecting, modelling and assigning plausibility to stock structure hypotheses. The objective of this Workshop was to begin to review work undertaken since the last *Implementation Review* and to develop, if necessary and possible, consensus advice on further analyses that will assist in the forthcoming *Implementation Review*. Stock structure discussions on common minke whales are detailed in Annex I, item 4.2.

This past lack of agreement with respect to the plausibility of existing stock structure hypotheses has, in part, revolved around how genetic analyses can be used to assign whales as part of the 'J' versus 'O' stocks. While some whales assign strongly to one of the two groups based on genetic data, the assignment of others is dependent on the assignment probability deemed sufficient to assign stock affinity. At the intersessional workshop (SC/67b/Rep05), the results of new stock structure-related analyses were reviewed by an advisory panel, and two recommendations were made with regard to additional genetic analyses needed to better understand stock structure. One of the recommended analyses involved evaluating the consistency of individual assignment probabilities when additional loci were genotyped. Progress with respect to that recommendation is discussed below.

The Workshop was also provided with an update to SC/67a/SCSP/13 that used information on the trend over time in the J:O stock ratio for common minke whale bycatches around Japan to draw various inferences, in particular about the value of the MSYR. The Workshop agreed that J:O stock ratios in bycatch will require attention when formulating stock distribution assumptions for the process of conditioning *IST*s in the coming *Implementation Review* and made some recommendations on how this could be achieved.

The Committee noted that the intersessional Workshop was held in an excellent spirit of co-operation among the participants and led to identification of additional data sets and analyses that should be taken forward. The Committee thanked Donovan for chairing the meeting, the Government of Japan for providing excellent facilities and all the participants for their contributions to progress the *Implementation Review*.

6.2.2 Progress since the intersessional Workshop

SC67b/SDDNA06 presented the results of the recommended analysis from the Workshop (see Item 6.2.1) and the Committee confirmed that the workshop's recommendation for this analysis had been properly completed.

Attention: SC

The Committee reviewed new results of genetic analyses that were recommended at the intersessional workshop (SC/67b/Rep05) to better evaluate the use of genetic data to assign stock affinity in North Pacific common minke whales. The Committee:

(1) ***agrees*** *that future analyses should incorporate a range of assignment thresholds to encompass uncertainty;*
(2) ***supports*** *the additional genetic analyses described in Annex I Appendix 5 relating to the second recommendation of the intersessional workshop and agrees that they should be performed prior to the next intersessional workshop; and*
(3) ***encourages*** *the inclusion of non-genetic biological data to inform stock structure where possible.*

SC/67b/RMP/02 aimed at suggesting a plausible range for $MSYR_{1+}$ for the western North Pacific common minke whales, and the relative plausibility of two stock structure hypotheses. The Committee thanked Kitakado for the updated analysis, which implemented some of the recommendations from the intersessional Workshop. Details of this paper and associated discussion can be found in Appendix D, Item 3.2.2. The Committee also discussed the analysis of genetic data conducted since the intersessional workshop (Annex I, Item 4.5).

Attention: SC, CG-A

The Committee ***agrees*** *that:*

(a) it is necessary to update the mixing matrices in the trial specifications to be more consistent with observed genetic and bycatch data, also taking into account sensitivity to alternative methods of genetic assignment to stock;
(b) whether it is possible to use the bycatch data to assign plausibility ranks to $MSYR_{1+}$ *values and stock structure hypotheses depends on assumptions regarding trends in fishing effort spatially and temporally; and*
(c) trials would need to consider different assumptions regarding the use of J:O bycatch ratios, including that these data do not provide information on $MSYR_{1+}$ *and the plausibility of stock structure hypotheses because of possible differential distributional changes by stock.*

The Committee therefore ***agrees*** *that scientists from Japan and Korea should provide data on the amount, location and timing (seasonal and annual) of fishing effort and bycatch to the First Intersessional Workshop (see item 6.2.3).*

6.2.3 Preparation for the First Intersessional Workshop

The Committee began preparations for the First Intersessional Workshop on the *Implementation Review* of western North Pacific common minke whales. It re-established the Steering Group (Annex Y) to organise this Workshop.

In accordance with the Committee's *'Requirements and Guidelines for Implementations and Implementation Reviews'* (IWC, 2012b), the primary objectives of the First Intersessional Workshop will be to: (a) consider plausible hypotheses and eliminate any hypotheses that are inconsistent with the data); (b) examine more detailed information in expected whaling operations, including options or suggested modifications to the pattern of those operations; (c) review the small geographical areas ('sub-areas') that will be used in specifying the stock structure hypotheses and operational pattern; and (d) specify the data and methods for conditioning the trials that will be carried out before the next annual meeting. An initial annotated agenda for the Workshop, highlighting the associated data and analysis requirements can be found in Annex D, appendix 5.

6.3 Workplan 2019-20

Details of work to be undertaken both before and during the 2019 Annual Meeting are given in Table 3.

Table 3

Work plan for RMP (*Implementation*-related matters)

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Item 6.1: Western North Pacific Bryde's whales	Finalise the projections and the application of the criteria for evaluating which RMP variants are acceptable, borderline, and unacceptable	Complete the *Implementation Review*		
Item 6.2: Western North Pacific minke whales	(a) conduct the First Intersessional Workshop; (b) code the resulting trials and condition the trials	Conduct the work required for the First Annual Meeting	Conduct the Second Intersessional Workshop	Conduct the work required for the Second Annual Meeting

7. ABORIGINAL SUBSISTENCE WHALING MANAGEMENT PROCEDURE (AWMP)

This item continues to be discussed as a result of Resolution 1994-4 of the Commission (IWC, 1995), which has been strengthened by Resolution 2014-1 (IWC, 2016a). The report of the Standing Working Group (SWG) on the development of an aboriginal whaling management procedure (AWMP) is given as Annex E. The Committee's deliberations, as reported below, are largely a summary of that Annex, and the interested reader is referred to it for a more detailed discussion. The primary issues at this year's meeting comprised: (1) finalising the development of *SLA*s (*Strike Limit Algorithms*) for Greenlandic hunts, with a focus on fin and common minke whales; (2) finalising the work on the scientific components of the AWS (Aboriginal Subsistence Whaling Management Scheme); (4) completion of the *Implementation Review* for Bering-Chukchi-Beaufort Seas stock of bowhead whales; and (3) providing management advice for aboriginal hunts (see Item 8).

Considerable progress on items (1) and (2) was made because of intense intersessional work including two workshops in Copenhagen in October 2017 and March 2018, as well as a small technical meeting in December 2018 at OSPAR headquarters in London.

7.1. *SLA* development for the Greenland hunts

7.1.1 Fin whales

SC/67b/Rep06 incorporated the discussions of the two intersessional Workshops and the small working group meeting. Considerable progress was made in relation to (a) updated abundance estimates; (b) finalisation of the trial structure; (c) review and approval of conditioning; and (d) initial consideration of new *Strike Limit Algorithms* (*SLA*s) and results.

The Committee thanked Donovan, the Workshop chair and the participants for the excellent progress made.

The final trial specifications for the West Greenland fin whales are provided in Annex E (Appendix 2).

Table 4 below summarises the main factors considered in the *Evaluation Trials*. The most influential involve different stock structure hypotheses, different productivity rates (MSYR) and different 'need' envelopes (need envelopes incorporate scenarios where need remains constant at the present level for 100 years (termed A), where it increases linearly to twice the present level over the 100-year simulation period (termed B) and where it increases linearly to three times the present level over the 100-year period (termed C).

Table 4

Summary of the key factors considered in the fin whale trials

7.1.1.1 CANDIDATE *SLA*S

The Committee received two papers with candidate *SLA*s, SC/67b/AWMP13 and SC/67b/AWMP15. The general properties of the three *SLA*s presented in SC/67b/AWMP13 involve taking an inverse variance weighted average of the last three estimates as an estimate of abundance and calculating the strike limit as a growth rate fraction of a lower percentile of the abundance (conditional on a trend modifier), a snap to need feature and a protection level. The three variants relate to how they are 'tuned' (the trade-off balance between conservation and need).

The three *SLA*s presented in SC/67b/AWMP15 are based on a weighted-average interim *SLA* which uses all abundance estimates, but where the earlier ones are down-weighted. An adjustment to the multiplier of the abundance estimate in the interim *SLA* is applied which depends on the trend of the abundance indices. The three variants relate to how they are 'tuned' (the trade-off balance between conservation and need).

7.1.1.2 REVIEW FINAL RESULTS AND PERFORMANCE

In total, seven potential *SLA*s (which include the 'Interim' *SLA* – a modified version of the *Interim SLA* used to provide advice previously by the Committee until the final *SLA*s had been developed) were considered. The full range of conservation and need statistics were reviewed for the *Evaluation Trials*[2], noting that the initial focus is on meeting the Commission's conservation objectives. Those candidate *SLA*s that meet these are then evaluated on their ability to meet need satisfaction. In summary, conservation performance is deemed satisfactory if either the population is not at MSYL but it is increasing towards it or the population is above MSYL (in which case it may be increasing or decreasing towards MSYL). These concepts are captured in the 'D1' and 'D10' statistics (defined fully in Annex E, table 2) and can be visualised in bivariate plots given in Annex E.

The Committee agreed that the proposed *SLA*s had performed satisfactorily on the joint conservation statistics for the A and B (but not for the C) need envelopes for all trials. The focus was then to evaluate the need satisfaction performance over 20 and 100 years and consider stability in catch levels. This performance was captured by examining three statistics:

---

[2] The Committee also examines the results of *Robustness Trials* to ensure that the *SLA* does not exhibit unusual behaviour in more extreme trials.

N9(20) the average need satisfaction over the first 20 years, N9(100) the average need satisfaction over the 100 years and N12 the mean down step statistic (these are also defined fully in Annex E, table 2). They can be visualised in 'Zeh' plots (e.g. see Annex E).

Given the present incorporation into the trial structure of two widely different stock structure hypotheses ('influx' and 'partial'- see Annex E, appendix 2) to explain the variability of the abundance estimates, the need satisfaction over 20 years was given more weight in the evaluation as it is likely that future *Implementation Reviews* may be able to remove one or other scenario.

After an examination of the full range of results, there was no obvious 'winner' between two of the *SLA*s (one from each developer). Depending on the trials considered, and which statistic was examined, they performed slightly differently but their performance overall was equivalent.

Following an approach originally adopted during the development of the *Bowhead SLA*, it was decided that an *SLA* which sets the strike limit to the average of the values obtained by the two *SLA*s[3] would be preferable, providing performance was as good or better than either individual *SLA*; no 'snap to need' for the averaged *SLA* has been applied. The results of the 'combined *SLA'* are summarised in Annex E, appendix 3[4].

7.1.1.3 CONCLUSIONS AND RECOMMENDATIONS

The management advice developed using this *SLA* is given under Item 8. 6.

Attention: C-A, SC

The Committee ***draws attention*** *to the extensive work undertaken over recent years to develop an* SLA *for the West Greenland hunt for fin whales. In concluding this work, the Committee:*

(1) ***agrees*** *that the combined* SLA *(which sets the strike limit to the average of the values obtained by the two best* SLAs *considered) performed satisfactorily in terms of conservation performance and was to be preferred over the individual SLAs in terms of need satisfaction;*
(2) ***recommends*** *that this* 'WG-Fin SLA' *be used to provide management advice to the Commission on the subsistence hunt for West Greenland fin whales (provided the need request falls within need scenarios A and B);*
(3) ***expresses*** *its great thanks to the developers, Brandão and Witting for the vast amount of work put into the development process and to Allison and Punt for their extensive work developing the operating models and running the trials; and*
(4) ***agrees*** *that one focus of the next* Implementation Review *will be to examine further stock structure in relation to the two hypotheses being considered at present, and especially the 'influx' model which was developed in the context of low abundance estimates in some years, rather than being based upon genetic information.*

7.1.2 Common minke whales (Greenland)

SC/67b/Rep06 incorporated the discussions of the two intersessional Workshops and a small working group meeting. Considerable progress was made in relation to (a) updated abundance estimates; (b) finalisation of the trial structure; (c) conditioning; and (d) initial consideration of new *Strike Limit Algorithms* (*SLA*s) and results.

The Committee thanked Donovan, the Workshop chair and the participants for the excellent progress made.

The final trial specifications for the West Greenland common minke whales are provided in Annex E (appendix 4).

Table 5 below summarises the main factors considered in the *Evaluation Trials* for common minke whales. The most influential involve different stock structure hypotheses, different productivity rates (MSYR) and different 'need' envelopes (see discussion under Item 7.1.1), where it increases linearly to twice the present level over the 100-year simulation period (termed B) and where it increases linearly to three times the present level over the 100-year period (termed C).

Considerable work was undertaken to finalise the list of trials, to ensure that the mixing matrices were correctly specified and to complete and agree conditioning. The final trial specifications are provided in Annex E, Appendix 4.

Table 5

---

[3] tuned to a D10 of 0.8 for the influx trial F34-1B

[4] Final validation and archiving of results will be undertaken by Allison in Cambridge.

7.1.2.1 CANDIDATE *SLAS*

SC/67b/AWMP14 developed a candidate *SLA* for common minke whales off West Greenland similar to that used for fin whales in SC/67b/AWMP13. It operates on an inverse variance weighed average of the last three abundance estimates. The strike limit is calculated as a growth rate fraction of a lower percentile of the abundance measure, conditional on a ‘snap to need’ feature, and a protection level. It does not include a trend modifier.

It was tuned to have a 5th percentile of D10 of 0.80 for need envelope A for the most difficult *Evaluation Trial* (trial M04-1A – see Annex E, appendix 4), where there are two sub-stocks in the western North Atlantic in which the mixing between the Central and the Western stock, and mixing between the putative western sub-stocks, is minimal, and where the MSYR is 1%).

7.1.2.2 CONSIDERATION OF RESULTS

Conditioning of the *Evaluation Trials* was completed satisfactorily and a summary of the results of the is provided in Annex E (appendix 5[5]). Annex E, fig. 3 provides the bivariate plot.

In determining satisfactory conservation and need performance when evaluating *SLA*s, the Committee considers the full range of results across all the *Evaluation Trials*, not simply the worst-case scenarios. Conservation performance was satisfactory for all but the most extreme trial (trial M04-1A) where it was slightly below for the lower 5th percentile. This trial had low MSYR and two W-stocks; it had been originally considered in the context of investigating potential problems for the hunt to simulate possible local depletion in the hunting area rather than for conservation reasons. Genetic stock structure in the entire North Atlantic is subtle such that even an hypothesis of almost complete panmixia is not rejected by most of the analyses and thus differentiation among ‘C’ and ‘W’ is very low. This is even more true for substructure within the W stock (if, indeed, there is any). Given that trials are conservative in so far as they overrate isolation among stocks, and the very subtle differentiation among stocks and sub-stocks in the North Atlantic, a single trial (which implements two fully separate W sub-stocks, for which there is little evidence) not meeting the D1/D10 criteria is not of conservation concern.

The SWG (Annex E, item 2.2.3) had noted that given the unforeseen situation with Secretariat computing, there had been insufficient time for it to consider the results of the *Robustness Trials* during its meeting. Such trials are not needed to determine an *SLA* but are examined to ensure that the selected *SLA* has no unforeseen properties in extreme trials. These were subsequently run prior to the plenary discussions and the results showed no unexpected properties.

7.1.2.3 CONCLUSIONS AND RECOMMENDATIONS

The management advice developed using the *WG-common minke SLA* is provided under Item 8.5.

Attention: C-A, SC

The Committee ***draws attention*** *to the extensive work undertaken over recent years to develop an* SLA *for the West Greenland hunt for common minke whales. In concluding this work, the Committee:*

(1) ***agrees*** *that the tested* SLA *which performed satisfactorily in terms of conservation performance;*
(2) ***agrees*** *that this ‘WG-Common minke SLA’ be used to provide management advice to the Commission on the subsistence hunt for West Greenland common minke whales provided the need request falls within need scenario A (i.e. does not exceed 164 annually);*
(3) ***expresses*** *its great thanks to the developers, Brandão and Witting for the vast amount of work put into the development process and to Allison and Punt for their extensive work developing the operating models and running the trials; and*
(4) ***agrees*** *that one focus of the next* Implementation Review *will be to examine further stock structure in relation to the two hypotheses being considered at present, should be consideration of the results of analyses of genetic data using additional samples from Canada (as well as the additional samples that will become available from West Greenland and Iceland); and*
(5) ***agree****s to establish an intersessional advisory group (Annex Y) to facilitate issues relating to samples.*

7.1.3 North Pacific gray whales (Makah whaling)

7.1.3.1 MANAGEMENT PLAN PROPOSED BY THE U.S. FOR MAKAH WHALING

The Makah Indian Tribe has requested that the U.S. National Marine Fisheries Service (NMFS) authorise a tribal hunt for Eastern North Pacific (ENP) gray whales in the coastal portion of its ‘usual and accustomed fishing area’ in Washington State. The Tribe intends to hunt gray whales from the ENP population, which currently numbers approximately 27,000 animals (Durban *et al.*, 2017). However, at certain times of the year there is a possibility that the hunt may take animals from the PCFG (Pacific Coast Feeding Group) and/or the WNFG (Western North Pacific Feeding Group). In an updated management plan – known as the Makah Management Plan (the Committee had approved an earlier plan for this hunt in 2012 (IWC, 2013), NMFS has taken measures to restrict the number of PCFG whales that are struck or landed in a given 10-year period and to avoid, to the extent possible, striking or killing a WNFG gray whale. The Government of the USA requested the Committee to test this plan to ensure that it meets IWC conservation objectives.

---

[5] Final validation and archiving of results will be undertaken by Allison in Cambridge.

This task was begun at the Fifth Rangewide Workshop on the Status of North Pacific Gray Whales (SC/67b/Rep07) from 28-31 March 2018. The major focus of the Workshop related to finalising the specifications for modelling, to enable results to be available for SC67b including incorporation of the Makah Management Plan (SC/67b/Rep07, Annex E, appendix 1) into the modelling framework. The factors taken into account in the trials are given in Table 6.

Table 6

Summary of the main factors considered in the Makah gray whale trials

Factor	
Model fitting related	Projection-related
Stock hypothesis	Additional catch off Sakhalin
MSYR	Catastrophic events
Mixing rate	Northern need in final year
Immigration into the PCFG	Struck and lost rate
Bycatches and ship strikes	Future effort
Pulse migrations into the PCFG	Factors related to obtaining and matching photographs

At the present meeting, the focus was on the conservation performance of the Makah Management Plan. Performance was evaluated in the same manner as described for the evaluation of the *SLA*s for West Greenland fin and common minke whales (see Items 6.1 and 6.2). The results can be found in Annex E (appendix 6). The only scenarios under which the plan might not perform adequately were considered to have low plausibility (e.g. a bycatch mortality of ~ 20 PCFG whales per year). Annex E, fig. 4 shows the bivariate plot.

7.1.3.2 CONCLUSIONS AND RECOMMENDATIONS

The management advice relating to the Makah Management Plan is provided under Item 8.2.

Attention: C-A, SC

The Committee reviewed a US Management Plan for a Makah hunt of gray whales off Washington State (the Committee had evaluated a previous plan in 2011 - IWC, 2011; 2012), using the modelling framework developed for its rangewide review of gray whales (SC/67b/Rep07). In conclusion, the Committee:

(1) ***agrees*** *that the performance of the Management Plan was adequate to meet the Commission's conservation objectives for the Pacific Coast Feeding Group, Western Feeding Group and Northern Feeding Group gray whales;*
(2) ***notes*** *that the proposed management plan is dependent on photo-identification studies to estimate PCFG abundance and the mixing proportions of PCFG whales available to the hunt (and to bycatch in its range);*
(3) ***stresses*** *that its conclusions are dependent on the assumption that these studies will continue in the future; and*
(4) ***expresses*** *its* ***great thanks*** *to Punt, Brandon and Allison for their excellent work in developing and validating the testing framework and running the trials.*

7.1.4 Conclusions on AWMP work

The Chair of the SWG on the AWMP, Donovan, noted that this meeting represented the end of a long journey – with the adoption of the two new *SLA*s, the SWG and the Committee has completed the development tasks it had been assigned by the Commission, originally in Resolution 1994-1. It was an immense task but a great pleasure to work with such dedicated and talented people. He thanked all of the scientists who have made such a wonderful contribution to this work over the years and especially Geof Givens, Kjartan Magnússon (sadly no longer with us), Eva Dereksdóttir, Lars Witting, Anabela Brandão, Doug Butterworth, Cherry Allison and André Punt – the SWG has, in his view, achieved ground-breaking work over the last two decades in a spirit of great collaboration and co-operation, even when there were disagreements, as inevitably there were. He also thanked the hunters and their representatives who had made major contributions in terms of not only data provision but also advice on the AWS (see Item 7.2). The Committee **concurred** that this was an excellent example of what the Scientific Committee could achieve with international collaboration. Finally, they **thanked** Donovan for his dedicated, good humoured and impartial leading of such a major piece of complex work over such a long period - this work has been central to the Committee's role in providing the best scientific advice to the Commission on aboriginal subsistence whaling hunts, bringing together conservation needs and the needs of the hunters.

7.2 Aboriginal Whaling Scheme (AWS)

7.2.1 Introduction

The Scientific Committee's Aboriginal Whaling Management Procedure (AWMP) applies stock-specific *Strike Limit Algorithms* (*SLA*s) to provide advice on aboriginal subsistence whaling (ASW) strike/catch limits.

ASW management (as part of an AWS, the aboriginal whaling scheme) incorporates several components, several of which have a scientific component:

(1) *Strike Limit Algorithms* (case-specific) used to provide advice on safe catch/strike limits;

(2) operational rules (generic to the extent possible) including carryover provisions, block quotas and interim relief allocations;
(3) Guidelines for *Implementation Reviews*; and
(4) Guidelines for data and analysis (e.g. guidelines for surveys, other data needs).

Considerable work on updating the AWS since the version presented (but not accepted by) to the Commission in 2002 (IWC, 2003) was undertaken by an intersessional correspondence group (SC/67b/AWMP 21) and at the intersessional workshops (SC/67b/Rep04).

7.2.2 Carryover request from the Governments of USA and Denmark/Greenland

The Governments of USA and Denmark/Greenland (SC/67b/Rep06, Annex F, appendix) had requested advice at the March intersessional Workshop on the conservation implications of carryover provisions allowed for a carryover provision that allowed use of unused strikes from the previous three blocks, provided that the number used in any year did not exceed 50% of the annual strike limit.

This request was tested on the two *SLA*s available for stocks hunted by the USA and Greenland at the time of the Workshop i.e. the *Bowhead SLA* (applicable to the Bering-Chukchi-Beaufort Seas stock) and the *WG-Humpback SLA* (applicable to West Greenland).

Three types of options were examined:

(1) baseline case - all strikes taken annually (i.e. no need for carryover);
(2) 'frontload' case - strikes taken as quickly as possible within block (+50% limit annually until the block limit is reached); and
(3) Two alternative scenarios where carryover strikes are accrued for one or three blocks, followed by a period of carryover usage subject to the +50% limit.

The three-block scenario considered in (3) served as a direct test of the provision described in the request of USA and Denmark/Greenland.

Attention: CG-A

The Committee received a request from the USA and Denmark/Greenland (SC/67b/Rep06, Annex F, appendix) on the conservation implications of carryover provisions that
'…allow for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit'.
The Committee reviewed the request using its simulation frameworks and the two SLA*s available for stocks hunted by the USA and Greenland available at the time of the Workshop i.e. the* Bowhead SLA *(applicable to the Bering-Chukchi-Beaufort Seas stock) and the* WG-Humpback SLA *(applicable to West Greenland) and*

(1) ***agrees*** *that a carryover provision for up to 3-blocks meets Commission's conservation objectives; and*
(2) ***reiterates*** *its previous advice, applicable for all* SLA*s, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable; and*
(3) ***agrees*** *to evaluate the above request for the other Greenland* SLA*s at the 2019 Committee meeting.*

7.2.3 Review proposed updates to the AWS

The proposed update to the previous AWS is provided in Annex E, appendix 8. It has sections on carryover, block quotas, interim relief allocation (and see Annex E, appendix 7), *Implementation Reviews* and guidelines for surveys and data.

7.2.4 Conclusions and recommendations

Attention: C-R

The Committee has been working for some years to update the scientific components of an Aboriginal Whaling Scheme. It has completed this work and ***recommends*** *the AWS provided in Annex E, appendix 8 to the Commission. It has sections on carryover, block quotas, interim relief allocation (and see Annex E, appendix 7), Implementation Reviews and guidelines for surveys and data. It* ***notes*** *that the Commission's AWS may include additional, non-scientific provisions.*

7.3 *Implementation Review* of BCB bowhead whales

According to the Committee's guidelines, the primary objectives of an *Implementation Review* are to:

(1) review the available information (including biological data, abundance estimates and data relevant to stock structure issues) to ascertain whether the present situation is as expected (i.e. within the space tested during the development of a *Strike Limit Algorithm* (*SLA*)) and determine whether new simulation trials are required to ensure that the *SLA* still meets the Commission's objectives; and
(2) to review information required for the *SLA*, i.e. catch data and, when available at the time of the *Review*, new abundance estimates (note that this can also occur outside an *Implementation Review* at an Annual Meeting).

The *Bowhead SLA* was adopted in 2002 (IWC, 2003, p.158) and there was an extensive *Implementation Review* completed in 2007 (IWC, 2008a, p.124) with a major focus on stock structure including three intersessional workshops. That included consideration of additional trials investigating management implications of assuming additional population structure even though these were considered of low plausibility. The Committee concluded that the *Bowhead SLA* remained the best tool to provide management advice. The next *Implementation Review* was completed in 2012 (IWC, 2013b, p.147); that concluded that there was no need to develop additional trials to those evaluated during the previous *Implementation Review* (IWC, 2008c).

The primary review was undertaken by the SWG on the AWMP (Annex E, Item 4) but the review benefitted from discussions within two other groups, SD-DNA (Annex I, Item X) and ASI (Annex Q, Item Y).

7.3.1 Stock structure: review new information

A full discussion of the work on stock structure can be found in Annex E (item 4.1) and Annex I. New information considered included genetic analyses (SC/67b/SDDNA 01) and telemetry results (SC/67b/AWMP04). SC67b/SDDNA01provided information on genetic analyses using samples from the BCB, Canadian and Okhotsk Sea stocks of bowhead whales. Within the BCB stock, no significant differences were identified in temporal or spatial comparisons, and age-related structure was not detected in comparisons between groups of large (old) versus small (young) whales. While comparisons of the BCB stock with the Okhotsk Sea stock revealed significant differences, there were only small, and in most cases statistically insignificant, differences between BCB and Canadian stocks. While this pattern could be related to historical connectivity between the two stocks, it could also, or additionally, be driven by some degree of contemporary gene flow.

Attention: SC

With respect to stock structure, considering the multiple lines of evidence, the Committee:

(1) ***agrees*** *that BCB bowheads comprise a single population, with no signs of substructure;*
(2) ***agrees*** *that there was no need to consider any new SLA trials regarding stock structure, since the trials conducted in 2002 and 2007 already covered all plausible stock structure hypotheses;*
(3) ***welcomes*** *the telemetry information provided, thanks the hunters involved for their skill and assistance;*
(4) ***encourages*** *additional telemetry efforts; and*
(5) ***agrees*** *with the suggestions for future genetic studies in the Arctic provided under Item 11.*

7.3.2 Abundance estimates: review new information

A new abundance estimate (SC/67b/AWMP) has been accepted for the year 2011 from a long-term photo-id capture-recapture study (27,133, CV=0.217; 95% CI from 17,809 to 41,337) that it has been agreed is suitable for providing management advice and for use in the *SLA* (Annex Q). The previously accepted, completely independent, 2011 abundance estimate from the ice-based survey (Givens *et al.*, 2016) is also acceptable for use in the *SLA* and has already been used in that regard (16,820, CV=0.052; 95% CI 15,176 to 18,643).

There are thus two independent estimates for the same year considered suitable for use in the *SLA* and this is considered under Item 8.3.

The Committee also discussed plans for future surveys (SC/67b/AWMP 12 and AWMP 16) in Annex Q (item 3.1.1.1). These plans are in accord with the AWS Guidelines that 'plans for undertaking a survey/census should be submitted to the Scientific Committee in advance of their being carried out, although prior approval by the Committee is not required.

7.3.3 Biological parameters: review new information

New and extensive information on biological parameters was received as discussed Annex E (item 4.3). These covered such matters: length at sexual maturity and pregnancy rate from hunted animals (SC/67b/AWMP 07); the potential use of samples from baleen plates to examine hormone cycles and pregnancy; and information on calves from aerial surveys (SC/67b/AWMP03).

Attention: SC

With respect to biological parameter information, the Committee:
(1) ***welcomes*** *the extensive information presented;*
(2) ***encourages*** *the continued collection of such data from the hunt;*
(3) ***encourages*** *the work on the baleen plate analyses to examine hormone levels and pregnancy;*
(4) ***encourages*** *continued aerial surveys under the ASAMM surveys and any future collaboration involving life history data from the harvest; and*
(5) ***agrees*** *that the information presented does not suggest the need to consider any new SLA trials regarding stock structure.*

7.3.4 Removals: review new information

The Committee received updated information about the 2017 harvest (SC/67b/AWMP 05) and long-term removals (SC/67b/AWMP 06). In 2017, 57 bowhead whales were struck resulting in 50 animals landed. The total landed for the hunt in 2017 was higher than the average over the past 10 years (2007-2016 mean of landed =41.7; SD=6.7). Efficiency (number landed / number struck) in 2017 was 88%, which was also higher than the average for the past 10 years (mean of efficiency=75.2%; SD=6.5%).

The Committee also received SC/67b/AWMP06 that provided a summary of bowhead whale catches in Alaska between 1974 and 2016. The authors pointed to the excellent cooperation and contribution of the whale hunters from the 11 villages that are members of the Alaska Eskimo Whaling Commission (AEWC). This information is discussed in Annex E (item 4.4).

From 2013 to 2017, four bowhead whales (2 females and 2 males) were harvested near Chukotka, mainly in Anadyr Bay (SC/67b/AWMP20). The average length was 14.5m (minimum 13.0m, maximum 17.0m). Although the portion of the annual strike limit allocated to Russia under their bilateral agreement with the USA is 5 animals, the actual annual take is usually only 1-2 whales per year, and this has been the case since at least 2004.

The Committee thanked the authors of the provision of this information, noting that catch and strike data are used in the *SLA* calculations (see Item 8.3).

7.3.5 Other anthropogenic threats and health: review new information

The Committee received extensive information related to threats and health ranging from entanglement, predation and health (body condition, pathology and parasite loads). The discussion of this can be found in Annex E (item 4.5).

Attention: SC

With respect to threats and health to the BCB bowhead whales, the Committee:
(1) ***welcomes*** *the extensive information presented;*
(2) ***agrees*** *that whilst the present level of unintentional human induced mortality is too low to require new Implementation trials or incorporation into the SLA calculations, the situation should continue to be monitored and evaluated at the next Implementation Review;*
(3) ***agrees*** *that the health analyses give no cause for concern with respect to the continued application of the Bowhead SLA; and*
(4) ***encourages*** *that the excellent work on health-related issues continues.*

7.3.6 Conclusions and recommendations (and, if needed, workplan to complete Review)

Attention: SC

With respect to the Implementation review of BCB bowhead whales, the Committee ***concludes*** *that:*
(1) the Implementation Review has been satisfactorily completed; and
(2) the range of hypotheses and parameter space already tested in Bowhead SLA trials was sufficient and therefore the Bowhead SLA remains the best way to provide management advice for this stock;
In addition, it ***thanks*** *the US scientists for the extremely hard work that they have put into providing comprehensive papers to facilitate this review.*

8. STOCKS SUBJECT TO ABORIGINAL SUBSISTENCE WHALING (NEW INFORMATION AND MANAGEMENT ADVICE)

The Committee noted that the Commission will be setting new catch/strike limits for at its 2018 biennial meeting in Brazil. It had received written or verbal requests for limits to be considered for each hunt as discussed below.

Attention: C-A

A general request had been received from the USA and Denmark (SC/67b/Rep06, annex F, appendix) for advice on whether there would be a conservation issue if there was a one-time 7-year block followed by a return to 6-year blocks to address logistical issues related to the Commission.

The Committee ***agrees*** *there are no conservation issues associated with this suggestion (and see the block quota section of the ASW in Annex E, appendix 8).*

8.1 Eastern Canada/West Greenland bowhead whales

8.1.1 New abundance information

Last year, the Committee had recommended that Canadian scientists attend the Committee to present the results of their work on abundance. It was very pleased that Doniol-Valcroze from Department of Fisheries and Oceans Canada, and the primary author of the paper on the 2013 aerial survey abundance estimate, was present at the meeting.

The Committee accepted, for the provision of management advice and use in an *SLA* (see Annex Q for details), the fully corrected abundance estimate (Doniol-Valcroze *et al.*, 2015) from a 2013 aerial survey of 6,446 bowheads (CV=0.26, 95% CI 3,722-11,200). The survey covered the major summering area for the Eastern Canada/West Greenland (EC/WG) stock.

The Committee recalled that the *WG-Bowhead SLA* had been developed on the conservative assumption that the abundance estimates for the West Greenland area alone (1,274 whales in 2012 (CV=0.12)) represented the abundance of the whole stock, as it believed that it was not possible to assume that a non-member country would continue with regular surveys. Doniol-Valcroze advised the Committee that the present management strategy of Canada does involves obtaining regular abundance estimates. The Committee noted it would be pleased to receive such estimates from Canada being presented to the Committee in the future.

Attention: SC

The Committee greatly appreciated the presence of a Canadian scientist at its meeting. The Committee:
(1) ***welcomes*** *the provision of the abundance estimate for the Eastern Canada/West Greenland stock and (see Item 8.1.2) the regular provision of information on catch data by Canada;*
(2) ***welcomes*** *the attendance of Canadian scientists at its meetings;*
(3) ***agrees*** *that consideration of how to incorporate abundance estimates from Canada should be one focus of the next Implementation Review for this stock;*
(4) ***notes*** *the regular collaboration of Canadian and Greenlandic scientists on other matters such as genetic sampling (inter alia for mark-recapture abundance estimation); and*
(5) ***encourages*** *further collaboration between Canada, Greenland and the USA for the study of bowhead whales across their range and the presentation of these results at future Committee meetings.*

8.1.2 New catch information

SC/67B/AWMP/10 provided an update of recent Canadian takes made in the Inuit subsistence harvest of the EC-WG bowhead whale stock. In the eastern Canadian Arctic, the maximum allowed take is 7 bowhead whales per year according to domestic policy, with no carry-over of unused takes between years. Since 2015, 5 strikes were taken and 4 bowhead whales were successfully landed (1 in 2015, 2 in 2016 and 1 in 2017). Witting reported that West Greenland hunters struck no bowheads in 2017. There was one 14.7m whale that died from entanglement in crab gear.

The Committee notes that the reported number of strikes was within the parameter space that was tested for the *WG-Bowhead SLA*, and encourages the continued collection of genetic samples from harvested whales.

8.1.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67 and no changes were requested for bowhead whales. The Committee therefore:

(1) ***agrees*** *that the WG-Bowhead SLA remains the best available way to provide management advice for the Greenland hunt;*
(2) ***notes*** *that this SLA had been developed under the conservative assumption that the number of bowhead whales estimated off West Greenland represented the total abundance between West Greenland and Eastern Canada;*
(3) based on the agreed 2012 estimate of abundance for West Greenland (1,274, CV=0.12), the catch of one whale in Canada in 2017, and using the agreed WG-Bowhead SLA, ***agrees*** *that an annual strike limit of two whales will not harm the stock and meets the Commissions conservation objectives; and*
(4) although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for the WG-Bowhead SLA, ***reiterates*** *its advice****,*** *applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next, is acceptable.*

8.2 North Pacific gray whales

8.2.1 New information (including catch data)

The Committee received considerable new information on the hunt off Chukotka as discussed in Annex E (item 5.2). In 2017, a total of 119 gray whales were struck in 2017 (37 males and 82 females). No whales were struck and lost, and no stinky (inedible) gray whales were taken. Similar whaling methods were employed as in recent years and the overall efficiency of the hunt was almost same as in 2016.

In advance of the gray whale *Implementation Review* that is scheduled to begin in 2019, the Committee reviewed new information regarding the stock structure of gray whales in the North Pacific (SC67b/SDDNA02 and SC67b/SDDNA03) – for details see Annex I. The results were based on whole genome sequence data from three individuals (one sampled off Barrow, Alaska and two sampled off Sakhalin Island, Russia) and SNP genotype data generated from larger sample sets representing whales sampled off Sakhalin and in the Mexican lagoons.

Attention: SC

*In reviewing the results of new genetic analyses of gray whales in the North Pacific, the Committee **agrees** that the genetic and photographic data for this species be combined to better assess stock structure-related questions. Given the potential for genomic data to aid in better evaluating the stock structure hypotheses currently under consideration for North Pacific gray whales, the Committee **encourages** the continuation of work to produce additional genomic data from sampled gray whales.*

8.2.2 Management advice

Attention: C-A

The Russian Federation (SC/67b/AWMP/17) had requested advice on the following provision:

'For the seven years 2019, 2020, 2021, 2022, 2023, 2024 and 2025, the number of gray whales taken in accordance with this sub-paragraph shall not exceed 980 (i.e. 140 per annum on average) provided that the number of gray whales taken in any one of the years 2019, 2020, 2021, 2022, 2023, 2024 and 2025 shall not exceed 140.'

The Committee therefore:
*(1) **agrees** that the* Gray Whale SLA *remains the best available way to provide management advice for the gray whale hunts;*
*(2) **advises** that an average annual strike limit of 140 whales will not harm the stock and meets the Commission's conservation objectives;*
*(3) **notes** that its previous advice that the interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next remains acceptable;*
*(4) **advises** that the Makah Management Plan (see Item 2.3) also is in accord with the Commission's management objectives.*

8.3 Bering-Chukchi-Beaufort Seas bowhead whales

8.3.1 New information

New information (on abundance and catches) was considered as part of the *Implementation Review* discussed under Item 7.3.

The USA had indicated that it was proposing no changes to the present catch/strike limits although it may suggest changes to its carryover request in light of the advice received by the Committee as discussed at the intersessional workshop (SC/67b/Rep06).

The Committee noted that there are now two independent estimates of abundance for this stock in 2011 (see Item 7.3.1). Recognising the need to formally consider the general question of how best to combine estimates in such cases as part of the workplan in the next biennium, the Committee noted that if they are combined as a weighted average by the inverse of their variances, there is little difference (it is slightly higher) between the combined estimate and that from the ice-based census estimate; the ice-based approach has been the method used for the other estimates used in the *SLA*. Therefore, the ice-based census estimate for 2011 (16,820, CV=0.052; 95% CI 15,176 to 18,643) is considered the most recent estimate of abundance for use in the *Bowhead SLA* this year.

8.3.2 Management advice

Attention: C-A

The USA indicated that it requested advice on the existing catch/strike limits. The Committee therefore:

*(1) **agrees** that the* Bowhead Whale SLA *remains the best available way to provide management advice for this stock;*
*(2) **advises** that a continuation of the present average annual strike limit of 67 whales will not harm the stock and meets the Commission's conservation objectives; and*
*(3) **advises** that provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit, has no conservation implications (see SC/67b/Rep04).*

8.4 Common minke whales off East Greenland

8.4.1 New information on catches

In the 2017 season, nine common minke whales (3 males and 6 females) were landed in East Greenland, and one was struck and lost. Genetic samples were obtained from 8 of the landed whales. One common minke whale died from entanglement in fishing gear.

8.4.1 New information on abundance

The Committee endorsed the 2015 aerial survey abundance estimate of 2,762 (CV=0.47; 95%CI 1,160-6,574). This is only a small part of the wider Western and Central stocks from which catches may occur.

8.4.2 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on an annual take of 20 animals (it had previously been 12). It had also requested advice on any conservation implications of a 12-month hunting season for common minke whales.

The Committee therefore:

*(1) **notes** that in the past its advice for the East Greenland hunt had been based upon the fact that the catch was a small proportion of the number of animals in the Central Stock;*
*(2) **notes** the process to develop an* SLA *for common minke whales off West Greenland resulted in a simulation framework that produces a considerably more rigorous way to provide advice for this hunt than before, by taking into account stock structure issues;*
*(3) **notes** that the results of the simulation trials that incorporated a continuing catch of 20 whales from East Greenland gave rise to no conservation concerns;*
*(4) **notes** that the 2015 aerial survey abundance estimate of 2,762 (CV=0.47; 95%CI 1,160-6,574) is only a small part of the wider western and central stocks;*
*(5) **advises** that a continuation of the present average annual strike limit of 20 whales will not harm the stock and meets the Commission's conservation objectives;*
*(6) **advises** that changing the length of the season to 12 months had no conservation implications; and*
*(7) **agrees** that an* SLA *should be developed for this hunt in the future; and*
*(8) **encourages** the continued collection of samples fro collaborative genetic analyses (and see Item 7.1.2.3).*

8.5 Common minke whales off West Greenland

8.5.1 New information on catches

In the 2017 season, 129 common minke whales were landed in West Greenland and four were struck and lost. Of the landed whales, there were 95 females, 33 males and one of unknown sex. Genetic samples were obtained from 104 whales, and the Committee was pleased to note that samples were already part of the data used in the genetic analyses of common minke whales in the North Atlantic. The Committee **encourages** the continued collection of samples and the collaborative approach of the genetic analysis.

8.5.2 New information on abundance

The Committee endorsed the 2015 aerial survey abundance estimate of 5,095 (CV0.46; 95%CI 2,171-11,961) as discussed in Annex Q.

8.5.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 164 animals (i.e. no change). It had also requested advice on any conservation implications of a 12-month hunting season for common minke whales.
The Committee therefore:

*(1) **agrees** that the WG-Common minke SLA is the best available way to provide management advice for this stock under need scenario A;*
*(2) **advises** that a continuation of the present average annual strike limit of 164 whales will not harm the stock and meets the Commission's conservation objectives;*
*(3) although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for this SLA, **reiterates** its previous advice**,** applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable;*
*(4) **advises** that changing the length of the season to 12 months had no conservation implications; and*
*(5) **encourages** the continued collection of samples for collaborative genetic analyses (and see Item 7.1.2.3).*

8.6 Fin whales off West Greenland

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 19 animals (i.e. no change).

8.6.1 New information on the catch
A total of seven fin whales (5 females and 2 males) was landed, and one was struck and lost, off West Greenland during 2017. The Committee was pleased to note that genetic samples were obtained from five of these, and that the genetic samples are analysed together with the genetic samples from the hunt in Iceland.

8.6.2 New information on abundance
The Committee endorsed the 2015 aerial survey abundance estimate of 2,215 (CV=0.41; 95%CI 1,017-4,823) for use in providing management advice and in the *SLA* as discussed in Annex Q (Item Y).

8.6.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 19 animals (i.e. no change). It also requested advice on whether there were any conservation implications of removing length limits (while retaining the prohibitions relating to calves.
The Committee therefore:

(1) ***agrees*** *that the WG-Fin SLA is the best available way to provide management advice for this stock;*
(2) ***advises*** *that a continuation of the present average annual strike limit of 19 whales will not harm the stock and meets the Commission's conservation objectives; and*
(3) although the Committee has not yet had time to examine the request from the US/Denmark (SC/67b/Rep06, annex F, appendix) for this SLA, ***reiterates*** *its advice****,*** *applicable for all SLAs, that interannual variation of 50% within a block with the same allowance from the last year of one block to the first year of the next is acceptable;*
(4) ***advises*** *that removing the length limits had no conservation implications; and*
(5) ***encourages*** *the continued collection of samples for collaborative genetic analyses (and see Item 7.1.1.3).*

8.7 Humpback whales off West Greenland
8.7.1 New information on catches
A total of two (both female) humpback whales were landed and none were struck and lost in West Greenland during 2017. Genetic samples were obtained from all the landed whales. The importance of collecting genetic samples and photographs of the flukes from these whales is emphasised.

Five humpback whales were observed entangled in fishing gear in West Greenland in 2017. Of these, one died, two became free and one was successfully disentangled by a disentanglement team. The remaining animal was alive and still entangled when it was last sighted.

Inclusion of bycaught whales had been incorporated into the scenarios for the development of the *Humpback SLA*. If high levels continued, then this will need to be taken into account in any *Implementation Review*. The Committee noted the IWC efforts with respect to disentanglement and prevention and welcomed the news that the Greenland authorities requested IWC disentanglement training that took place in 2016 and that they successfully disentangled one humpback whale.

8.7.2 New information on abundance
The Committee endorsed the 2015 aerial survey abundance estimate of 993 (CV=0.46; 95%CI 434-2,272) as discussed in Annex Q (Item Y) for use in the provision of management advice and in the SLA.

8.7.3 Management advice

Attention: C-A

SC/67b/AWMP19 reported Greenland's plans for requesting aboriginal whaling provisions at IWC67. It requested advice on annual strikes of 10 animals (i.e. no change).
The Committee therefore:
(1) ***agrees*** *that the* WG-Humpback SLA *is the best available way to provide management advice for this stock;*
(2) ***advises*** *that a continuation of the present average annual strike limit of 10 whales will not harm the stock and meets the Commission's conservation objectives;*
(3) ***advises*** *that that provisions allowing for the carry forward of unused strikes from the previous three blocks, subject to the limitation that the number of such carryover strikes used in any year does not exceed 50% of the annual strike limit' has no conservation implications (see SC/67b/Rep04); and*
(4) ***encourages*** *the continued collection of samples and photographs for collaborative analyses.*

8.8 Humpback whales off St. Vincent and The Grenadines
The alternate Commissioner for St Vincent and the Grenadines advised that no change to the present limits were envisaged.

8.8.1 New information on catch
It was reported that one humpback whale was struck and landed in 2017 by St. Vincent and The Grenadines.

8.8.2 New information on abundance

Last year, the Committee had requested that the USA provide a new abundance estimate for the western North Atlantic based upon the available NOAA data. A progress report on this work was provided with a focus on information on abundance estimates generated by the MONAH study, conducted in 2004 and 2005 on Silver Bank (a breeding ground in the West Indies) and in the Gulf of Maine feeding ground. The best estimate around 12,300, similar to the Committee endorsed best estimate from the YONAH project from 1992/93, which was 10,400 (8,000, 13,600). The lack of strong population growth was unexpected given information on rates of increase from some other areas of the North Atlantic, and may reflect either a true rate of increase, unidentified sampling bias, and/or the idea that Silver Bank as a habitat has reached maximum capacity. It is not clear whether the MONAH estimate is representative of the entire population, nor the extent to which the full estimate can be applied to the southeastern Caribbean in the context of the St Vincent hunt. However, four animals from the Gulf of Maine have been linked to animals seen in the southeastern Caribbean (including one that was caught in the hunt).

The Committee also noted several endorsed recent abundance estimates of humpback whales in parts of the North Atlantic including: 993 (95% CI: 434-2,272) in West Greenland in 2015; 4,223 (95% CI: 1,845-9,666) in East Greenland in 2015; and 12,879 (95% CI 5,074; 26,455) in the Iceland-Faroes region in 2007.

It has now been nearly two decades since the IWC has done an In-Depth Assessment on North Atlantic humpback whales. The Committee **agrees** that it would be a valuable exercise to perform a North Atlantic Rangewide review of humpback whales, similar in scope to the Rangewide Review for North Pacific gray whales and taking into account recent work on stock structure including that of Stevick *et al.* (2018).

8.8.3 Management advice

Attention: C-A

The alternate Commissioner for St Vincent and the Grenadines advised that no change to the present limits were envisaged. The Committee therefore:

(1) ***notes*** *that is does not have an approved abundance estimate for western North Atlantic since that in 1992;*
(2) ***notes*** *that in accord with the advice provided in the AWS (see Annex E, Appendix 8), it therefore considered the available evidence to see if was sufficient to provide safe management advice;*
(3) ***advises*** *that, given the information above on recent abundance in the North Atlantic combined with the size of the requested catch/strikes (an average of four annually), continuation of the present limits will not harm the stock;*

The Committee also ***reiterates*** *its previous advice that:*

(1) the status and disposition of genetic samples collected from past harvested whales be determined and reported next year;
(2) photographs for photo-id (where possible) and genetic samples are collected from all whales landed in future hunts; and that
(3) the USA (NOAA, NMFS) provides an abundance estimate from the MONAH data as soon as possible for the Committee.

8.9 Workplan 2019-20

Table 7 summarises the work plan for work related to aboriginal subsistence whaling. The Committee also established an Intersessional Correspondence Group to work on ASW related issues (Annex Y).

Table 7

Work plan for matters related to aboriginal subsistence whaling

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
(1) Annual review of catch/strike limits		Carry out		Carry out
(2) *Implementation Review*		Gray whales based upon rangewide review		West Greenland humpback whales
(3) *SLA*s		Consider development of an *SLA* for the hunt of common minke whales off East Greenland based on operational models developed for the West Greenland hunt		Adopt *SLA* if it is decided one is necessary
(5) Interim relief allowance testing	Run trials for gray whale hunts	Review results	Run trials for West Greenland common minke whales and fin whales	Review results
(6) Carryover (US/Denmark request)	Run trials for remaining Greenland hunts (West Greenland common minke whales, bowhead whales and fin whales	Review results		

9. WHALE STOCKS NOT SUBJECT TO DIRECTED TAKES

9.1 In-depth Assessments

Donovan gave a presentation explaining a streamlined procedure hereby the Committee, via its sub-groups, can undertake Comprehensive Assessment (traditionally the first time an assessment is undertaken for a particular species/ocean basin) or an in-depth assessment (assessments subsequent to a comprehensive assessment). This can be found as SC/67B/GEN04 and is summarised in Fig. 1. The objective is to provide a consistent approach (including methods) that initially focusses on ensuring that sufficient data are available to undertake an assessment (the pre-assessment approach that will normally be undertaken at annual meetings) and then follows this with a concentrated effort (ideally two workshops and two annual meetings, with no new data) to complete the assessment. The objective is to provide Commission with robust information on present status. This involves identifying:

(1) if populations are recovering, recovered or if there is cause for concern;

(2) factors that may be or are affecting status so that conservation and management needs can be determined; and

(3) information gaps and ways to address these in order to reduce uncertainty at the next assessment.

9.1.1 Comprehensive Assessment of North Pacific humpback whales

Work towards a Comprehensive Assessment of North Pacific humpback whales began in 2016, and included an intersessional workshop held in April 2017 (IWC, 2018b). After the 2017 Committee meeting, an intersessional steering group continued preparing the input data and assessment model (IA/67b/IA03). The assessment model is a simplified age-aggregated model of the breeding and feeding grounds. The development of the input data (stock structure, abundance, catches, and life history parameters) continued during the year but given the slower than initially expected progress, particularly with respect to narrowing down the number of stock structure hypotheses, the steering group had agreed that it was premature to hold the anticipated workshop prior to SC67b.

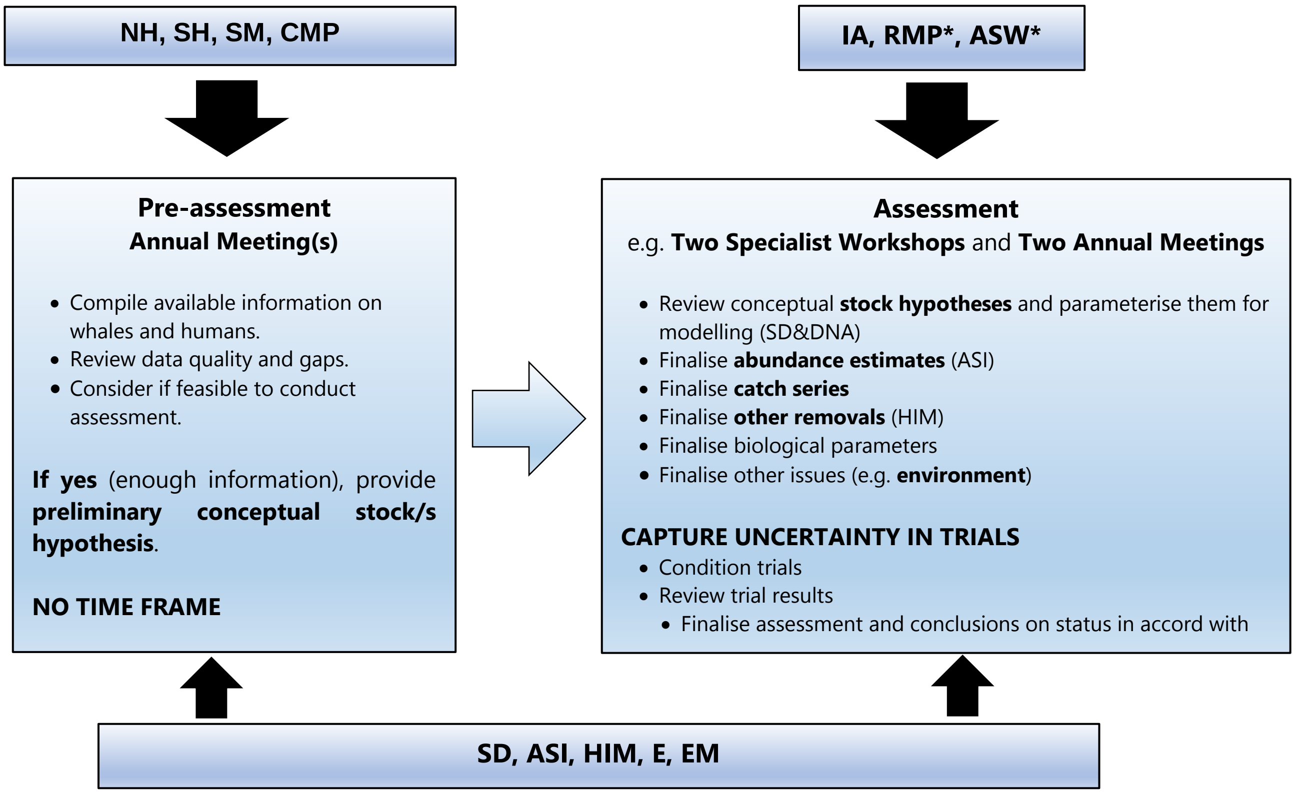

Fig. 1. Schematic of the approach to conduct assessments within the Scientific Committee. Acronyms refer to sub-groups. Normally the final assessment will take place in the sub-committee on in-depth assessments but for stocks subject to direct catches it may occur in the context of the RMP or AWMP sub-groups as appropriate.

Work continued at this meeting and the detailed discussions can be found in Annex F (item 4). The subdivisions of the North Pacific humpback whale feeding and breeding grounds in Annex F (fig. 1) are broadly consistent with existing data; identified uncertainties will be addressed in the assessment by evaluating four scenarios with different numbers of feeding and breeding grounds. This work will be greatly assisted by undertaking comparisons of humpback whale photographs from the Pacific obtained after the conclusion of the photographic component of the SPLASH (Structure of Populations, Levels of Abundance and Status of Humpback Whales) programme in 2005 (e.g. see Calambokidis *et al.*, 2008).

The general underlying structure of the assessment model has been developed but before the model can be run the input data (e.g. catches and abundance estimates) need to be updated and allocated for each stock structure hypotheses and mixing matrices developed and parameterised.

Attention: SC, G

The Committee is undertaking a Comprehensive Assessment of North Pacific humpback whales. To complete this assessment the Committee ***agrees*** *that:*

(1) a large-scale matching effort of post-2005 photo-identifications should be undertaken (see Annex F, item 4 for methods); and
(2) this matching effort will (a) help clarify the connections among the feeding/breeding areas within the North Pacific; and (b) assist in developing updated abundance estimates where appropriate.
The Committee ***stresses*** *that to obtain the most robust assessment and thus conservation advice, all available data should be included in the matching effort. Therefore, the Committee* ***strongly encourages*** *all catalogue holders to participate in this exercise, after the appropriate data sharing agreements are made.*

The Committee also ***welcomes*** *the provision of new abundance estimates (e.g. those from the IWC-POWER surveys and from local areas in Japan), noting that they will also need to be adjusted for the various stock structure hypotheses.*

The Committee ***agrees*** *that the next assessment workshop should take place at a time prior to SC68b when the intersessional Steering Group (Annex Y) decides sufficient progress has been made.*

9.1.2 Comprehensive Assessment of North Pacific sei whales

The Committee began what was called an in-depth assessment of North Pacific sei whales in 2015 (IWC, 2016c) but, in keeping with the discussion under Item 9.1 will now be termed a Comprehensive Assessment for consistency. Work has focussed since then on finalising the stock structure hypotheses (two have been agreed for use in the assessment - a single-stock hypothesis and a five-stock hypothesis), developing an appropriate population model and finalising the model inputs in accordance with these hypotheses (including catches, mark-recovery locations, abundance estimates, estimates of mixing between sub-areas, and life history parameters).

Considerable progress was made with this work intersessionally and at this meeting as discussed in Annex H, item 3.

Attention SC, G

The Scientific Committee intends to complete the Comprehensive Assessment of North Pacific sei whales within the next biennial period. It notes the progress made at this meeting with respect to stock structure, abundance estimates, marking data, catch history, life history parameters and the assessment model. To complete this work, the Committee ***agrees*** *to:*

(a) the work undertaken to finalise input data for the assessment (Annex F, appendices 2-7);
(b) support the modelling work identified in Annex F; and
(c) re-establish the intersessional steering group to oversee the assessment.

In addition, the Committee ***encourages*** *telemetry work in waters outside the 'pelagic' sub-area to assist in quantifying the movement patterns of animals.*

9.1.3 In-depth Assessment of Indo-Pacific Antarctic minke whales

An intersessional correspondence group under Murase completed its task to finalise a document synthesising the results of the 2001 - 2014 in-depth assessment of an eastern Indian stock (I-stock) and a western South Pacific stock (P-stock) of Antarctic minke whales distributed between 35°E and 145°W.

The Committee **commends** the authors for completing this paper and submitting it to the *Journal of Cetacean Research and Management.* As the paper has just entered the review process, the intersessional correspondence group (Annex X) has been re-established to see the paper through to publication.

9.1.4 Workplan 2019-20

The work plan for Comprehensive and in-depth assessments for the next biennium is provided in Table 8.

Table 8

Work plan for in-depth assessments

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting (SC/68b)
In-depth Assessment of Indo-Pacific Antarctic minke whales	Complete review of paper submitted for publication	-	-	-
Comprehensive Assessment of North Pacific sei whales	Re-establish the ISG (Annex Y) to further data preparation and development of the assessment model	Review progress of intersessional work and continue the assessment	Finalise preparation of assessment	Review progress of intersessional work and finalise the assessment
Comprehensive Assessment of North Pacific humpback whales	Re-establish the ISG (Annex Y) to further data preparation, development of the assessment model and hold a Workshop	Review progress of intersessional work and continue the assessment	Finalise /continue preparation of assessment	Review progress of intersessional work and continue/finalise the assessment

9.2 Evaluation for potential new Comprehensive or In-Depth Assessments

9.2.1 North Pacific blue whales

The Committee welcomed the report of an intersessional group that had been determining the data that are available on items required to carry out a Comprehensive Assessment of blue whales in the North Pacific. The status of the eastern North Pacific population is well known and a stock assessment was reviewed and accepted by the Committee in 2016 (Monnahan and Branch, 2015). However, information from the central and western North Pacific is sparser. Information presented at this meeting concerned stock structure, catch history, biological parameters, photo-identification, Discovery marks and sighting surveys. Details can be found in Annex G (item 6.1).

Several papers and datasets were discussed including: the use of blue whale sounds to identify stocks; morphological data; genetic data; sightings data (SC/67b/IA02; SC/67b/SCSP06; SC/67b/SCSP07; SC/67b/NH08).

Attention: SC

*The Committee **agrees** the following priorities to progress the pre-assessment:*

(1) obtain abundance estimates from the IWC-POWER surveys;
(2) obtain abundance estimates from the JARPN and JARPNII surveys;
(3) analyse and compare genetic samples from ENP, IWC-POWER and ICR biopsy samples to determine stock structure throughout the North Pacific;
(4) compare photo-identification data from POWER, JARPN/JARPNII and other ENP catalogues;
(5) Review new acoustic locations and information and conduct fine-scale analysis of song features for central Pacific blue whale calls, with particular focus on calls around Japan;
(6) Obtain better life history parameters (especially age at sexual maturity and calving interval) from the Cascadia Research Collective, the Mingan Island Cetacean Study Research Station and the CICIMAR-IPN photo-ID dataset;

*With respect to (3), the Committee **requests** the collection of about 20 biopsy samples if possible during the NEWREP-NP surveys in the western North Pacific to improve the power to evaluate stock structure and **encourages** genetic analysis of the existing Japanese samples.*

*With respect to (5), the Committee **requests** a reanalysis of recordings from the Northern Mariana Islands (Saipan and Tinian) collected by the Pacific Islands Fisheries Science Center to look for the presence or absence of the new song type recorded from Japan. It also **encourages** passive acoustic data collection during surveys (e.g. IWC-POWER, university/training cruises) from the region of high blue whale density southeast of the Kamchatka Peninsula to determine the song type produced by animals in that region.*

*The Committee **agrees** that the intersessional correspondence group continue to review data needed for an assessment of North Pacific blue whales be reappointed under Branch (Annex Y).*

9.2.2 Non-Antarctic Southern Hemisphere blue whales

9.2.2.1 SOUTHERN HEMISPHERE POPULATION STRUCTURE

The Committee is currently preparing for a Comprehensive Assessment of pygmy blue whales. For this reason, it continues to gather information on population structure (see Item 3.1, IWC, 2018a). This year, the web-based pygmy blue whale song library funded by the IWC will be launched (SC/67b/SH12). This will enable researchers to compare their acoustic recordings with validated song archetypes and greatly assist the determination of Southern Hemisphere blue whale distribution patterns and stock structure. Photo-ID and genetic evidence support the idea that each distinct pygmy blue whale song represents a geographically and genetically distinct population of pygmy blue whales around the Southern Hemisphere. A full description of the discussion of the use of songs in this pre-assessment is given in Annex H (item 3.1), including comparison with genetic and photo-identification data. The Committee also received information from whale bones and notes that further analysis of blue whale bones from old whaling land stations will be helpful to establish the past distribution of these stocks.

Assessments require catches to be allocated to populations and in 2016 the Committee funded an examination of regional catches to assign them to each putative population (Item 5.1, IWC, 2017a). The results of this work are provided in SC/67b/SH23 and discussed in Annex H (item 3.1). Total pygmy blue whale catches were estimated at 12,184 with totals for each population of 1,228 (Northern Indian Ocean), 6,889 (South West Indian Ocean), 3,646 (South East Indian Ocean) and 421 (South West Pacific Ocean).

The Committee also discussed an intersessional effort to identify and standardise genetic markers used in Southern Hemisphere blue whale research (only four loci were common across all research laboratories) and received a progress report (SC/67b/PH04) on matching within the Southern Hemisphere Blue Whale Catalogue, which has been supported by funding from the Committee (Item 10.2.2, IWC, 2017a). This helps understanding of blue whale movements between regions, and allows estimation of regional abundance. The catalogue is currently being migrated to IWC servers (and see Item 23.2.3.2).

Attention: SC, G

In order to progress its work towards an assessment of pygmy blue whales, the Committee:

(1) ***agrees*** *that further work is needed to identify high and base case catch scenarios for pygmy blue whales;*
(2) ***encourages*** *deployment of more acoustic recorders in the southern Indian Ocean;*
(3) ***agrees*** *that further population modelling is needed to assess pygmy blue whale populations;*
(4) ***strongly encourages*** *blue whale research groups to publish the metadata associated with their sequences in order that levels of sample overlap can be established and datasets compared;*
(5) ***agrees*** *that the Southern Hemisphere Blue Whale Catalogue should be continued to help understand blue whale movements, with a priority focus on matching photographs within regions to measure regional abundance of pygmy blue whales.*

9.2.2.2 INDONESIA/AUSTRALIA BLUE WHALES

The Australian blue whale photo-ID catalogue data have now nearly all been uploaded and matched within the Southern Hemisphere Blue Whale Catalogue, at which point quality control analysis can begin. This will allow the potential for using these data for mark recapture abundance estimation to be assessed. The Scientific Committee was informed that mark-resighting data from the Perth Canyon (Australia) will be analysed intersessionally, to provide a new estimate of Australian blue whale abundance which assist in a future assessment of this population.

Attention: SC, G

The Committee ***encourages*** *analysis to provide an estimate of Australian blue whale abundance using mark-resighting data.*

9.2.2.3 MADAGASCAR BLUE WHALES

The Committee was informed that passive acoustic monitoring of blue whales in the Mozambique Channel detected both South West Indian Ocean (SWIO) and Antarctic blue whale song types, as well as fin and Antarctic minke whales (SC/67b/SH14). In addition, SC/67b/SH24 reported an unidentified blue whale song off Oman. A full discussion of the results of these papers can be found in Annex I (item 3.3.2).

This new information means that the blue whale catch allocations for the Indian Ocean, currently only ascribed to a single ‘NIO’ population in the Northern Indian Ocean, will need revision to take this new acoustic pattern into account.

Attention: SC, G

The Committee notes that the distribution and population isolation of blue whales is poorly understood in the northern and western Indian Ocean. The Committee therefore:

(1) ***strongly encourages*** *further acoustic work in the western Indian Ocean and Arabian sea to better understand the distribution, seasonality and overlap of blue whale calls;*
(2) ***strongly encourages*** *the collection and analysis of available tissue samples for analysis of genetic population structure in this region to assist with characterising these populations; and*
(3) ***agrees*** *that catch allocations of blue whales be revised to include the new blue whale song in the northwest Indian Ocean as a potential distinct ‘stock’.*

9.2.2.4 NEW ZEALAND BLUE WHALES

Three papers were presented on blue whales off New Zealand (see Annex H, item 3.3.4 for a full discussion).

SC/67b/SH09 reported a recent study of blue whale movement and habitat use in the Taranaki region of New Zealand in which two animals were tagged. However, due to the small sample size and La Niña conditions, it is uncertain how representative these movements are for blue whales in New Zealand waters.

SC/67b/SH05 summarised a multi-disciplinary study included acoustics, genetics and photo-identification in the same area, and provided a conservative estimate of blue whale population abundance (see Annex Q, item 3.1.1.9), to consider if this estimate can be used in the upcoming regional assessments of pygmy blue whales. SC/67b/SH04 reported projects underway to assist regional conservation management, including a description of fine-scale habitat use during summer months in the South Taranaki Bight, and response to local acoustic disturbance.

Attention: SC, G

With respect to information on blue whales off New Zealand, the Committee:

*(1) **welcomes** the work being undertaken to understand abundance and connectivity, which will contribute towards the pygmy blue whale population assessments; and*
*(2) **agrees** that New Zealand photo-identifications should be combined with others within the Southern Hemisphere Blue Whale Catalogue to provide the fullest possible assessment of regional abundance and connectivity*

9.2.2.5 SOUTHEAST PACIFIC BLUE WHALES

The Committee received two papers relevant to blue whales off Chile and the full discussion can be found in Annex H (item 3.3.1). SC/67b/SH03 presented a morphometric analysis of Chilean blue whales which reinforces the argument that Chilean blue whales should be considered a separate sub-species from the Antarctic and pygmy forms. (Bedrinana-Romano *et al.*, 2018) reported distribution modelling of blue whales using Chilean Northern Patagonia waters. Preliminary delimitations of possible blue whale conservation areas in this region overlap with highly used vessel navigation routes and areas allocated for aquaculture. The Committee was also informed that predictions of southeast Pacific blue whale habitat following Redfern *et al.*, (2017) will be completed intersessionally.

Attention: SC, G

In view of the recent identification of movements of Chilean blue whales into the South Atlantic and ongoing questions about the distribution of this population, the Committee:

*(1) **encourages** further satellite tracking and surveys (including collection of photo-ID and genetic data) to assess the population limits, habitat use and abundance and sub-species identity of blue whales in Chile;*
*(2) **encourages** compilation of morphometric data available for northeast Pacific blue whales and comparison with Chilean data, to assess morphological differentiation of these whales in the eastern Pacific and evaluate sub-species identity; and*
*(3) **welcomes** plans for further photo-ID catalogue matching within this region to assist with regional abundance estimation.*

9.2.2.6 WORK PLAN

The work plan for all Southern Hemisphere blue whales is given in Table 9.

9.2.3 Antarctic blue whales (Areas III and IV)

Undertaking a regional population assessment of Antarctic blue whales is challenging due to the scarcity of whales and logistical challenges. The Committee received new information this year on sightings, abundance and genetic studies.

SC/67b/SH08 presents a preliminary estimate of abundance (the first using photo-ID data) and this is discussed in Annex Q (see item 3.1.19) where suggestions were made to refine the analyses. Reports from two 2017/18 NEWREP-A summer cruises included sightings of blue whales and information on biopsy sampling (SC/67b/SP08 and SC/67b/ASI07). An IWC-SORP Southern Ocean blue whale-focussed cruise is planned for January to March 2019 (140°E-175°W), which intends to describe krill swarms in relation to blue whale density and distribution (SC/67b/SH07).

With respect to genetic work, IWC-SORP funded work on blue whale bones to compare past and current genetic diversity levels is reported in SC/67b/SH02 and discussed in Annex I (item 4.4.2). The Committee was also updated about ongoing work to analyse a collection of 1,626 baleen plates (roughly 50:50 blue and fin whales) from the Japanese whaling in the 1940s and held at the Smithsonian Natural History Museum, USA. A pilot study has established that mitochondrial DNA can be sequenced from these plates. Further analyses including of stable isotope and hormone levels are planned for these samples.

Attention: SC, G

*The Committee **welcomes** the progress being made towards being able to undertake am in-depth assessment of Antarctic blue whales. The Committee:*

*(1) **encourages** further work to update the abundance estimate for Antarctic blue whales following Committee recommendations;*

(2) ***strongly encourages*** *continued opportunistic photo-ID data collection in the Antarctic to assist with developing estimates of population abundance for this subspecies; and*
(3) ***encourages*** *continued collection and analysis of bone and baleen from historical Antarctic commercial whaling samples and sites to evaluate loss of genetic diversity and shifts in population structure.*

9.2.3.1 WORK PLAN

The work plan for all Southern Hemisphere blue whales is given in Table 9.

Table 9.

Workplan for Southern Hemisphere Antarctic and pygmy blue whales

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Antarctic blue whales				
Catalogue matching	Catalogue matching of photo-IDs (Annex Y)	Report	Catalogue matching (opportunistically collected photos)	Report
Abundance estimation	Mark recapture modelling work to update SC/67b/SH08 Annex Y	Report		
Photo-ID outreach material	Create photo-ID information booklets for distribution via IAATO operators	Report		
SH non-Antarctic blue whales				
Population assessment	Improve catch separation model, explore alternative catch allocation models (Annex Y)	Report	Population assessment. Analyse minimum and extrapolated recovery status of all populations for which abundance is available	Report
Catalogue matching	Catalogue matching of photo-IDs within southeast and central east Pacific (Annex Y)	Report	Catalogue matching (opportunistic photos from citizen scientists and collaborators) if funds are available	Report
Blue whale song library	Finish implementation of blue whale song library (Annex Y)	Report		
Australian abundance estimate	Analyse Perth Canyon abundance using mark recapture data (Annex Y)	Report		

9.2.4 Southern Hemisphere fin whales

9.2.4.1 POPULATION STRUCTURE

As part of its pre-assessment work, the Committee is gathering information on Southern Hemisphere fin whales in order to: (1) clarify the subspecies status of these whales (currently two Southern Hemisphere subspecies are recognized, Committee on Taxonomy, 2017); and (2) measure population differentiation around the Southern Hemisphere to establish whether any distinct populations exist.

A summary of available data on Southern Hemisphere fin whale structure was presented in SC/67b/SH15 and is discussed in detail in Annex H (item 4.1). The only evidence for any structure comes from acoustics. A genetic study from the southeast Pacific (SC/67b/SH13) found high local diversity in Chile, with no significant differentiation from the other Southern Hemisphere datasets. The Committee noted however that genetic differentiation can be difficult to detect when diversity levels are high and genetic differentiation is low (see Annex H, item 4.1).

Attention: SC, G, S

Knowledge of population structure is essential to future efforts to assess Southern Hemisphere fin whales. To determine the differentiation and potential sub-species structure among fin whales the Committee:

(1) ***agrees*** *that analysis of concurrently collected acoustic recordings of fin whales, to assess song variation around the Southern Hemisphere, is a priority;*
(2) ***agrees*** *that a review of all Discovery mark data published on fin whales to assess population connectivity patterns should be carried out; and*

(3) ***requests*** *that the Secretariat provide a letter of support for a study examining the evidence for* B. physalus patachonica, *which requires access to the holotype for this species from the Bernardino Rivadavia Natural Sciences Museum in Buenos Aires.*

The Committee also ***encourages:***

(1) analysis of fin whale distribution and geographic aggregations using all available catches;
(2) strategic biopsy sampling and analysis to measure the genetic differentiation of fin whales around the Southern Hemisphere;
(3) further biopsy sampling and sequencing of multiple nuclear loci to establish Chilean fin whale differentiation patterns, with co-collection of photo-IDs and body length measurements to establish population identity;
(4) satellite telemetry to discern seasonal movements; and
(5) photo-identification to understand site fidelity and residency patterns and linkages between high- and low-latitude grounds.

9.2.4.2 DISTRIBUTION AND ABUNDANCE

The Committee welcomed a review of the available metadata on Southern Hemisphere fin whales (SC/67b/SH19), compiling data from dedicated and opportunistic surveys, moored acoustic recorders, sonobuoy surveys, photo-identifications, satellite tagging and biopsy sampling. The Committee also welcomed a summary of recent work by the Brazilian Antarctic Program to conduct dedicated fin whale research using sighting surveys, photo-ID, biopsy sampling and telemetry.

Reports from two 2017/18 NEWREP-A summer cruises included sightings of fin whales and information on biopsy sampling (SC/67b/SP08 and SC/67b/ASI07). A new abundance estimate for fin whales using sightings data from the third IDCR-SOWER circumpolar survey is expected to be available for review at next year's meeting.

SC/67b/14 provided information on the presence of fin whales in the Mozambique Channel and a new lower-latitude song. Details of the discussions can be found in Annex H (item 4.2).

The Committee was also informed that an analysis has suggested that Antarctic fin whales are sufficiently well marked to enable to use in photo-ID projects (SC/67b/PH01) and this is discussed in Annex S (item 4.1).

Attention: SC, G, CG-A

With respect to obtaining information on the distribution, movements and abundance of Southern Hemisphere fin whales for use in a future assessment, the Committee:

(1) ***encourages*** *a meta-analysis of the Antarctic Peninsula and Scotia Sea sightings data, to measure recent fin whale distribution, density and habitat use;*
(2) ***strongly encourages*** *continued work by the Brazilian Antarctic Program towards the understanding of fin whale population structure, movements and habitat use*
(3) ***agrees*** *that a new abundance estimate for fin whales from the IWC IDCR/SOWER programme should be presented for review at next year's meeting,*
(4) ***welcomes*** *news that fin whales can be used in photo-ID studies, and* ***encourages*** *further photo-ID data collection at high latitudes.*

9.2.4.3 WORK PLAN

The work plan for Southern Hemisphere fin whales is given in Table 10.

Table 10

Work plan for Southern Hemisphere fin whales

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Fin whale acoustic structure	Review fin whale call patterns across Southern Hemisphere, investigate call variation (Annex Y)	Report	Complete review of fin whale call patterns (Annex Y)	Report
Discovery marks	Review available Discovery mark data on fin whales (Pastene and Jackson)	Report		
Catch maps	Update fin whale catch model to include Soviet catch data (de la Mare)	Report		

9.2.5 North Atlantic sei whales

The Committee welcomed information on two separate habitat-based density modelling efforts, using visual survey data to produce seasonal abundance estimates for sei whales from the purported 'Nova Scotia' stock, ranging from Nova Scotia to the southeastern USA (SC/67b/NH07). There was also some consideration of passive acoustic and strandings data from the US eastern seaboard. No new data are available from around Iceland or Norway, partially due to difference in timing between surveys and species' arrival in regional waters. This information was discussed in Annex G (item 6.2). An intersessional correspondence group (Annex Y) will compile additional information this species in the North Atlantic and the Committee looks forward to a further update on reanalysis of historical data, particularly related to stock structure and strandings, next year.

9.2.6 North Atlantic right whales

Since 2016, the Committee has recommended a comprehensive update on North Atlantic right whales. SC/67b/NH05 summarised the information on the status of the North Atlantic right whale. This population has been slowly declining since 2010 and the abundance at the end of 2015 was estimated to be around 460 individuals (Pace *et al.*, 2017[6]). Of particular concern is the lower annual survival rate of females than males and poor recent calving (five in 2016/17 and none so far in the 2017/18 calving season). The observed number of dead whales in 2017 was 17 whales, several showing signs of death from fishing gear or blunt force trauma. These clearly represent minimum numbers and there was some discussion as to whether it was possible to scale minimum observed mortalities to an overall estimate but several confounding factors preventing this were identified (see Annex F, item 6.3 and Annex J, item 2.1.2).

Due to the increased 2017 Canadian interactions in the Gulf of St. Lawrence, on 19 April 2018 the Government of Canada implemented mitigation measures to reduce future interactions (DFO, 2018), including: closing a large part of the Gulf of St. Lawrence snow crab fishery on 30 June; creating a dynamic 15-day fishing closure; introducing a 10 knot speed restriction when any single right whale sighting in any area is detected; putting in place mandatory gear marking and reporting of any lost gear; minimising the allowable amount of floating line at surface; and using vessel monitoring systems that reports the boats position every 5 minutes.

A substantial increase in collaboration and data sharing between the US and Canada has occurred as a result of these mortalities.

Attention: C-A, CC

The Committee reiterates its serious concern over the status of the western North Atlantic stock of right whales as it is probably the only viable population of this species, for which entanglements and ship strikes have long been identified as key threats.

This year, the Committee:
(1) ***recognises*** *that entanglements have now replaced ship strikes as the primary cause of deaths (Kraus et al. 2016);*
(2) ***reiterates*** *its recommendation for the USA to submit a comprehensive update on the status of North Atlantic right whales (IWC, 2017:40) including an update of the Pace* et al. *abundance estimate, prior to the 2019 meeting;*
(3) ***stresses*** *that this update will allow time for explanations or additional analyses to be undertaken before the proposed 2019 Workshop on the Comparative Biology, Health, Status and Future of North Atlantic Right Whales: Insights from Comparative with other Balaenid Populations (including bowheads);*
(4) ***encourages*** *updates from the US Large Whale Take Reduction Team (ALWTRT) on progress of the Whale Safe Rope and Gear Marking Feasibility Subgroups; and*
(5) ***requests*** *that the Commission asks the IWC Executive Secretary to write to the U.S. National Marine Fisheries Service (NMFS) and the Canadian Department of Fisheries and Oceans, informing them of the Committee's serious concerns over the declining population trend of this species, and stressing that,* ***as a matter of absolute urgency****, every effort be made to reduce human induced mortality in the population to zero.*

9.2.7 North Pacific right whales

The Committee received a report of a dead right whale caught in a set net off Izu, Japan in 2018 (SC/67b/NH06) – the first in a set net since one in Korea in 2015 (Kim *et al.*, 2015).

The Committee welcomed information on a single sighting off Hokkaido (and a biopsy sample) from a Japanese national cruise (SC/67b/ASI10). It also welcomed information on North Pacific right whales from the visual, acoustic and biopsy sampling components of the 2017 IWC-POWER cruise in the eastern part of the Bering Sea. A total of 9 schools and 18 individuals (including 2 duplicate schools of 3 individuals) of right whales were sighted with photo-identification of 12 individuals and biopsy samples from 3 individuals. Discussion of these sightings can be found in Annex G (item 6.4).

In response to a recommendation made last year (IWC, 2018c), US and Japanese scientists presented the results of new genetic analyses of right whales in the North Pacific. Comparison of whales sampled in the eastern and western North Pacific revealed statistically significant differentiation based on mtDNA data, supporting presumed separation of the two stocks based on gaps in the spatial distribution of sightings (and also see discussion in Annex I, item 4.3).

---

[6] Any revised estimate from the Pace *et al.* 2017 paper will be reviewed by the ASI sub-committee during SC68a.

Attention: SC

The results of new genetic analyses support the recognition of separate stocks of right whales in the eastern and western North Pacific. Given the importance of this work and the precarious situation of this species, especially in the eastern North Pacific, the Committee ***encourages*** *the publication of this information as soon as possible.*

9.2.8 Workplan 2019-20

The Committee agreed to the two-year workplan in Table 11.

9. 3 New information and workplan for other northern stocks *(NH)*

9.3.1 North Pacific fin whales

The Committee received new information on studies of North Pacific fin whales. New sightings of fin whales were reported in the papers (SC/67b/ASI12, SC/67b/ASI10, SC/67b/SCSP06) during the POWER cruise in the Bering Sea and the two surveys in the western North Pacific (Areas 7, 8 & 9). Over 260 schools found, many individuals were photo-identified and biopsy samples were obtained from 28 whales.

9.3.2 Omura's whale

The Committee welcomed the new information on this species (SC/67b/NH09) from the west coast of Madagascar, supporting the current understanding that the population is resident and non-migratory with strong site fidelity. Likely threats to the Madagascar population include entanglement in local fisheries, impacts from oil and gas exploration, and most imminent the risk of coastal water contamination from a recently initiated mining operation for Rare Earth Elements. Future work should include a long-term latitudinal study that incorporates multiple methodologies to investigate all aspects of the species biology and conservation threats to the population.

Kim and colleagues reported on the first confirmed documentation of Omura's whale in the waters of South Korea. Two of six large baleen whales bycaught were confirmed by genetic analysis to be Omura's whale. This bycatch reinforces the concept that this coastal species is vulnerable to anthropogenic impacts, especially entanglement in fishing gear.

Attention: SC, G

The Committee notes that little information is available to assess the status of Omura's whale. The Committee:

(1) ***recognises*** *the significant contribution the research efforts off Madagascar have made to the understanding of this species and* ***encourages*** *this work to be continued and expanded into the future; and*
(2) ***encourages*** *identification of study sites that are suitable for long-term comparative study on Omura's whales in other parts of its range (e.g. New Caledonia, Komodo Islands, Indonesia, and the Bohol Sea, Philippines).*

Table 11

Workplan for other Northern Hemisphere stocks

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
North Pacific blue whales	Data collection and review with focus on catches and stock structure	Review especially stock structure	Develop proposal for stock structure	Agree stock structure hypotheses
North Atlantic sei whales	Review distribution, strandings, sightings and stock structure	Review new information for assessment	Develop proposal for stock structure	Agree stock structure hypotheses
North Atlantic right whales		Review status and mortality data		Review status and mortality data
North Pacific right whales		Review new information for assessment		Review new information for assessment
North Atlantic humpback whales		Consider information for new assessment		Develop plans for new assesssment
Gulf of Mexico Bryde's whale		Review new information on mortality		Review new information on mortality
All other stocks		Review new information		

9.3.3 North Atlantic Bryde's whales

SC/67b/ASI01 presented sightings collected during recent coastal surveys off Guinea, Sierra Leone and Liberia in March 2018. During this survey, two groups of five individual Bryde's whales were observed.

The Committee welcomed this information and **encourages** future surveys in this region.

9.3.4 North Atlantic blue whales

The Committee welcomed new information from the USA on blue whales in the North Atlantic including recent sightings, serious injuries or mortalities, seasonal occurrence based on acoustics. Lesage *et al.* (2018) provides an extensive summary of recent data collected in Canadian waters. This is discussed in Annex G (item 7.6) where it was noted that multiple new datasets (including from passive acoustic monitoring) have been recently collected and may provide more information on blue whale distribution in North Atlantic waters

Attention: SC, G

The Committee notes that there has been a recent increase in information available on North Atlantic blue whales. The Committee:

(1) ***draws attention to*** *the lack of data on interchange between blue whales in the eastern and western North Atlantic and* ***recommends*** *that U.S., Canadian and Icelandic colleagues conduct a new comparison of blue whale photo-identification catalogues and present this information at SC/68a; and*
(2) ***encourages*** *Canadian colleagues to generate a new population abundance estimate as soon as feasible, and looks forward to updates on new passive acoustic and visual sightings data SC/68a.*

9.3.5 North Atlantic humpback whales

The Committee received new information (NOAA, 2018b) on humpback mortalities along the US coast (vessel strikes and entanglements were noted as the primary causes of anthropogenic mortality). An ‘Unusual Mortality Event’ was declared by the USA for humpback whales in April 2017. This is discussed further in Annex G (item 7.7. New abundance estimates for parts of the North Atlantic are discussed in Annex Q (item 3.1.1.3) and presented in Item 12.1. Consideration of the need for a new in-depth assessment of North Pacific humpback whales is given in Annex E (item 5.8.2) and Item 8.7.3.

9.3.6 North Atlantic bowhead whales not subject to aboriginal subsistence whaling

No new information was available to the Committee.

9.3.7 North Pacific bowhead whales not subject to aboriginal subsistence whaling

No new information was available to the Committee.

9.3.8 North Pacific sperm whales

Three papers (SC/67b/ASI10,12 and SC/67b/SCSP06) provided new information of sperm whale occurrence and distribution was collected during 2017 in the western North Pacific, eastern Bering Sea. An intersessional correspondence group to examine possible ways to assess sperm whales has been reappointed (Annex Y)

9.3.9 Gulf of Mexico Bryde’s whales

9.3.9.1 NEW INFORMATION

The Committee received an update on activities related to monitoring and new research plans for the critically endangered Gulf of Mexico sub-species of Bryde’s whale. The Southeast Fisheries Science Center undertook a shipboard survey in the northern Gulf of Mexico in 2017, including known habitat of the Gulf of Mexico Bryde’s whale. Passive acoustic data were collected in historic habitat of the central and western Gulf from June 2016 to June 2017. The In the USA, there is legislation that provides funds to restore and protect ecosystems of the Gulf of Mexico following the Deepwater Horizon oil spill (2010); this work will include research on the Gulf of Mexico Bryde’s whale.

Attention: SC, G

The Committee ***agrees*** *that the NOAA scientists working with this sub-species should present results from shipboard and acoustic data analyses to the IWC at the 2019 Scientific Committee meeting and looks forward to receiving a report from the Workshop held in conjunction with the initiation of research associated with funds to restore and protect ecosystems of the Gulf of Mexico following the Deepwater Horizon oil spill.*

The Committee also ***encourages*** *U.S. and Mexican scientists to collaborate in efforts to determine whether any of these whales occur in Mexican waters (e.g. Bay of Campeche) where a major oil spill of three million barrels occurred in 1979. This should include consideration of the use o9f passive acoustics as well as visual surveys focusing on areas of habitat similar to that found in the core known range in the north-eastern Gulf. It was further noted that passive acoustic data or specimen records from the northern coast of Cuba would be useful to determine potential occurrence of this subspecies in that region.*

9.3.9.2 CONSERVATION ADVICE

Attention: CG-R, S
The small population size, known human related mortality, restricted range and low genetic diversity place the Gulf of Mexico sub-species of Bryde’s whale (added to the Critically Endangered category of the IUCN Red List in 2017) at significant risk of extinction. The Committee ***reiterates*** *its previous* ***recommendations*** *that US authorities:*

(1) make full and immediate use of available legal and regulatory instruments to provide the greatest possible level of protection to these whales and their habitat;
ensure that seismic surveys and associated activities that degrade acoustic habitat are excluded from the region of the eastern Gulf of Mexico inhabited by these whales, including an appropriate geographic buffer against acoustic impacts from activities in the Central Planning Area and active leases in the Eastern Planning Area;
(2) characterise the degree of overlap between the whales' currently known preferred habitat and ship traffic, and immediately implement appropriate measures to reduce the risk of ship strikes (e.g. re-routing, speed restrictions);
(3) based on the known distribution of these whales and overlap with certain fisheries, improve understanding of potential for interaction with fishing gear, and expand and implement appropriate measures, such as area closures, to reduce the risk of entanglement throughout their range;
(4) develop and implement restoration projects (with funds from the Deepwater Horizon oil spill settlement) for these whales and their habitat as a priority and ensure that a robust monitoring and adaptive management plan is in place to evaluate the effectiveness of all restoration efforts;
(5) design and conduct research programmes (sighting surveys, acoustic monitoring, genetic mark-recapture, photoidentification if feasible, satellite tagging if feasible, health studies if feasible) to further investigate these whales' distribution, movements, habitat use, health, survival and fecundity - this should include efforts to better document the whales' total geographic range and to document causes of mortality through necropsies when carcasses are reported; and
(6) *ensure that information about core known habitat and movements in the Gulf of Mexico is transmitted to the U.S. Coast Guard, shipping industry trade organizations, and Gulf of Mexico port authorities (e.g. in Tampa, Florida) for their consideration to mitigate ship-strike risk.*

In addition, the Committee ***reiterates*** *its recommendation that the IWC Secretariat (i) communicate the above concerns and recommendations to range state authorities and (b) specifically explore in collaboration with the International Maritime Organization the feasibility of providing internationally recognized forms of protection to these whales (e.g. designation of an Area to be Avoided) that would reduce the risk of ship strike and help mitigate degradation of acoustic habitat by ship noise.*

9.3.10 Other stocks - Northern Indian Ocean sperm whales

No new information was available to the Committee.

9.3.11 Workplan 2019-20

The Committee agreed to the two-year workplan in Table 11.

9.4 New information and workplan for other Southern stocks

9.4.1 Southern Hemisphere humpback whales

9.4.2.1 BREEDING STOCK D

The assessment of the Breeding Stocks D (West Australia), E1 (East Australia) and Oceania was completed in 2014 (IWC, 2015a), but there were substantial associated problems in obtaining a reliable estimate of absolute abundance for Breeding Stock D. See Annex H (IWC, 2017a; 2018a) for a detailed discussion of these issues. Last year (IWC, 2018c), the Committee had agreed that efforts should focus on designing and implementing a new 'survey' (perhaps using new approaches such as drones), and recommended that prior to implementation, an assessment of the feasibility of such a 'survey', focusing in particular on the study conducted by du Fresne *et al.*, (2014), is conducted.

Attention: SC, G, CG-R

The Committee ***agrees*** *that obtaining a reliable estimate of absolute abundance for humpback whale Breeding Stock D (west Australia) is a priority for any future in-depth assessment. The Committee* ***reiterates*** *its recommendation that an evaluation of abundance survey feasibility be carried out for this population, focusing in particular on the study conducted by du Fresne et al. (2014), with a view to implementing a new survey of this population in the future.*

9.4.2.2 WORK PLAN

The work plan for Southern Hemisphere humpback whales is given in Table 12.

Table 12.
Work plan for Southern Hemisphere humpback whales

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Survey feasibility	Reanalyse pilot study to assess feasibility of future West Australia surveys (Kelly)	Receive report		

9.4.3 Southern Hemisphere right whales not the subject of CMPs

The Committee would like to progress regional population assessments for southern right whales (Item 10.8.1.5, IWC, 2017b) This requires a good understanding of population structure, abundance, trend and past exploitation levels. It was agreed that Australia should be the highest priority region for the next assessment (Item 9, IWC, 2018a).

9.4.3.1 SOUTH AFRICA

SC/67a/SH01 provided the results of the 2017 survey of southern right whales flown along the coast of South Africa, part of a long-term monitoring programme since 1979. Since 2015 there has been a marked decline in the presence of unaccompanied adults and cow-calf pairs for unknown reasons (see discussion in Annex S, item 5.1.3). Photo-ID analyses indicated an increasing occurrence of apparent 4- and 5-year calving intervals since 2014. SC/67b/SH22 applied a life history model to photo-ID data collected from 1979 to 2017. They showed that a model variant which allows the probability of a resting female remaining in the resting phase (rather than having a calf) to vary through time provided a better fit to the data than a time-invariant model. They calculate an annual population growth rate of 6.5% and measure first year survival at 0.852, with subsequent annual survival of 0.988.

Attention: SC, G, C-A, CG-A

The Committee is ***concerned*** *that the future of the exemplary long-term monitoring programme of right whales in South African waters remains uncertain. The Committee therefore* ***reiterates*** *that it:*

(1) ***strongly recommends*** *continuation of the survey;*
(2) ***requests*** *the Commission to urge South Africa to do all it can to ensure the long-term future of this vital monitoring programme; and*
(3) ***encourages*** *South African scientists to investigate the offshore movements and locations of southern right whales with future surveys.*

9.4.3.2 AUSTRALIA

The Committee was informed about the latest of a series of aerial surveys conducted in South and West Australia in 2017. The 2017 counts were the highest yet in the series and an exponential increase of ~6% per year remains a good description of the data. Funding has been obtained for the next three years of surveys. The Committee was also informed about: (a) a 26-year cliff-top study conducted at the Head of the Great Australian Bight (south Australia) on right whale population trends and identifications (Charlton *et al.*, In prep); and (b) an aerial survey in southeast Australia where small numbers of whales have been sighted (Watson *et al.*, 2015). Right whales in southeast Australia are genetically and geographically distinct from the large population in south/southwest Australia (e.g., Carroll *et al.*, In press).

The Committee was advised that the Australian Government has recently allocated funds towards a two-year project that will provide an abundance estimate for Australia's two southern right whale populations. It will investigate life history characteristics as well as connectivity between breeding areas on the eastern, southern and western coasts of Australia.

Attention: SC, G, CC, CG-A

The Committee ***recognises*** *the value of the Australian long-term right whale monitoring programmes to understand right whale population trends and dynamics, and* ***recommends*** *that this monitoring continues.*
In regard to right whales in southeast Australia, the Committee ***reiterates*** *concerns expressed in 2017 that abundance remains low despite this area having been a significant historic calving ground. The Committee therefore:*

(1) recommends an assessment of the likely effects of fish farms and other developments in hindering population recovery in this region; and
(2) encourages further work to estimate the abundance of the southeast Australia population.

9.4.3.3 NEW ZEALAND

The Committee welcomed information that surveys will be conducted in the Auckland Islands in 2020/21 to estimate abundance (updating the last estimate from 2009), to assess trend and population age structure, as well as changes in genetic diversity of right whales using this calving ground.

9.4.3.4 FEEDING GROUNDS

The Committee welcomed the results of a visual and acoustic survey of southern right whales off South Georgia/Islas (SC/67b/SH20). SC/67b/SH06 used genotypic markers to assess re-sight rates and sex ratios from biopsy samples (*n*=157) collected during 14 summer surveys in Antarctic Area IV. A preliminary abundance estimate was calculated using these data and further mark recapture analyses will be conducted intersessionally to provide an abundance estimate for review at next year's meeting. To further investigate linkages it was suggested that these high latitude data be compared the western Australia stock to investigate what population component is using this high latitude area.

Attention: SC

The Committee ***encourages*** *further mark recapture analysis of the genotype data of the 14-year dataset collected in the high latitudes of Area IV, to estimate the abundance of southern right whales in this feeding area and* ***agrees*** *that this will be considered at next year's meeting.*

9.4.3.5 PROGRESS TOWARDS POPULATION ASSESSMENT

This year, the Committee reviewed newly available information on population structuring of southern right whales around the Southern Hemisphere (Carroll *et al.*, In press) which further confirms the genetic differentiation of regional calving grounds off Argentina, South Africa, New Zealand and Australia, showing limited migratory movements between these areas (see Annex H, item 5.1,).

The Committee was provided with updates on trends and distribution for calving grounds off South Africa and off south and southwest Australia. Recent published data on population size and trend for calving grounds across the Southern Hemisphere were summarised in Annex H (table 2); this will be reviewed at next year's meeting. Given the trends in abundance and calving rates reported this year (Items 9.4.3.1 and 9.4.3.2), integration of these analyses in a common modelling framework was suggested as a useful way to evaluate common patterns and changes in demography and investigate the relative importance of environmental drivers in determining these patterns.

Another important aspect of population assessment is to update the pre-modern catch series for southern right whales, to better reflect patterns of regional exploitation. The Committee was informed that substantial new data are available on offshore whaling patterns and extent, particularly from American and British voyage logbooks (see Annex H, item 5.2,), which are likely to increase regional catch estimates and provide revised estimates of the numbers of whales struck but lost at sea by the different fisheries.

Attention: SC, G

To better understand patterns of right whale population dynamics around the Southern Hemisphere, and further the work on updated assessments, the Committee:

(1) ***agrees*** *that analysis of three southern right whale calving grounds (Head of the Bight and southwest Australia, southwest Atlantic and south Africa) should be undertaken using the same life-history model, to estimate regional demographic parameters and investigate commonalities in the population dynamics of these populations; and*
(2) ***supports*** *the compilation of new data on pre-modern right whale catches, and the organisation of a workshop to investigate regional right whale catches and rates of whales struck but lost by fisheries, in order to proceed toward regional population assessments.*

9.4.3.6 WORK PLAN AND BUDGET REQUESTS FOR 2019-2020

The work plan for southern right whales not the subject of a CMP is given in Table 13.

Table 13.

Workplan for southern right whales that are not the subject of a CMP

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Southern right whales	Examine southern right whale demographic parameters across multiple calving grounds using a common modelling framework	Review progress		Complete comparison
Southern right whales	Plan right whale catch series workshop	Progress update	Organise catch series workshop	Workshop report

10. STOCKS THAT ARE OR HAVE BEEN SUGGESTED TO BE THE SUBJECT OF CONSERVATION MANAGEMENT PLANS (CMPs)

10.1 Stocks with existing CMPs

This item covers stocks (with a focus on progress with scientific work and information) that are either: (1) the subject of existing CMPs; or (2) are high priority candidates for a CMP. It also considers stocks that have previously been considered as potential CMPs, recognising that the Commission has stressed the need for Range States to support any IWC CMPs.

10.1.1 SE Pacific southern right whales

10.1.1.1 NEW INFORMATION

The Committee received information on advances with respect to sightings (SC/67b/CMP20) and acoustic monitoring (SC/67b/CMP08; SC/67b/CMP18) of the critically endangered population of SE Pacific southern right whales. This information is discussed in detail in Annex O (item 2.1.1). Four confirmed observations were made off Chile in 2017 (three opportunistic sightings and one entangled carcass) and there was another, as yet unconfirmed sighting involving adults and calves. Analysis to date of acoustic data collected off the southwestern tip of Isla de Chiloe in 2012 has provided valuable new information about call parameters and patterns.

10.1.1.2 PROGRESS WITH THE CMP

The Committee received information on progress in implementing priority actions of the CMP (SC/67b/CMP20) as discussed in Annex O (item 2.1.1.2).

This progress includes:

(1) deployment of Passive Acoustic Monitoring (PAM) devices along the coast of Chile and Peru (SC/67b/CMP18) in two locations that will also be used as the focus of educational and capacity-building activities in communities near the monitoring sites;
(2) additional capacity-building and awareness efforts (including posters, press releases and social media) including advice on how fishermen and the public can provide information to the national sighting network; and
(3) additional training towards increasing the capacity of range states to respond to entanglements.

Attention: SC, CC

The Committee ***reiterates*** *the importance of the CMP for the conservation of this critically endangered population of southern right whales in the southeastern Pacific,* ***welcomes*** *the progress being made in its implementation by Chile and Peru. It therefore:*

(1) ***commends*** *the scientific work and international co-operation being undertaken for the PAM project and looks forward to receiving the results of the acoustic studies such that future sighting surveys will be more informed and baseline information on the location of breeding grounds will be available; and*

(2) ***advises*** *that satellite imagery be explored as an additional means to inform the design of sighting surveys because it is likely that line-transect surveys would not successfully identify whales in some areas even if they were present.*

10.1.2 Southwestern Atlantic southern right whales

10.1.2.1 NEW INFORMATION

The Committee was pleased to receive a considerable amount of new information on the southwest Atlantic population of southern right whales; this is fully discussed in Annex O (item 2.1.2.1).

With respect to abundance, SC/67b/CMP/05 suggested that although the population has continued to increase, the rate may have been slowing, perhaps as a consequence of changes in distribution due to density-dependence processes (SC/67b/CMP02).

The Committee has for some time been focussing on the die off at Peninsula Valdes (e.g. IWC, 2011; 2015) and the excellent work of the Southern Right Whale Health Monitoring Program. New and updated information was presented this year on strandings and investigations related to health including examination of levels of stress hormones in baleen and kelp gull attacks (SC/67b/CMP04) and nutritional condition (SC/67b/CMP03). This work is ongoing.

Information was received on telemetry studies (one animal in 2016 and 8 in 2017) as part of an ongoing long-term study to understand the migratory routes and destinations of southern right whales wintering off the coast of Argentina (SC/67b/CMP17. Tracks reveal that these animals are found across a vast extent of the South Atlantic and each season visit multiple potential feeding areas.

The Committee also received the report of a land-based survey of whales near Miramar on the southwest coast of the Buenos Aires Province, Argentina, where there has been a recent expansion of right whales into the region where they have been seen from May to October with peaks in August and September (SC/67b/CMP21).

Attention: SC, G

The Committee ***reiterates*** *the importance of continued monitoring of the southwestern Atlantic population of southern right whales and research into threats that it may face. The Committee therefore:*

(1) ***commends*** *the work being undertaken on understanding the mortality events and* ***encourages*** *its continuation;*
(2) ***encourages*** *the researchers working on stress hormones in baleen to increase their sample size, consider suggestions for additional studies provided in Annex O (item 2.1.2.1) and present a full report to the Committee when it becomes available;*
(3) ***commends*** *the telemetry work,* ***encourages*** *its expansion and draws attention to additional analyses that could be addressed using the telemetry data suggested in Annex O (item 2.1.2.1).*

10.1.2.2 PROGRESS WITH THE CMP

The overall objective of the southern right whale CMP is to protect their habitat and minimise anthropogenic threats to maximise the likelihood that the population will recover to healthy levels and recolonise its historical range. The Committee was pleased to receive information on progress with the actions of the CMP from Argentina (SC/67b/CMP14), including the work described under Item 10.1.2.2, and Brazil (Annex O, appendix 2). Work in Brazil includes long-term monitoring via sightings and strandings networks, mitigation of entanglements and the development of a management plan for whalewatching (see Annex O, item 2.1.2.2).

Attention: SC, CC

The Committee ***reiterates*** *the importance of the CMP for the conservation of the southwestern Atlantic population of southern right whales. The Committee therefore:*

(1) ***welcomes*** *the progress being made in the implementation of the CMP reported by Argentina and Brazil and supports its continuation;*
(2) ***encourages*** *the continued co-operation and collaboration amongst range states towards implementing the CMP and addressing mortality evens in this population; and*
(3) recognising the report of a ship-struck southwestern Atlantic southern right whale in the range of the southeastern Pacific (Estrecho de Magallanes), ***encourages*** *co-operation with those involved in the southeastern Pacific CMP to facilitate a regional assessment; and*
(4) ***encourages*** *the research work identified under Item 10.1.2.1.*

10.1.3 North Pacific gray whales

10.1.3.1 RANGEWIDE ASSESSMENT

Donovan summarised the report of the Fifth Rangewide Workshop on the Status of North Pacific Gray Whales (SC/67b/Rep07) held at the Granite Canyon Laboratory, California of the Southwest Fisheries Science Center from 28-31 March 2018. The primary tasks of the workshop were to (a) review the results of the modelling work identified at the fourth rangewide workshop (IWC, 2018a) and the 2017 Scientific Committee meeting (IWC, 2018b), (b) examine the new proposed Makah Management Plan (submitted by the USA – given as Annex E, Appendix 1) for gray whaling off Washington state and (c) to update as possible, and develop a workplan for, updating the scientific components of the Conservation Management Plan (CMP) for western gray whales.

A full discussion of the workshop can be found in Annex O (item 2.1.3.1). The Workshop finalised its work on (a) prioritising stock structure hypotheses, (b) finalising inputs for the modelling work especially related to bycatch; and (c) incorporating the Makah Management Plan (SC/67b/Rep07, Annex E, Appendix 1) into the modelling framework.

Two stock structure hypotheses (3a and 5a) were given priority whilst others were used in sensitivity tests. In summary, Hypothesis 3a assumes that whilst two breeding stocks (Western and Eastern) may once have existed, the Western breeding stock is extirpated. Whales show matrilineal fidelity to feeding grounds, and the Eastern breeding stock includes three feeding aggregations: Pacific Coast Feeding Group (PCFG), Northern Feeding Group (NFG), and the Western Feeding Group. Hypothesis 5a assumes that both breeding stocks are extant and that the Western breeding stock feeds off both coasts of Japan and Korea and in the northern Okhotsk Sea west of the Kamchatka Peninsula. Whales feeding off Sakhalin include both whales that are part of the extant Western breeding stock and remain in the western North Pacific year-round, and whales that are part of the Eastern breeding stock and migrate between Sakhalin and the eastern North Pacific.

In discussion of the report and intersessional progress, the Committee thanked Donovan, Punt and the participants for the progress made, approved the conditioning results developed after the workshop, noted the preliminary results from the modelling and agreed a strategy for obtaining conservation advice (see recommendation below under Item 10.3). The management implications of the results for the Makah Management Plan are found under Item 7.1.3.

10.1.3.2 REGIONAL STUDIES

The Committee was pleased to receive recent information from long-term studies in the breeding lagoons of Mexico (SC/67b/CMP09) as discussed in Annex O (item 2.1.3.1.1).

The Committee received several updates on work undertaken in the Russian Federation (see Annex O, item 2.1.3.2). It welcomed the annual update of activities from the IUCN Western Gray Whale Advisory Panel (see Annex O, appendix 3) which highlighted work to develop a monitoring and mitigation plan for a 2018 seismic survey being undertaken near the feeding grounds off Sakhalin Island, Russia and issues related to fishing gear. SC/67b/CMP07 updated findings from the long-term monitoring programme carried out by the Russian Gray Whale Project off Sakhalin Island, Russia. The research programme run in the same area by two oil companies was presented in SC/67b/ASI04 and discussed in Annex S (item 4.2).

The recent status of conservation and research on gray whales in Japan was reported in SC/67b/CMP12. During May 2017-April 2018, no anthropogenic mortalities were reported from the adjacent waters off Japan, while two opportunistic sightings of gray whales were made near Aogashima Island in May 2017 and February 2018.

Finally, SC/67b/CMP11 reported on the possible occurrence of a gray whale off the east coast of Korea; work is continuing to try to confirm the species identification; if confirmed it will be the first record in these waters in over 40 years.

Attention: CG-R, SC, G

The Committee ***reiterates*** *the importance of long-term monitoring of gray whales,* ***recommends*** *that range states support such work and* ***welcomes*** *the information provided this year. In particular, the Committee:*

(1) ***commends*** *the work in the breeding lagoons and urges its continuation;*
(2) ***encourages*** *an additional calf-count survey for Punta Banda to address apparent differences in numbers of calves observed in the lagoons with counts from California;*
(3) ***reiterates its concern*** *at the risk of whales becoming entangled in gear placed by the salmon trap-net fishery off Sakhalin Island, recognises that disentanglement training has occurred but* ***recommends*** *that measures to be taken to reduce risk;*
(4) ***encourages*** *continued genetic analyses to assist in stock structure discussions especially related to a western breeding stock;*
(5) ***welcomes*** *the continued provision of information from Japan and* ***encourages*** *researchers to continue to collect as much information on sightings as possible, including, if feasible, attempting to obtain biopsy samples; and*
(6) ***welcomes*** *the information from Korea and the willingness of researchers to investigate sightings from social media as a form of 'citizen science', which can be especially valuable for areas where occurrence is very rare animals in areas with little to no information on critically endangered species.*

10.1.3.3 PROGRESS WITH THE CMP

As noted above, one of the objectives of the fifth rangewide workshop was to progress work with updating the scientific components of the original IWC/IUCN CMP in the light of the results of the rangewide review. Although some work was undertaken, there was insufficient time at the workshop to complete this although a workplan to achieve it was suggested (see SC/67b/Rep07). The Committee concurred with this view and this is incorporated into the workplan below.

Another important component of the CMP effort is the need for a stakeholder workshop (tentatively forecast to occur in 2019) to finalise the CMP and develops a strategy for its implementation. The plan is for a workshop, co-sponsored by IWC, IUCN and the signatories to the Memorandum of Cooperation, to: (1) review and updating of the CMP; (2) establishing a stakeholder Steering Group to monitor CMP implementation, (3) arrange for a coordinator of the CMP and (4) establish a work plan and consider funding mechanisms to implement the actions of the plan.

Attention: C-A, CG-R, CC, SC

The Committee ***reiterates*** *the importance of the CMP for the conservation of western gray whales. The Committee therefore:*

(1) ***recognises*** *the tremendous work undertaken in the rangewide assessment and the value of the modelling framework developed;*
(2) ***agrees*** *that the next part of the process is to develop conservation-related questions and to use the framework to address these with a view to examining results at SC68a;*
(3) ***agrees*** *that a small group meeting (see Item 27) attended by at least the national co-ordinators of the Memorandum of Co-operation on gray whales, Reeves, Punt and Donovan be held to: (a) draft an update to the CMP; and (b) identify conservation-related questions to be addressed by the modelling framework and to present results at SC68a;*
(4) ***requests*** *those signatories to the Memorandum of Co-operation on western gray whales who have not yet named a national co-ordinator to do so promptly; and*
(5) ***supports*** *the holding of a stakeholder workshop in 2019 co-sponsored by the IWC, IUCN and the states that have signed the Memorandum of Co-operation and* ***welcomes*** *the valuable assistance of IUCN in organising the workshop.*

10.1.4 Franciscana

10.1.4.1 NEW INFORMATION

The Committee received valuable new information on franciscana at this meeting related to fisheries and bycatch from five localities in North Espírito Santo State, Brazil (SC/67b/SM30) – bycatches of Guiana dolphins was also reported. Additional information was presented assessing fisheries that operate in Fisheries Management Area (FMA) Ib for their compliance with Brazilian ordinance (IN) 12 (e.g. with respect to gill-net regulations and no-take zones) and risk of bycatch (SC/67b/SM05) – compliance was limited and enforcement poor. Both projects were funded by the IWC Small Cetacean Fund and the Government of Italy. This information is discussed in Annex O (item 2.1.4.1) and a related recommendation is given under Item 10.4.2.2.

10.1.4.2 PROGRESS WITH THE CMP

The overall objective of the CMP, submitted by Argentina, Brazil and Uruguay (IWC/66/CC11) and adopted in 2016, is to protect franciscana habitat and minimise anthropogenic threats, especially bycatch. It includes seven high priority actions, ranging from public awareness and capacity building through research to mitigation. Coordination with Uruguay to implement the CMP in this area will be initiated during a workshop that will take place in May 2018 with the main stakeholders (SC/67b/CMP16). The CMP is funded by the IWC CMP Voluntary Funds and the World Wildlife Fund.

Attention: CG-R

The Committee ***emphasises*** *the importance of the CMP for the conservation of franciscana in the waters of Argentina, Uruguay and Brazil. The Committee therefore:*

(1) ***stresses*** *the value of the actions included in the CMP towards future assessments of the status of franciscana, which is imperative for determining the effectiveness of conservation efforts;*
(2) ***recommends*** *that research be undertaken to estimate the abundance of franciscana dolphin off Buenos Aires province, Argentina; and*
(3) ***recommends*** *that additional research be undertaken to determine the effectiveness of management measures, such as that described in SC/67b/SM05 for other ports (e.g. Macaé, Tamoios (Cabo Frio) and Armação dos Búzios – the fishery in Tamoios coincides with a high diversity of marine megafauna).*

The Committee established an intersessional correspondence group that will help co-ordinate the presentation of CMP projects for this species across sub-committees at SC/68a (Annex Y).

10.2 Progress with identified priorities

10.2.1 Humpback whales in the northern Indian Ocean including the Arabian Sea

10.2.1.1 NEW INFORMATION

The Committee received several papers that improved knowledge of Arabian Sea humpback whales and a full discussion can be found in Annex O (item 2.2.1). It welcomed the information on the progress of work being undertaken by the Arabian Sea Whale Network (ASWN) formed in 2015 (SC/67b/CMP10). The ASWN is an informal collaboration of researchers, consultants and conservation and governmental organisations interested in the conservation of whales in the Northern Indian Ocean. A primary goal of the ASWN is to promote and foster research and collaboration in previously unsurveyed parts of the Arabian Sea humpback whales' suspected range, as well as in Oman where surveys have been conducted since 2000. Work has focused on collecting data on whale distribution and status (including through increased awareness and an observer programme – described in SC/67b/CMP15)), the introduction and implementation of a regional online data platform (SC/67b/PH03) and providing updates on research activities in Oman, India, Pakistan and Sri Lanka (SC/67b/INFO07). Two marine protected areas have been established in Pakistan (Astola Island and Indus Canyon).

Madhusudhana *et al.* (2018) reported on and compared humpback whale songs recorded off India, Oman, Reunion Island and Comoros Islands in the southwest Indian Ocean. The results highlighted (a) the distinct nature of the Arabian Sea population and (b) that SW Indian Ocean whales may move into the Arabian Sea more commonly than previously thought.

SC/67b/CMP13 reported on a humpback whale tagged off Oman that moved to the southern tip of India and back again - the first recorded movement of a whale across the Arabian Sea. Four additional satellite tags were deployed where the whales remained over the continental shelf of central and southern Oman.

Attention: G, SC

The Committee ***welcomes*** *the new information from the region on this critically endangered population and* ***commends*** *the researchers for their initiatives and collaborative efforts. In light of the information presented, the Committee:*

(1) ***encourages*** *the collection of genetic information which would be helpful for identifying stock structures within the area;*
(2) ***recommends*** *future use of unoccupied aerial systems to (i) measure whale health, (ii) develop long-term health metrics, (iii) compare body condition to stock C in the Southern Hemisphere, which is the presumed 'source' population for whales in the Arabian Sea and (iv) assess for evidence of anthropogenic threats;*
(3) ***commends*** *the use of fishing crew as observers and* ***advises*** *that the crew-based observer programme continue, recognising that it is not clear if the timing of the sightings reflects the seasonal distribution of whales or the seasonal nature of fishing effort and* ***encourages*** *future research to tease apart timing of the distributions using targeted surveys;*
(4) ***advises*** *that capacity building for local scientists be continued such that surveys can be deployed in suspected areas of humpback whale distribution and data can be gathered for future assessments;*
(5) ***advises*** *the continuation of monitoring songs of Arabian Sea humpback whales and that additional data sets be acquired comparison purposes, particularly from the southwest Indian Ocean, if they exist, to further (i) detect the movement of southwestern Indian Ocean animals in Boreal winter, (ii) document potential diffusion of southwestern Indian Ocean song, (iii) provide a long-term data set for the comparison of songs across Oman, Pakistan and India to assess continuity of whales in the Arabian Sea and (iv) evaluate the unprecedented temporal stasis of song in the Arabian Sea; and*
(6) ***agrees*** *that an intersessional correspondence group (Annex Y) be formed to review the methods used for the preliminary estimates of abundance, in order to increase their robustness by taking into account the non-random survey approach that violates some key assumptions of mark-recapture models.*

10.2.1.2 PROGRESS WITH INTERNATIONAL CO-OPERATION AND REGIONAL MEASURES SUCH AS CMPS

A Concerted Action for Arabian Sea humpback whales under the Convention on Migratory Species (CMS; SC/67b/INFO06) was drafted and passed with wide support from Arabian Sea range states at the CMS COP in October 2017. It is hoped that this Concerted Action can be implemented in conjunction with a CMP as a means to translate current research and conservation efforts and plans into concrete, government-supported conservation measures in Arabian Sea humpback whale range states.

Attention: *C-A, S*

The Committee ***reiterates*** *its serious concern about the status of the endangered Arabian Sea humpback whale population and the anthropogenic threats it faces. It therefore:*

(1) ***commends*** *efforts to develop the Concerted Action under the CMS, noting that it covers many of the elements required for a CMP;*
(2) ***stresses*** *the value of regional initiatives and* ***encourages*** *range states to explore future sources of collaboration; and*
(3) ***encourages*** *continued efforts between range states and Secretariats to work toward a joint CMS-IWC CMP.*

10.2.2 Mediterranean fin whales

The ACCOBAMS Meeting of Parties has endorsed the development of a CMP, ideally jointly with the IWC, for fin whales in the Mediterranean Sea. A small group will meet in the summer of 2018 to draft an outline for a CMP that can be presented at SC/68a. ACCOBAMS is also considering the development of CMPs for other species in the region.

10.2.3 South American River Dolphins

Advice was sought regarding the development of a CMP for South American river dolphins, which currently have several actions plans endorsed by various range states.

Attention: CG-A

The Committee ***advises*** *that the applicable range states work towards developing a draft CMP for presentation at SC/68a.*

10.3 Workplan 2019-20

The workplan on matters related to stocks that are or might be the subject of CMPs is given as Table 14.

Table 14

Summary of the work plan on conservation management plans.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Southeast Pacific right whales	.	Review progress with scientific aspects of the CMP		Review progress with scientific aspects of the CMP
Southwestern Atlantic right whales		Review progress with scientific aspects of the CMP		Review progress with scientific aspects of the CMP
Gray whales	Hold workshop on scientific aspects of CMP and use of modelling framework.	Review results and provide advice on scientific aspects of CMP	Stakeholder workshop	Review scientific aspects of results of stakeholder workshop
Franciscana		Pre-assessment for in-depth review		Continue pre-assessment and develop plan for in-depth assessment
Humpback whales in Northern Indian Ocean	Intersessional email group (Annex Y) on abundance estimates	Review new information and progress towards CMP		Review new information and progress towards CMP
Mediterranean fin whales	Develop outline draft	Review draft and progress towards CMP		Review progress towards CMP
South American river dolphins		Review new information and progress towards CMP		Review new information and progress towards CMP

11. STOCK DEFINITION AND DNA TESTING

This agenda item merges two previously separate sub-groups, the Working Group on Stock Definition and the Working Group on DNA. During SC67b, the Stock Definition and DNA Testing Working Group assessed genetic methods used for species, stock and individual identification, including matters associated with the maintenance of DNA registers (see 11.1); continued to develop and update guidelines for preparation and analysis of genetic data within the IWC context (see 11.2); and provided the Committee with feedback and recommendations concerning stock structure related methods and analyses (see 11.4), including those relevant to other sub-committees (see 11.3). The Report of the Working Group is given as Annex I.

11.1 DNA testing

This item has been considered since 2000 in response to a Commission Resolution (IWC, 2000).

11.1.1 Genetic methods for species, stocks and individual identification

The Committee received two papers relating to the use of genetic methods for species, stock and individual identification. The first paper (Carroll *et al.*, 2018) provided a review of how technological advances, particularly those associated with the development of high throughput sequencing (HTS) technology, can aid in genetic monitoring. Of particular interest to the Committee was discussion of targeted capture approaches that allow for microsatellite genotyping via HTS (e.g. De Barba *et al.*, 2017). Much of the past genetic work has relied on generating microsatellite datasets, including the work to maintain DNA registries of bycaught or direct catches (see Items 11.1.2 and 11.1.3). These 'legacy' datasets may include microsatellite genotypes for thousands of individuals. While technical challenges exist, microsatellite genotyping via HTS could 'bridge the gap' by maintaining the utility of these legacy datasets while also taking advantage of the newer HTS approaches.

The second paper (Baker *et al.*, In press) presented the results of a study confirming the potential to detect environmental DNA (eDNA) in seawater collected from the wake of killer whales. This is a new approach for detecting and identifying cetacean species, including those that may be elusive to study using other methods. Although eDNA has been more broadly used to detect the occurrence of species in an area (i.e. DNA barcoding), it could provide sequence data useful for stock-level identifications of cetaceans under certain circumstances (e.g., when a single animal is present). It was noted, however, that its utility in addressing questions requiring individual identification via multi-locus genotyping is, at least currently, limited for scenarios in which the water sample could contain DNA from multiple individuals.

Attention: SC

The Committee ***welcomes*** *the opportunity to review papers that take advantage of technological advances to improve the ability to detect and identify species, stocks, and individual cetaceans. It* ***encourages*** *the submission of similar papers in the future and recognises the relevance of these techniques to the Committee's work.*

11.1.2 'Amendments' of sequences deposited in GenBank

While *GenBank*[7] is an important scientific resource, it is an uncurated database of DNA sequences and thus contains sequences that are misidentified or have other annotation problems. While retaining the 'raw data' represented in *GenBank* is valuable, less-experienced users may be unaware that additional sequence validation may be needed when incorporating *GenBank* sequences into a study. The Committee has agreed (IWC, 2018c, p. 228) that its revised DNA quality guidelines will contain a section discussing the precautions that should be taken when including GenBank sequences in a study. This text has been drafted and will be incorporated into the revised guidelines (see Item 11.2).

11.1.3 Collection and archiving of tissue samples from catches and bycatches and
11.1.4 Reference databases and standards for diagnostic DNA registries

The Committee previously endorsed a new standard format for the updates of national DNA registers to assist with the review of such updates (IWC, 2012a, p. 53), and the new format has worked well in recent years. This year, the update of the DNA registers by Japan, Norway and Iceland were based again on this new format. Details are given in Annex I (appendices 2-4) for each country, covering the period up to and including 2017. Almost all samples in the three registries have been analysed for microsatellites, and work on unanalysed samples is continuing. Almost all samples in the registries of Japan and Iceland have also been analysed for mtDNA.

During last year's discussion of the Norwegian minke whale DNA register (IWC, 2018c, p. 228-229), the Committee was informed that mtDNA analysis on Norwegian samples had been discontinued and that microsatellite typing would eventually be replaced by SNP analysis. The Committee had expressed concern regarding the comparability of the DNA registers in the future. This year, the Committee noted that Norway had discontinued mtDNA typing of samples and substituted it with SNP genotyping.

Attention: CG-A

The Committee ***expresses appreciation*** *to Japan, Norway and Iceland for providing updates to their DNA registries using the standard format agreed in 2011 and providing the detailed information contained in their DNA registries.*

11.2 Guidelines and methods for genetic studies and DNA data quality

Two sets of guidelines have been developed for reference in the Committee's discussions of stock structure. The most recent version of the guidelines for genetic data analyses are in press with the Commission's *Journal of Cetacean*

---

[7] https://www.ncbi.nlm.nih.gov/genbank/

Research & Management. The DNA data quality guidelines address DNA validation and systematic quality control in genetic studies, and are currently available as a 'living document' on the IWC website[8]. In recent years, it has become common for the Committee to review papers using data derived from Next Generation Sequencing (NGS) approaches, including SNPs, to address stock structure questions (see Item 11.3).

Attention: SC

The Committee ***emphasises*** *the importance of keeping its guidelines related to genetic data quality and analyses up to date. It therefore:*

(1) ***reiterates*** *the need to update these guidelines to incorporate the discussion of data quality measures used for Next Generation Sequencing data; and*
(2) ***agrees*** *to continue the intersessional correspondence group (Annex Y) to review revised sections of the DNA data quality guidelines that apply to data generated from next generation sequencing platforms, including SNPs and whole genome sequencing, with the goal of posting an updated version of the guidelines on the website next year.*

11.3 Provide advice on stock structure to other sub-groups

The Working Group on Stock Definition and DNA also has the task of discussing high-priority stock related papers from other sub-committees and working groups to provide them with stock structure related feedback and recommendations. These discussions often refer to the genetic analysis guidelines and genetic data quality documents.

The discussions (see Annex I for details) are summarised under the relevant stock agenda items in this report. Two, more general issues arose from discussions of Southern Hemisphere stocks and North Atlantic common minke whales. These are considered below.

11.3.1. Southern Hemisphere whale stocks and use of samples

The Committee reviewed the results of genetic analyses of Southern Hemisphere whale stocks, including Southern Hemisphere blue, fin, right and sei whales. These results highlighted the value of existing collections of tissue samples to address stock structure questions.

Attention: SC

In reviewing the results of stock structure analyses of Southern Hemisphere whale stocks, the Committee expresses ***concern*** *regarding the depletion of tissue samples in existing collections (including those collected during the IWC SOWER surveys, although the Steering Group does take this into account when reviewing requests). Given recent advances in high throughput sequencing technology, the Committee* ***agrees*** *that an intersessional correspondence group (Annex Y) should be formed to provide recommendations on genomic approaches to maximise the utility of these samples for future studies.*

11.3.2. North Atlantic common minke whales

The Committee reviewed the results of genetic analyses pertaining to the stock structure of North Atlantic minke whales (SC/67b/Rep06). The analyses presented involved the use of a new approach to evaluate stock mixing proportions by (1) identifying a 'reference' year in which mixing of stocks was considered low based on a lack of heterogeneity in genetic characteristics estimated for each area, and (2) using principal component analysis of the genetic data to assign stock affinities in the non-reference years based on proximity to mean values in the reference year.

Attention: SC, C-A

The Committee reviewed the use of a new approach that used ordination analyses of genetic data to assign stock mixing proportions. Recognising that this new approach requires making certain assumptions about the data, the Committee:

(1) ***agrees*** *that the inference of mixing rates was informative for AWMP/RMP simulation trials in the absence of empirical data; and*
(2) ***encourages*** *the attempt to use genetic data to estimate mixing rates in the context of other IWC-related tasks.*

11.4 New statistical and genetic issues relating to stock definition

11.4.1. Simulation tools for spatial structuring

TOSSM was developed with the intent of testing the performance of genetic analytical methods in a management context using simulated genetic datasets (Martien *et al.*, 2009), and more recently the TOSSM dataset generation model has been used to create simulated datasets to allow the plausibility of different stock structure hypotheses to be tested (Archer *et al.*, 2010; Lang and Martien, 2012). The Working Group noted that while TOSSM has been particularly valuable in

---

[8] http://iwc.int/scientific-committee-handbook#ten

informing the interpretation of results of stock structure related analyses, it has not been broadly used within the IWC Scientific Committee for this purpose.

In recent years, a wide-range of software packages have become available for producing simulated datasets that can be used for statistical inference and/or validating statistical methods (Hoban, 2014, and see ; IWC, 2017c p.44), and in 2016 the Committee agreed to expand this item (formerly specific to TOSSM) to include a broader range of tools (IWC, 2016c p.44).

Attention: SC

The Committee noted that while simulation-based approaches have been particularly valuable in informing the interpretation of results of stock structure-related analyses, they have not been broadly utilized within the Committee for this purpose. The Committee ***agrees****:*

(1) to continue an intersessional review via an email correspondence group (Annex Y) of the available simulation tools and their potential utility to the Committee; and
(2) to consider bringing in invited expertise to present an overview of the applicability of such approaches in order to expedite progress on this agenda item.

11.4.2. Terminology

Defining and standardising the terminology used to discuss 'stock issues' remains a long-standing objective of the Working Group, in order to help the Committee report on these issues according to a common reference of terms (IWC, 2014 p.287-8). At SC67b, the status of the existing draft glossary on key terms related to stock definition was revisited.

Attention: SC

The Committee ***agrees*** *to establish an intersessional correspondence group (Annex Y) to revisit terminology with specific reference to the implications of inferred stock structure in other sub-committees, particularly those that deal with large whale assessments, and suggest revisions where appropriate for consideration at SC68a.*

11.4.3. Close-kin mark-recapture

An overview of the close-kin mark-recapture (CKMR) approach (Bravington *et al.*, 2016) was presented to the Committee last year (IWC, 2018c p.40). CKMR uses multi-locus genotyping to find close relatives among tissue samples from dead and/or live animals; the number of kin-pairs found, and their pattern in time and space, can be embedded in a statistical mark-recapture framework to infer absolute abundance, parameters like survival rate, and stock structure. No papers applying the CKMR approach were reviewed by Committee this year, although the value of integrating data from epigenetic aging (see 11.4.4) into CKMR was noted.

Attention: SC, G

Given that close-kin mark-recapture has multiple applications that fall within the Committee's scope of work, the Committee ***encourages*** *the submission of papers using this approach in the future.*

11.4.4. Epigenetic ageing

Information on estimated age of individuals can be used in many aspects of the Committee's work, including (1) discriminating between the parent and offspring among genetically identified parent-offspring pairs, which can inform both assessment of stock structure as well as genetic mark-recapture estimates of abundance (e.g. CKMR); and (2) integrating age information into the population modelling exercises integral to assessment work (e.g. on RMP implementation). Recently, epigenetic (DNA-methylation) ageing has been successfully used to estimate age in humpback whales (Polanowski *et al.*, 2014). This year, the Committee invited Jarman, the lead scientist on the humpback whale work, to give an overview presentation to the Committee. This session was organised as a special evening session in order to enable participation across sub-committees and Working Groups. He covered issues specific to age estimation in cetaceans, including how DNA methylation-based age estimation are likely to perform in cetaceans and what current and near-future prospects there are for this class of methods (see Annex I, item 5.5).

The Committee also reviewed the results of a study to evaluate the feasibility of using the DNA-methylation technique to estimate age in Antarctic minke whales (SC/67b/SDDNA04). This study was initiated in response to a recommendation made during the Expert Panel review of the NEWREP-A proposal (SC66A/REP06, p17). DNA-methylation rates were examined for seven methylation sites (CpG sites) within three genes, and regressions of each CpG methylation site against age determined by earplug were conducted. When all sites were incorporated, the assay predicted age from skin samples with a standard deviation of about 8.9 years. While some sites showed age-related effects, others did not show such correlation. Thus, using only those loci that appear to have an age-related effect might reveal a stronger relationship between methylation rates and age.

During the discussion (Annex I, item 5.5) it was noted that the humpback whale age assay, which used the same sites, reports a precision of 2.99 years, measured as the average of the absolute values of the differences between known and estimated ages (Polanowski *et al.*, 2014). During the presentation, the precision as measured by the standard deviation for absolute age prediction was reported as 4.8 years. That was a preliminary study demonstrating the fundamental feasibility of this approach, and is not as accurate or precise as tests developed for humans and mice based on analysis of many more CpG sites. While precision is expected to improve with the inclusion of more CpG sites, the maximum precision possible for any DNA methylation-based age estimator is likely limited by the imperfect relationship between chronological age and biological age. To date, that precision has ranged from 3.9% in humpback whales (Polanowski *et al.*, 2014 assuming a 95-year lifespan), to 3.2% of lifespan in humans (e.g. Horvath, 2013) and 1.7% of lifespan in mice (Stubbs *et al.*, 2017). These observations indicate that the SD and 95% CI for age estimation described in Polanowski *et al.* (2014) and in SC67b/SDDNA04 could be substantially improved before an inherent limit is reached. These precision estimates adhere to age determination in individual specimens. Hence, averaged age estimates over cohort will improve over larger sample sizes and may be more precise.

The Committee noted that the implications of this upper limit on precision in estimating age for individuals would need to be evaluated in the context of the specific application for which the age data were being used. For example, although additional precision is helpful, CKMR studies may be informed by relatively crude estimates of age allowing the parent to be discriminated from the offspring (i.e. ordinal age).

Attention: SC

The Committee welcomed the results of the study to evaluate the feasibility of using epigenetic techniques to estimate age in Antarctic minke whales and ***agrees****:*

(1) that the current set of loci did not provide sufficient precision for use in the population dynamics modelling exercise recommended for NEWREP-A; and
(2) that identification of additional sites with an age-related DNA-methylation pattern is encouraged, as it would likely allow more precise estimates of age to be made in the future; and
(3) given that there is an upper limit to the degree of precision that can be achieved using this technique, the utility of epigenetic age estimation to the Committee should be further evaluated by the sub-committees concerned with regard to the degree of precision needed for the specific application of interest.

11.5 Workplan 2019-20

The details of the workplan are given in Table 15.

Table 15

Workplan on topics related to genetics.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
3.1 DNA quality guidelines	Intersessional group (Annex Y) to review recent revisions to the DNA quality guidelines that pertain to data produced using NGS approaches.	Report and finalise updated guidelines		
4.4.2 Recommendations to avoid sample depletion	Intersessional email group to provide recommendations on genomic approaches to maximize the utility of tissue samples that are in danger of becoming depleted in the future.	Report and provide advice		
4.5 North Pacific minke whale stock structure	Perform genetic analyses detailed in Appendix 5; report results at intersessional workshop on the North Pacific minke whale IR.	Review results and provide advice		
5.1 Simulations	Intersessional email group to review software packages and evaluate utility to the Committee.	Report	Continue as needed	Report (if needed)
5.3 Terminology	Intersessional email group to continue discussions of the use of stock structure-related terms within the Committee.	Report	Continue as needed	Report (if needed)

12. CETACEAN ABUNDANCE ESTIMATES, STOCK STATUS

The Committee received new information from the Standing Working Group on Abundance Estimates, Status and International Cruises (ASI) that had been established (IWC, 2017c, p. 94) to formally review and agree on the status of the abundance estimates submitted to the Scientific Committee across all of the Committee's sub-committees and working groups. It also assists the Committee and the Secretariat in developing a biennial document reporting to the Commission on the abundance and status of whale stocks.

12.1 Summary of abundance estimates and update of IWC consolidated table

Appendix 3 of Annex Q provides detailed information about abundance estimates agreed by the Committee, including estimates received prior to and during 2017, as well as ones evaluated this year. The Secretariat maintains a consolidated table.

Broadly, cetacean abundance estimates are usually obtained in one of three ways. Line transect surveys require observers on ships or aircraft to detect animals while the observers are traveling on paths traversing the survey area. Statistical methods are used to estimate how many animals were not seen, usually by evaluating how detection deteriorates as sighting distance increases and by extrapolating to survey areas beyond visual detection distance. Mark-recapture studies require multiple attempts to 'capture' individuals that are mixing between attempts. For cetaceans, individual animals are usually identified - and hence 'captured'- on the basis of matching photographs of whale markings, or by genetic analysis of biopsy samples of live animals. Statistical methods are used to estimate how many animals were never captured, based on information about the probability of capture, which is inferred from instances when the animal was sometimes captured and sometimes not. Population model based abundance estimates use information from a variety of sources to build a mathematical model of how a population changes over time. Important data and parameters in such models include survival rates, productivity rates, and previous abundance estimates. By fitting (and possibly projecting) this model, an estimate of current abundance is achieved.

Many sophisticated abundance estimation methods are hybrids or extensions of these basic approaches.

This year, the Committee **endorses** the following:

(1) a photo-id mark-recapture estimate of 2011 abundance for Bering-Chukchi-Beaufort Seas bowhead whales;
(2) an aerial line transect estimate of 2013 abundance of East Canada / West Greenland bowhead whales;
(3) aerial line transect estimates of 2015 abundance of East Greenland and West Greenland North Atlantic humpback whales;
(4) ship-based line transect abundance estimates of North Atlantic humpback whales in Iceland/Faroe Islands in 2007 and 2015;
(5) aerial line transect abundance estimates of East Greenland (2015) and West Greenland (2007 and 2015) North Atlantic minke whales;
(6) ship-based line transect abundance estimates of North Pacific Bryde's whales for several areas and time periods;
(7) aerial line transect abundance estimates of East Greenland (2015) and West Greenland (2005, 2007 and 2015) North Atlantic fin whales; and
(8) genetic mark-recapture abundance estimates for Maui's dolphins in New Zealand for several years.

Table 16 summarises key information about the **agreed** abundance estimates. Full details are given in Annex Q (item 3 and appendix 3).

Attention: SC, S, C-A

Abundance estimates are a key parameter in determining status. The Committee:

(1) ***endorses*** the new abundance estimates *presented in Annex Q, Appendix 3 for inclusion in the IWC Table of Accepted Abundance Estimates;*
(2) ***agrees*** *that they should be incorporated into that table and uploaded to the IWC website; and*
(3) ***agrees*** *that the table should continue to be updated intersessionally by the Steering Group (Annex Y).*

12.2 Process to review abundance estimates

Abundance estimates are needed to assess the status of cetacean populations and are used extensively by the Committee, including for providing management advice. These estimates are often computed by standard, but technically advanced methods. In addition, because of the high scientific standards found within the Committee's work, it is not uncommon for the Committee to receive estimates of abundance computed using novel methods and non-standard software/code. The review of these estimates can be complex and time consuming. At last year's meeting, the Committee noted that adequate time is needed to review abundance estimates and agreed that a process to facilitate the review of these estimates be developed (IWC, 2018c). In addition, the Committee noted that reviews would benefit if minimum requirements for the presentation of abundance estimates are established.

Table 16

Abundance estimates, CVs and 95% confidence intervals for estimates agreed at the 2018 meeting.

Whale and Region	Year	Estimate	CV	95% Confidence Interval
North Pacific Bryde's whales				
Area 1W	1995	12,149	0.41	5,579-26,454
	2000	6,894	0.47	2,872-16,549
	2011	25,158	0.38	12,202-51,872
Area 1E	1995	15,695	0.42	7,079-34,801
	2000	19,200	0.56	6,929-53,204
	2011	9,315	0.33	4,957-17-505
Area 2	1995	4,340	0.45	1,876-10,039
	2000	6,083	0.61	2,030-18,229
	2014	6,491	0.36	3,254-12,950
North Atlantic common minke whales				
East Greenland	2015	2,762	0.47	1,160-6,574
West Greenland	2007	9,066	0.39	4,333-18,973
	2015	5,095	0.46	2,171-11,961
North Atlantic fin whales				
East Greenland	2015	6,440	0.26	3,901-10,632
West Greenland	2005	9,800	0.62	3,228-29,751
	2007	15,957	0.72	4,531-56,202
	2015	2,215	0.41	1,017-4,823
North Atlantic humpback whales				
East Greenland	2015	4,223	0.44	1,845-9,666
West Greenland	2015	993	0.44	434-2272
Iceland/Faroe Islands	2007	18,105	0.43	7,226-45,360
	2015	10,031	0.36	4,962-20,278
Bowhead whales				
Bering-Chukchi-Beaufort Seas	2011	27,133	0.22	17,809-41,377
East Canada / West Greenland	2013	6,446	0.26	3,722-11,200
Gray whales				
Western North Pacific	1995	74	0.05	66-81
	2015	200	0.03	187-211
Maui's dolphin				
North Island, New Zealand	2016	57	n/a	44-75

This year, the Committee developed a process to improve the review of abundance estimates, including a prioritisation of the estimates according to the timeline they need to be used by the Committee. This process is described in detail in Annex Q, item 2.1. In addition, minimum requirements to present abundance estimates for review by the Committee were established. Details are given in item 2.2 of Annex Q.

The Committee noted that validation may be needed before estimates computed using novel methods and non-standard software are used to provide management advice (Annex Q, item 2.3). The Committee also noted the need to consider how estimates of abundance from population models are reviewed before they are included in the Table of Accepted Abundance Estimates (Annex Q, item 2.4).

Attention: SC, S

*The Committee **reiterates** the importance of using high quality, fully reviewed abundance estimates for its work. To achieve this the Committee **agrees**:*

(1) to adopt the process to improve the review of abundance estimates given in Annex Q (item 2.1);
(2) the minimum requirements for the presentation of estimates for review by the Committee given in Annex Q (item 2.2);
(3) to host a pre-meeting before next year's meeting (SC68a) to develop (a) a process to validate abundance estimates computed with non-standard methods, noting the value of simulated datasets in this process; (b) a process to review estimates of abundance computed with population models is needed.

12.3 Methodological issues

12.3.1 Model-based abundance estimates (and amendments to RMP guidelines)

The Committee noted that there was a need for RMP guidelines to be modified in order to incorporate spatial modelling approaches to estimate abundance.

Attention: SC

*The Committee noted that whilst much progress has been made with respect to considering model-based estimates (IWC, 2016c), the 'Requirements and Guidelines for Conducting Surveys and Analysing Data within the Revised Management Scheme' need to be modified. The Committee **agrees** that an intersessional steering group (Annex Y) will develop instructions and select a candidate to modify the Guidelines.*

12.3.2 Review new survey techniques/equipment

The Committee received information on the use of unmanned aircraft vehicles (UAVs) to improve estimation of abundance of river dolphins in the Amazon. Details are provided in Annex Q, item 5.

Attention: SC, G

The Committee ***looks forward*** *to receiving information on new survey technologies used to improve estimates of abundance of cetaceans.*

12.4 Consideration of the status of stocks

The Committee noted that further consideration on how to report status of cetacean stocks is needed.

Attention: SC

The Committee ***recognises*** *the need to further consider how to report status of stocks to the Commission in a consistent manner and* ***agrees*** *to address this topic at a pre-meeting to be held prior to next year's SC meeting (SC68A).*

12.5 Workplan 2019-20

The Committee **agrees** to the workplan given in Table 167

Table 17

Workplan on abundance estimates and status.

Topic	Intersessional 2018-19	SC68a	Intersessional 2019-20	SC68b
Review of Abundance Estimates	Review estimates identified at SC67B (New Zealand Blue Whales, Arabian Sea humpback whales) – Annex Y	Review intersessional progress and estimates available at SC68A	Review estimates identified at SC68A	Review intersessional progress and estimates available at SC68A
Upload the estimates accepted at the annual meeting to the IWC website and continue to update the IWC Abundance Table	Update the table with estimates accepted at SC67B (Annex Y)		Update the table with estimates accepted at SC67B	
Review and provide advice on plans for future surveys		Receive, review and provide feedback to research plans to conduct abundance estimates		Receive, review and provide feedback to research plans to conduct abundance estimates
Pre-meeting to consider: (a) validation of non-standard software and methods, (b) estimates of abundance computed from population models and (c) Status of populations	Meeting Preparation	Review of progress		
Amend the RMP Guidelines to consider abundance estimates computed with model-based methods.	Identify a candidate to update the RMP Guidelines (Annex Y)	Review an updated document of the Guidelines		
Develop simulation software to evaluate methods for abundance estimates		Review Progress		

13. BYCATCH AND ENTANGLEMENTS

13.1 Review new estimates of entanglement rates, risks and mortality (large whales)

The Committee received three papers relating to the bycatch of large whales. SC/67b/HIM03 provided information on stranded humpback whales stranded along the southeastern coast of Brazil in 2016 and 2017 including records of entanglements over the São Paulo coast. SC/67b/HIM09 focussed on ten baleen whale populations for which bycatch appears to be a component of substantial conservation problems and the authors categorised priorities for action. SC/67b/AWMP08 provided information on Bering-Chukchi-Beaufort Seas stock of bowhead whales. Discussion can be found in Annex J (item 2.1).

13.2 Reporting of entanglements and bycatch in National progress reports

Reports of large whale bycatch are summarised in Annex J (item 2.4) and the issue of partial reporting discussed. Issues related to reporting and progress reports is given under Item 3.2.

13.3 Mitigation measures for preventing large whale entanglement

Mattila, the IWC's technical advisor for reducing unintended human impacts, reported on relevant activities under the entanglement initiative. Details can be found in Annex J (item 2.5). Since last year's meeting, IWC entanglement trainings have been conducted in Sakhalin (Russia), Arica (Chile), Sortland (Norway) and Bahía Solan (Colombia). This brings the total number of trainees in this initiative to 1,130 from 27 countries. In addition, two apprentices were hosted this year, one from Chile and one from Oman. Mattila also presented the IWC's work with entanglement in two workshops at the Society for Marine Mammalogy Biennial conference (2017). The Committee thanked Mattila for his exemplary work in coordinating the Global Whale Entanglement Response Network.

13.4 Review proposal for global entanglement database

The Committee considered progress with the development of a dedicated entanglement database. This will be considered further at the June 2018 meeting of the Global Whale Entanglement Response Network (see Annex J, item 2.3).

13.5 Estimation of rates of bycatch, risks of, and mortality for small cetaceans

13.5.1 Small cetacean bycatches in Peru

The Committee received a report (SC/67b/HIM01) summarising monitoring efforts of beach-cast cetaceans in 11 locations along the Peruvian coast from 2000-2017. Full discussion can be found in Annex J (item 2.1.2) that showed clear evidence of continued high bycatch rates and some intentional takes. Burmeister's porpoises accounted for 66% of the specimens and the low proportion (25%) of dusky dolphins contrasted with 1985-1990 statistics, when dusky dolphins accounted for three quarters of all cetacean captures. This reiterated prior concerns (Van Waerebeek, 1994) about a persistent long-term trend of a significant decline in prevalence of Peruvian dusky dolphin in catch and stranding records.

The observed high mortality levels in Burmeister's porpoise are a serious concern, and action is needed to avoid the same critical situation as with the closely related vaquita. Burmeister's porpoise is already included in a preliminary list for potential Conservation Management Plan development (Genov *et al.*, 2015), and dusky dolphin could potentially also be included. The Committee reiterated recommendations from 2008 regarding bycatch monitoring programmes and mitigation efforts in these fisheries (IWC, 2009, p. 323).

Attention: C-A, CC

*The Committee **draws the attention** of the Commission to its **serious concern** over the high mortality levels from bycatches in Peru and especially those of the Burmeister's porpoise and dusky dolphin. It **stresses** that action is needed to avoid the same critical situation for Burmeister's porpoise as with the closely related vaquita. In this regard the Committee:*

*(1) **reiterates** its advice (IWC, 2009, p. 323) on bycatch monitoring and mitigation in these fisheries;*
*(2) **reiterates** that the Burmeister's porpoise is a potential candidate for a Conservation Management plan;*
*(3) **highlights** opportunities to focus on the bycatch of small cetaceans in Peru through the new IWC Bycatch Mitigation Initiative and **recommends** that they are considered as a potential pilot project; and*
*(4) **offers its assistance** to the Government of Peru; and*
*(5) **requests** that the Commission, through the Secretariat, transmits the Committee's concern and offer of assistance to the Government of Peru.*

13.5.2 Franciscana bycatch in Brazil

Considerable information was provided on the Santos Basin Beach Monitoring Project required by the Brazilian authorities for licensing oil and gas production and transport (see Annex J, item 2.1.2). This provided information *inter alia* on stranded franciscana. From October 2015 to September 2017, 1,123 carcasses were recorded stranded in the area and interactions with fishing gear was reported for over 85% of necropsied individuals with signs of human activities.

Attention: CG-A

*The Committee **draws attention** to the fact that the franciscana remains under strong pressure from human activities, especially bycatch, in Brazilian waters despite fishing net regulations established by the government. The Committee:*

*(1) **advises** that the existing regulation on gillnets, implemented in 2012, is either not being effectively enforced or is not effective in reducing bycatch; and therefore*
*(2) **recommends** the need for this to be investigated further by the Brazilian authorities.*

13.5.3 Estimating bycatch from strandings data

Estimates of common dolphin mortality in the Bay of Biscay based on strandings data (Peltier *et al.*, 2016) had been discussed at SC67a. SC/67B/HIM/05 and SC/67B/HIM/08 provided further analyses related to using stranding data to make inferences about small cetacean mortality. An intersessional group was established at SC67a to provide advice on consistent ways to estimate bycatch across both large and small cetaceans, and specifically, to review the methods applied in Peltier *et al.* (2016) focused on small cetaceans. Discussion of the report of the intersessional group and some additional related papers (SC/67b/ HIM05 and SC/67b/HIM08) can be found in Annex J (item 2.1.2).

In discussion of other ways to estimate bycatch, the Committee noted that Bartholomew *et al.* (2018) had concluded that Remote Electronic Monitoring can provide a time- and cost-effective method to monitor target catch in small-scale fisheries and can be used to overcome some of the challenges of observer coverage. This requires consideration by the Committee.

Attention: CG-A, SC, G

With respect to methods for obtaining bycatch estimates the Committee:

(1) ***agrees*** *with the recommendations of its intersessional group regarding (a) uncertainties in bycatch estimates derived from strandings; (b) the use of bycatch estimates derived from strandings; and (c) assessing whether strandings can identify gaps in observer coverage;*
(2) ***notes*** *the importance of observer programmes, including electronic monitoring, and the limitations of stranding information for determining the type of fishing gear implicated in a bycatch event, or in determining reliable bycatch estimates;*
(3) ***recognises*** *that in small scale fisheries (a) observer programmes are particularly complicated, given the small size of vessels and (b) electronic monitoring may not capture the animals falling from the net during hauling*
(4) ***advises*** *that a robust evaluation of the effectiveness of bycatch mitigation measures requires a combination of monitoring measures, including well-designed and effectively implemented observer programmes, electronic monitoring and stranding programmes;*
(5) ***advises*** *that the above advice is relevant to the situation of the franciscana in Brazil; and*
(6) ***agrees*** *that given the increased use of Remote Electronic Monitoring techniques and the rapid development of camera and associated electronic technology, these techniques should be a focus topic at SC68a.*

13.6 Scientific aspects of mitigation measures

13.6.1 The IWC Bycatch Mitigation Initiative

The Committee considered the outcomes of an assessment on the potential work areas for the new IWC Bycatch Mitigation Initiative (SC/67b/HIM12). This resulted in several recommendations for the Committee in relation to potential work areas, including:

(1) identification of priority fisheries/sites/species/populations to be considered for pilot projects based on conservation need and the establishment of bycatch baselines for relevant cetacean populations where mitigation is to be trialled;
(2) leading in communicating the need for increased research on mitigation measures/management approaches for cetaceans to the broader scientific community;
(3) annually reviewing mitigation measure tables;
(4) providing technical assistance to the coordinator and the expert panel in the development of scientific trials/monitoring programmes to evaluate mitigation measures; and
(5) collaborating with researchers identifying fishing effort using vessel monitoring and tracking systems and assessing bycatch risk, with a focus on small scale fisheries.

With respect to the identification of priorities, five criteria for the selection of pilot projects were identified:

(1) urgency of conservation situation driven by bycatch or concern over situations with little or no data on bycatch, but suspected overlap between high risk fishing gears and vulnerable cetacean species;
(2) enabling conditions necessary for success;
(3) scope for IWC to contribute (e.g. enhanced international cooperation);
(4) ability to monitor effectiveness of mitigation actions; and
(5) potential for the project to contribute to mitigation of bycatch in other areas.

A list of information sources (including SOCER) was created at the meeting to assist Tarzia, the new BMI coordinator, to identify potential projects, after which she will consult with the expert panel to apply the above criteria, including contact with any of the governments involved, to select the projects for review by the initiative's Standing Working Group which can be presented to the Commission. The Committee suggested that identified fisheries in the Republic of Congo, Peru, Ecuador, Pakistan and India appear to fulfil many of the criteria and are locations where past or present IWC work is being carried out which is relevant to bycatch.

Attention: C-R, SC, CC

The Committee discussed the strategic assessment of the Bycatch Mitigation Initiative (BMI) and the role of the Committee. The Committee:

(1) ***welcomes*** *the progress made thus far under the BMI, including the Strategic Assessment;*
(2) ***thanks*** *Tarzia for the excellent work she has carried out since her appointment as co-ordinator;*
(3) ***agrees*** *to incorporate in its workplan the five work areas listed in its report under Item 13.6.1 and also consideration of 'rapid bycatch and risk assessment' tools;*
(4) ***agrees*** *to the criteria listed in its report under Item 13.6.1 when identifying priority fisheries/sites/species/populations; and*
(5) ***recommends*** *to the Commission that the BMI continues and is supported, including the provision of ongoing support for the BMI coordinator.*

13.6.2 Collaboration with FAO

FAO held an Expert Workshop on Means and Methods for Reducing Marine Mammal Mortality in Fishing and Aquaculture Operations in March 2018 which had been attended by several members of the Committee. The workshop report contained a review of mitigation measures and a decision tree providing guidance on choosing a bycatch mitigation pathway. The IWC Executive Secretary and BMI Coordinator will attend the FAO Committee on Fisheries (COFI) meeting in July 2018 where the report will be reviewed.

Attention: C-R, S

The Committee ***welcomes*** *the efforts of the FAO to consider cetacean bycatch and* ***recommends*** *that the IWC Secretariat continues to collaborate with the FAO on this issue.*

13.7 New information on cetacean bycatch in the Western, Central and Northern Indian Ocean

Last year (IWC, 2018c, p. 46), the Committee had recommended that in light of the scope and scale of cetacean bycatch in the Western, Central and Northern Indian Ocean and the considerable data gaps associated with intensive and extensive gillnet fisheries, the topic be included in the work plan for this meeting and the Secretariat establish communications on the issue with the Indian Ocean Tuna Commission (IOTC). SC/67B/HIM/07 provided updated information on this topic, as discussed in Annex J (item 2.7). The IWC's Executive Secretary provided an update on engagement with the IOTC, including a recent teleconference with the IOTC Executive Secretary.

Attention: C-A, CC, SC

With respect to bycatches of cetaceans in the Indian Ocean, the Committee:

(1) ***reiterates*** *its willingness to collaborate with the IOTC on this issue; and*
(2) ***encourages*** *the Secretariat to continue to work with the IOTC Secretariat.*

13.8 Workplan 2019-20

The Committee's workplan on bycatch and entanglement is given in Table 18.

14. SHIP STRIKES

14.1 Review estimates of rates of ship strikes, risk of ship strikes and mortality

The Committee received information on a pilot study to better characterise ship strikes in Southeastern Alaska (see Annex J, item 3.1) and looks forward to further updates on this work.

14.1.1 Review progress on ship strike database

The IWC continues to develop a global database of ship strike incidents as discussed in Annex J (item 3.1.1). The primary task is ongoing review of previously reported records by two data coordinators in conjunction with a data review group (SC/67b/HIM11). It is expected that the review process for all historical records will be completed in the next biennium.

Attention: C-R, S

The Committee ***reiterates*** *the importance of the global ship strikes database to its work. It therefore:*

(1) ***welcomes*** *the work undertaken thus far;*
(2) ***recommends*** *the continuation of this work including (a) that of the co-ordinators and Data Review Group on the review of historical records and (b) the Secretariat on upload tools.*

Table 18

Workplan on bycatch and entanglement related issues.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Bycatch Mitigation Initiative		Review aspects relevant to Committee and respond to requests for advice		Review aspects relevant to Committee and respond to requests for advice
Rates and risks		Review new estimates of entanglement rates, risks and mortality		Review new estimates of entanglement rates, risks and mortality
Mitigation		Review new information on mitigation		
Inferences from strandings	Consider new information and issues that need to be addressed at SC68a	Review new information		
Rapid risk assessment		Consideration of 'rapid risk assessment' tools and outputs		
Electronic monitoring		Consideration of remote electronic monitoring and vessel tracking		
Mitigation measures tables		Develop table of mitigation measures for small cetaceans and update table for large whales from 2017 if needed.		
Global disentanglement database	Discussion at GWERN workshop	Review Progress	Advance database development if considered feasible	Review Progress
Collaboration with FAO	Secretariat attend COFI meeting	Review FAO outputs on bycatch	Continue collaboration	Continue to review
Encouraging innovative research on mitigation	BMI through existing networks, at conferences, workshops and with students – all members of Committee with relevant expertise	Review progress		

14.2 Mitigation of ship strikes in high risk areas

The Pelagos Sanctuary in the Mediterranean is a recognised high risk area for ship strikes to fin and sperm whales. In France, the REPCET reporting system became mandatory on 1 July 2017 for French passenger, cargo vessels (SC/67b/HIM04). As discussed in Annex J (item 3.2.1), 'alerting' systems such as REPCET require a trained observer and a subsequent avoidance action of some sort by the vessel in order to be a considered as a mitigation tool.

The Committee had previously agreed that the available data supported a proposal to IMO to move the shipping lanes off the southern coast of Sri Lanka to reduce the risks of ship strikes to Northern Indian Ocean blue whales. In 2017, major shipping organisations represented at IMO also wrote to the Sri Lankan government requesting the routing change to reduce ship strike risks and improve maritime safety. So far, there has been no response from Sri Lanka.

The Hellenic Trench west of Greece is also an identified high risk area for sperm whales and in 2015 (IWC, 2016d), the Committee recommended that interested parties (including Greece, ACCOBAMS and the shipping industry) move forward with Greece in order to develop a proposal for routing measures.

The IUCN Marine Mammal Protected Areas Task Force process for identifying Important Marine Mammal Areas (IMMAs) may assist in identifying high risk areas for ship strikes. The Committee and the IWC's Ship Strike Standing Working Group have previously encouraged cooperation on this between the IUCN Task Force and the IWC.

Attention: C-A, CC, SC, G

The Committee has continued its work on identifying high risk areas for ship strikes and potential mitigation measures. In this regard the Committee:

(1) ***recommends*** *continued work to develop and evaluate mitigation measures, such as speed restrictions, that might be associated with the designation of a Particularly Sensitive Sea Area (PSSA) in the Pelagos Sanctuary area;*
(2) ***reiterates*** *its previous recommendations on the importance of evaluating the efficacy of the REPCET system for reducing the risk of ship strikes;*
(3) ***requests*** *the Commission, via the Secretariat, to remind the authorities in Sri Lanka of its previous offer of assistance from the IWC on this issue;*
(4) ***requests*** *the Commission via the Secretariat, to follow up on previous correspondence on the ship strike risks to sperm whales off Greece;*
(5) ***agrees*** *to support a workshop to evaluate how the data and process used to identify IMMAs can assist the IWC to identify areas of high risk for ship strikes; and*
(6) ***agrees*** *to continue ongoing IWC engagement with the process to identify IMMAs, including consideration of their utility to address other threats.*

14.3 Co-operation with IMO Secretariat and relevant IMO committees

The Committee has long recognised the importance of co-operation with IMO on matters related to shipping including ship strikes.

Attention: C-R, S

*The Scientific Committee **reiterates** the importance of cooperation with IMO and:*

*(1) **welcomes** the ongoing co-operation the Secretariat has maintained with IMO and its Secretariat on ship strike issues, including meetings during IMO MEPC 72; and*
*(2) **recommends** that this dialogue continue.*

14.4 Work Plan

The Committee's work plan on matters related to ship strikes is given as Table 19.

Table 19

Workplan on matters related to ship strikes

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Rates and risks		Review estimates of rates of ship strikes, risk of ship strikes and mortality		Review estimates of rates of ship strikes, risk of ship strikes and mortality
Mitigation		Review new information on mitigation		
Advice on routing measures related to ship strike risk	Provide advice as required (Annex Y)	Review advice	Provide advice as required (Annex Y)	Review advice
Follow up on previous contacts offering IWC assistance regarding high risk areas	Secretariat to contact Sri Lankan and Greek authorities	Review progress on identified high risk areas in IWC Ship Strike Strategic Plan		
Continued co-operation with IMO	Secretariat to maintain dialogue with IMO Secretariat. Attend relevant IMO meetings.	Review cooperation		
Ship strike database	Continue ongoing data entry into Ship Strike Database and validation of records	Review progress against specific deliverables and time line	Continue ongoing data entry into Ship Strike Database and validation of records	Review progress against specific deliverables and time line
Provision of AIS data	Secretariat to develop MOU with Marine Traffic for provision of data	Consider best way to handle requests for data through the MOU		
Use of IMMAs to identify high risk areas for ship strikes	Hold workshop to evaluate how the data and process used to identify IMMAs can assist the IWC to identify areas of high risk for ship strikes.	Review workshop report		

15. ENVIRONMENTAL CONCERNS

The Commission and the Scientific Committee have increasingly taken an interest in the environmental threats to cetaceans. In 1993, the Commission adopted a resolution on research on the environment and whale stocks and on the preservation of the marine environment, IWC Resolution 1993-12 (e.g. IWC, 1996; 1997; 1998; 1999; 2010). As a result, the Committee formalised its work by establishing a Standing Working Group that has met every year subsequently. This year, it has been established as a sub-committee and its report can be found in Annex K.

15.1 Pollution 2020

15.1.1 Review on intersessional progress on the Pollution 2020 initiative

The individual based model to investigate the effects of pollutants on cetacean populations (SPOC) has been finalised. A peer-reviewed paper detailing the model and applying it to a number of case studies has been published in *Environmental Pollution* (Hall *et al.*, 2018) and the model's R code is available through the repository associated with the paper. The web-based, user-friendly version is now available through the Sea Mammal Research Unit, University of St Andrews server (*http://www.smru.st-andrews.ac.uk/reports/*) and a link will be added to the IWC webpages on the Chemical Pollution page. There are new data on the combined effects of persistent organic pollutants (POPs) on the immune system of killer whales (Desforges *et al.*, 2017) and this will be integrated into the model in the next year.

As noted in Annex K (item 2.1), the contaminant mapping tool will be completed next year, with the inclusion of the data on the concentrations of mercury in cetacean tissues by time and region. This online resource that will be made available through the IWC website and will be updated with new information identified in the SOCER annual reviews.

Research to estimate how long it is likely to take for POPs in the blubber of cetaceans to observably decline, following a reduction in environmental levels, will be completed next year.

Attention: SC

*The Committee **agrees** that the Pollution 2020 initiative should be completed and presented at SC/68a. It also **encourages** a paper to be presented at SC/68a summarising the potential mitigation measures for reducing exposure of cetaceans to polychlorinated biphenyls (PCBs) in particular and persistent organic pollutants (POPs) in general.*

15.1.2 Report on mercury in cetaceans

The impact of mercury exposure is still an issue of concern for cetaceans. SC/67b/E08, reviewed mercury in cetaceans, in response to Commission Resolution 2016-4, 'Resolution on Minamata Convention'. The paper (see discussion in Annex K, item 2.2) highlights continued global exposure and potential effect of mercury on cetaceans. Although cetaceans have a unique detoxifying mechanism which may protect them from the health effects of organic mercury, the resulting mercuric-selenide complexes may cause adverse effects in individuals experiencing other physiological and metabolic challenges. Research into identifying the toxic thresholds for mercury in cetaceans is still required.

The Committee also received several papers presenting information on mercury in cetaceans including river dolphins (SC/67b/E06), humpback whales (SC/67b/E09) and gray whales off Chukotka (SC/67b/E03). The Committee highlighted the need for standardisation in reporting units. It also discussed preferred tissues for mercury analyses. Discussion of these papers can be found in Annex K (item 2.2)

Attention: SC, CG-R

The Committee continued to work on mercury in cetaceans in response to Resolution 2016-4. It therefore:

*(1) **encourages** the continued provision of information on mercury and cetaceans;*
*(2) **encourages** researchers presenting such information to report concentrations on both wet and dry weight bases; and*
*(3) **recommends** that Contracting Governments support the continued monitoring of mercury in cetaceans, as this is required in order to assess the medium- and long-term impact of the Minamata Convention.*

15.1.3 Impact of heavy fuel oils on cetaceans

There is a paucity of information on the impacts of heavy fuel oils on cetacean health (Annex K, item 2.3). However, some new information comparing the occurrence of cancer and elevated PAH levels in St Lawrence Estuary white whales with similar cancers in the local human population, was highlighted. In addition, behavioural changes in white whales in the White Sea following exposure to oil have been observed.

Attention: CG-A, SC, G

The Committee:

*(a) **reiterates** the need to estimate the risk and impact of oil spills, particularly to cetaceans in the Arctic;*
*(b) **notes** that heavy fuel oil could pose an environmental threat in many regions due to its high viscosity and chemical composition;*
*(c) **notes** that heavy fuel oil poses a special threat in the Arctic due to difficulties in recovery and potential impacts of some recovery measures (e.g. dispersant use and in situ burning); and*
*(d) **encourages** the collection of baseline data for cetaceans, including standardisation of measures.*

15.1.4 Other pollution issues

Understanding the effects of oil dispersants and dispersed oil on cetaceans is a gap in our current knowledge. To address this need, the Coastal Response Research Center (CRRC) in the USA has co-ordinated a discussion among scientists with dispersant research expertise, as well as those with Arctic expertise, to determine the state-of-science regarding dispersants or dispersed oil, as it applies to Arctic waters. The Committee looks forward to the publication of the final report.

Attention: CG-A, SC, G

*The Committee **draws attention to** the lack of data the effects of oil dispersants and dispersed oil on cetaceans. It therefore:*

(1) ***encourages*** *Contracting Governments to support research on the effects of dispersants or dispersed oil to the Arctic and other ecosystems; and*
(2) ***requests*** *that the results of such research be brought forward to future meetings of the Scientific Committee.*

15.2 Cumulative effects

The Committee welcomed the summary of the Cumulative Effects Workshop (see Annex K, item 3) and looked forward to receiving the report. Overall, the Workshop found that there is considerable uncertainty in addressing this topic and thus in developing assessments and management advice.

The Scientific Committee also received a report on a workshop entitled 'Towards understanding the overlap of selected threats and Important Marine Mammal Areas (IMMAs) across the Mediterranean Sea', which was held jointly by the IUCN Joint Species Survival Commission/World Commission on Protected Areas (SSC/WCPA) Marine Mammal Protected Areas Task Force (the 'Task Force') and by the Agreement on Conservation of Cetaceans of the Black Sea, Mediterranean Sea and contiguous Atlantic area (ACCOBAMS). The workshop provided the opportunity to support the ongoing effort to map specific threats to cetaceans in the ACCOBAMS area by overlaying the Mediterranean IMMAs with the available area-explicit information on shipping and seismic surveys, thereby giving preliminary indications of new Cetacean Critical Habitats in the ACCOBAMS area and facilitating the implementation of conservation actions at the regional level.

Attention: SC, G

The Committee ***recognises*** *the importance of understanding cumulative effects of threats on populations of cetaceans, as well as its complexity. It therefore:*

(1) ***concurs*** *with the Cumulative Effects Workshop recommendations (see Annex K, item 3) to improve our knowledge and enable quantitative assessments;*
(2) ***highlights*** *the recommendation that consideration needs to be given to 'developing a widely applicable approach for providing precautionary advice for populations in which cumulative effects are of concern';*
(3) ***agrees*** *to establish cumulative effects as a standing item on its agenda;*
(4) ***notes*** *the work on Important Marine Mammal Areas (IMMAs) and* ***encourages*** *additional efforts to identify the relevant threats in these, in order assist with the management of cumulative effects;*
(5) ***endorses*** *the results of the recent IUCN/ACCOBAMS workshop entitled 'Towards understanding the overlap of selected threats and Important Marine Mammal Areas (IMMAs) across the Mediterranean Sea';*
(6) ***encourages*** *that such an effort – aimed at overlaying different sources of threat and pressure on existing Important Marine Mammal Areas (IMMAs) – be continued and carried out in more detail in the other marine regions where IMMAs have already been identified; and*
(7) ***offers*** *its assistance in such assessments.*

15.3 Strandings and mortality events

15.3.1 Update on the IWC Strandings Initiative

The IWC strandings initiative was agreed by the Commission at its 2016 meeting (IWC, 2017d) and details can be found in Annex K (item 4.1). It noted that the rescue and welfare aspects of live strandings will be addressed by the Strandings Initiative but that this aspect is not within the purview of the Committee.

Attention: C-R, S, SC

The Committee ***reiterates*** *the importance of the IWC Strandings Initiative. It therefore:*

(1) ***welcomes*** *the excellent progress that has been made in the Strandings Initiative and the appointment of Sandro Mazzariol (Italy) as the Chair of the Strandings Expert Panel and Karen Stockin (New Zealand) as the Stranding Coordinator;*
(2) ***recommends*** *that the Commission (a) endorses the Strandings Initiative governance structure in Annex K (appendix 2) and (b) endorses the continuation of the Strandings Coordinator position for another two years (until IWC68) subject to available funding and requests the Secretariat make the necessary arrangements;*
(3) ***recommends*** *that the Strandings Initiative Steering Committee and Expert Panel, with the support of the Secretariat, should explore the best ways to gather information on strandings events and what basic data about these events should be recorded, focussing on what is useful for the Committee and the Commission;*
(4) ***agrees*** *that a phased approach to this, starting with an initial pilot project, will assist in this endeavour; and*
(5) ***agrees*** *that criteria for allocating funds for emergency responses should be developed by the Steering Committee and the Expert Panel and should be presented to the Committee at SC/68a.*

15.3.2 New information on unusual mortality events

Cetacean morbillivirus continues to be a major disease issue for cetaceans and a cause of unusual mortality events in dolphins in and around the Atlantic. Focus this year was on an outbreak of cetacean morbillivirus in the South Atlantic Ocean (SC/67b/E14) that is discussed in Annex K (item 4.2).

Attention: CG-R, SC

The Committee ***commends*** *the impressive rapid and comprehensive response to the cetacean morbillivirus outbreak in Brazilian Guiana dolphins. It therefore:*

(1) ***encourages*** *further work on the longer-term impact of the outbreak and the investigation of the occurrence and impact of this disease in cetaceans across different geographical areas;*
(2) ***draws attention to*** *the large number of animals that died during the outbreak (particularly mature females) and the historical high levels of human impacts affecting Guiana dolphins in Rio de Janeiro state, such as bycatch, chemical and noise pollution;*
(3) ***recommends*** *that immediate actions should be taken to protect affected populations in order to increase the chances of population recoveries;*
(4) ***draws attention to*** *the increase in Guiana dolphin deaths reported in Sao Paulo and Espirito Santo states in the weeks following the onset of the cetacean morbillivirus outbreak in Rio de Janeiro; and*
(5) ***encourages*** *the monitoring of the virus presence in neighbouring coastal dolphin populations, particularly species and populations in which immunosuppressive conditions or cumulative threats are identified.*

15.4 Noise

The Committee welcomed an update on international efforts addressing anthropogenic noise and their impacts on cetaceans, particularly regarding the appropriate assessment and protection of acoustic habitat quality as discussed in Annex K (item 5), and commended IWC engagement with organisations such as IMO and the UN.

Guidelines developed by the Convention on Migratory Species (CMS) Secretariat, also on behalf of the ASCOBANS and ACCOBAMS Secretariats, for Environmental Impact Assessments for noise-generating offshore industries were presented to the Scientific Committee. These guidelines had been endorsed through CMS Resolution 12.14 on Adverse Impacts of Anthropogenic Noise on Cetaceans and Other Migratory Species, and provide a pathway to implementing the Best Available Techniques (BAT) and Best Environmental Practice (BEP).

The Committee also considered the results of a study utilising modelling approaches to evaluate relative levels of communication masking for four baleen whale species in the Stellwagen Bank National Marine Sanctuary, in Massachusetts Bay, USA Cholewiak *et al.* (In press).

Attention: SC, G, CG-A

Recalling its previous recommendations on noise and the importance of addressing its impacts on cetaceans, the Committee:

(1) ***welcomes*** *and* ***draws attention*** *to the Convention on Migratory Species Family Guidelines on Environmental Impact Assessments for Marine Noise-Generating Activities (https://www.cms.int/en/guidelines/cms-family-guidelines-EIAs-marine-noise), noting that these guidelines will help improve global standards for environmental impact assessments;*
(2) ***recommends*** *that levels of anthropogenic noise and its effects on marine species be explicitly considered in the management of marine protected areas;*
(3) ***welcomes*** *the information received on using marine soundscape planning strategies to reduce interference between hydroacoustic instrumentation (e.g. echosounders and airgun arrays) and marine mammals, and* ***encourages*** *work to further develop this approach;*
(4) ***recognises*** *the commonalities identified among the concurrent efforts of multiple international bodies to develop national guidance on noise strategies, and* ***encourages*** *continuing efforts to identify synergies and develop priorities for actions to reduce exposure of cetaceans to anthropogenic noise;*
(5) ***welcomes*** *the work on modelling cetacean communication space, and* ***encourages*** *scientists engaged in the development of modelling techniques that address multiple anthropogenic impacts, such as noise and entanglement in fishing gear to bring these forward to the Scientific Committee;*
(6) ***agrees*** *that a pre-meeting on noise be organised for SC/68b and that an intersessional steering group be convened (Annex Y) to develop the agenda for that pre-meeting.*

15.5 State of the Cetacean Environment Report – SOCER

The Scientific Committee **thanks** the editors of the State of the Cetacean Environment Report (SOCER) for their work and commended them on compiling this information on the Mediterranean and Black Seas. Next year's region will be the Atlantic Ocean. The Scientific Committee would welcome input from the members for information on this region. A 5-year global compendium is being produced in cooperation with the Secretariat that will receive a dedicated webpage on the IWC website in time for presentation to the 2018 Commission meeting.

15.6 Update on other standing topics

15.6.1 Marine debris[litter]

The Committee received and discussed a number of papers relating to several aspects of marine debris as discussed under Annex K (item 7.1). Exposure to marine debris and microplastics in cetaceans is now widespread and common. However the impacts on cetacean health and populations is not fully understood.

Attention: C-A, SC

The Committee ***draws attention*** *to the fact that marine debris remains a threat, and that in particular, exposure to plastics (including microplastics) is a rapidly emerging area of concern.* It therefore:

(1) ***agrees*** *that an intersessional workshop on Marine Debris should take place, preferably to coincide with the World Conference on the Biology of Marine Mammals in Barcelona in December 2019.*

15.6.2 Climate change

Climate change was highlighted at SC/67a as being an overarching issue that is important to various topics, and that where relevant its impact should be discussed in conjunction with that topic (see discussion in Annex K, item 7.2). Notwithstanding that, the Committee may want to initiate a specific activity related to climate change in future (see intersessional correspondence group in Annex Y).

Attention: C-A, CG-A, SC

The Committee ***draws attention*** *to the fact that climate change remains a threat that interacts with other threats and stressors impacting cetacean populations.*

15.6.3 Cetacean diseases of concern

Monitoring health and disease agents in large whales in the Arctic is continuing to provide important information on changing patterns in prevalence, environmental status, and potential impacts. In addition, morbillivirus and Brucella continue to be important pathogens causing disease and increased mortality in cetaceans in the Atlantic.

Remote methods for assessing health and condition using visual and aerial photography (e.g. SC/67b/CMP13), is a major rapidly developing field, due to the widespread availability and reduced cost of unmanned aerial vehicles (UAVs). Standardisation efforts (e.g. see Annex S) for measuring body condition using UAVs for photogrammetry, and for collecting blow samples, should progress to ensure this useful tool can provide comparable data across studies, taking into account the differences between the various platforms available. Cross-validation with current methods for assessing body condition from visual health assessments is essential.

Attention: SC

The Committee ***agrees*** *to hold a focussed session next year (SC/68a) on our current understanding of the pathology and epidemiology of morbillivirus and* Brucella *and the potential for identifying and understanding the cumulative effects of exposure to other immunosuppressive stressors in cetaceans.*

15.7 Progress on previous recommendations

15.7.1 Pollution

The SC/67a recommendations were to (a) make the effect of contaminants on cetacean populations (SPOC) model available to the public; (b) review mercury in cetaceans; and (c) include new data into the contaminant mapping tool. These have all been completed.

15.7.2 Cumulative effects

As recommended last year, a workshop on understanding the cumulative effects of multiple stressors was held as a pre-meeting to SC/67b.

15.7.3 Diseases of concern

The Committee noted that the content on the Cetacean Diseases of Concern (CDoC) website will now be utilised and merged with the Strandings Initiative for the development of their training and outreach materials.

Whilst the recommended quarterly CDoC updates remain of interest to the Committee, a means of progressing this on a voluntary basis has not yet been identified although efforts to find such assistance are ongoing.

15.7.4 Strandings

The Strandings Initiative has progressed as recommended at SC/67a and a full progress report can be found in Annex K, Appendix 2.

15.7.5 Noise

In response to a previous recommendation, that Committee has received the recently developed seismic survey guidelines by the New Zealand government, a link to the technical working group reports created during the NZ seismic guidelines review is now available (*http://www.doc.govt.nz/our-work/seismic-surveys-code-of-conduct/work-of-the-technical-working-groups/*). However, these guidelines have not yet been discussed by the Committee.

As recommended and noted earlier under Item 15.5, the intersessional group assisted in the development of a summary of the IWC recommendations relevant to shipping noise for presentation to the International Maritime Organization's Marine Environment Protection Committee in 2018.

15.7.6 Thanks

The Committee would like to thank Teri Rowles for her exceptional support and hard work as Chair of the sub-committee on environmental concerns over recent years. Her extensive knowledge, expertise and guidance has been most appreciated and will be missed.

15.8 Workplan 2019-20

The Committee's workplan on environmental concerns is given as Table 20.

Table 20

Work plan for matters related to environmental concerns (for more details see Annex K, Appendix 4).

Item	SC68a	SC68b
Pollution 2020 (including oil spills)	If new information	Primary topic (including oil spills and mercury), summary report to Commission
Cetacean diseases of concern (incl. HAB toxins)	Primary topic	Primary topic
Strandings	If new information	Primary topic
Noise		Noise focus session
Marine litter	Pre-meeting on litter and plastics focus session	If new information
Cumulative impacts	If new information	If new information
Emerging issues	If new information	If new information
SOCER	Receive report	Receive report
Climate change	Over-arching topic	Over-arching topic

16. ECOSYSTEM MODELLING

The report of the Working Group on Ecosystem Modelling is given as Annex L. This group was first convened in 2007 (IWC, 2008b). It is tasked with informing the Committee on relevant aspects of the nature and extent of the ecological relationships between whales and the ecosystems in which they live.

Each year, that Working Group reviews new work on a variety of issues falling under three areas:

(1) reviewing ecosystem modelling efforts undertaken outside the IWC;
(2) exploring how ecosystem models can contribute to developing scenarios for simulation testing of the RMP; and
(3) reviewing other issues relevant to ecosystem modelling within the Committee.

16.1 Cooperation with CCAMLR on multi-species modelling

The Committee has been considering plans for joint workshops with CCAMLR on ecosystem modelling for some time (e.g. see IWC, 2017c, p.56), although this has not yet happened, the Committee remains interested.

Attention: SC

The Committee ***reiterates*** *its interest in holding joint workshops with CCAMLR. It* ***agrees:***

(1) that a two-year delay in the occurrence of the workshop will provide the opportunity to pursue and complete the relevant work with input from CCAMLR as needed; and
(2) that collaboration between SC-IWC/SC CCAMLR should be on going, and that the revised plan for the workshops (IWC, 2018e) be implemented.

16.2 Applications of species distribution models (SDMs) and ensemble averaging

The Committee had agreed in 2015 to review the application of species distribution modelling (SDM) and associated techniques as they pertain to the goals of the Committee and to develop good practice guidelines and recommendations. While the review has occurred (IWC, 2016b), there has been no significant progress in the intersessional correspondence group set up to develop the guidelines.

Attention: SC

The Committee ***reiterates*** *the importance of developing good practice guidelines and recommendations for species distribution modelling and* ***agrees*** *that this should be pursued by an intersessional correspondence group (Annex Y) with a view to reviewing and adopting guidelines within the next biennium.*

16.3 MODELLING OF COMPETITION AMONG WHALES

16.3.1 Individual-based energetic models

Enhancements to an individual-based energetics model (IBEM) were presented to the Committee (SC/67b/EM07). These included the explicit modelling of feeding on migration, individual dives and searching for prey schools. Results showed that carrying capacity and productivity were sensitive to the level of food available during migration, making it important that ecosystem models to cover the entire migratory range of the species. This is an important contribution to the determination of species' function response, which can play a pivotal role in ecosystem modelling. This approach is also discussed under Item 5.1.

16.3.2 Modelling of relationship between whales and prey

The Committee reviewed three papers relevant to modelling of the relationships between whales and prey, SC/67b/EM04, SC/67b/EM06 and de la Mare *et al.* (*in press*). The discussion of these can be found in Annex L (item 3.2).

16.3.3 Modelling of competition among baleen whales

The Committee noted that multi-species individual based energetic models (IBEM) such as those described under Items 16.3.1 and 16.3.2 could be used to model direct and indirect competition of different whale species in the same environment, and that relevant modelling work was nearing completion.

16.3.4 Stable isotope analyses

The Committee received preliminary results of the analysis of stable carbon (δ13C) and nitrogen isotope ratios (δ15N)) on samples from the edge of baleen plates in Antarctic minke whales (SC/67b/SP09). The details can be found in Annex L (item 3.5).

16.4 Standing topics

16.4.1 Effects of long-term environmental variability on whale populations

How long-term environmental variability might affect stock assessments is of particular interest to the Committee. Given the need for a literature review on the subject to facilitate discussions, an intersessional correspondence group (Annex Y) has been established.

16.4.2 Update on body condition analyses for the Antarctic minke whales

For several years, the Committee has been discussing whether there has been a statistically significant (5% level) decline in the blubber thickness and fat weight of Antarctic minke whales over the course of the JARPA surveys. In 2014, the Committee had agreed that there had been such a decline (IWC, 2015b). Since then, scientists from Australia, Japan and Norway have presented a series of models both supporting and challenging this conclusion. There has been collaboration over this period and significant development in the types of models used. In addition, there have been in-depth discussions regarding the proper handling of data, the explanatory variables to be included in the analysis and the appropriateness of various statistical methods.

New analyses were presented this year and detailed discussions can be found in Annex L, item 2. This year the debate focused on three points; (1) the use of a new variable of primary interest (the 'accumulated blubber thickness in each feeding season); (2) the use of FIC and (3) the appropriate handling of the data.

Attention: SC, G

The Committee has been discussing whether there has been a statistically significant (5% level) decline in the blubber thickness and fat weight of Antarctic minke whales over the course of the JARPA surveys for several years. In conclusion, the Committee ***agrees****:*

(1) that, for the data set considered as a whole, all approaches result in point estimates reflecting a decline when fit to a linear trend in time;
(2) however, the extent of the decline estimated differs amongst the methods, and is not statistically significant at the 5% level for all approaches;
(3) for some approaches, when the data are disaggregated by gender and/or area, some point estimates of trend are not negative;
(4) there are some indications of temporal variation that is more complex than linear.

In addition, the Committee:

(1) ***encourages*** *the authors to publish the results of their study in peer-reviewed journals; and*
(2) ***agrees*** *that this matter will not be considered during the forthcoming biennium.*

In discussion of the above, Norwegian scientists stated that since an error in parts of the Australian scientists' calculations has recently been acknowledged by them, and parts of the Australian scientists' conclusion and appendix had recently been withdrawn, the overall position regarding the blubber thickness and fat weight analyses now became as follows. There are no new analyses from the Australian scientists on the five response variables which have been considered and discussed in the Committee from 2011 to 2017. The results presented this year by the Norwegian scientists (SC/67b/EM02), which took into account some of the queries from the Australian scientists from last year, confirmed results presented by the Norwegian scientists earlier. Thus, the conclusions by the Committee in 2014 and 2017 on these variables remain valid. For this meeting the Australian scientists had presented analyses related to a new difficult dependent variable 'increase in blubber thickness during summer feeding in Antarctic waters' estimated from the blubber thickness at position BT11. The conclusion above about variables with a non-significant decline now pertains to the new variables only (points (2) and (3) above). The Norwegian scientists' position is that the conclusion drawn above was heavily influenced by the results of the calculations subsequently withdrawn, so that parts of those conclusion are no longer valid.

In response, the Australian scientists stated that results of some calculations carried out earlier were withdrawn because of a previously unidentified problem with a standard statistical package failing to converge on a solution without giving an error message. Subsequent collaborative checking with the Norwegian scientists led to the discovery of this problem. Withdrawing this calculation (which the Australian scientists had carried out to illustrate a property of the Norwegian scientists' methods) had no effect on the main results which the Australian scientists had presented in SC/67b/EM03. Nor did this retraction affect the results of analyses the Australian scientists had presented in 2017 showing non-significant trends in fat weight and blubber thickness (De La Mare *et al.*, 2017a; 2017b). The Australian scientists held the view that the assertion by the Norwegian scientists that "There are no new analyses from the Australian scientists on the five response variables which have been considered and discussed in the SC from 2011 to 2017" was not correct; the Australian scientists had provided full results of fitting models to BT11 in SC/67b/EM03. The main results in SC/67b/EM03 were based on differences between early- and late-season predictions from models with BT11 as the dependent variable. This difference was a simple measure of feeding in Antarctica. The earlier conclusion should not be materially affected by withdrawing the Australian scientists' compromised demonstration in relation to the Norwegian scientists' methods.

16.4.3 Review the information on krill distribution and abundance by NEWREP-A

The Committee received the results of the krill and oceanographic surveys during the third NEWREP-A survey in Area V-E and VI-W (SC/67b/EM05). Discussion of this information can be found in Annex L (item 6.1).

16.4.4 Ecosystem functioning

Resolution 2016-3 tasked the Committee with investigating the contribution of cetaceans to ecosystem functions. Last year, the Committee noted that its focus would be on scientific aspects of the issue and it established an intersessional correspondence group to progress this work. Progress made by that group, including development of a final terms of reference, can be found in Annex L, item 6.2. The Committee notes that the Conservation Committee will focus on the conservation and social science aspects of this issue.

It was noted that there is broad interest in understanding the role of cetaceans in ecosystem functions, and that the Committee's expertise relates to the scientific aspects of the issue. Given the broad international interest, it is suggested that the Committee work in collaboration with interested parties (e.g. CMS, CCAMLR, SCAR and SCOR) to share information and avoid the duplication of work.

C-A, CC, SC

Commission Resolution 2016-3 tasked the Committee with investigating the contribution of cetaceans to ecosystem functions. The Committee notes that the Conservation Committee will focus on the conservation and social science aspects of this issue. In responding to the Resolution 2016-3, the Committee ***advises*** *the Commission that with respect to the scientific aspects on the contribution of cetaceans to ecosystem functioning:*

(1) it is unlikely that the ultimate goal of reliably determining the contribution of cetaceans to ecosystem functioning could be achieved in under a decade, given the complexity of the issue and the data gaps; and
(2) a more immediate and achievable goal is the carrying out of a gap analysis to identify knowledge gaps and to develop a plan to address them.

To further this work, the Committee ***agrees****:*

(1) to hold a workshop to (a) define short- and medium-term objectives to be addressed and (b) to identify what further research is required in order to begin initial modelling of the contribution of cetaceans to ecosystem function; and
(2) that the Secretariat in conjunction with the Steering Group (Annex Y) should contact CMS to determine their interest in participating in such a workshop.

16.6 Workplan 2019-20

The Committee's work plan on ecosystem modelling is provided in Table 21.

Japan referred to its statement on the adoption of the Agenda (Annex Z) and considered that several of the items for the proposed workshop (Item 16.4.4 and Item (7) in Table 1) are outside the competence of IWC. Therefore, it cannot support the proposed workshop or associated funding from the Committee's budget.

Table 21

Summary of the two-year work plan on matters related to ecosystem modelling

Item	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting (SC/68b)
(1) Ecosystem modelling in the Antarctic Ocean	Continue further analyses.	Review results of further analyses	Continue further analyses.	Review results of further analyses
(2) Application of species distribution models (SDMs)	Intersessional group activity (Annex Y)	Review progress		
(3) Effect of long-term environmental variability on whale populations	Continue further analyses. Intersessional group activity (Annex Y)	Review results of further analyses. Review progress	Continue further analyses	Review results of further analyses
(4) Further investigation of individual-based energetic models	Continue further analyses	Review results of further analyses	Continue further analyses	Review results of further analyses
(5) Modelling of competition among whales	Continue further analyses	Review results of further analyses	Continue further analyses	Review results of further analyses
(6) Update of any exercises on krill distribution and abundance	Conduct NEWREP-A krill survey and an international cooperative krill survey. Conduct simulation analyses to resolve issues on survey design.	Review results of survey and analyses.	Conduct NEWREP-A krill survey. Conduct analysis of data taken by the international survey.	Review results of survey and analyses.
(7) Cetaceans & Ecosystem Functioning: a gap analysis workshop or pre-meeting	Review relevant scientific studies before the workshop in addition to preparation of workshop (Annex Y).	Review outcomes of workshop and develop clear work plans with priorities.	Continue analyses	Review results of analyses.

17. SMALL CETACEANS

The report of the Committee on Small Cetaceans is given as Annex M.

17.1 Overview of taxonomy, distribution and abundance for *Inia* and *Sotalia*

In this assessment, two species and two sub species of dolphins were considered, some of which have several common names. In addition, a new species has been proposed but has not yet been recognised (Table 22).

Table 22

Summary of names used in the description of *Inia* and *Sotalia*

Scientific name	Common Name
Inia geoffrensis	boto, Amazon River dolphin
I. g. boliviensis	Bolivian bufeo
I. g. geoffrensis	Common boto
I. araguaiensis	Araguaian boto
(proposed species)	(from the Tocantins and Araguaia basins)
Sotalia fluviatilis	tucuxi, delphín gris, bufeo negro
Sotalia guianensis	Guiana Dolphin

The river and estuarine dolphins of South America are subject to various threats from habitat degradation, competition with fisheries, bycatch and direct exploitation. A major threat to river dolphins in South America is population fragmentation, altered habitat productivity and regulation of natural river flow as a result of dam construction. The cumulative impacts from this type of infrastructure at the macrobasin scale exacerbate the threats to river dolphins and their habitat in the Amazon and Orinoco basins. It was estimated that more than 50% of the range of Araguaian *Inia* is affected by damming.

Two genera were discussed in depth, *Inia* and *Sotalia,* from the vast and convoluted systems within the Amazon, Orinoco, Tocantins and Araguaia River basins. In the case of *Sotalia,* two species are recognised: *Sotalia guianensis* (marine) and *Sotalia fluviatilis,* (freshwater) in the Amazon basin. *S. guianensis* in the Orinoco basin likely represents an independent population unit as it is isolated from other coastal populations. Two intersessional workshops have been proposed that aim to elucidate the status of *S. guianensis* and it is that divisions within this genus will be clearer on the completion of this work in 2020. The taxonomoy of *Inia* has a complex history and at this time, one species and two sub species are recognised: *Inia geoffrensis*, the Amazon river dolphin, *I. g. boliviensis*, the Bolivian bufeo, and *I. g. geoffrensis*, the common boto. There is a third putative subspecies, *I. g. humboldtiana*, in the Orinoco basin of Venezuela and Colombia. The information currently available suggests that *I. g. boliviensis* should be elevated to species level and that *I. g. humboldtiana* should be recognised. Another new species, *I. araguaiensis*, has been proposed for the dolphins that inhabit the Tocantins and Araguaia basins of central Brazil as this area is geologically and hydrologically separate from the Amazon basin.

Attention: SC, G

Given the incomplete resolution of Inia *taxonomy, the importance of clarifying and solidifying recognition (or elevation to species) of the* Inia *subspecies found in different river basins, the possibility that in such complex habitats localised specialisation is likely, and the need to focus attention on the conservation of demographically independent populations, the Committee* ***encourages*** *support for efforts to resolve* Inia *spp. taxonomy in light of the significant and diverse threats affecting the populations inhabiting the Amazon-Orinoco-Tocantins/Araguaia drainages.*

17.1.1 Inia

For *Inia*, there are estimates of abundance for some rivers, however, there is little information on population trends. It was suggested that new technologies, such as Unmanned Aerial Vehicles (UAV), may help to better refine population survey techniques. From telemetry studies and two long term studies some information on population parameters is available. In particular, the Committee commends an ongoing telemetry study as it begins to address some of the most important scientific questions concerning *Inia* ecology, habitat use, behaviour and, particularly movements.

In addition, and central to IUCN assessments, a generation time for *Inia* has been calculated as 24.8 years from a long-term mark and recapture study. Given the estimated rate of population decline, this equates to a loss of 82% per generation and in excess of 99% over three generations. Such values are well above the threshold for a Red List assessment of a species as Critically Endangered. Concern was also expressed at the high rate of mortality of <1 year calves in one study site, where examined carcasses show evidence of both deliberate killing and net entanglement.

The information presented on population parameters were based on direct observations in a very small geographic area of the Amazon and therefore, a very small proportion of the total range of *I. geoffrensis.* As such, extrapolation to the whole region would be unwarranted, nonetheless these results and their implications for population decline are alarming.

Attention: CG-A, G

The Committee ***draws attention*** *to declines in Inia numbers documented in two study areas and the lack of abundance surveys in most parts of its range. The Committee therefore* ***encourages*** *the collection of data, calculation of abundance estimates and undertaking of analyses to estimate population trends for* Inia *throughout its range, for use in assessments of the status of the species, subspecies, and regionally isolated populations.*

17.1.2 Sotalia

Sotalia fluviatilis, known as tucuxi (Brazil) delphín gris (Colombia) or bufeo negro (Peru and Ecuador) is restricted to the Amazon basin in Ecuador, Peru, Colombia and Brazil and has a more limited distribution than *Inia*. *Sotalia guianensis*, the Guiana dolphin, occurs mainly in nearshore and estuarine waters of the Atlantic from southern Brazil, along the coast of Central America, to Nicaragua and possibly Honduras. Small populations in Lake Maracaibo and in the lower reaches of the Orinoco River, Venezuela, were highlighted as being heavily impacted.

In the Mamirauá Reserve, Brazil, the population of *S. fluviatis*, has shown a precipitous decline in abundance over a 22-year study period. Using the average observed decline of 7.4% per year, and, from literature, a generation time estimate of 15.6 years, the Mamirauá population trend equates to a 97% reduction over 3 generations, qualifying this population as Critically Endangered under IUCN Red List criteria. Unlike *Inia*, which is heavily exploited for use as bait in the piractaninga fishery, the primary driver of the decline in Sotalia in this region is gillnet entanglement.

17.1.3 Threats shared by dolphins in the Amazon and Orinoco River systems and Lake Maracaibo

Throughout the range of both genera, illegal hunting was highlighted as a transnational problem, making it difficult to create and enforce effective conservation measures. This issue is severe for *Inia* throughout its range and, for *Sotalia* in the Orinoco River and particularly in Lake Maracaibo, Venezuela.

Attention: C-A, G, CC

The Committee ***draws attention to*** *the serious situation reported for Lake Maracaibo in Venezuela, where both directed takes and oil pollution are thought to be having serious impacts on populations of* S. guianensis. *The Committee* therefore ***recommends*** *that NGOs and researchers focus on documenting the threats to* Sotalia *and work with local communities to mitigate the impacts on these dolphin populations.*

In addition to direct exploitation, there are numerous other threats to both species throughout their habitat in South America: the recent increase in deforestation effects their prey species, as there is no deposition of seeds and fruits into the rivers to support productivity and sustain fish stocks; hydropower developments and channel dredging affects flows regimes, the connectivity of rivers, the migrations of fish and can fragment dolphin populations, as has already occurred in the Tocantins River basin; heavy metals, such as mercury, have been measured in high concentrations in dolphin tissues; negative interactions with fisheries, in addition to directed takes for use as bait and food, also include bycatch, deliberate poisoning and 'control' killing.

Attention: CG-A, G, CC

The Committee ***draws attention to*** *the multiple threats associated with development, habitat degradation and fragmentation, and pollutants facing river dolphins in the Amazon, Orinoco and Tocantins basins. It therefore:*

(1) ***advises*** *the Brazilian, Bolivian and Peruvian Governments, as they carry out their reviews of proposed construction of new dams for hydroelectric energy production, to explicitly consider the potential impacts on river dolphins (e.g. isolation, loss of genetic diversity, habitat degradation;*
(2) ***discourages*** *water pumping in the Araguaia-Tocantins river basin for agricultural use as such a practice causes dramatic decreases in water levels in rivers, thereby increasing the probability that dolphin populations will be extirpated;*
*(3) e****ncourages*** *range states of the Amazon basin and its tributaries to support and carry out baseline research into the impacts of the development of commercial waterways in the Amazon (hydrovias) and their potential impacts on dolphin populations and habitats, including but not limited to the ecological impacts of dredging, noise pollution, channelisation by embankments, altered sediment suspension and transfer, and changes in turbidity, light, oxygen availability and primary productivity, and (b) work to minimize or at least mitigate these impacts;*
*(4) e****ncourages*** *(a) a review of the status of dolphins trapped within dammed stretches of the Tocantins and Madeira rivers and (b) evaluation of possible relocation (translocation) of animals when environmental conditions create a high likelihood that they cannot continue to survive in this severely compromised habitat; and*
*(5) e****ncourages*** *the review of the effects and the scale of contaminant and heavy metal (e.g. mercury) pollution on river dolphins in key areas of the Amazon (Japura/Caquetá, Içá/Putumayo, in Brazil and Colombia) and Orinoco (Venezuela) basins.*

17.2 *Tursiops* populations occurring in estuarine areas in southern Brazil

Discussion focused on two populations of Lahille's bottlenose dolphins (*Tursiops truncatus gephyreus*) in Patos Lagoon Estuary (PLE) and Laguna (LGN), Brazil. Both have been the focus of long-term ecological studies that provide a good source of information on the conservation status of the subspecies. Mark-recapture studies indicate year-round residency and permanent emigration is unlikely. Population sizes are small (85 dolphins in PLE and 60 in LGN) with low to moderate genetic diversity (mtDNA and nuclear DNA variation) in both areas. Pollutant analyses indicated moderate levels of persistent organic pollutants (POPs). Of additional concern is a chronic dermal infection which is apparent in 14% of the LGN population, which may be related to pollution but this is not clear. The greatest threat to both populations is bycatch in artisanal gillnet fisheries. Whilst there is no clear evidence of a negative trend in abundance, there is a high probability of population decline in the near future, given the small population, the high degree of residency and the continuing mortality as a consequence of IUU (illegal, unreported, unregulated) fishing and other human activities in these areas.

In Santa Catarina, Paraná, and São Paulo provinces, Brazil, north of LGN and PLE, a total of 119 bottlenose dolphins (sub species unknown) and 442 Guiana dolphins were recorded stranded over 2 years. There was strong evidence that entanglement was indicated as the cause of death for bottlenose dolphins. The Committee was informed that the Brazilian Government is looking into this issue and is seeking ways to improve legislative effectiveness in protecting dolphins and other threatened species in these locations.

Attention: SC, CG-R

The Committee draws the attention of the range states (Argentina, Brazil, Uruguay) to its conservation concerns over the entire sub-species of Lahille's bottlenose dolphins (T. t. gephyreus) given their relatively small population sizes and constricted ranges, the high levels of bycatch and the high incidence of individuals with chronic dermatitis. The Committee therefore recommends:

(1) immediate action to reduce the level of bycatch in the southern Brazil populations;
(2) continued monitoring and photo-identification work on the populations throughout the subspecies' range to refine survival estimates and to assess trends in abundance and the prevalence and etiology of the chronic skin infections; and
(3) that the conservation status of the subspecies be prioritised for assessment in the future.

17.4 Franciscana CMP

In 2016, the IWC created a Conservation Management Plan (CMP) for the franciscana – see Item 10.1.4. In 2019, a review will be presented to the Committee. The review will be jointly conducted by the SM and CMP sub-committees and will include input from other relevant sub-committees.

17.5 Report of the 2018 *Tursiops* Taxonomy Workshop

In 2014 (IWC, 2015b) it was agreed that the Committee would undertake a review of taxonomy and population structure in the genus *Tursiops*, over several meetings. Understanding whether there is any consistency in the derivation of various local forms across the range, and to which taxonomic or population unit(s) they belong, has been challenging, and the taxonomy of the various forms is still unresolved. An additional aim of this exercise was to develop a widely applicable taxonomy assessment framework for small cetaceans. The review process concluded with an intersessional workshop, held in La Jolla in January 2018.

The 3-year review and workshop brought together researchers and experts from around the world to discuss this topic, motivated focussed research, and promoted new collaborations. Results from studies presented at previous meetings (2015-2017) and at the workshop itself were compiled and formed the basis for evaluation of taxonomic and population distinction issues in each geographic region.

Attention: SC, G

Having reviewed the extensive information included in the 2015-2017 review and 2018 workshop for evaluation of Tursiops *species, subspecies and population distinctions, the Committee* ***draws attention to*** *the need for* Tursiops *research in the areas identified as data deficient (the African coast of the eastern Atlantic, southern and eastern Mediterranean Sea, eastern South Pacific, Pacific coast north of California and off the Mexican mainland, Central American coast of the eastern North Pacific, Central American Atlantic and Caribbean Sea and Atlantic coast of northern and north-eastern Brazil, eastern Australia and in the western Pacific the islands of Micronesia, Melanesia, Polynesia, the Philippines and Vietnam). The Committee therefore* ***encourages****;*

(1) collection of additional data, including morphometrics, and high-resolution genetic analyses (e.g. ddRAD which may also be useful in other areas where there are similar questions requiring high-resolution analysis), to better characterise divergence between coastal and offshore forms in the western South Atlantic Ocean, to help confirm whether subspecies or species classification is more appropriate for T. t. gephyreus;
(2) further investigation of T. aduncus *lineages in the Indian Ocean and western South Pacific to assess potential subspecies recognition, extending the geographic coverage to include eastern Africa, the region between Pakistan and Indonesia, and the region between Australia and China;*
*(3) continued study of the genetics and morphology of southern Australia bottlenose dolphins with the "*T. australis*" mtDNA lineage, in the context of both* T. truncatus *and* T. aduncus;
(4) examination of the level of male-mediated gene flow between the coastal and offshore forms in the western North Atlantic to determine whether the coastal form should be elevated to species or subspecies status;
(5) more comprehensive morphometric analyses comparing T. truncatus in the Mediterranean, Black Sea, and eastern Atlantic to integrate with genetic data and evaluate whether any regions in addition to the Black Sea (T. t. ponticus) harbour a taxonomic unit above the level of population;
(6) comprehensive morphometric analyses of coastal and offshore T. truncatus in the eastern North Atlantic and comparison to those from the western North Atlantic to better evaluate potential regional differences;
(7) morphometric analyses of Gulf of California coastal and offshore dolphins relative to those from California and the eastern tropical Pacific, with a particular focus on the level of divergence of coastal dolphins in the upper Gulf of California to other areas; and
(8) the collection of additional genetic and morphological data throughout the eastern South Pacific and further studies to investigate coastal versus offshore forms throughout the region, including coastal and offshore waters from Central America to Mexico, and if possible around the southern tip of South America to Argentina.

The Committee also ***agrees*** *to continue compilation of specimen, study, and researcher details, and concentrated effort to improve our understanding of* Tursiops *in data-deficient areas.*
Finally, after reviewing the 2018 Tursiops *Taxonomy Workshop's evaluation of the support provided for taxonomic (subspecies, species) and population-level distinctions proposed in the publications reviewed, the subcommittee* ***concludes*** *that:*

(1) the current taxonomy provided for Tursiops *by the Society for Marine Mammalogy's Committee on Taxonomy is well supported by morphological and molecular genetic data, as well as ecological and distributional data; and*
*(2) discordance in currently available results from morphometric analyses and across different genetic markers of the recently described '*T. australis*' from southern Australia calls into question its validity at this time.*

In addition to the information and recommendations on *Tursiops*, the Committee noted that the review provided an opportunity to formulate some generic conclusions on taxonomic issues related to small cetaceans.

Attention: SC, G

After reviewing the development and use of a strategy for objective evaluation of species, subspecies, and population-level distinctions by the 2018 Tursiops *Taxonomy Workshop, the Committee:*

(1) ***agrees*** *with the strategy implemented at the workshop for the evaluation of species, subspecies and population level distinctions;*
(2) ***encourages*** *use of the criteria and guidelines in Reeves et al. (2004) for the assessment of species-level taxonomy, in Taylor et al. (2017) for subspecies-level taxonomy, and in Martien et al. (2015) for Demographically Independent Populations; and*
(3) ***concludes*** *that future taxonomic questions should be examined within an appropriately wide and inclusive geographic context and that multiple lines of evidence are necessary when positing taxonomic changes.*

The Committee applauded Natoli, Rosel and Cipriano for their considerable work and organisational skills during this effort.

17.6 Poorly documented takes for food, bait or cash and changing pattern of use

17.6.1 Intersessional Workshop on the use of Small Cetaceans for Food and Non-Food Purposes in South America

The poorly documented take of small cetaceans for use as wildmeat has been assigned as a priority topic. An ICG (and see Annex Y) has been tasked with the development of a toolbox of techniques that could guide and co-ordinate research into this topic, and as such a series of workshops were proposed to fulfil this task. The second of these workshops focused on South America and incorporated a detailed review of the use of Amazon river dolphins as bait in the piracatinga fishery, which, in turn, fed into the priority topic of the 2018 meeting.

Information was summarised for all countries, except Guyana and Suriname, and it was recognised that products from small cetaceans have been used throughout the region for both food and non-food purposes. This type of use is referred to as ‘aquatic wildmeat’. The usefulness of various tools and techniques was discussed, including data gathering techniques and forensic investigation. A database, comprising more than 3000 references, was used to map existing knowledge and understand data gaps. A framework was also established that had the purpose of standardised future data collection. The workshop participants populated a database from which regional patterns were mapped. Areas that were highlighted as a cause of conservation concern were; Bolivia, Brazil, Colombia, Costa Rica, Ecuador, Peru and Venezuela.

The take of Amazon river dolphins as bait in the piracatinga fishery was also reviewed. All range countries of *Inia* and *Sotalia* have laws in place to protect dolphins and prohibit intentional killing. Fishing for piracatinga is banned in Brazil and its trade is prohibited in Colombia, due to its impact on river dolphins and other wildlife. The practice of using dolphins as bait has recently expanded to Peru, Bolivia and Venezuela, following the imposition of restrictions in Brazil, however, no other range country has developed specific legislative or regulatory action, beyond the general protection of river dolphins, in response to the emergence of this practice.

The workshop concluded that some species and population required urgent attention both due to the extent of their use as wildmeat and from other threats.

17.6.1.1 SCIENTIFIC CONCLUSIONS AND RECOMMENDATIONS

Attention: SC, G, CG-A

The Committee ***endorses*** *the scientific conclusions and recommendations from the recent intersessional workshop on the use of Small Cetaceans for Food and Non-Food Purposes in South America aimed at improving regional knowledge and conservation research. In particular, the Committee:*

(1) ***agrees*** *that potential divisions within the genus* Inia *should be evaluated and genetic conservation units established;*
(2) ***agrees*** *that an evaluation of historical data on river dolphins should be undertaken to better understand other threats (e.g., from bycatch), to provide further insights into current trends;*
(3) ***encourages*** *the use of new technologies, such as drones and satellite telemetry, to establish trends, habitat use and dispersion patterns of Inia within Amazon River Basin and*
(4) ***encourages*** *new efforts to improve regional research capacity.*

The Committee ***draws attention*** *to the evidence showing that several small cetacean species and/or populations are being negatively impacted by their use as wildmeat in South America, and therefore* ***recommends*** *that abundance and distribution surveys, in tandem with investigation into the magnitude of aquatic wildmeat use, be conducted on these species. Appropriate survey designs should be implemented that consider the statistical power required to detect trends and the resultant data should then be used to estimate the impact of deliberate take for wildmeat on the following populations:*

(1) Boto in Purus and Japurá rivers, Brazil, and Içá/Putumayo river in both Brazil and Colombia, using previously established standardised methods (studies should also be expanded into other areas where take for bait may be a cause for concern);
(2) Chilean dolphin in Chile;
(3) Burmeister's porpoises in both Chile and Peru, noting that current evidence suggests that the Peruvian population is distinct;
(4) Dusky dolphins in Peru, noting that evidence shows that landings of this species has decreased and populations may have been heavily impacted;
(5) Guiana dolphins and other small cetaceans in Amapá, Pará, Maranhão, Piauí, Ceará, Espírito Santo, São Paulo and Paraná, in Brazil, where there is a documented use of bycatch for wildmeat purposes;
(6) Bottlenose dolphins and pantropical spotted dolphins) in Bahia Solano, Colombia, noting that deliberate takes for a long line fishery is ongoing;
(7) Tucuxi throughout its range, in Brazil, Colombia, Ecuador, as it shares most of the same threats as Inia geoffrensis, *and may also be used as bait in the piracatinga fishery; and*
(8) Guiana dolphin (Sotalia guianensis) in Lake Maracaibo in Venezuela, noting that deliberate take for food is ongoing.

The Committee also ***draws attention to*** *the Boto dolphins that have been isolated within the dam system of the Tocantins and Maderia Rivers in Brazil. Given the confined condition of the dolphins' habitat, the Committee* ***agrees*** *that the status of these dolphins be evaluated, to include abundance, genetic, habitat, prey availability assessments, with a view to developing a translocation protocol, including under what circumstances such a protocol should be enacted.*
Finally, given the concerns over the extensive habitat modification that will result from the Mega Project 'Arco Minero del Orinoco', a large scale mining operation proposed along the river and watershed of Venezuela, the Committee ***recommends*** *that population sizes and trends of both* Inia geoffrensis *and* Sotalia guianensis, *in the Orinoco River basin, be monitored before and during this project.*

17.6.1.2 CONSERVATION AND MANAGEMENT ISSUES

Attention: CG-R, S, CC

The Committee ***draws attention to*** *the management recommendations within the Report of the Workshop on the Use of Small Cetaceans for Food and Non-Food Purposes in South America, in particular, the need to have a regionally co-ordinated fisheries management plan for the Amazon River basin and a regional strategy for the conservation of river dolphins. Given continued concern over the use of dolphins as bait in the piracatinga fishery, the Committee:*

(1) ***commends*** *the Government of Brazil on its swift action in declaring a moratorium on the piracatinga fishery and respectfully requests that it maintains the moratorium to allow sufficient time to evaluate the effectiveness of protective measures and ensure the necessary protection of river dolphins;*
(2) ***reiterates*** *previous recommendation of the IWC Scientific Committee that range states (Bolivia, Brazil, Colombia, Peru and Venezuela) engage in a co-ordinated effort to strengthen legislative, enforcement, management and scientific efforts to ensure protection of the Amazon River dolphins;*
(3) ***encourages*** *range state authorities to work together and exchange information on the movement of piracatinga products across international borders; and*
(4) ***requests*** *that progress reports be submitted to the Scientific and Conservation Committees.*
(5) ***recommends*** *that the Commission asks the IWC Secretariat to send a letter to the Buenos Aires Group highlighting the issue of dolphins being used as bait in the piracatinga fishery and requesting joint efforts to enhance enforcement on wildlife and trade laws.*

17.6.2 Wildmeat Database

In 2016 (IWC, 2017) an intersessional group was established to work with the IWC Global Database Repositories Convenor, to develop an overarching aim for any future cetacean wildmeat database and identify the specific questions that such a database might address. The results of this work were presented, including a research agenda the formulation of key questions that could be addressed through the development and analysis of an aquatic wildmeat database. The Aquatic Wildmeat Database, developed independently of the IWC, was presented again and the Committee was updated on its improvements made following suggestions made last year. The future value of this data repository was highlighted and this and related issues will be considered intersessionally (see Annex Y).

The work of the Steering Group (see Annex Y) will continue and a third workshop, focusing on Africa, will be conducted intersessionally. The framework for an IWC Wildmeat database established at the workshop in South America will be further refined and will be used at the forthcoming workshop.

17.7 Small cetacean task team

The Scientific Committee continues to support the Task Team Initiative and the latest Task Team, for the South Asia River Dolphin, is in the process of being established with Dipani Sutaria and Nachiket Kelkar nominated as co-conveners. The task team currently comprises 14 members with representation from Bangladesh, India, Nepal and Cambodia and includes university associated researchers and NGOs (WWF and the Wildlife Institute of India).

Under its Task Team Initiative (e.g. IWC, 2016), the Committee ***strongly supports*** *the work of a Task Team for the South Asia River Dolphin and* ***agrees*** *that its first meeting which will occur before the 2019 meeting, if sufficient funding is available.*

17.8 Progress on previous recommendations

17.8.1 Vaquita

The Report of the Tenth Meeting of the International Recovery Team for Vaquita (CIRVA-10) was summarised and the results of the acoustic monitoring program for vaquitas were presented (SC/67b/SM01). This shows a continued decline in vaquita detections with no change in the trend since the last report in 2016. A brief review of the VaquitaCPR project was presented. This initiative, conducted in October and November 2017, aimed to capture vaquitas and bring them into human care. Ninety experts from nine countries were involved, including researchers experienced in the capture and handling of harbour porpoises, animal care professional, and veterinarians. Two vaquitas were successfully captured (an immature female [V01F] and an adult female [V02F]). In both cases, medical and behavioural evaluations were conducted to determine the suitability of the animals for transport to the floating pen or shore-based facility. Through the whole process the animals' health was continuously monitored by a team of experienced marine mammal veterinarians. The first vaquita caught (V01F) was in good condition initially, but did not acclimate to either the vaquita care centre pool or to the sea-pen facility, and the vaquita was released. V02F was also considered to be in good condition for transport to the sea-pen, however, after initially showing signs of adapting to the facility, the animal stopped swimming and an emergency release was initiated. The release was unsuccessful and the vaquita was quickly recaptured for administration of emergency care. Following three hours of emergency response, the animal went into cardiac arrest and did not respond to resuscitation attempts. Analyses of tissues and material obtained from VH02 is ongoing and a full report on VaquitaCPR will be reported at SC68A.

The survival of the vaquita depends on gillnet-free habitat and efforts to remove gillnets, both derelict and active, have increased dramatically in the last three years, particularly, during the ongoing 2017-18 totoaba season. The net removal programme demonstrates that illegal totoaba gillnets are still routinely set in great numbers in vaquita habitat. Despite enhanced enforcement efforts, there is a continued failure to prevent illegal fishing. CIRVA have stated that immediate action is needed to improve the situation through implementation of a series of recommendations. In particular, CIRVA recommended that the Government of Mexico establish an enhanced enforcement area, extending the boundaries of the existing vaquita refuge.

Attention: SC, CC, CG-R

The Committee has stressed for many years that the vaquita population is at a critically low level, and the most recent evidence demonstrates that the cause of the decline – use of illegal large-mesh gillnets – continues, making extinction in the wild increasingly likely; *the long-term decline in the vaquita reported previously has continued in 2017.* The Committee yet again **re-emphasises the serious concerns** it has raised on the status of the vaquita, and in particular its recommendations of the past two Committee meetings. Whilst again **commending** the Government of Mexico for its attention and response to the CIRVA findings and recommendations, the Committee:

(1) respectfully ***requests*** *that reports continue to be provided annually to the IWC Scientific Committee on actions and progress towards saving the vaquita;*
(2) ***strongly endorses*** *the recommendations of CIRVA10 that:*

(a) the CIRVA10 acoustic monitoring programme, critical for evaluating the effectiveness of conservation actions, be continued as in previous years to provide an annual empirical estimate of population trend;
(b) all Mexican enforcement agencies increase their efforts on land and in water immediately and continue this enhanced enforcement programme for the duration of the period of illegal totoaba fishing (at least until June 2018) to eliminate all setting of gillnets in the range of the vaquita;
(c) emergency regulations be promulgated immediately to strengthen the current gillnet ban and enhance enforcement and prosecution by:

- *(i) eliminating all fishing permits for transient fishermen and limiting fishing access to only those fishermen who can demonstrate residency in the fishing villages;*
- *(ii) confiscating any vessel that does not have the appropriate vessel identification, permits, and the required vessel monitoring system;*
- *(iii) requiring vessel inspection for each fishing trip at the point of departure and landing;*
- *(iv) prohibiting the sale or possession of gillnets on land and at sea within the area of the current gillnet ban and on adjacent lands within a specified distance of the coastline.*
- *(v) requiring that all gillnets be surrendered or confiscated and destroyed.*

(vi) eliminating the exemptions for all gillnet fisheries, including the curvina and sierra fisheries.

(d) efforts to remove gillnets from vaquita habitat be continued and enhanced and the numbers and locations of new nets recovered be published monthly;
(e) the number of inspections, interdictions, arrests, sentences, and other enforcement actions be published monthly, together with information on observed levels of illegal activities obtained from intelligence operations, for example from drones;
(f) successful prosecution and subsequent penalties be sufficient to deter illegal fishing; and
(g) development of gillnet-free fisheries be enhanced and linkages to incentivise the conversion of the fleet to gillnet-free operations be strengthened.

17.8.2 Yangtze finless porpoise

A rangewide survey of Yangtze finless porpoises (*Neophocaena asiaeorientalis asiaeorientalis*) was conducted in 2017, giving a preliminary abundance of around 1,000 individuals. This indicates that the rapid decline observed between 2006 and 2012 has now slowed, and that numbers may even be increasing in some areas. Nevertheless, the Critically Endangered status of this species remains unchanged. The survey results were encouraging and regarded as a possible indication that *in situ* conservation of Yangtze finless porpoises is feasible, given the marked increase of the number of individuals in Dongting and Poyang Lakes. For the population to make a sustained recovery in both numbers and range, current measures directed towards improving the habitat in the Yangtze River as well as the Dongting and Poyang Lakes must be continued and expanded. The Government of China was commended for the efforts undertaken to improve the YFP habitat. Nevertheless, concern remain over threats such as vessel strikes, bycatch, underwater noise and bridge construction. In addition, the planned construction of a dam across the channel connecting Poyang Lake to the river is an additional concern.

Attention: SC, CG-R

Given the extensive and pervasive nature of the threats facing the Yangtze finless porpoise population, the Committee:

*(1) **commends** the efforts of the Government of China to improve its habitat; and*
*(2) **reiterates** that the primary conservation actions should focus on (a) restoring and maintaining suitable habitat throughout the Yangtze River and associated lakes, including the maintenance of a network of* in situ *reserves and (b) ensuring that genetic diversity is preserved and that harmful human activities are limited.*

17.8.3 Maui Dolphin

The Government of New Zealand reported that its review of management measures is scheduled for later this year. An update was provided on observer coverage of the set net fishery in Taranaki and the trawl fisheries adjacent to existing closure areas (95.5%, and 88.3%, respectively). Outside of this target coverage area, an additional 114 trawl fishing days were observed. No captures of Māui dolphins were reported by observers or fishermen in commercial fisheries in the 12-month reporting period to 31 March 2018. A species-specific, spatially explicit, multi-threat risk assessment is being developed for Māui and Hector's dolphins, the results of which will inform an updated Threat Management Plan later in 2018.

Attention: SC, CG-R, CC

The Committee notes that no new management action regarding the Māui dolphin has been enacted since 2013. It therefore concludes, as it has repeatedly in the past, that existing management measures in relation to bycatch mitigation fall short of what has been recommended previously and expresses continued grave concern over the status of this small, severely depleted subspecies. The human-caused death of even one individual would increase the extinction risk. In addition, the Committee:

*(1) **re-emphasises** that the critically endangered status of this subspecies and the inherent and irresolvable uncertainty surrounding information on most small populations point to the need for precautionary management;*
*(2) **reiterates** its previous recommendation that highest priority should be assigned to immediate management actions to eliminate bycatch of Māui dolphins including closures of any fisheries within the range of Māui dolphins that are known to pose a risk of bycatch to dolphins (i.e. set net and trawl fisheries);*
*(3) **notes** that the confirmed current range extends from Maunganui Bluff in the north to Whanganui in the south, offshore to 20 n. miles, and it includes harbours - within this defined area, fishing methods other than set nets and trawling should be used;*
*(4) **welcomes** the update on Maui dolphins provided and looks forward to receiving the species-specific, spatially explicit, multi-threat risk assessment in 2019.*
*(5) **respectfully encourages** the New Zealand; Government to commit to specific population increase targets and timelines for Māui dolphin conservation,*
*(6) **respectfully requests** that reports be provided on progress towards the conservation and recovery goals as updates become available.*

17.8.4 Cruise report from North Western Africa

For the third year, survey results were reported from cruises conducted in north western Africa waters. Fourteen schools comprising some five species and totalling 433 individuals were sighted, including bottlenose dolphins, both pantropical and Atlantic spotted dolphins and, spinner dolphins. This area is poorly surveyed and the continuation of this work was encouraged. The Committee **suggests** that a more substantive analysis of the data from all surveys be conducted and reported back next year, particularly as SC68A priority topic will be on African small cetacean species.

17.8.5 Monodontids Workshop Report

NAMMCO hosted a workshop and produced a Global Review of Monodontids. Researchers and subsistence hunters from across the Arctic and subarctic participated. Several IWC scientists also participated, including Litovka, Reeves, and Suydam. The report[9], summarises what is known about the status of 12 stocks of narwhals and 22 stocks of white whales. There may be more stocks than this as information on stock structure is incomplete for some areas. The summary information and identification of threats and concerns within the report will be helpful in prioritising future research. Some stocks are doing well, but conservation actions are desperately needed for some others. The IUCN Red List status and documentation for both species was updated to Least Concern in December 2017 and that the information summarised in the NAMMCO review was very useful for those assessments.

Attention: C-A

The Committee ***welcomes*** *the report of the NAMMCO workshop reviewing the monodontids[9]. It* ***draws attention to*** *the recommendations contained in the report and* ***encourages*** *their implementation, particularly those pertaining to the stocks of greatest concern.*

17.9 Takes of small cetaceans

7.9.1 New information on takes

The Committee received the summary of takes of small cetaceans in 2016–17 extracted from the online National Progress Reports and prepared by the IWC Secretariat, in addition to information obtained online.

No direct takes of small cetaceans were reported in the 2017 National Progress Reports. The Committee **notes** that it would be helpful if the Secretariat encouraged all member countries and IGOs (e.g. NAMMCO) to submit information on direct takes as a routine procedure.

The content of the Japan Progress Report on Small Cetaceans, a public document available from the website of the Fishery Agency of the Government of Japan[10], was summarised. It was noted that catch statistics in the Japan Progress Report on small cetacean cover catches in the calendar year, that is, from 1 January to 31 December, following the guidelines for IWC National Progress Report, while the catch quota of small cetacean fisheries are set seasonally. Thus, in some cases, the calendar yearly catch may exceed the seasonal (yearly) catch in appearance, but in such cases, the actual seasonal catch is aligned with the allocated catch quota. The Committee noted that the catch of 1,057 Dall's porpoises in the hand harpoon hunt was significantly lower than previously recorded reported and below the quota. It was stated that this is a result of the destruction of the community that conducts this hunt, rather than a change in the cetacean population, following the earthquake and tsunami of 2011.

7.9.2. Live captures

The Pacific Scientific Research Institute of Fisheries and Oceanography (TINRO) will consider a quota of 13 killer whales for 2018 and a public hearing was held on 3 May 2018 to make comments on this plan. This proposed new quota considers killer whales in the Sea of Okhotsk as one population, which is estimated to have an abundance of over 3,000 individuals. This number is considered minimal as only 50% of the sea was surveyed. In addition, the information available to the Russian Government on colour and fin patterns, feeding behaviour and distribution do not allow clear identification of different ecotypes, and that all genetic samples analysed to date belong to a single population. It was noted that most published information on Okhotsk Sea killer whale abundance and stock structure is in Russian-language literature, or as part of internal documentation.

Attention: C-A, CG-A
With respect to live captures, and specifically the capture of killer whales from the Sea of Okhotsk, the Committee:

(1) ***reiterates*** *its long-standing recommendation that no small cetacean removals (live capture or directed harvest) should be authorised until a full assessment has been made of their sustainability;*
(2) ***notes*** *that this is especially important for killer whales because populations are generally small and have strong social bonds and removals have unknown effects on their demographic structure; and*
*(3) r****eiterates*** *its concern that removals of killer whales are occurring from the Okhotsk Sea population.*

---

[9] https://nammco.no/wp-content/uploads/2018/05/report-global-review-of-monodontids-nammco-2018_after-erratum-060518_with-appendices_2.pdf
[10] *http://www.jfa.maff.go.jp/j/whale/w_document/attach/pdf/index-9.pdf*

In light of the verbal report received at this meeting that Russian authorities intend to proceed to consider limits of allowable live-capture removals of killer whales in the Sea of Okhotsk on the basis that there is no stock structure and there are no ecotype differences between the populations in this region, the Committee:

(1) ***encourages*** *more extensive effort to examine these issues; and*
(2) ***requests*** *that relevant analyses be provided for the Scientific Committee's consideration at its next meeting.*

17.10 Status of the voluntary fund for small cetacean conservation research

In 2017, donations for the Voluntary Fund for Small Cetacean Conservation Research totalling £13,122 were received from the Government of Italy. At the end of the financial year 2017, this brought the total of the fund to £81,077.

The Committee **expresses its sincere gratitude** for Italy's contributions and notes that these funds support critical conservation research projects of direct relevance to the work of the Committee.

Five projects were offered funding in 2016 and were implemented in 2017. One of the projects has since been withdrawn and one project, the Indus river dolphin abundance survey, was completed and reported on in 2017. The remaining three projects, on the 'Chilean Dolphin' in Chile, the 'Use of small cetaceans as wildmeat in China' and the 'Development of a business model for sustainable fisheries in the Upper Gulf of California, Mexico', are all near completion and will be reported on fully next year. Updates are available on the IWC website.

17.11 Work plan and budget requests

17.11.1 Priority topics for 2019 to 2024

The sub-committee on Small Cetaceans discussed ongoing priorities and will continue the development of these intersessionally; however, given the location of the meeting it is likely that the focus will be on African species or areas during 2019-20. Other potential priorities identified in discussions were *Inia* (e.g. taxonomy), *Sotalia guianensis*, *Phocoena phocoena*, *Delphinus delphis*, southern hemisphere beaked whales, *Steno bredanensis*, Northwest Pacific *Orcinus orca* and 'the Caribbean'.

17.11.2 Work plan for 2019 – 2020

The workplan on issues related to small cetaceans is given in Table 23.

Table 23

Work plan on small cetaceans

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Franciscana CMP	ICG (Annex Y) to co-ordinate outcomes of CMP across sub-committees	Report	ICG (Annex Y) to synthesis actions from 2019 SC report and develop a work plan	Report
Wildmeat	ICG (Annex Y) to plan and conduct African Workshop.	Report	ICG (Annex Y) group to summarise workshop series and develop future work plan.	Report
Small Cetacean Task Team	Intersessional Workshop on South Asian river dolphins.	Report	Act on recommendations from 2018/19 River dolphin workshop.	Report
Sotalia	SG (Annex Y) to plan and conduct workshop #1 (at SOLOMAC)	Report	SG (Annex Y) to plan and conduct workshop #2	Report

18. WHALE WATCHING[11]

The report of the sub-committee on whale watching is given as Annex N.

18.1 Assess the impacts of whale watching and swim-with-whale operations on cetaceans

18.1.1 Review progress of Modelling and Assessment of Whale Watching Impacts (MAWI)

Modelling and Assessment of Whale Watching Impacts (MAWI) has been on the Committee's agenda for several years. In April 2018, an intersessional workshop was held to identify the key research questions for understanding the potential impacts of whale watching on cetaceans (SC/67b/Rep03). A number of issues were highlighted, including: (a) the need to better understand the impact of recreational whale watching vessels as compared to commercial vessels; (b) the importance of looking at the potential impact of whale watching at short-term (e.g., behaviour change), mid-term (e.g., shift in habitat use) and long-term (e.g., population dynamics) time scales; (c) the use of existing and new data to explore the mid- and long-term impacts, as opposed to replicating short-term studies; and (d) the importance of building scientific capacity in the locations where the research would take place. More information can be found in Annex N, item 2.1.

---

[11] In response to a request from the Chair of the Whale Watching Working Group of the Conservation Committee, we have changed our past practice of treating whalewatching as a single word to the use of two words.

Attention: SC, C-R

The Modelling and Assessment of Whale Watching Impacts (MAWI) initiative held a workshop in Italy in April 2018, in conjunction with the 32nd European Cetacean Society conference.

The Committee ***endorses*** *the following recommendations from this workshop:*

(1) the incorporation of both social and natural sciences to better understand whale watching impacts;
(2) the development of a Strategic Framework, supported by a Decision Tree, to aid in the prioritisation of policy and research choices;
(3) the development of toolkits and resources that can be accessed globally; and
(4) the standardisation of data collection.

The Committee also ***agrees*** *that a third MAWI workshop be held intersessionally, ideally just before or after the 2nd World Marine Mammal Science Conference in 2019, in Barcelona, with the following objectives:*

(1) to determine in detail which data should be collected to best answer the natural and social science research questions developed in SC/67b/Rep03;
(2) to identify the best locations for conducting research projects that address these questions; and
(3) to continue to develop modelling approaches for assessing the long-term impacts of whale watching on cetacean populations (using data on short- and mid-term impacts).

18.1.2 Review specific papers assessing impacts

The Committee received several papers regarding impacts to cetaceans from whale watching activities. Those papers included (1) efforts to assess stress hormones in baleen of southern right whale calves, (2) ‘solitary sociable’ cetaceans, (3) land-based observations in the Canary Islands to assess and mitigate potential impacts of whale watching vessels on cetaceans, (4) a Whale Welfare Assessment Tool (also presented and discussed in Plenary) and (5) the 15th year of a summary of papers published in the previous year related to a better understanding of impacts, mitigation and compliance to regulations. Additional details on these papers and projects can be found in Annex N, item 2.2.

Attention: SC, CG-A

The term ‘solitary sociable dolphin’ or cetacean is usually taken to apply to cetaceans that have little or no contact with conspecifics and who regularly closely approach humans, often including touch, social, sexual and play behaviours (Wilke et al.*, 2005). Given that solitary sociable cetaceans often end up in circumstances where they are harmed and killed and that they may come to present a threat to human swimmers, the Committee:*

(1) ***agrees*** *to continue intersessionally to monitor the phenomenon of solitary sociable cetaceans as part of its work;*
(2) ***advises*** *that, where these animals occur, research be conducted to determine whether the emergence of harmful behaviours either to the animal or to people can be reversed; and*
(3) ***advises*** *local authorities and other concerned parties to keep people away from them in order not to encourage behaviour that may prove harmful to the animal or swimmers.*

In addition, the Committee ***agrees*** *that the Whale Welfare Assessment Tool (currently being developed at the Royal Veterinary College, University of London, in the context of the IWC Whale Killing Methods and Welfare Issues Action Plan), for which a hypothetical whale watching case study was trialled (Annex N, item 2.2), be applied to real-world whale watching situations. The southern resident killer whales in Washington, USA and the bottlenose dolphins in Bocas del Toro, Panama were proposed. These two populations are subject to intense whale watching pressure and may be suffering welfare and health impacts related to this pressure. Both locations have data relevant to the assessment tool and therefore seem ideal as pilot projects for its application.*

18.1.3 Consider documented emerging areas of concern (e.g., habituation, new areas/species, new technologies, in-water interactions) and how to assess them

The Committee received several papers about emerging areas of concern regarding whale watching, including (1) human-induced behavioural changes, (2) impacts from recreational in-water interactions with cetaceans and (3) purposeful and inadvertent feeding by humans.

The Secretariat for the Convention of Migratory Species (CMS) submitted several documents to SC/67b including a global review of in-water interactions with aquatic mammals. That review had resulted in a CMS resolution that encouraged Parties to facilitate research allowing for an assessment of the long-term effects and biological significance of disturbances from ‘swim-with-marine-mammal’ programmes. The topic of swimming with cetaceans is also addressed under Item 18.6.

The Committee received reports about several studies to assess the impacts and compliance with regulations of commercial ‘swim-with-whale’ operations in Australia. The discussion of this issue can be found in Annex N, item 2.3.

Attention: SC, CC, S

*The Committee **agrees** that the habituation intersessional correspondence group, now named human-induced behavioural changes of concern, should continue (see Annex N, table 3).*

Given the substantial effort the Convention on Migratory Species (CMS) Secretariat has made in preparing several documents for the Committee to consider this year, the Committee:

*(1) **recommends** a continuation and an expansion of this exemplary collaboration between the IWC and CMS Secretariats and their various committees;*
*(2) **endorses** the intention of CMS to work with the IWC Scientific Committee on guidelines for in-water interactions with aquatic mammals and **offers** to provide the scientific underpinning for these guidelines;*
*(3) **agrees** that the Committee's intersessional correspondence group on swim-with-whales work intersessionally with the CMS Aquatic Mammals Working Group to develop draft guidelines; and*
*(4) **offers** to review draft guidelines when they are ready, with a view to **agreeing** a joint product of the IWC and CMS and hosted by both websites as a global resource.*

See also Item 18.6 for additional recommendations related to swimming with cetaceans.

18.2. Consider information from platforms of opportunity of potential value to the Scientific Committee

The Committee received examples of several platforms of opportunity where data have been collected concerning habitat use, behaviour, changes in distribution and potential risks from shipping for multiple different species in several different areas. Of particular interest was Peninsula Valdés, Argentina, where approximately 460,000 photographs have been taken from whale watching boats and provided to researchers from the Instituto de Conservación de Ballenas and Ocean Alliance (SC/67b/WW04). See Annex N, item 3.

The Committee offered numerous suggestions as to how to handle the large number of images and **encourages** the researchers to network with other researchers around the world, particularly humpback whale researchers dealing with similarly large numbers of photographs and multiple catalogues, to improve the processing time of the photographs.

18.3 Whale watching in east Africa and the wider Indian Ocean

A proposal for Concerted Action for Arabian Sea humpback whales was passed by CMS with strong support from range states. This was discussed in Annex N, item 4.

Attention: CC, S, CG-A

Noting the Committee's discussions over several years on the status of the Arabian Sea humpback whales (see Item 10.2.1), the Committee:

*(1) **welcomes** the CMS proposal for Concerted Action for Arabian Sea humpback whales;*
*(2) **notes** that humpback whales are the target of one emerging whale watching operation in the south of Oman and **highlights** the likelihood that the population could become the target of future whale watching activities;*
*(3) **emphasises** the need for regulators and scientists to work with the industry to ensure that whale watching does not add to the many other pressures on this small, isolated, non-migratory and endangered population.*

The Committee therefore:

*(1) r**ecommends** that building capacity to conduct needed research and to ensure consistent training of whale watching operators be a high priority for Omani authorities and other parties working on the recovery of the endangered Arabian Sea humpback whale population;*
*(2) **notes** that boat operators for cetacean watching operations appear to turn over at a high rate in this area, and **recommends** that training workshops should be regularly offered and conducted;*
*(3) **welcomes** the offer from the Pacific Whale Foundation to help organise and conduct another training workshop, but **recommends** a more comprehensive plan be implemented by the Omani authorities, working with the IWC and other interested parties, to build local capacity for such training; and*
*(4) **agrees** to retain a review of whale watching in east Africa and the wider Indian Ocean region in its work plan (see Annex N, table 4) and to conduct an intersessional review of whale watching in these areas, to be presented at SC/68a.*

18.4 Review Whale Watching Strategic Plan (2018-2024) and joint work with the Conservation Committee

18.4.1 Review and provide recommendations on the draft Strategic Plan

At SC/67a, the Conservation Committee's SWG on Whale Watching requested the Scientific Committee to review a draft of the next iteration of the IWC's Strategic Plan (2018-2024) on Whale Watching (see SC/67b/WW02). This was accomplished primarily during a SC/67b pre-meeting and then further discussed in Annex N (item 5 and appendix 2).

Attention: CC

The Committee ***draws the attention*** *of the Conservation Committee's Standing Working Group on Whale Watching (SWG) to Annex N, appendix 2, which provides a full set of comments on the draft Strategic Plan (2018-2024) on Whale Watching. The most important comments and recommendations from the appendix are highlighted below:*

(1) The addition of an Action 1.5: Develop a communications strategy to actively promote IWC whale watching resources (e.g., the Handbook, reports and training opportunities), with approaches tailored to target key audiences. These audiences include the public and whale watching managers, researchers, operators, and on-board naturalists. Communication actions could include preparing publicly accessible summaries of IWC whale watching reports, improving the whale watching pages on the IWC website (which is already underway with the new Whale Watching Handbook, see Item 18.5), and promoting resources on social media, at key meetings and via press releases to industry bodies and trade publications. The implementation of this action could be coordinated intersessionally via the Secretariat. A joint intersessional working group, which includes key Secretariat staff, could develop a communications strategy for consideration at IWC/67 (the Brazil Plenary meeting) and/or the joint session of the CC/SC at SC/68a.

(2) The replacement of the actions of Objective 2 in the draft Strategic Plan with the following:

a) Action 2.1 – Continue the Modelling and Assessment of Whale Watching Impacts (MAWI) initiative, to develop tools and methodologies to assist researchers and managers in their efforts to assess potential impacts of whale watching on cetaceans and to mitigate them. This initiative is ongoing and could focus on:

i) Investigating modelling methods to link short- (e.g., behavioural reactions) and medium-term (e.g., changes in population distribution) responses with potential impacts from whale watching to long-term (i.e., >10 to 20 years) consequences (e.g., vital rates).

ii) Establishing standard data collection methodologies, including from platforms of opportunity.

iii) Identifying key locations for whale watching research projects and programmes, taking into consideration logistics, capacity and management urgency;

b) Action 2.2 – Develop a long-term integrated research programme to better understand the potential impacts of whale watching on the demographic parameters of cetacean populations. Seek to:

i) Investigate whether there is a causal relationship between whale watching exposure and the survival and vital rates of exposed cetacean individuals and populations;

ii) Understand the mechanisms involved in causal effects, if they exist, in order to define a framework for improved management;

c) Action 2.3 – Develop processes and mechanisms for whale watching activities to collect and provide scientifically robust and useful data to researchers and research programmes; and

d) Action 2.4 – Develop an approach (e.g., hold an intersessional workshop; establish a joint intersessional working group) to integrate social and ecological scientific research within the IWC to inform whale watching management and promote potential benefits. This is a coordinated action between the SWG and the sub-committee.

In particular, Action 2.2 will require a dedicated person to guide and coordinate the development and implementation of a research programme or plan. The best option would be for the SWG to contract with someone, full- or part-time, to carry out this task, whilst recognising the budgetary concerns. Therefore, the Committee ***recommends*** *that the search for funding for this and all other actions in the Strategic Plan be focused, broad-ranging, and innovative. An alternative, if budgetary issues are prohibitive, is to have the research programme developed intersessionally by an intersessional correspondence group or the convenor and co-convenor of the Committee's sub-committee on whale watching.*

Lastly, the Committee ***reiterates*** *its previous recommendation to improve the coordination between the SWG and the Committee's sub-committee on whale watching in the development and implementation of a Strategic Plan on Whale Watching. This year's 21 April pre-meeting to review the draft Strategic Plan was intended to improve coordination and provided an opportunity to contribute to the draft Strategic Plan but it did not completely achieve the goal of coordination, as a limited number of SWG members were able to attend the pre-meeting.*

18.4.2 Develop procedures to provide scientific advice as requested in the plan (including the online handbook) and make the Committee more effective at providing information to the Commission

The revised Actions 2.1-2.4 in Item 18.4.1 outline how the sub-committee on whale watching will collect information needed to inform the Conservation Committee's SWG on Whale Watching. Procedures for providing this advice will be discussed and determined cooperatively with the Conservation Committee, during the joint meeting immediately after SC/67b and intersessionally through the intersessional correspondence group (see Annex N, table 3,).

18.5 Whale watching handbook

18.5.1 Review and provide comments on the IWC's Whale Watching Handbook

The Whale Watching Handbook (Handbook) was presented. Before being made available to the public it will also be translated into French and Spanish with support from CMS. Annex N (item 6) provides additional comments and suggestions for fine-tuning and improving the already-admirable Handbook.

Attention: CG-R, SC, S, CC, C-R

The Committee ***welcomes*** *the presentation of the online Whale Watching Handbook and* ***agrees*** *that it is comprehensive, scientifically substantive, user-friendly and well designed.*

To ensure the IWC Whale Watching Handbook comes to the attention of the international whale watching community, including managers, operators and the public, the Committee ***recommends*** *that all Contracting Governments provide a link to the Handbook on the relevant agency pages of their own government websites once the Handbook goes 'live'.*

The Committee also ***recommends*** *that the Conservation Committee and the Commission develop a plan for identifying and securing long-term funding for the further development (e.g., translations into additional languages, writing additional case studies or country profiles) and the ongoing maintenance (e.g., periodic reviews of content) of the IWC Whale Watching Handbook. The Handbook must be updated regularly to remain a vibrant, living document.*

18.6 Review reports from intersessional correspondence groups

The Committee received information from the intersessional correspondence groups (ICG) of swim-with-whale operations and communication with IORA. Annex N provides details of (1) the discussion related to the intersessional work of the ICG on swim-with-whale operations (item 7.1) and (2) the discussion related to the intersessional work of the ICG on IORA communication (item 7.2).

Attention: S, SC, CC, CG-A, CG-R

Regarding swim-with-cetacean operations, the Committee:
(1) ***agrees*** *that the intersessional correspondence group on swim-with-whale operations (Annex N, table 3) should continue;*
(2) ***draws attention*** *to guiding principles for whale watching, including in-water interactions, that are being or have been developed by various regional bodies, such as the Convention on Migratory Species and UNEP in the Wider Caribbean (see Annex N, item 2.3 and UNEP-CEP, 2012), that advise that swimming with cetaceans be discouraged where it is not already established; and*
(3) ***recommends*** *that, in jurisdictions where swim-with-cetacean activities have not been occurring or are just starting, this practice be prohibited until there is scientific evidence that supports allowing it, noting that the risks to both humans and cetaceans are substantial if operators are inexperienced and not following any relevant guidelines; and*

The Committee also ***welcomes*** *the increased communications between IORA and the IWC over the past year. The IORA Sustainable Whale and Dolphin Watching Tourism Network was established and Australia will convene the Network in its first year of operation and will produce a biannual newsletter. Consequently, the Committee:*

(1) ***agrees*** *that the intersessional correspondence group on communication with IORA (Annex Y) should continue; and*
(2) ***encourages*** *greater engagement between the IWC and IORA on whale watching, beyond the exchanges amongst the intersessional correspondence group (Annex N, table 3).*

18.7 Review progress on scientific recommendations

18.7.1 Global influence of recommendations

The Committee received information about the influence of previous recommendations in numerous countries. Details can be found in Annex N, item 8.1.

18.7.2 Tracking progress on previous recommendations

The sub-committee on whale watching reviewed 27 of its recommendations and agreed statements from the past two years. Of those, 15 were completed or partially completed, nine are on-going, and three have not yet been addressed. Annex N, item 8.2, provides details about those recommendations and agreed statements. There is also ongoing work to update and finalise the terms of reference for the sub-committee on whale watching.

18.7.3 Update on dolphin watching in Bocas del Toro, Panama

Concern continues about the number of dolphins from the small population in Bocas del Toro, Panama that are found dead. Nine deaths in 2016 and 2017 are known to have occurred, five of them confirmed boat strikes. These losses are unsustainable. Research to better understand impacts on the population includes measuring stress hormones in biopsy samples and acoustic monitoring. A regulatory update to strengthen management of whale and dolphin watching in Panama, including Bocas del Toro, was released in October 2017, with the support of the Ministry of Environment.

Attention: SC, C, CG Panama

The Committee ***reiterates*** *its grave concern regarding the intense and uncontrolled dolphin watching in Bocas del Toro, Panama. This concern has been expressed and reiterated for several years due to continuing mortalities, including from vessel strikes, in this small population (probably fewer than 100 animals). In this regard, the Committee:*
(1) ***welcomes*** *the ongoing research to monitor this dolphin population and the impacts it is facing from dolphin watching;*
(2) ***reiterates*** *its welcome of Panama's increased responsiveness to protect the local dolphin population by minimising negative impacts from dolphin watching (IWC, 2018a) and* ***welcomes*** *the regulatory update, supported by the Ministry of Environment, which is meant to lead to stronger management of whale and dolphin watching in Panama, including Bocas del Toro; and*

(3) ***expresses serious concern*** *at the number of deaths reported in 2016 and 2017 and* ***recommends*** *action from the Government of Panama as a matter of urgency, including the immediate and committed implementation of the updated regulations.*

18.8. Work plan and budget requests for 2019-2020

18.8.1 Work plan for 2019-2020

The work plan for matter related to whalewatching is shown in Table 24.

Table 24

Summary of the work plan for matters related to whale watching. Many of these items have intersessional correspondence groups (ICG) or intersessional advisory groups (IAG). Those groups will work intersessionally and provide updates at SC/68a (see Annex X)

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting

19. SPECIAL PERMITS

19.1 General considerations on improving the evaluation process

This issue is considered as part of the process to revise ‘Annex P’ (see discussion in Item 28.3).

19.2 NEWREP-A

Summaries of NEWREP-A papers are given in Annex U1.

19.2.1 Report on ongoing research

In plenary, the Committee received and briefly discussed four papers on ongoing work – as indicated below, some of these were discussed more fully in sub-groups.

SC/67b/SP08 presented the results of the third biological field survey of NEWREP-A during the 2017/18 austral summer season. In discussion, it was noted that the high apparent pregnancy rate (95.3%; 122 of 128 mature females) of Antarctic minke whales was consistent with previous results (e.g. from JARPA and JARPA II).

SC/67b/ASI07 presented a summary of results of the NEWREP-A dedicated sighting survey during the 2017/18 austral summer season whilst SC/67b/ASI11 presented the research plan for the next systematic vessel-based sighting survey in the Antarctic under NEWREP-A 2018/19. The new NEWREP-A 2018/19 sighting survey plan has been endorsed by the Committee; Annex Q (item 4.2) provides more details on both these papers.

SC/67b/EM05 presented results of the krill and oceanographic surveys undertaken during the third NEWREP-A survey in Area V-E and VI-W (see Annex L, item 6.1 for details).

19.2.2 Update on previous recommendations

19.1.2.1 AGE DATA AND RMP/IST (RECOMMENDATION 1)

SC/67b/RMP03 provided updated draft specifications for an RMP/IST type simulation exercise to evaluate management procedures based on modified catch limit algorithms that use information on recruitment inferred from age data from Antarctic minke whales. Details and discussion are given in Annex D, section 2.3.2.

Attention: S

The Committee ***agrees*** *that methods currently used or proposed to be used in the Committee that use age data should (as necessary) be investigated to evaluate the relationship between their results and the accuracy and precision of the age data that they use where this is pertinent to the results of import from these methods. The Committee* ***agrees*** *to include this as an agenda item for next year’s meeting.*

19.1.2.2 BIOPSY SAMPLING AND TELEMETRY FEASIBILITY STUDIES (RECOMMENDATIONS 4 AND 5)

SC/67b/SP04 summarised the results of a feasibility study on biopsy sampling and satellite tagging of Antarctic minke whales under NEWREP-A. The authors concluded that in the context of the NEWRREP-A objectives, (a) the efficiency of biopsy sampling is much lower than that of lethal sampling for Antarctic minke whales and (b) that the amount of tissue derived from biopsy samples is insufficient to conduct the suite of biomarkers targeted by NEWREP-A. They therefore concluded that biopsy sampling was not a feasible approach to fulfil the objectives of NEWREP-A.

This paper prompted considerable discussion in the Committee, both with respect to 'efficiency' of the method and the amount of material required.

One issue raised was that there was the need for better clarification of terminology used in the paper (e.g. 'sampling' versus 'killing) in order, for example, to interpret properly the conclusion that biopsy sampling took approximately three times longer than lethal sampling. It was not clear, for example, whether the median times for biopsy and lethal sampling provided were truly comparable because of the lack of information on when the time for these methods started and ended. In particular, handling time for lethal sampling appeared to not be included in the total time calculations.

The authors responded that in SC/67b/SP04 'the efficiency' of sampling techniques was defined as 'Success Proportion' rather than 'Time of Experiment' because 'Success Proportion' represents a better indicator of the efficiency. To fulfil the purposes of NEWREP-A, random sampling is required in which generally only one animal from a school is sampled. Notwithstanding this clarification, they provided definitions of 'Time of Experiment' (see details in Yasunaga *et al*. in Annex U2).

Another issue raised was that the NEWREP-A review workshop (ref) had suggested 'involving people with expertise in successfully biopsy sampling common minke whales in the North Atlantic', meaning collaborating in the field with experienced foreign experts. However, Table 2 of SC/67b/SP04 showed an ongoing decline in success proportion (number of biopsy samples / number of targeted whales which were chased for sampling by the SSVs) between 2015/2016 and 2017/2018 rather than the increase one would expect with increasing experience. The authors responded that they had consulted with foreign scientists although they were not on the vessels, that they used experienced marksmen and that the decline was an artefact of weather and sea state conditions under which samples were collected. However, the counter-comment was made that in authors' analyses, the best model did not include "weather conditions" as a significant factor.

In response the authors provided results of a GLM analysis based on the binomial distribution assumption to examine the differences in success proportion in the biopsy sampling experiment using research seasons as explanatory variables. The coefficients for each year were not significant, suggesting that the differences of success proportions among the seasons are not statistically significant and consequently provide no evidence that shooters' efficiency has decreased significantly over the three research seasons (see details in Yasunaga *et al*. in Annex U2).

Some Committee members (see Clapham et al. I, in Annex U2) disagreed with the authors' conclusion that the study revealed that biopsy sampling was not feasible for the NEWREP-A programme. Rather, they believed that it showed that it was both feasible and appropriate. They also disagreed that the amount of tissue obtained was insufficient, citing the large number of research programmes that successfully use biopsy samples to fulfil research objectives including using a single sample for a variety of biomarkers (e.g. stable isotopes, fatty acids, hormones, genetics).

In response, the authors agreed that the amount of epidermal tissue collected by biopsy sampling is enough for the requirement of genetic, epigenetic and stable isotope analyses. However, they stressed that the amount of adipose tissue collected by biopsy sampling was not large enough to measure progesterone, lipid content and fatty acid in the context of the objectives of NEWREP-A (see details in Yasunaga *et al*. in Annex U2).

In their closing comments, the authors stated that in response to the recommendation of the Expert Panel, dedicated experiments for biopsy sampling of Antarctic minke whales had been carried out which had generated the results presented at this meeting and from which the authors had drawn their conclusions. No further dedicated time for biopsy experiments was planned at this stage, but this could be reconsidered at the mid-term review. Meanwhile, NEWREP-A will only collect additional biopsy samples opportunistically.

With respect to the best approach to assess the efficiency of biopsy versus lethal sampling, a standard approach for measuring the efficiency of biopsy sampling and to compare this to the process of lethal sampling was proposed (Clapham et al. II, in Annex U2).

Attention: S

The Committee had last year agreed on establishing an intersessional Advisory group tasked 'to provide advice on developing an experimental protocol for ascertain whether it is possible to reliably biopsy minke whales and, if so, under what circumstances (experience, vessel type, equipment, environmental conditions, etc.). This group could use as starting point the advice provided by the Expert Panel' (JCRM 19 suppl:431-490). Due to a clerical error the group did not convene. Attention was drawn to a protocol to evaluate non-lethal techniques presented to SC66b (Mogoe et al., 2016). This protocol included four questions to help identify the feasibility and practicability of non-lethal methods.

The Committee ***agrees*** *to re-establish the Advisory group (Annex Y), under Palka for consideration at SC68a. It also* ***agrees*** *that suggestions for refining questions in the method used by Mogoe and colleagues (2016) should be added to the tasks of this group.*

19.1.2.3 EPIGENETIC AGEING (RECOMMENDATION 8)

Recently, epigenetic (DNA-methylation) ageing has been successfully used to estimate age in humpback whales (Polanowski *et al.* 2014). As noted under Item 11.4.4, this year, the Committee invited Jarman, the leading specialist in this technique to give an overview presentation to the Committee as a special night session. This covered topics such as current and future prospects for this class of methods (see Annex I, item 5.5).

SC/67b/SDDNA04 presented a feasibility study on epigenetic ageing in Antarctic minke whales in response to Recommendation 8 from the Expert Panel (for details see Annex I, item 5.5).

Some suggestions were made on how to improve resolution (in particular, evaluate more loci and then restrict to those loci highly correlated with age); the current set of loci do not provide sufficient precision for use in the population dynamics modelling exercise recommended for NEWREP-A. Given that there is an upper limit to the degree of precision that can be achieved using this technique, the Committee noted that the utility of epigenetic age estimation (and other methods of age determination) will depend on the degree of precision needed for the specific application of interest (see recommendation under Item 11.4.1).

19.1.2.4 DETERMINING SEXUAL MATURITY IN BLUBBER (RECOMMENDATION 9)

SC/67b/SCSP05 presented results from the NEWREP-A research component focused on determining sexual maturity in female Antarctic minke whales, during the feeding season based, on concentrations of progesterone in blubber. The authors concluded that the progesterone concentration in blubber samples cannot be used as a diagnostic index to discriminate between mature and immature female Antarctic minke whales and that lethal sampling is required to obtain information on sexual maturity for use in population dynamic models.

Some members of the Committee disagreed with that conclusion, as they demonstrated that the amount of misclassification in immature versus mature females would be small (~1%, see Wade *et al.* in Annex U2) and thus that progesterone levels in biopsy samples would allow discrimination between mature and immature animals.

They noted that the stated purpose of the study was to discriminate between immature and mature females for fitting population dynamics models such as the catch-at-age analysis; the only misclassification that occurred was a total of 3 (out of 230) whales between the resting and the immature classes, and therefore the only misclassification rate that is important remains ~1% of the total sample.

Some other members noted, also in relation to recommendation 10, that misclassification for discriminating between resting and immature animals was higher and thus the method less reliable for that task.

In response to a request, the authors provided a histogram showing the numbers of immature, resting, ovulating and pregnant animals (Figure 1 of Yasunaga *et al.* in Annex U2). Based on the assumption of cut off values (1.0 ng/g) of progesterone set in Wade *et al.* (see in Annex U2), six of 56 immature whales and three of 11 resting whales were misclassified. Misclassification ratios were thus10.7% and 27.2%, respectively, and these were not considered negligible by the authors (see details in Yasunaga *et al.* in Annex U2).

19.1.2.5 SAMPLE SIZES REQUIRED TO DETECT CHANGE IN ASM (RECOMMENDATION 26)

SC/67b/SCSP01 focused on the need to complete NEWREP-A recommendation 26 on the calculation of sample size. The Committee discussed its previous conclusions in this regard. In 2016, the Committee assessed that three of six aspects of the Expert Panel's recommendations had been adequately addressed in relation to sample sizes. Some members of the Committee consider that until the proponents fully implement the Expert Panel recommendations for calculating sample sizes, the proponents have not demonstrated that they are able to meet their stated objectives in relation to the NEWREP-A programme. The proponents' position and that of some Committee members is that the work has been completed to a reasonable level and that any further work on sample sizes will be afforded a low priority.

The Proponents reiterated their position regarding the work on and status of recommendation 26 ('Provide a thorough power analysis of sample sizes required to detect change in ASM and follow the other recommendations in this item') from the NEWREP-A Review Workshop (IWC, 2016). In view of the proponents, the work on recommendation 26 has been completed to a reasonable level. Details can be found in GOJ (2015; 2016a) and GOJ (2016b). The IWC SC has already concluded that the approach being taken to address the recommendation is appropriate (IWC 2018). Consequently, the proponents have concluded that the reasonableness of the proposed sample size (333) has been adequately demonstrated. The proponents recognize that in 2016 the Scientific Committee suggested some further refinement work; however, they consider that such refinement work goes beyond the original scope of recommendation 26 from the NEWREP-A review workshop. Nevertheless, in deference to the Committee, it was the proponent's intention to address the refinement work for this year's Scientific Committee. However, because of unanticipated specialist personnel unavailability, this has had to be postponed. The proponent's intention is to continue contributing to this work subject to logistical constraints and the availability of specialist analysts.

19.1.2.6 COMMITTEE'S ADVICE

The table in Annex U4, provides a detailed update of the Committee's view of progress on previous recommendations. An overview is given in Table 25.

Table 25

NEWREP-A – Overview on progress with recommendations.

Recommendations in are not in priority order. Recommendations that relate to purposes A, B, C and D are higher priority for completion. Recommendations coded uniquely as "*E: Relevant to improve existing components of the proposed programme*" are excluded from this table as they were optional. Key for 'Purpose': *A: To evaluate the contribution of a particular objective or sub-objective of the programme to meet conservation and management needs*; *B: To evaluate the feasibility of particular techniques (whether lethal or non-lethal)*; *C: Relevant to a full evaluation of whether any new lethal sampling is required*; *D: Relevant to issues related to sample size (irrespective of method used to obtain data).*

Recommendation	Purpose	Deadline	Proponents self-evaluation on progress as of SC67b	Committee's comments
(1) Age data and RMP/IST	A, C, D	August 2016	Completed to a reasonable level	SC66b: A range of opinions as to the extent to which this recommendation has been addressed. SC67a: No new information. SC67b: Some information presented (See section 19.1.2.1).
(2) Stock definition	A, D	May 2016	In progress.	SC66b: No progress. SC67a: As in SC66b. SC67b: As in SC66b.
(3) Mixing rates (simulations on precision and bias)	A, D	May 2016	To be completed by the mid-term review.	SC66b: No progress. SC67a: As in SC66b. SC67b: As in SC66b.
(4) Biopsy feasibility study	B, C, D, E	Field season 2017-2018	Completed.	SC66b: Some progress (SC/66b/IA05). SC67a: Some progress (SC/67a/ASI07). SC67b: Partially completed, further refined analysis is needed (see 19.1.2.2). A WG was formed to review and improve methods.
(5) Telemetry feasibility study	B, E	Field season 2018-2019	Completed.	SC66b: Some progress (SC/66b/IA05). SC67a: Some progress (SC/67a/ASI07). SC67b: Completed.
(8) DNA methylation ageing technique	B, C, D	March 2017	Completed.	SC66b: No progress. SC67a: As in SC66b. SC67b: Partially completed, further refined analysis is encouraged. See section 19.1.2.3.
(9) Hormones in blubber and sexual maturity	B, C, D	March 2018	Completed.	SC66b: No progress. SC67a: As in SC66b. SC67b: Blubber hormones analysis completed. On accuracy see section 19.1.2.4.
(10) SCAA and misassignment 'resting' females/immature females.	A, C, D	August 2016	To be completed by the mid-term review*.	SC66b: No progress. SC67a: As in SC66b. SC67b: New information presented (SC/67b/SCSP05).
(11) SCAA, density- dependence, and stock mixing	A, C, D	May 2016	Completed*.	SC66b: Partially completed: updates on stock mixing and mixing rates still necessary. SC67a: As in SC66b. SC67b: As in SC66b.
(12) Time-varying natural mortality and SCAA	A, C, D	August 2016	To be completed by the mid-term review*.	SC66b: No progress. SC67a: As in SC66b. SC67b: As in SC66b.
(13) Time varying ASM data and SCAA	A, C, D	May 2016	To be completed by the mid-term review*.	SC66b: No progress. SC67a: As in SC66b. SC67b: As in SC66b.
(15) Krill acoustic sampling	B, E	March 2017	Completed.	SC66b: Completed.
(17) Power analysis for krill abundance	A, E	August 2016	To be addressed.	SC66b: Will be addressed in consultation with CCAMLR specialists SC67a: No progress. SC67b: As in SC66b.
(18) Stomach contents vs krill survey	A, B, C	May 2016	To be addressed.	SC66b: Will be addressed in consultation with CCAMLR specialists SC67a: No progress. SC67b: As in SC66b.
(22) Energy intake (requirements)	A, B, D	August 2016	To be addressed. Need clarification from the IWC SC	SC66b: No Progress. SC67a: As in SC66b. SC67b: As in SC66b.
(23) Stable isotopes in baleen plates	B	August 2016	Completed.	SC66b: Will be addressed in consultation with other research institutions. SC67a: Some progress presented. SC67b: Completed.
(26) Sample sizes required to detect change in ASM	D	May 2016	Completed to a reasonable level	SC66b: Overall, the approach being taken to address the recommendation is appropriate, but some further refinements are required. SC67a: No Progress. SC67b: As in SC67a.

*See note in Table #, Annex U4.

19.3 JARPN II

The new information provided on JARPN II is relevant only to the discussion of the NEWREP-NP 'non-lethal vs lethal' feasibility study (see Item 19.3).

19.4 NEWREP-NP

19.4.1 Report on ongoing research

Three papers were presented on progress made during the 2017 surveys of different aspects of the NEWREP-NP programme (SP03, 06, 07, see Annex U3 for summaries).

In particular, SC/67b/SP03 reported the results of the satellite tagging ofn North Pacific sei whales. A total of 44 tagging attempts were made using SPOT6 tags with the LKArts attachments system. A total of 15 tags were deployed on sei whales, and eight whales were tracked. Two sei whales were tracked for more than 35 days, and both showed longitudinal movement. The authors concluded that the tagging experiment showed that deploying such tags from sighting/sampling vessels was practical, but identified technical improvements to try to increase the tracking period.

In discussion, it was noted that the proportion of successful deployments was low (7 failures in 15 attempts); and suggestions on how to improve this included: (a) strategic placement of tags on the upper body of whales to ensure tag longevity and reduce potential physical impacts (e.g. lesions) and (b) replacement of the current screw-on anchor system with an integrated tag design to decrease the possibility of tag breakage. It was noted that guidelines for cetacean tagging should become available within the next year and published in the IWC Journal. It was noted by the authors that the cause of the failures in SP03 were difficult to evaluate since a tag in an optimal position on the whale had also failed. New tags with a modified anchor system and stopper will be used during the next season.

The Committee welcomes new information on the feasibility of satellite tagging sei whales and notes the valuable movement data collected from two of the longer-term (>35 days) deployments. The Committee **encourages** the collection of more telemetry data and notes that this may help improve abundance estimation (by providing information on correction factors) and provide inferences on stock structure.

SC/67b/ASI10 presented a summary of results of the NEWREP-NP dedicated sighting survey in the western North Pacific in 2017 whilst SC/67b/ASI06 presented the research plan for the next systematic vessel-based sighting survey in the western North pacific under NEWREP-NP in 2018 and 2019. As indicated under Item 24.3, the new NEWREP-NP sighting cruise plan has been endorsed by the Committee; Annex Q (item 4.2) provides more details on both these papers.

19.4.2 Update on previous recommendations

The table in Annex U4, provides a detailed update of the Committee’s view of progress on previous recommendations. An overview is provided in Table 26 (see next page).

Table 26

Summary of status of recommendations relevant to NEWREP-NP

No. of recommendation	Priority by the Committee	Timeline	Proponents self-evaluation on progress as of SC67b	Scientific Committee Evaluation
(1) Lethal vs non-lethal quantitative review of data	Very high	Before start	SC67a: Completed.	SC67a: Different opinions as to whether the recommendation has been met. SC67b: No progress.
(3) Sexual maturity (blubber and serum)	High	Before start	SC67a: Completed.	SC67a: The Proponents demonstrated intention to include analysis of blubber for progesterone, but there are few details of how. SC67b: Partially addressed.
(4) Sightings surveys	High	Before start and annually	Addressed and ongoing.	SC67a: Completed: survey plan was presented. SC67b: Completed: survey plan was presented.
(5) Stomach contents	High	Before start	SC67a: Completed.	SC67a: Completed.
(7) Immune function assays	High	Before start	SC67a: Completed.	SC67a: Completed.
(8) Lipophilic compounds	High	Before start	SC67a: Completed.	SC67a: Completed.
(10) Coordination with IWC-POWER	High	Before start and annually	Addressed and ongoing	SC67a: Completed annually.
(11) Coastal component: sampling strategy	High	Before start	Disagree with Panel	SC67a: No progress as proponents disagree with Panel. SC67b: No progress.
(12) Offshore components: sampling strategy	Very high	Before start	SC67a: Completed.	SC67a: Completed.
(13) downweight historical age-composition data	Very high	Before start	Disagree with Panel.	No progress.
(15) efficiency of biopsy sampling (additional captures unnecessary)	Very high	High priority ASAP in 2017	Disagree with Panel.	No progress.
(17) Telemetry	High	Before start	Ongoing	SC67a: Partially addressed. SC67b: New information (SC/67b/SCSP03).
(21) Sample size (potential reduction of lethal sample size)	Very high	Before start	To be considered by the mid-term review.	SC67a: The possibility for further work has been considered. SC67b: No progress.
(22) Sample size (in general)	Very high	Before start	Not relevant.	SC67a: Small progress. SC67b: No progress.
(23) Impact of catches on common minke whales (subset of 2013 *Implementation*)	Very high	Before start	Disagree with Panel.	SC67a: Major concerns addressed. SC67b: Completed. Refined analyses were presented. It could be reconsidered in the next *Implementation Review.*
(24) Impact of catches on common minke whales (new abundance)	Very high	Before start	Disagree with Panel.	SC67a: Major concerns addressed. SC67b: Completed. Refined analyses were presented. It could be reconsidered in the next *Implementation Review.*
(25) Sei whale (abundance, $MSYR_{1+}$=1%, $MSYR_{mat}$=4%)	Very high	Before start	SC67a: Completed.	SC67a: Completed.
(27) Higher priority to analyses and modelling	High	Before start	Ongoing	SC67a: It is not clear that additional qualified personnel have been hired. SC67b: No progress.
(28) Sample and data archiving, relational database(s)	High	Before start	Ongoing	SC67a: Partially addressed for DNA data and associated biological information.
(29) Contingency plan	High	Before start	Ongoing	SC67a: Partially addressed.

20. WHALE SANCTUARIES

20.1 Review of the Southern Ocean Sanctuary Management Plan

The Schedule amendment establishing the Southern Ocean Sanctuary (SOS) requires the Sanctuary to be reviewed at succeeding ten-year intervals, unless otherwise revised by the Commission. The first review of the SOS took place in 2004 (IWC, 2005) and the second review was completed in 2016 (IWC, 2017). In 2014 (IWC, 2015c), the Commission adopted eight objectives for the SOS (summarised in Annex R, item 3). The Commission also provided terms of reference for the review to be undertaken by the Scientific and Conservation Committees. The Scientific Committee review made several recommendations (IWC, 2017c). These recommendations were taken into account in a draft Southern Ocean Sanctuary Management Plan (SC/67b/SAN01) developed by Australian scientists and discussed in Annex R (item 3). It was noted that, while the draft Plan does contain performance measures, it does not contain criteria for its own review.

The purpose of the draft Management Plan is twofold: (1) to inform the Commission and public about the sanctuary objectives and actions planned for the next ten years; and (2) to propose strategies toward the achievement of the SOS's goals using the best means available and provide clear performance measures for each proposed action.

The operative part of the Plan is a Research and Action Plan that involves assessing and addressing threats and research on the recovery of whale populations and their habitats. The Research and Action Plan is structured based on the Commission's agreed objectives for the SOS. Each objective is linked directly to a measurable objective, action or approach and performance measure.

The Committee also discussed the potential contributions that data and results from the Japanese whale research programme in the Southern Ocean (NEWREP-A) could make to the objectives and goals of the Plan and the Committee agrees to incorporate reference to NEWREP-A under Objectives 4-6.

The amended Plan, with Objectives 1 and 8 (relating to policy) and the chapeau of Objective 5 redacted to clarify that the Committee did not address these elements of the Plan, is given as Annex R (Appendix 2).

A statement from the Government of Japan regarding its position on the SOS and this draft Management Plan is attached as Annex R, Appendix 3.

Attention: C-A, CC, SC,

The Committee reviewed the components of a draft Management Plan for the Southern Ocean Sanctuary (SOS) that are related to science and therefore within its remit and:

(a) ***endorses*** *the measurable objectives, approach/actions and performance measures of Objectives 2 -7 of the amended draft Southern Ocean Sanctuary (SOS) Management Plan (Annex R, appendix 2); and*
(b) ***agrees*** *to include a new standing item on the agendas of all relevant sub-committees and working groups: 'new information relevant to the SOS Management Plan' in order to assist the Commission in monitoring and measuring progress on the scientific objectives of the Plan.*

---

21. SATELLITE TAGGING DEVELOPMENT AND BEST PRACTICES

21.1 Tag Workshop Meeting, Silver Spring, MD, USA 6-8 September 2017

A workshop on cetacean tag development, tag follow-up and tagging best practices was held at the National Marine Fisheries Service in Silver Spring, Maryland, USA from 6-8 September 2017. The workshop was co-sponsored by the Office of Naval Research (ONR), the International Whaling Commission (IWC), and the National Oceanic and Atmospheric Administration's National Marine Fisheries Service (NOAA/NMFS). The purpose of the workshop was to review and evaluate progress in tag design and attachment since the 2009 ONR Cetacean Tag workshop (ref - attached), with an emphasis on (a) recent tag attachment improvements, (b) follow-up studies that examined the effects of tagging, and (c) reviewing and providing input on draft cetacean tagging best practices guidelines.

Several presentations were made, with a focus on sharing information and discussion of the best available science of design and effects of tagging to facilitate future advancements in tag design and application, maximising attachment durations to the extent required to answer the questions being posed, whilst minimising potential impacts to the animals.

Discussion on the status of tag attachment development and follow-up studies occurred, along with extensive discussion regarding the cetacean tagging best practices guidelines. While much was accomplished towards the collective goals of the workshop, one item not covered in sufficient detail was discussion on the future directions in tag attachment technology. Therefore, a second smaller workshop will be convened in June of 2018 with a subset of the original attendees that focus specifically on tag attachments. The final report will merge the results of the September 2017 workshop and the June 2018 workshop.

22. IWC LIST OF RECOGNISED SPECIES

The Committee has agreed to follow the guidance of the Society for Marine Mammalogy's Committee on Taxonomy. This year (see Item 17.5), in completing its review of the taxonomy of *Tursiops*, the Committee noted that the current taxonomy provided by the SMM Committee for *Tursiops* was well supported by morphological and molecular genetic data, as well as ecological and distributional data.

23. IWC DATABASES & CATALOGUES

23.1 Guidelines for IWC catalogues and photo-ID databases

At last year's meeting, the Committee agreed IWC Guidelines for Photo-identification Catalogues (IWC, 2018f), noting that adding technical Appendices would be valuable in the future. Draft items for inclusion as Appendices were discussed by the *Ad hoc* Working Group on Photo-identification (Annex S, item 5.1) covering five issues: (1) cataloguing software; (2) image matching software; (3) seminal papers defining individual identification, by species; (4) photo quality guides; and (5) photo/data collection apps. Work will continue on developing these appendices intersessionally (Annex Y).

23.2 Progress with existing or proposed new catalogues

23.2.1 Integration of eastern South and Central Pacific blue, humpback, and fin whale photo-catalogues

There was no new information specific to this item this year.

23.2.2 Southern Hemisphere and Indian Ocean humpback whale catalogues

23.2.2.1 ANTARCTIC HUMPBACK WHALE CATALOGUE

The Antarctic Humpback Whale Catalogue (AHWC), maintained at College of the Atlantic, USA, was established in 1987 and during the past 30 years its data have been used in dozens of studies and publications (Stevick *et al.*, 2017). With a recent loss in funding, the catalogue database is now 'frozen' and is not being actively updated. The Working Group expressed strong disappointment at this news as well as the hope that the AHWC's funding situation will change and enable the catalogue to continue.

Attention: SC, G

The Scientific Committee has been informed that due to a loss of funding, the Antarctic Humpback Whale Catalogue curated by the College of the Atlantic, USA will no longer be updated. The Committee:

(1) ***draws attention*** *to the great value this catalogue (established in 1987) has provided to the Committee, including receiving photographs from the IWC IDCR and SOWER cruises and providing information for the Committee's Comprehensive Assessment of Southern Hemisphere humpback whales;*
(2) ***welcomes*** *news that the existing catalogue will remain a resource for scientists; and*
(3) ***encourages*** *potential funders to support future continuation of the catalogue.*

The Committee also received an update on the development and status of 'Happywhale', a web-based marine mammal photo-ID crowd-sourcing platform (SC/67b/PH05)[12]. This is discussed in Annex S (item 2.2). In recent months Happywhale provided images to catalogues relevant to the IWC and IWC-SORP of Southern right whales, Antarctic blue whales, and Antarctic killer whales. It will also contribute to the ongoing in-depth assessment of North Pacific humpback whales (see Annex F item 4.2.1).

23.2.2.2 ARABIAN SEA WHALE NETWORK'S FLUKEBOOK

In 2016 (IWC, 2017), the IWC approved funding for the development of a regional data platform for the Arabian Sea Whale Network (ASWN), to be implemented in collaboration with Wild Me, the developers of Flukebook. This year the Committee received information SC/67B/PH/03 that described Flukebook, a non-profit, open source cetacean data archiving and photo matching tool as discussed in Annex S (item 2.1; SC/67B/PH/03). The ASWN is joining Flukebook with two primary objectives: (1) to consolidate and more effectively manage humpback whale and other cetacean data collected in Oman over the past 20 years; and (2) to provide an online platform that will allow comparison and regional-level analysis of cetacean data collected by different research groups throughout the Arabian Sea (so far photographs are mainly from Oman, with a few from Pakistan and India). The Committee **looks forward** to updates on this work.

23.2.3 Southern Hemisphere Antarctic and pygmy blue whales: Catalogues and databases

23.2.3.1 SOUTHERN HEMISPHERE BLUE WHALE CATALOGUE (SHBWC)

The SHBWC has become the largest repository of Southern Hemisphere blue whale photo-identifications. It now includes a total of 1,519 individual blue whale photo-identifications from areas off Antarctica, Chile, Peru, Ecuador-Galapagos, Eastern Tropical Pacific (ETP), Australia, Timor Leste, New Zealand, southern Africa, Madagascar and Sri Lanka. The Committee received information on the progress made with the catalogue (SC/67B/PH/04), especially in light of the recommendations made last year to conduct catalogue comparisons in the Indo-Australian region (IWC, 2018b). This is discussed in more detail in Annex S (item 3.2). Comparison work (SC/67B/SH16) found (a) no matches between Australia, New Zealand and Sri Lanka, reinforcing the hypothesis of separate populations; and (b) exchange within Australia, suggested a single population; and (c) re-sights found in New Zealand suggest some site fidelity. Additional work is underway. The relevance of the catalogue to population assessments is discussed in Annex H Item 7.1.1.2.

23.2.3.2 ANTARCTIC BLUE WHALE CATALOGUE (ABWC)

In 2017, the Antarctic Blue Whale Catalogue compared photographs from the IWC IDCR/SOWER cruises in 1989/1990, 1993/1994, and 1997/1998 as well as opportunistic photographs collected by collegial scientists, naturalists, and tourists 2015-2018. The catalogue now contains almost 460 individuals. The results of the comparison of new Antarctic blue whale identification photographs to the ABWC is summarised in SC/67B/PH02 and discussed in Annex S (item 3.1); 17 new individual blue whales were identified. The collection of Antarctic blue whale identification photographs provide data for capture-recapture estimates of abundance (SC/67B/SH08) as well as information on the movement of individual blue whales within the Antarctic region. The relevance of the catalogue to population assessments is discussed Annex H, Item 7.1.1.1.

Attention: SC

(1) The Southern Hemisphere Blue Whale Catalogue provides data useful for estimating abundances and examining connectivity between feeding and breeding grounds. The Committee ***agrees*** *that the catalogue continue.*
(2) The Committee ***agrees*** *that the Antarctic Blue Whale Catalogue continue its work collecting adding photo-identification data to the catalogue in order to assist with developing estimates of population abundance for Antarctic blue whales.*
(3) The Committee ***agrees*** *that the development of a simple guide (physical and electronic versions) to help tourists and naturalists take photos that are suitable for photo-identification should be undertaken. This will support the photo-ID*

---

[12] https://happywhale.com

catalogues from the Antarctic region for use in population assessments by the IWC, particularly for blue whales, right whales, fin whales, and humpback whales.

23.2.4 Southern Hemisphere fin whale photo catalogues

The Committee received information on on a new photo-identification catalogue of Antarctic fin whales. Photographs from SOWER cruises 2004-2008 are included as well as those collected opportunistically near the South Orkney Islands during a Commission for the Conservation of Antarctic Marine Living Resources (CCAMLR) fisheries research voyage (SC/67B/PH01). This is discussed in Annex S (item 4.1). The catalogue serves as a foundation for future photo-ID studies, especially those proposed for the western Antarctic Peninsula. The relevance of the photo-identification of fin whales to population assessments is discussed Annex H, Item 7.1.2.

Attention: S, SC

1) The Committee ***encourages*** *continuation of the Antarctic Fin Whale Catalogue which can potentially provide data toward estimating abundance or identifying movement patterns.*
2)The Committee ***agrees*** *that an exhaustive search be conducted to locate SOWER photos that are missing from the IWC archives, including those of fin whales.*

23.2.5 Western Pacific gray whale photo catalogues

The Committee received information on two photo-identification catalogues relating to the Sakhalin Island feeding aggregation: one (SC/67B/ASI04), based on work undertaken as part of an industry-sponsored Exxon Neftegas Limited-Sakhalin Energy Investment Company joint monitoring program discussed in Annex S, item 4.2); and the other conducted by the Russia gray whale project (SC/76b/CMP/7) discussed in Annex O (item 2.1.3). The Committee welcomed news that the two catalogues would be unified under the auspices of the IWC.

23.3 Work plan

The work plan on work related to catalogues is provided in Table 27.

Table 27

Work plan on issues related to catalogues.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Appendices for IWC Guidelines for Photo-identification	Continue compilation	Appendices ready for review	Continue compilation	Appendices ready for review
Upload all available New Zealand blue whale identification photographs to SHBWC (also pertains to Annex H item 7.1.1)	Cross-reference between separate area catalogue holdings before uploading to SHBWC avoid duplication; intersessional correspondence group (Annex Y)	Included in SHBWC report	-	-
Development of how-to photo-ID materials for naturalists and citizen scientists (also pertains to Annex H item 7.1.1.2)	Prepare hard copy and PPT photo-ID guides	Guide completed and available (pending funding)		
4) Search for missing SOWER photographs, especially fin whale photos from 2006/2007	Search Secretariat archives and contact SOWER researchers for personal copies of photos	Report		

23.4 Potential future IWC databases

23.4.1 Global database for disentanglement activities

As discussed under Item 13.2, development of a dedicated entanglement database will be considered further at the June 2018 meeting of the Global Whale Entanglement Response Network (see Annex J, item 2.3).

23.4.2 Global bycatch database

No new information was presented on the development of a global bycatch database was presented this year. Consideration of such a database could take place as part of the Bycatch Mitigation Initiative and should it be taken further, follow the guidelines for the proposal of new databases developed last year (IWC, 2018, pp. 403-404).

23.4.3 Development of simple technical guidelines for new proposals

No changes were suggested to the guidelines developed at last year's meeting (IWC, 2018, pp. 403-404).

24. IWC MULTINATIONAL RESEARCH PROGRAMMES AND NATIONAL RESEARCH CRUISES THAT REQUIRE IWC ENDORSEMENT

24.1 IWC-POWER

The Committee received the results of the 8th annual IWC-POWER cruise conducted between 3 July and 25 September 2017 in the eastern Bering Sea. Researchers from Japan, USA and IWC participated on the surveys (SC/67b/ASI12). The Committee also received the report of the planning meeting for the 2018 IWC-POWER cruise, which will be conducted in the central Bering Sea, and cruise plans for the 2019 and 2020 cruises (SC/67b/Rep02). Details and preliminary results of the 2017 IWC-POWER survey and future plans for 2018, 2019 and 2020 are provided in Annex Q, item 4.1.

Attention: SC, C-A, CG-R

The Committee ***reiterates*** *to the Commission the great value of the data contributed by the IWC-POWER cruises which cover many regions of the North Pacific Ocean not surveyed in recent years and so address an important information gap for several large whales. The Committee:*

(1) ***thanks*** *Japan who generously supplies the vessel and crew, for their continued support of this IWC programme;*

(2) ***thanks*** *the USA who provided an acoustician and acoustic equipment for the 2017 cruise and will do so for the 2018 cruise;*

(2) ***agrees*** *that the 2017 cruise was duly conducted following the requirements and guideline of the Committee (IWC, 2012) and looks forward to receiving abundance estimates based on these data;*

(3) ***endorses*** *the plans for the 2018, 2019 and 2020 POWER cruise and* ***recommends*** *a meeting of the Technical Advisory Group along with the planning meetings for 2019 and 2020 cruises;*

(4) ***strongly recommends*** *that Russia facilitates the proposed research by providing permits for the IWC-POWER cruise to survey the Russian Exclusive Economic Zone in 2019;*

(5) ***looks forward*** *to receiving a report from the 2018 survey at the next SC meeting.*

24.2 Southern Ocean Research Partnership (IWC-SORP)

The Southern Ocean Research Partnership (IWC-SORP) was established in March 2009 as a multi-lateral, non-lethal scientific research programme with the aim of improving the coordinated and cooperative delivery of science to the IWC. The Partnership currently has 13 member countries: Argentina, Australia, Belgium, Brazil, Chile, France, Germany, Italy, New Zealand, Norway, South Africa, the United States of America, and Luxembourg was welcomed at this meeting. New members are warmly welcomed.

There are five ongoing IWC-SORP themes:

(1) ‘The Antarctic Blue Whale Project’;

(2) ‘Distribution, relative abundance, migration patterns and foraging ecology of three ecotypes of killer whales in the Southern Ocean’;

(3) ‘Foraging ecology and predator-prey interactions between baleen whales and krill’;

(4) ‘Distribution and extent of mixing of Southern Hemisphere humpback whale populations around Antarctica?’ focused initially on east Australia and Oceania; and

(5) ‘Acoustic trends in abundance, distribution, and seasonal presence of Antarctic blue whales and fin whales in the Southern Ocean’.

Bell presented the IWC-SORP Annual Report 2017/18 on the continued progress of research undertaken researchers involved in the five themes since last year (SC/67b/SH21). This progress includes the production of 33 peer-reviewed publications during 2017/18, bringing the total number of peer-reviewed publications related to IWC-SORP since the start of the initiative to 126. In addition, 125 IWC-SORP related papers have been submitted to the Scientific Committee, 22 of them this year.

Fieldtrips were undertaken to a variety of places during the past year, including the western Antarctic Peninsula, Marion Island, the Ross Sea, the Chesterfield-Bellona Reef complex west of mainland New Caledonia, and the Great Barrier Reef, Australia. Thousands of images for photo-identification have been collected; a variety of satellite tag-types deployed on Antarctic minke whales, humpback whales and killer whales as well as biopsy samples collected from these same species; video suction cup tags have been deployed on Antarctic minke whales and humpback whales; and hundreds of hours of acoustic recordings have been made and analysed. The support of tour companies in providing opportunistic research platforms to facilitate these activities and external data contributors were acknowledged by the Committee.

Attention: SC, G

The Committee reiterates the great value of the IWC-SORP (Southern Ocean Research Partnership) programme to its work. The Committee:

(1) ***encourages*** *the continuation of the Southern Ocean Research Partnership programme;*

(2) ***commends*** *the researchers involved who are key to the overall success of the Partnership in IWC-SORP for:*

(a) the impressive quantity of work carried out across diverse member nations;

(b) their contributions to the work of the Committee; and

(3) ***encourages****:*

(a) the continued development, testing and implementation of leading edge technology; and

(b) the continued development of collaborations between ships of opportunity and external bodies that can provide platforms for research and/or contribute data, inter alia, photo-identification data, to IWC-SORP and the wider Committee

24.2.1 Workplan

The work plan for issues related to IWC-SORP is given in Table 28.

Table 28

Workplan for the Southern Ocean Research Partnership.

Topic	Intersessional 2018/19	2019 Annual Meeting (SC/68a)	Intersessional 2019/20	2020 Annual meeting
Analyses	Continued analysis of data/samples from previous IWC-SORP voyages/fieldwork	Report	Continued analysis of data/samples from previous IWC-SORP voyages/fieldwork	Report
Voyages	Argentine coastguard '*Tango'* voyage along Western Antarctic Pensinsula (early 2019)	Cruise report		
	Almirante Maximiano voyage along Western Antarctic Pensinsula (early 2019)	Cruise report		
	Australian-led *RV Investigator* voyage to Ross Sea (early 2019)	Cruise report		
	New Zealand-led *RV Tangaroa* voyage to Ross Sea (early 2019)	Cruise report		
	German-led *RV Polarstern* voyage to Scotia Sea (early 2019)	Cruise report		
	Baleen whale and krill research voyages along Western Antarctic Peninsula	Reports	Baleen whale and krill research voyages along Western Antarctic Peninsula	Reports
Ships of opportunity	Continued use of ships of opportunity to conduct cetacean research	Reports	Continued use of ships of opportunity to conduct cetacean research	Reports
Acoustics	Retrieval and redeployment of passive acoustic recorders	Report	Retrieval and redeployment of passive acoustic recorders	Report
	Completion of annotated library of acoustic detections	Report		

24.3 National cruises that require IWC oversight

The Committee welcomed plans for national research cruises to be conducted in the intersessional period of 2018-2019. Details on the cruise plans and cruise reports are presented in Annex Q, item 4.2.

Attention: SC, C-A

The Committee ***recognises*** *the great value to its work provided by data from national cruises. The Committee:*

(1) ***endorses*** *the proposed sighting survey plans for cruises to be conducted with IWC oversight in the southwestern Okhotsk Sea by Russia, and in the North Pacific and the Antarctic by Japan; and*
(2) ***encourages*** *submission of abundance estimates from these studies the future.*

24.4 Review of cruise reports from national programs with IWC oversight

The Committee considered a process to optimise the review of cruise reports from national research programs with IWC oversight. Details are given in Annex Q, item 2.7

Attention: SC, CG-R

*The Committee **recognises** the value of information provided by national cruises with IWC oversight. The Committee noted that a process to optimise the review of national cruise reports is needed and*

*(1) **recommends** contracting governments to submit reports of multi-year cruises with IWC oversight biennially, in years between Commission meetings (e.g., SC "A" years);*
*(2) **agrees** that cruise reports will be summarised in a table;*
*(3) **notes** that that in certain circumstances, cruise reports may require additional evaluation; and*
*(4) **agrees** that the 'Requirements and Guidelines for Conducting Surveys and Analysing Data within the Revised Management Scheme' should be modified at next year's meeting to accommodate procedural changes with respect to the submission and review of national cruise reports.*

24.5 Work Plan

The Committee's work plan for continuing the IWC-POWER programme in 2019 and 2020 is provided below in Table 29.

Table 29

Workplan for issues related to IWC-POWER.

Item	Intersessional 2018-19	SC68a	Intersessional 2019-20	SC68b
IWC-POWER Cruise	Conduct 2018 survey and planning meeting for the 2019 Cruise (Bering Sea)	Review cruise report, report from the planning meeting and new abundance estimates from IWC-POWER cruises.	Conduct 2019 survey and planning meeting for the 2020 Cruise	Review cruise report, report from the planning meeting and new abundance estimates from IWC-POWER cruises.

25. SCIENTIFIC COMMITTEE BUDGET FOR THE CURRENT BIENNUM

25.1 Status of previously funded research, workshop proposals, data processing and computing needs

25.1.1 Funded proposals for the current biennium 2017-2018

Table 30summarises the status of the work funded by the Committee last year. The majority have been completed, but several remain ongoing. The projects all contributed considerably to the work of the Committee and the Committee thanked all of those involved.

25.1.2 Funded proposals in previous years still ongoing

A number of projects from previous years are still ongoing (see Table 30). These are all still of great value to the Committee and should be completed before the next meeting. Details of all ongoing projects can be found in SC/67B/01 Rev1.

25.1.3 Report on funds reallocations and contingencies for the Research Fund, Voluntary Fund for Small Cetaceans and SORP Voluntary Fund

SC/67b/01Rev1 provides information on the actual position against budget for the Research fund for 2017 as well as the position to 31st March for the 2018 financial year. The paper gives summary level and detailed information for the Research fund as well as the expected level of contingency available, which remains static at around 10% of the Research budget, or £32k. The document also provides details of the reallocations of budget amongst budget headings for 2017 and the 2018 year-to-date. Annex 1 gives a detailed position along with a status report for each budget line. Section 3 also provides details of voluntary funds which relate to Scientific Committee business – the Gray Whale Tagging Fund, the Small Cetaceans Fund and the SORP fund. For each there is an update of 2017 expenditure and 2018 to-date information along with details of commitments to future work in these funds.

Table 30

Summary of progress on proposals funded at SC67a

SC/67a RP no.	Title	Status
SC01	Invited Participants - SC/67b	Completed
IA01(67a)	Workshop for an in-depth assessment of North Pacific humpback whales	Ongoing (Annex F)
EM01	Two joint SC-CAMLR and IWC-SC Workshops	Ongoing (Annex L)
AWMP01	AWMP first intersessional Workshop and genetic work	Completed (SC/67b/Rep06)
AWMP02	AWMP second intersessional Workshop	Completed (SC/67b/Rep06)
CMP01(67a)	5th Workshop on the rangewide review of population structure and status of North Pacific gray whales	Completed (SC/67b/Rep07rev1)
BRG04	Satellite tagging best practices Workshop	Ongoing, Item 21
WW01	Intersessional Workshop: data gaps and modelling requirements for assessing the impacts of whale watching	Completed (SC/67b/Rep03rev1)
RMP01	Intersessional Workshop: *Implementation Review* of North Pacific Bryde's whales	Completed (SC/67b/Rep02)
RMP01(67a)	Intersessional Workshop: *Implementation Review* for Western North Pacific minke whales	Completed (SC/67b/Rep05)
WW01(67a)	Review CC Strategic plan on whalewatching pre-meeting on intersessional workshop	Completed (Annex N)
E05/E01(67a)	Cumulative impacts - pre-meeting or intersessional meeting	Completed (Annex K)
SM01	Intersessional Workshop: resolving *Tursiops* taxonomy	Completed (SC/67b/SM18rev1)
SM01(67a)	Intersessional Workshop: boto mortality	Completed (SC/67b/Rep01)
SH07	Defining blue whale population boundaries and estimating associated historical catches, using catch data in the Southern Hemisphere and northern Indian Ocean	Completed (SC/67b/SH23)
AWMP02	AWMP developers fund	Completed (Annex D)
IA02	Assessment modelling for an in-depth assessment of North Pacific sei whales	Ongoing (SC/67b/IA01)
RMP02	Essential computing support to the Secretariat for RMP	Completed (Annex D)
Research		
BRG01	Aerial photographic survey of southern right whales on the South Africa Cape nursery ground	Completed (SC/67b/SH01)
BRG03	Passive acoustic monitoring of the eastern South Pacific southern right whales, improving CMP outputs	Completed (SC/67b/CMP18)
SH03a	Northern Indian Ocean humpback subspecies determination-genetics	Ongoing (Annex H)
IA03	IWC-POWER cruise	Completed (SC/67b/Rep04)
SH01(67a)	Coding for Australian blue whale photo catalogue	Ongoing (Annex PH)
E02(67a)	Mercury in cetaceans (requested by the Commission)	Ongoing (SC/67a/E08)
SH02	Southern Hemisphere Blue Whale Catalogue	Completed (SC/67a/PH04)
SH08	Development of a permanent blue whale song reference library	Completed (SC/67a/SH11Rev1)
HIM01	Ship Strike Database Coordinator	Completed (SC/67a/HIM11)
E01	Cetacean Diseases of Concern	Ongoing (Annex K)
E03(67a)	IWC strandings initiative	Ongoing (Annex K)
E04	SOCER (State of the Cetacean Environment Report)	Completed (SC/67a/E01)

The Committee received a brief report on the IWC-SORP Research Fund. Following an open, competitive Call for Proposals (26 July to 17 August 2016) a total of £144,058 GBP was allocated from the IWC-SORP Research Fund to 10 research projects, ahead of the 2016-2017 austral summer survey season. Progress on these projects is detailed in SC/67b/SH18.

The Committee also noted that since SC67a, substantial vessel time has also been secured by IWC-SORP researchers for the 2019 and 2020 austral field seasons.

Attention: C, F&A, S

A full report on the new Call for Proposals, opened in September 2017 and closed in January 2018, was also received. A total of 19 proposals were received and evaluated by the Assessment Panel under the coordination of the Chair of the Scientific Committee. The Committee thanks Fortuna for convening the Assessment Panel and expressed its gratitude to the Panel members who all provided valuable and thoughtful input into the assessment process. The Committee welcomes the outcome of the Assessment Group and agrees with the allocation of a total of £493,544 GBP from the IWC-SORP Fund to 15 projects (Table 31).

The Committee agrees on these recommended allocations and requests the Secretariat to submit them to the Finance and Administration Committee, as soon as feasible, for it consideration. Should the Commission endorse these financial recommendations, the Committee requests the Secretariat to inform successful and unsuccessful proponent immediately after the next Commission's meeting.

Table 31
List of the funding allocations by project recommended by the IWC-SORP Assessment Panel

ID	Chief Investigator	Title	Requested amount (£)	Recommended amount (£)	Level of funding (Partial/Full)
1	Baker & Steel	Is migratory connectivity of humpback whales in the Central and Eastern South Pacific changing? A decadal comparison by DNA profiling	27,598	26,375 (deducted in house instrument expenses)	P
2	Charrassin	Application of satellite telemetry data to better understand the breeding strategies of humpback whales in the Southern Hemisphere	21,200	21,200	F
3	Branch	Modelling somatic growth and sex ratios to predict population-level impacts of whaling on Antarctic blue whales	32,594	32,594	F
4	Friedlaender & Constantine	Pregnancy rates in Southern Ocean humpback whales: implications for population recovery and health across multiple populations	29,334	19,984 (equipment deducted and some analytical costs)	P
5	Herr	Recovery status and ecology of Southern Hemisphere fin whales (*Balaenoptera physalus*)	82,300	81,900 (equipment deducted)	P
6	Friedlaender & Constantine	A circumpolar analysis of foraging behaviour of baleen whales in Antarctica: Using state-space models to quantify the influence of oceanographic regimes on behaviour and movement patterns	34,711	34,711	F
7	Buchan & Miller	A standardized analytical framework for robustly detecting trends in passive acoustic data: A long-term, circumpolar comparison of call-densities of Antarctic blue and fin whales	43,369	41,369 (publication costs)	P
8	Lang & Archer	Inferring the demographic history of blue and fin whales in the Antarctic using mitogenomic sequences generated from historical baleen	22,710	22,710	F
9	Zerbini & Clapham	Assessing blubber thickness to inform satellite tag development and deployment on Southern Ocean whales	22,646	22,426 (supply costs deducted)	P
10	Širović & Stafford	Acoustic ecology of foraging Antarctic blue whales in the vicinity of Antarctic krill studied during AAD interdisciplinary voyage aboard the *RV Investigator*	34,183	30,107 (airfares deducted)	P
12	Kelly &Maire	Development of statistical and technical methods to support the use of long-range UAVs to assess and monitor cetacean populations in the Southern Ocean	30,576	30,576	F
13	Reisinger & de Bruyn	An integrative assessment of the ecology and connectivity of killer whale populations in the southern Atlantic and Indian Oceans	33,650	33,650	F
14	Bengston Nash	Implementation of humpback whales for Antarctic sea-ice ecosystem monitoring; Inter-program methodology transfer for effective circumpolar surveillance	91,202	51,555 (equipment costs deducted)	P
17	Carroll, Torres, Graham	Circumpolar foraging ecology of southern right whales: past and present	21,290	21,290	F
18	Iñíguez Bessega	Habitat use, seasonality and population structure of baleen and toothed whales in the Scotia sea and the western Antarctic Peninsula using visual and passive acoustic methods and genetics	26,579	23,097 (equipment costs reduced, communication & network costs deducted)	P
		TOTAL	693,195	493,544	

Finally, the Committee was informed that the next Call should open prior to SC/68b (i.e. late 2019/early 2020) in readiness for IWC68 (2020). This timing would allow strategic prioritisation of the research toward which the Call is directed in order to meet IWC-SORP and IWC/SC priorities; allow knowledge gaps to be identified; and allow the IWC-SORP SSC to seek additional funding to augment the funds available in the IWC-SORP Research Fund.

26. COMMITTEE PRIORITIES AND INITIAL AGENDA FOR THE BIENNUM 2019-2020

The Committee's priorities and work plan by broad subject matter are provided in Tables under the relevant agenda items.

The Committee ***agrees*** *that the Chair, Vice-Chair and Head of Science, in co-operation with the Convenors, should examine the individual work plans by topic and develop an overall Committee biennial workplan and priorities taking into account the overall work load, meeting venues and efficiency. This should be submitted to the Commission meeting as an Annex to their two-year overview.*

27. SCIENTIFIC COMMITTEE BUDGET FOR THE BIENNUM 2019-2020

27.2 Budget for the next biennium

As in 2016, the Committee has developed a two-year budget, based on the proposed work plans. The process given in Annex S IWC, 2016) was applied, with extensive discussion carried out in each of the sub-committees and Working Groups to establish priorities among the presented proposals. Funding was not approved for one project (*Gulf of Penas, Southern right whales*) as further information is needed before funding can be agreed. The savings from 2018, some self-reductions and adjustments between years allowed inclusion of all funding proposals for 2019 and 2020 in the new budget of £315,800 per year.

Table 32

Workshop proposals agreed during this meeting (TBD: to be decided).

Title	Relevance	Date	Venue
Western gray whale update of CMP and conservation issues within modelling framework	CMP		
Marine debris	E	December 2019	Barcelona, Spain
Noise pre-meeting	E	Pre-meeting 2020	TBD
Cetaceans & ecosystem functioning: a gap analysis*	EM	TBD	TBD
Joint IWC-IUCN workshop to evaluate how the data and process used to identify Important Marine Mammal Areas (IMMAs) can assist the IWC to identify areas of high risk for ship strike	HIM	April 2019	Greece
Comprehensive Assessment of North Pacific humpback whales	NH		
Comparative biology, health, status & future of NA right whales	NH	Late 2019	Boston, USA
Implementation Review: North Pacific minke whales	RMP		
Catch series: Southern right whales	SH	Pre-meeting 2020	TBD
Intersessional workshop of the task team on South Asian River dolphins	SM	Feb 2019	TBD
Guiana dolphin pre-assessment	SM	October 2019	Curitiba, Brazil
Modelling whale watching impacts (MAWI)	WW	December 2019	
POWER planning meeting	ASI	Oct 2018	Tokyo, Japan
Wildmeat workshop	SM	Late 2019/early 2020	Africa
Tagging best practices	ASI	Jun 2018	Seattle, USA

* Japan referred to its statement on the adoption of the Agenda (Annex Z) and considered that several of the items for the proposed workshop (Item 16.4.4) are outside the competence of IWC. Therefore, it cannot support the proposed workshop or associated funding from the Committee's budget.

Table 33 shows the Committee budget requests for the biennium for each of the proposed priority activities.

27.2.1 Invited Participants

INVITED PARTICIPANTS

Invited participants (IPs) are a vital component of the working of the IWC's Scientific Committee. IPs contribute in many ways including as sub-committees and Working Groups Convenors, co-Convenors and rapporteurs, subject area experts and Convenors of intersessional groups. All sub-committees and Working Groups benefit from this budget item. This year under this budget item, 62 scientists from Australia, Argentina, Belgium. Brazil, Canada, Chile, China, Colombia, France, Germany, Italy, Japan, Mexico, Netherlands, Norway, Oman, Peru, Slovenia, South Africa, Spain, UK, USA were supported.

27.2.2 Workshops

RP16 WESTERN GRAY WHALE UPDATE OF CMP AND CONSERVATION ISSUES WITHIN MODELLING FRAMEWORK

The CMP is over 10 years old and requires updating. Initial work has been undertaken but the results of the rangewide workshop need to be incorporated and conservation-related questions need to be developed that can be addressed within the new population modelling framework developed as a result of the Committee's work. This is primarily related to the CMP and AWMP groups, however, it is also of importance to the work of IA and ASI in terms of precedents for future assessments and the work of HIM in terms of examining scenarios that take into account bycatch and the uncertainty associated with estimating it.

RP06 MARINE DEBRIS WORKSHOP

There remains an urgent need to better understand and address the threats posed by marine debris to cetaceans. The most effective way to do this, building on earlier work by the IWC and taking into account the greatly expanded interest in this topic by many other international bodies, is to hold a workshop. It is proposed that the workshop is held in Barcelona in December 2019 just before the World Conference on Marine Mammalogy (the joint meeting of the SMM and ECS).

RP05 NOISE PRE-MEETING

The sub-committee on Environmental Concerns will address Anthropogenic Noise as a focus topic during the Scientific Committee meeting in 2020. A pre-meeting workshop is proposed for SC68b, to address emerging issues related to the management of underwater noise and its impacts on marine species.

RP08 CETACEANS & ECOSYSTEM FUNCTIONING: A GAP ANALYSIS

Experts on the role and impact of cetaceans on ecosystem functioning will participate in a workshop/pre-meeting to discuss the current state of knowledge on the ecosystem functioning provided by cetaceans as requested by the Commission in Resolution 2016-3. This Resolution directed 'the Scientific Committee to further incorporate the contribution made by live cetaceans to ecosystem functioning into [its] work' and asked 'the Scientific Committee to screen the existing research studies on the contribution of cetaceans to ecosystem functioning, to develop a gap analysis regarding research and to develop a plan for remaining research needs'.

RP17 JOINT IWC-IUCN WORKSHOP TO EVALUATE HOW THE DATA AND PROCESS USED TO IDENTIFY IMPORTANT MARINE MAMMAL AREAS (IMMAS) CAN ASSIST THE IWC TO IDENTIFY AREAS OF HIGH RISK FOR SHIP STRIKE

The identification of 'high risk areas' for ship strikes of cetaceans is a key step toward establishing mitigation actions, through scheduling, re-routing or speed reduction. IUCN's proposed initiative to identify Important Marine Mammal Areas (IMMAs), would likely assist this effort. The SC has encouraged cooperation with the IUCN Task Force on this. The IUCN TF has completed three regional IMMA workshops, including the Mediterranean Sea. This proposed joint workshop will focus on identifying overlap between shipping and the IMMAs identified in the Mediterranean Sea.

Table 33

Summary of budget requests for the 2019-20 period. For explanation and details of each project see text.

RP no.	Title	Sub-committee/ working group	2019 (£)	2020 (£)
Invited Participants				
	Invited Participants - SC/68a and SC/68b	SC	85,000	65,000
Meeting/Workshop				
RP16	Western gray whale update of CMP and conservation issues within modelling framework	CMP	10,500	0
RP06	Marine debris	E	0	20,000[1]

	Implementation: resolutions and instructions from Commission & follow up from previous years' recommendations	SC	10,313	28,470
Total request			£315,800	£315,800

Notes: [1]Budget was reduced from £22,200, [2]£20,300 was the expected financial need for 2019 but savings from 2018 allowed for the reduced budget of £0; [3]£11,400 was the expected financial need for 2019 but savings from 2018 allowed for the reduced budget of £1,000; [4]£15,000 was the expected financial need for 2019 but savings from 2018 allowed for the reduced budget of £13,000. [5]Budget was reduced from £8,958, [6]£20,000 was the expected financial need for 2020 but financial savings for 2018 allowed for the reduced budget of £17,000, [7]£32,500 was the expected need for 2019 but financial savings from 2017 allowed for the reduced budget of £22,500, [8]£32,500 was the expected need for 2020 but financial savings from 2018 allowed for the reduced budget of £22,500, [9]The requested budget was £15,000 but further information is required before funding can be considered. The project will be re-evaluated at the 2019 SC meeting, [10]£6,185 was the expected financial need for 2019 but financial savings from 2018 allowed for the reduced budget of £0, [11]budget was reduced from £10,000, [12]budget was reduced from £10,000, [13]funding of approximately £7,280 may be requested for 2020 next year depending on progress, [14]£4,000 was the expected financial need for 2019 but savings from 2018 allowed for the reduced budget of £0, [15]budget was reduced from £4,000, [16]budget was reduced from £4,000.

27.2.1 Invited Participants

INVITED PARTICIPANTS

Invited participants (IPs) are a vital component of the working of the IWC's Scientific Committee. IPs contribute in many ways including as sub-committees and Working Groups Convenors, co-Convenors and rapporteurs, subject area experts and Convenors of intersessional groups. All sub-committees and Working Groups benefit from this budget item. This year under this budget item, 62 scientists from Australia, Argentina, Belgium. Brazil, Canada, Chile, China, Colombia, France, Germany, Italy, Japan, Mexico, Netherlands, Norway, Oman, Peru, Slovenia, South Africa, Spain, UK, USA were supported.

RP19 COMPREHENSIVE ASSESSMENT OF NORTH PACIFIC HUMPBACK WHALES

At SC67a, following discussion of the results of an assessment workshop held in April 2017, a Steering Group was established to facilitate a second North Pacific humpback whale assessment workshop, and to coordinate work required for this meeting. This meeting was not held prior to SC67b and the workshop is now planned for prior to the 2019 meeting of the Scientific Committee, with a view to completing or significantly advancing the assessment.

RP37 BALAENID WORKSHOP: BIOLOGY, HEALTH, STATUS

The North Atlantic right whale's population rate of increase is much lower than that of all other well-studied balaenid populations. This workshop will compare reproductive biology, health and status of North Atlantic right whales with those of other balaenid populations with the goal of determining their potential for growth and assessing the role of anthropogenic mortality as a driver of current population decline. Possible causes of the NARW's lower reproductive rate need reassessment include: sub-lethal effects of entanglements; environmental contaminants or marine biotoxins; inadequate prey base; stress from noise; genetic factors; and infectious diseases. This review will also help understanding of population changes for other balaenid populations.

RP21 *IMPLEMENTATION REVIEW*: NORTH PACIFIC MINKE WHALES

These workshops are essential in order for the Committee to conduct a full *Implementation Review* for Western North Pacific common minke whales following the Committee's Requirements and Guidelines. Conducting *Implementation Reviews* are a required activity under the RMP.

RP29 CATCH SERIES: SOUTHERN RIGHT WHALES

A new review of available catch data for measuring regional takes of southern right whales is overdue and the availability of new sources suggests that it is timely to do this. The expected outcome of this workshop is updated regional estimates of southern right whale catches, which can be used to conduct regional assessments of southern right whale past exploitation and develop population trajectories to measure past abundance and current recovery levels.

RP25 INTERSESSIONAL MEETING OF THE TASK TEAM ON SOUTH ASIAN RIVER DOLPHINS

The South Asian river dolphin, *Platanista gangetica*, is listed as an endangered cetacean species by the IUCN Red List assessment. Across its range, in the countries of India, Pakistan, Nepal, and Bangladesh, the species remains highly threatened by a range of anthropogenic activities at multiple scales. These range from localised threats caused by hunting, fisheries bycatch, or local disturbances as well as from large-scale alterations of the rivers by dams, barrages, waterways and river-linking schemes. In particular, large-scale and rapidly accelerating water development in the Indo-Ganges-Brahmaputra floodplains make the outlook for the South Asian river dolphin conservation grim. In recognition of this situation, the Scientific Committee has established a Task Team for the species and the team of experts will meet in person and discuss how to go forward.

RP26 GUIANA DOLPHIN PRE-ASSESSMENT (*SOTALIA GUIANENSIS*)

An intersessional workshop will assess the geographic extent of Guiana dolphin threats and conservation measures needed in both national and international contexts. The outcomes of the workshop shall include: (1) a Comprehensive Assessment of the status of Guiana dolphins; (2) recommendations to potentially improve management actions and the monitoring efforts associated with the current conservation plans of actions; and (3) a consolidated report to be presented to the SC at next year's meeting for review.

RP27 MODELLING WHALE WATCHING IMPACTS (MAWI)

There is little research on the potential mid- and long-term impacts of whale watching on cetacean populations. This is due to the complexity of the required modelling approaches, lack of clarity regarding the data needed to inform them, and the need to identify locations suitable for data collection. Without addressing these issues understanding the potential mid- and long-term impacts of whale watching is not possible. The workshop will bring together modellers and field researchers to achieve the following outcomes: (1) identify existing modelling approaches that could be used to understand the potential mid- and long-term impacts of whale watching, and determine whether new approaches are required; (2) determine which data currently being collected are suitable for answering questions regarding the mid- and long-term impacts of whale watching, and what new data are required; and (3) determine the feasibility of data collection, and identify locations where this has already been done or could be achieved.

27.2.3 Modelling/computing

RP20 ASSESSMENT MODELING FOR AN IN-DEPTH ASSESSMENT-NORTH PACIFIC SEI WHALES

The IA sub-committee is currently conducting a Comprehensive Assessment for North Pacific sei whales. This involves evaluating the status of a population using a population dynamics model that is specific to the biological parameters and movement behaviour of that particular population and is fitted to monitoring data. During the intersessional periods after the 2018 SC meeting and possibly also after 2019 SC meeting, it is expected that population dynamics models will be finalised and run using the existing data. This will result in an assessment of the status of the population.

RP22 DEVELOP AN AGE-STRUCTURED EMULATOR FOR THE INDIVIDUAL-BASED ENERGETICS MODEL (IBEM)

An IBEM provides an alternative population dynamics model to the usual cohort models, particularly because density dependence in births, growth and age-specific mortality are emergent properties of a species in a given environment (which can be stochastic). The IBEM is computationally infeasible for conducting *IST*s; the proposal is to develop a computationally efficient cohort model (emulator) which uses demographic parameters and their covariances generated using the IBEM.

RP23 ESSENTIAL COMPUTING SUPPORT TO THE SECRETARIAT

Regular *Implementation Reviews* are required under the RMP and AWMP. Computing support is alos required for Comprehensive and in-depth assessments. The Committee is currently about to undertake an *Implementation Review* for the North Pacific common minke whales, and more will follow. The Committee has developed a complex trials structure for *Implementation Reviews*. A key task in this process is to develop and validate the code for the simulation trials that are the core component of this process. Experience has shown that the Secretariat staff alone cannot handle this complete process themselves, so computing support is needed.

RP36 SIMULATING LINE TRANSECT DATA TO INVESTIGATE ROBUSTNESS OF NOVEL ANALYSIS METHODS

The IWC SC has already invested time and money in developing simulated line transect data to evaluate the robustness of the Norwegian minke whale and Antarctic minke whale survey data. This project will update the old code for the simulator to make it more user-friendly so that it can be made available to all SC members and to produce some standard data sets in accordance to the specifications of the ASI sub-committee.

27.2.4 Databases/catalogues

RP01 IWC-POWER CRUISE

The Committee has strongly advocated the development of an international medium- to long-term research programme involving sighting surveys to provide information for assessment, conservation and management of cetaceans in the North Pacific, including areas that have not been surveyed for decades. This is one of the most important international collaborations undertaken by the IWC and the cost to the IWC is minimal given the generous contribution of a vessel by Japan and acoustic equipment by the USA . Committee objectives have been developed for the overall plan and requested funding will allow for the continuing work of the initial phase and progress on developing the medium-term phase. The IWC contribution is for: (1) IWC researchers and equipment; (2) to allow the Committee’s Technical Advisory Group to meet to review the multi-year results thus far and develop the plans for the next phase of POWER based on the results obtained from Phase I; and (3) to enable analyses to be completed prior to the 2020 Annual Meeting.

RP11 ABUNDANCE ESTIMATES OF THE FRANCISCANA DOLPHIN IN BUENOS AIRES PROVINCE, ARGENTINA

Abundance estimates of franciscanas will be based on a series of aerial surveys along the coast of Buenos Aires Province, with the same survey design of surveys carried out in 2003 and 2004 (Crespo *et al*., 2010). The new estimate will allow comparing density values with those obtained in the previous surveys. This item represents only one third of the funds required for the project, with the remainder being provided by the Government of Argentina.

RP09 GULF OF PENAS, SOUTHERN RIGHT WHALES

Eastern South Pacific (ESP) Southern right whales (SRW) are classified as critically endangered as there are no more than 50 SRW in this population and there is no information on the ESP SRW breeding and feeding grounds. Gulf of Penas is one of the most remote and exposed areas in Chile, with limited access and wild weather that have prevented its exploration. The largest baleen whale mass mortality of almost 400 sei whales occurred in this area and almost remained unnoticed. Recently, a local living nearby the Gulf of Penas recorded the presence of SRWs, including several calves. The Gulf might be the unknown breeding ground of the ESP SRW. This area will be explored during the austral winter breeding season with a group of researchers and government officers to confirm this finding and if so, start immediately working towards the protection and management of the species and the area.

RP10 POPULATION DYNAMICS OF SOUTHERN RIGHT WHALES AT PENÍNSULA VALDÉS, ARGENTINA: THE INFLUENCE OF KELP GULL LESIONS ON THE HEALTH, CHANGES IN INCREASE AND MORTALITY RATES IN THE CONTEXT OF A DENSITY-DEPENDENT PROCESS

The recent mortality of southern right whales at Península Valdés, Argentina is the highest ever recorded for the species. Understanding the causes is critical to propose management and mitigation actions. Preliminary results from glucocorticoids in baleen from stranded calves show that stress from injuries due to Kelp Gull attacks negatively affects their physiological homeostasis, potentially leading to death. Also, aerial counts show an important reduction in population rate of increase as a whole (from 7% in the past to 0.5% at present), and changes in distribution (mainly of adults) and density along the Argentinian coast.

RP12 PASSIVE ACOUSTIC MONITORING OF THE EASTERN SOUTH PACIFIC SOUTHERN RIGHT WHALE

The Eastern South Pacific southern right whale population is Critically Endangered and in 2012 the IWC adopted a Conservation Management Plan (CMP). Over the years, few opportunistic sightings have been recorded and no breeding area has yet been identified. Until a breeding ground is found many CMP priority actions cannot be implemented. Thus, in 2016 the IWC Scientific Committee decided to support this passive acoustic monitoring (PAM) project to facilitate the identification of potential breeding areas along the coast of Chile and Peru. This project seeks to obtain temporal coverage over a complete annual cycle and spatial coverage depending on the number of sites. The PAM project is likely the most cost-effective way to investigate the seasonal and temporal distribution of southern right whales along the coast of Chile and Peru. The information will be crucial to identify aggregation areas and facilitate the implementation of CMP for this population.

RP13 SAMPLE THE HOLOTYPE SPECIMEN OF *MEGAPTERA INDICA* (GERVAIS, 1883) AT THE MUSÉUM NATIONAL D'HISTOIRE NATURELLE (PARIS)

Several lines of evidence suggest that humpback whales in the Arabian Sea/Northern Indian Ocean comprise a discrete, isolated and non-migratory population that merits a taxonomic revision. Genetic analyses of available samples are now underway in order to determine whether sub-species/species designation is merited. The resultant nomenclature will necessarily draw on a description of the type specimen of *Megaptera indica*, which is held at the Muséum National d'Histoire Naturelle in Paris. This work will develop an approach for examining and sampling this specimen so that the taxonomy of Arabian Sea humpback whales can be accurately defined, better informing regional conservation efforts, highly relevant to the IWC's stated interest in the establishment of a Conservation Management Plan for Arabian Sea humpback whales.

RP14 ASSESSING ISOLATION OF THE ARABIAN SEA HUMPBACK WHALE POPULATION AND CONTINUITY ACROSS THE ARABIAN SEA THROUGH GEOGRAPHIC VARIATION IN SONG

A study of geographic variation in humpback whale song indicates that the Arabian Sea song from Oman is distinct from the Southwest Indian Ocean (SWIO) song, and evidence from a small Indian sample suggesting continuity in song between the western and eastern Arabian Sea. This work will be followed up on with a detailed comparison of song across the Arabian Sea and continued assessment of song differences with the SWIO: The project will (1) assess the connectivity of Arabian Sea humpback whales from Oman to India by comparing existing samples of song between the two regions from several different years; and (2) assess and re-examine the differences in song exhibited between Oman and the SWIO with more recent data, particularly in light of evidence that SWIO singers were found off Oman during the Boreal summer of 2012.

RP15 A QUANTITATIVE ASSESSMENT OF THREATS TO ARABIAN SEA HUMPBACK WHALES USING EXISTING PHOTOGRAPHIC AND UAV DATA

The research will assess the prevalence of anthropogenic and natural threats to Arabian Sea humpback whales through a robust and quantitative assessment of available photographic data. These data include the entire Oman photo-ID catalogue, imagery recently acquired using UAVs (drones) and images provided by third parties. The latter include several images from elsewhere in the populations range. The project will provide an assessment of the relative prevalence of a suite of indices typically associated with major threats (fisheries entanglements, ship-strikes, other scars) as well as scars associated with natural sources (barnacles, cyamids, Penella sp., killer whales). Project outcomes will include assessment of the risks posed by each threat, as well as the development of a set of metrics with which further changes can be monitored. Project results will be reported to the IWC SC in 2019 and will contribute to the development of a draft Conservation Management Plan for this population.

RP24 COLLABORATIVE ANALYSIS OF WNP MINKE WHALE STOCK STRUCTURE USING JAPANESE MICROSATELLITE DNA DATABASE AND SPATIALLY EXPLICIT POPULATION STRUCTURE ANALYSES.

This item will help address the recommended 'analysis 2' from the report of the workshop on Western North Pacific common minke whale stock structure (SC/67b/Rep05) in support of the next intersessional meeting on WNP common minke whale stock structure. This specific aspect of the work will apply spatially explicit population structure analyses that provide greater power than the program STRUCTURE together with geographic context. The data will be analysed as a total dataset (not based on any assignment in STRUCTURE), but also include temporal subdivision to assess possible seasonal changes in patterns of connectivity. The latter aspect may be critical to understanding the true pattern of structure, but it will also be the most time-consuming, requiring extensive replication of the analyses. The results of these analyses will provide an assessment of structure in the context of biogeography using methods that have considerably more power than the program STRUCTURE and using an approach that will consider temporal patterns of movement.

RP28 UPDATED CATCH SERIES AND ASSESSMENTS OF FOUR PYGMY BLUE WHALE POPULATIONS

The SH sub-committee is conducting in-depth assessments of populations of Southern Hemisphere blue whales. Assessments have previously been conducted for two of the six populations (Antarctic blue whales, and Chilean blue whales), but not for the four pygmy blue whale populations addressed by this research. This project will provide crucial catch separation data and associated uncertainty needed to conduct stock assessments and provide the first stock assessments for each of the four populations. Such data are critical inputs for the assessments planned by the SC.

RP30 MULTI-OCEAN ANALYSIS OF SOUTHERN RIGHT WHALE DEMOGRAPHIC PARAMETERS AND ENVIRONMENTAL CORRELATES

This study aims to compare population demographics of southern right whales in Southern Hemisphere wintering grounds and investigate correlations between reproductive success and abundance trends, and environmental variables. This study is a component of the proposed SORP project - The right sentinel for climate change: linking foraging ground variability to population recovery in the southern right whale.

RP 31 ANALYSIS OF FIN WHALE SONG VARIABILITY ACROSS SOUTHERN HEMISPHERE

Fin whale songs consist of short pulses repeated at regular interpulse intervals (IPIs). These songs have been suggested as a tool to distinguish populations. Features that have be used for fin whale song separation include: spectral structure of individual pulses; their patterning; the IPIs; and presence of a higher frequency component of the pulses. Based on this higher frequency component, there appear to be two fin whale song types in the Southern Ocean. We propose to use a combination of song feature measurements to identify whether fin whale songs in the Southern Hemisphere could be indicative of population structure. Data to be used include recorders deployed in the Western Antarctic Peninsula, Weddell Sea, and Eastern Antarctica (Kerguelen and Casey) from 2014-16. Additional SH lower-latitude recordings are available in southeastern Pacific and South Indian Ocean. Overall, the analysis will enable a comprehensive review of fin whale song variability across the SH.

RP34 PHOTO-IDENTIFICATION INFORMATION PLACARDS FOR NATURALISTS AND CITIZEN SCIENTISTS

Pre-cruise training and reference placards describing examples of photo-identification subjects (large whales) will be developed for distribution to the tourist vessel industry in the South Georgia and Antarctic Peninsula region. Information will include primary ID features used for seven species likely to be encountered; right, blue, sei, fin, humpback, sperm and killer whales (key species). A Powerpoint presentation will be developed for distribution to naturalists working on tourist vessels, to orient them and their clients to the basics of whale identification photography. Minimal training is required for a considerable improvement to the quality of identification photographs that are collected by naturalists and citizen scientists and ultimately provided to the established photo-ID catalogues from the region. A formal collaboration with the global photo-ID platform, HappyWhale will be established.

RP07 IWC STRANDINGS INITIATIVE – EMERGENCY RESPONSE AND INVESTIGATIONS

Over the next two years, the Emergency Response and Investigations fund will support response, collection of data to determine the cause(s) or contributing factors for the event and/or to fill critical data gaps identified by the SC or Commission. The Initiative will be evaluated annually and policies and procedures adapted according to feedback from responses and through Steering Group/Expert Panel advice.

27.2.5 Databases and catalogues

RP18 SHIP STRIKE DATABASE COORDINATOR

The ongoing development of the IWC ship strike database requires data gathering, communication with potential data providers and data/database management. This project will provide support for expanding and maintaining the database.

RP33 ANTARCTIC BLUE WHALE CATALOGUE: COMPARISON OF NEW PHOTOGRAPHS FROM 2014-2020

In year one (2019) this project will compare the identification photographs of an estimated 45 individual Antarctic blue whales collected during ICR cruises 2014-17, to the Antarctic Blue Whale Catalogue. These identifications would increase the size of the catalogue (458 individuals) by almost 10%. In year two (2020) additional photos representing approximately 12 IDs are expected from collaborating scientists and citizen scientists that will be compared to the catalogue. The expected outcome is an expanded dataset that may improve estimates of population abundance and reveal new information on movement patterns.

RP32 SOUTHERN HEMISPHERE BLUE WHALE PHOTO CATALOGUE

The Southern Hemisphere Blue Whale Catalogue (SHBWC) is an international collaborative effort to facilitate cross-regional comparison of blue whale photo-identifications catalogues. To date more than 1,500 individual blue whales have been contributed to the SHBWC from researchers groups working on areas off Antarctica, Chile, Peru, Ecuador-Galapagos, Eastern Tropical Pacific, Australia, Timor Leste, New Zealand, Madagascar and Sri Lanka. Therefore, the SHBWC has become the largest repository of Southern Hemisphere blue whale photo-identifications. Results of comparisons among different regions will improve the understanding of basic questions relating to blue whale populations in the Southern Hemisphere such as defining population boundaries, migratory routes, visual health assessments, and to model abundance estimates. The results will contribute primarily to the IWC Southern Hemisphere blue whale assessments.

RP38 DATABASE MANAGEMENT

The IWC Secretariat hosts several databases for the SC. These have annual service costs associated with them including, web/database servers, storage, backups, software licences and other associated infrastructure or costs.

27.5.6 Reports

RP03 MERCURY IN CETACEANS: BIOGEOCHEMICAL CYCLING, TOXICOLOGICAL IMPACTS

In response to the Commission resolution on mercury, the objective of the work is to comple the global review of mercury in cetaceans, resulting in the documentation and mapping of decadal trends. The Scientific Committee will also invite experts in mercury in the environment and its cycling and in mercury and selenium cetacean toxicology to participate to provide further detail and interpretation of the current status and potential impact of mercury on cetacean populations at an ocean basin scale.

RP04 PRODUCTION OF ANNUAL STATE OF THE CETACEAN ENVIRONMENT REPORT (SOCER) FOR THE SCIENTIFIC COMMITTEE AND COMMISSION (2019 AND 2020)

SOCER is a long-standing effort to provide information to Commissioners and Committee members on key current global developments that are affecting the cetacean environment. Focus will be on the Atlantic Ocean (2019) and the Pacific Ocean (2020). It will, in both years, also present key current global developments that are affecting the cetacean environment. It will also contain a glossary of technical terms used and species names. A 5-year compendium spanning all regions is also being produced.

RP02 AMENDMENT OF THE RMP GUIDELINES TO INCORPORATE SPATIAL MODELLING APPROACHES TO ESTIMATE ABUNDANCE

The ‘Requirements and Guidelines for Conducting Surveys and Analysing Data within the Revised Management Scheme’, referred to as the ‘RMP Guidelines’ (IWC, 2012) constitutes a document prepared by the Scientific Committee to state the requirements and to guide the collection and analysis of survey data to compute abundance estimates for use in the Revised Management Procedure (RMP). Currently this document provides detailed guidance for developing estimates using design-based line transect shipboard and aerial surveys. Amendments are required to consider other methods, for example, model-based analysis of survey data and mark-recapture models. This project will update the RMP Guidelines as required by the Scientific Committee. This update will be completed in consultation with the project’s steering committee and presented for consideration of the SC by SC68b. The expected outcome is a new, revised document of with the ‘RMP Guidelines’.

27.5.7 General items

***IMPLEMENTATION*: RESOLUTIONS AND INSTRUCTIONS FROM COMMISSION & FOLLOW UP FROM PREVIOUS YEARS’ RECOMMENDATIONS**

This line is required to accommodate additional work requested by the Commission at IWC67 and work generated by meetings, workshops and projects funded and concluded in the first year (2019). This line can also accommodate new project proposals generated during the 2019 Scientific Committee meeting.

28. WORKING METHODS OF THE COMMITTEE

28.1 Rules of Procedure of the Scientific Committee

Attention: C, S

As per usual practice in the last biennium the Committee has been reviewing its working methods to improve transparency and align its processes with the biennial pace of the Commission. These changes and a number of changes that were made in previous years and approved by the Commission (i.e. SORP Voluntary Fund, new process to allocate and manage the Research Fund and the Small Cetacean Voluntary Fund Rules of Procedure) require a number of adjustments and additions to the Commission Rules of Procedure, Financial Regulations and Scientific Committee Rules of Procedure. The Committee ***agrees*** *to submit all proposed amendments to the Commission for its consideration (Annex W).*

The updated Rules also refer to the online ‘Scientific Committee Handbook’ that has been updated at this meeting. The Committee ***requests*** *the Secretariat to post the updated version online as soon as feasible. The Committee also* ***agrees*** *to that a pdf version of the Handbook be made available as a document for the Commission meeting.*

28.2 Biennial reporting and related matters

At its 2015 meeting, the Joint Conservation Committee and Scientific Committee Working Group (Joint CC/SC WG) agreed to undertake a collation and analysis of conservation-relevant recommendations from the Scientific Committee and organise these recommendations into key issues/areas highlighting those that feature regularly, including the creation of a pilot database. Double, Convenor of the Global Databases and Repositories Steering Group (GDR), presented an update on the development of this database. The Scientific Committee is fully engaged in this process and, this year, a standing agenda item was added to all sub-committee agendas to ensure a regular, more formal review of progress in delivering recommendations than was the case in the past.

Attention: SC, CC

The Committee ***welcomes*** *the development of the IWC Database of Recommendations, noting that this tool will give recommendations more prominence and improve the ability to measure progress. The Committee* ***agrees*** *to:*

(1) continue to improve its standardised way to present recommendations to include core information[13] *to facilitate input into the database; and*
(2) to work closely with the Secretariat to assist with the overall process of data entry.

28.3 Additional proposals for revisions to ‘Annex P’

The Committee continued this year the work begun last year to update Annex P in response to Commission Resolution 2016-2 and recommendations by previous Expert Panels.

Attention: C-R, SC,

The Committee ***recommends*** *the revisions to the previous Annex P reported in Annex P in response to Resolution 2016-2 and recommendations made by Expert.*

---

[13] IWC/MAY18/CCSC/01

28.4 Succession plan for key Scientific Committee experts

Last year, the Committee had identified the need to consider 'succession planning' for key participants, particularly in relation to the *Implementation Reviews* and assessment processes. Informal discussions continued informally during the intersessional period and invitations were issued to three modellers to evaluate their interest in becoming active members of the IWC Scientific Committee, but only one could attend. Concern regarding succession planning of these other key positions on the Committee still remains and an intersessional group has been re-established to look at this and report back to the Committee next year (Annex Y).

The Committee also refers to its discussion related to a Deputy Head of Science in its review if the governance report (see Item 28.6.2).

28.5 Update on Data Availability requests

Suydam provided a summary of requests received under the Data Availability Agreement shown in Table 34.

Table 34

Summary of requests under the Data Availability Agreement.

Date	Requested by	Objective/Subject	Outcome
June 2015	de la Mare Australia) – Procedure B	(a) Consistent with recent advice of the Scientific Committee with particular respect to minke whale nutritive condition analyses, to develop a set of models that best capture the Committee's previous recommendations, taking into account the structure of the underlying processes giving rise to the data; and (b)To provide analyses relevant to the determination of sample sizes for detecting specified trends in the age at sexual maturity (ASM).	SC/66B/EM/02, SC/67A/EM/01, SC/67A/EM/02, SC/67A/EM/03, SC/67A/EM/04, SC/67A/EM/07, SC/67A/EM/08, SC/67B/EM/01 Rev1, SC/67B/EM/02, SC/67B/EM/03, SC/67B/EM/08, See EM Annexes, 2016 to 2018. Differing results between research groups about changes in body condition of Antarctic minke whales
January 2018	Baker (USA	The intent of the request is to examine plausible stock hypotheses. Analyses will rely primarily on tests of Hardy-Weinberg expectations, exact tests of differentiation, randomized Chi-squared tests (contingency tables), Analyses of Molecular Variance (AMOVA), as well as mixed-stock analyses, clustering methods and kinship (parent offspring pairs), to investigate dispersal and differences in haplotype frequencies, genotypes and sex for various geographic and temporal strata.	On-going

28.6 Any other matters

28.6.1 Welfare Assessment Tool

Since our last discussion in 2015 on animal welfare related matters relevant to the Committee (IWC, 2016, p.86), Dr. Nicol (Professor of the Royal Veterinary College, London) developed a 'Welfare Assessment Tool' following the recommendations of the Workshop to 'Develop Practical Guidance for the Handling of Cetacean Stranding Events' (South Africa, 2016) on this matter. This year, the Committee received a report from Nicol on the latest phase of the development of such a tool, that is being developed to help assess non-hunting related threats in the context of the IWC's Welfare Action Plan and in a joint project between the RVC and Humane Society International, supported by the UK Department for Environment, Food and Rural Affairs (Defra). The approach is based on application of the 'five domains model' (Beausoleil and Mellor, 2015; Mellor *et al*., 2015) and two hypothetical case studies have been explored, one related to marine debris and the other to whale-watching.

Trial assessments were presented and the Scientific Committee was asked for assistance and advice in the development of real examples for consideration. The Committee welcomed the information provided and further discussions were held informally. The Tool was also considered by the Whale Watching Subcommittee (see Annex N) and will be presented for consideration by the Commission at the next meeting of the Working Group on Whale Killing Methods and Associated Welfare Issues.

28.6.2 Review of the IWC review report

The final report from the Governance Review was released on the 16th April 2018 (downloadable here: https://archive.iwc.int/?r=6890). The Independent Review Panel report represents the view of the three panellists, based on a survey, in-person interviews and analysis of documents. It represents only the first step of the Governance Review process. The Chair of the Operational Effectiveness Working Group of the Finance and Administration Committee asked the Scientific Committee to provide a voluntary feedback to the Commission on recommendations related to the Committee.

The Scientific Committee formed an *ad hoc* Working Group to develop an initial response, which was then discussed in Plenary. The initial WG membership was restricted to the Scientific Committee Chair and Vice Chair, all Heads of Delegations present at the meeting, sub-groups Convenors that are also delegates, and former Scientific Committee Chair present at the meeting. This subset represented the view of Committee members that, given their roles, had a strong knowledge on the current and past structure and procedures of the Committee. More delegates and invited participants joined the discussion in Plenary. The final version of this preliminary feedback, which has the support of all 32 delegations attending the meeting and additional members of the Scientific Committee is provided in Annex X.

The Scientific Committee organised its discussion and feedback on Review Panel's recommendations and comments around five mutually exclusive subject areas (pre-eminence of the Scientific Committee, IWC strategic planning, communication, Scientific Committee function in relation to Commission and other subsidiary bodies, Secretariat function in relation to the Scientific Committee). Within each subject area, those recommendations of perceived importance to the WG were identified. Where feasible, a timeline for developing a response was proposed.

Attention: C, SC

Given the fact that both the Chair of the Commission (Morishita) and the Chair of the F&A Working Group on Operational Effectiveness (Phelps) reminded the Committee that the Commission has not yet decided the fate of the 'IWC review report', nor has yet requested a full engagement by the Committee, the Committee ***agrees*** *to submit the preliminary feedback on the report (Annex X) for the Commission's consideration.*

In addition, given the productive exchange of opinions and ideas on several aspects of the Committee working methods that occurred in during its discussions, the Committee ***agrees*** *to establish an Intersessional Correspondence Group on 'Improving on-going working practices of the IWC Scientific Committee' under DeMaster (see Annex Y). The ICG will provide a written summary of its proposals to the Scientific Committee 60 days prior to the start of the annual meeting of the Scientific Committee in 2019. This ICG will also be in charge dealing with the preparation of a draft document for the follow-up on Governance Review, should the Commission instruct the Committee to do so at its next biennial meeting.*

28.6.3 Additional discussion on other issue related to the Committee working procedures

A number of suggestion for improving the ability to follow a topic during the Scientific Committee meeting were discussed by the Committee and the Convenors group. In order to facilitate the full participation of members of the Committee to various sub-groups and, especially, to the discussion of cross-cutting issues relevant to different groups, the Committee **agrees** that next years the Convenors should: (a) organise joint-sessions early in the meeting and release draft reports of those discussion, as soon as feasible; (b) adopt a simple coding system for 'hot topics' (e.g. North Pacific common minke whales: NPMW, Antarctic minke whales: AMW; biopsy sampling; etc.), which will be included in the daily timetable together or instead of the Agenda item. The Convenors group will carefully consider these issues intersessionally.

29. PUBLICATIONS

The Secretariat reported on the excellent progress made with the *Journal* this year, and in particular that the previously noted backlog has now been dealt with. This has been particularly assisted by the excellent work of the new Associate Editors including Fortuna, Leaper, New, Jackson, Punt, Tiedemann, Zerbini. The Committee **thanked** the Publications Team for its dedication and hard work and **reiterated** the importance of the *Journal* and *Supplements* to its work.

30. ELECTION OF OFFICERS

This was the final year of office for the Chair (Fortuna) and the Vice-Chair (Suydam). In accordance with its Rules of Procedure, the Vice-Chair becomes the new Chair for the next three years. The Committee elects Zerbini (Brazil) to be the new Vice-Chair by consensus. The outgoing Chair will provide the formal report to IWC67 in Florianopolis, Brazil of the SC Reports from the 67a and 67b SC meetings.

The Committee rose in appreciation to thank the outgoing Chair. It wished to formally record its immense gratitude for her excellent leadership over the past three years. Dr. Fortuna's scientific and organizational skills provided a lasting legacy to the Committee. She adeptly faced the many complex and challenging issues during her term and tremendous progress has been made for the benefit of the entire Commission in meeting its science and stewardship objectives. The Chair, Head of Science, and Executive Secretary of the Commission added their thanks and congratulations to the many participants expressing their appreciation to Dr. Fortuna.

The Committee also welcomed with enthusiasm the new team of Suydam and Zerbini and looked forward to working with them over the next three years.

31. ADOPTION OF REPORT

The Committee adopted the report at 17:45 hrs on 6 May 2018, apart from the final items discussed during the last session. As is customary, these items were agreed by the Chair, rapporteurs and convenors. The Chair thanked the participants for their scientific contributions as well as their constructive dialogue. Given the sensitivity of several agenda items, this positive approach helped ensure that all views could be presented and rigorously discussed for a productive outcome. The Chair especially thanked the convenors, rapporteurs, Head of Science, and Vice-Chair for their excellent assistance. Finally, she reiterated her thanks to the government of Slovenia and the hotel staff for the facilities and great service, which contributed greatly to the success of the meeting.

Fortuna concluded that it had been an honour to serve as the IWC Scientific Committee Chair over the past three years. She expressed her gratitude for all the support provided by so many as she led this effort. She voiced her thanks for the Secretariat, and in particular her deep appreciation for the guidance provided by the Head of Science (Donovan) without whom she could not have accomplished her work.

Suydam congratulated Fortuna for having expertly led the Scientific Committee as their Chair over the past three years. He noted that the praise and applause from the participants in the room were well very much deserved given her outstanding leadership. Suydam noted that it will be a particular challenge to follow the incredible example set by Fortuna and thanked her for her mentorship. The Executive Secretary (Lent) added to these words of gratitude and commendation on behalf of the Secretariat and wished her all the best. She also offered the full support of the Secretariat to the incoming SC Chair Suydam.

Echoing the sentiments raised under Item 30, participants thanked the Chair for her adept, fair and efficient handling of the meeting, her unflagging dedication and her great contribution to the effective working of the Committee.

ABSTRACT

Shore based surveys of northbound eastern North Pacific gray whale calves were conducted between March and June from the Piedras Blancas Light Station on the central California coast each year from 1994-2016. Estimates of the total number of northbound calves displayed a high degree of inter-annual variability, ranging from 254 calves in 2010 to 1528 calves in 2004. Calf production has been particularly high during the past 5 years (2012-2016) with a total of >6,500 calves estimated during this period, including four of the highest years of calf production (>1,000 calves per year) since our calf counts began in 1994. The 2016 estimate of calf production (1,351) is about 5% of the reported total abundance (26,960) for the eastern North Pacific population. A trend in median migration dates was observed, indicating that the midpoint of the migration is now occurring about a week later than it did in the mid-1990s. The 23-year data set described herein serves as an excellent foundation upon which to examine the inter-play between changing environmental conditions and gray whale population dynamics.

INTRODUCTION

The majority of Eastern North Pacific gray whales *(Eschrichtius robustus)* annually migrate southward from summer feeding grounds in the Pacific Arctic to wintering areas off Baja California, Mexico (Rice and Wolman 1971, Perryman and Lynn 2002). Both the southward and northward migration is segregated, to a large extent, by age, sex and reproductive condition. During the northward migration, females with their calves of the year are the last to depart the Baja wintering areas. These mother-calf pairs are observed on the migration route between March and May and typically arrive to the summer feeding grounds between May and June.

Shore-based counts of northbound gray whale calves have been conducted off central California each spring from 1994 to 2016. This report presents an overview of results from this 23-year time series of estimates of gray whale calf production.

METHODS

Shore-based counts of northbound gray whale calves have been conducted from the Piedras Blancas Light Station (north of San Simeon, California) each spring from 1994 to 2016. Data collection methods and analytical techniques have remained consistent each year and follow those reported elsewhere (see Perryman *et al*. 2002, 2011). Briefly, counts were conducted by four observers, with two on effort at any one time, rotating through the following schedule: (a) 90-min on effort as the offshore search area observer, (b) 90-min on effort as the inshore search area observer, (c) 3-hr off effort. Weather permitting, this work was carried out for 12 hours per day; 6 days per week in 1994-2003 and 2005 and 5 days per week in 2004 and 2006-2016. Primary search effort was carried out with unaided eye but 7x50 and 25x150 binoculars were also used when needed.

Based on night/day migration rate data derived from thermal sensors (1994-1996) and aerial surveys (1994-1995) to determine offshore distribution (Perryman *et al*. 2002), we assumed that: (1) the number of gray whale calves passing the survey site far enough offshore to be undetectable by visual observers was negligible, and (2) day and night passage rates were equivalent. We also assumed that detection probabilities were the same across acceptable sighting conditions (see Reilly *et al*. 1983; Reilly 1992). To correct for imperfect probability of detection of calves by the visual observers, we corrected the observer estimates of northbound calves by the average detection probability estimates from seven consecutive years (1994-2000) of replicate counts (mean = 0.889; SE = 0.06375).

Each day of survey effort was divided into four 3-hr periods and passage rates during these periods were calculated from the observed counts multiplied by the inverse of the detection function. To correct for periods when observers were not on watch (e.g. poor weather, night time, days off), we embedded the estimators in a finite population model that was stratified by week to account for varying passage rates (Cochran 1977). A Taylor series expansion (Seber 1982) was used to calculate the variance of the estimates.

RESULTS

Estimates of the total number of northbound calves showed a high degree of inter-annual variability, ranging from 254 calves in 2010 to 1528 calves in 2004 (Table 1). Calf production has been particularly high during the past 5 years (2012-2016) with a total of >6,500 calves estimated during this period, including four of the highest years of calf production (>1,000 calves per year) since our calf counts began in 1994 (Fig. 1). The 2016 estimate of calf production (1,351) is about 5% of the reported total abundance (26,960; Durban et al. SC/67a) for the eastern North Pacific population in 2016.

A trend in median migration dates was observed in the time series, indicating that the midpoint of the migration is now occurring about a week later than it did in the mid-1990s. The slope of the migration timing is significant (F = 6.030, p = 0.023) if the outlier from 1999, the first year of an unusual mortality event for the eastern North Pacific population, is deleted from the data set (Fig. 2).

DISCUSSION

During the 23-year time series reported here, estimates of gray whale calves displayed a high degree of inter-annual variability. Based on data from 1994 to 2000, Perryman *et al*. (2002) suggested that the reliance of female gray whales on stored fat resources during pregnancy combined with sea ice regulated access to food during the beginning of a feeding season may impact their ability to carry existing pregnancies to term. When these calf estimates were examined in the context of environmental data from the northern Bering Sea, a relationship was found between the timing of seasonal ice melt and estimates of northbound gray whale calves counted the following spring. In heavy ice years, when ice extends far to the south, the temporary lack of access to foraging areas appears to have a negative impact on calf production.

The particularly high calf production observed during the past 5 years (2012-2016), including four years of the highest calf production recorded (>1,000 calves per year) since our counts began in 1994 suggests that gray whales have been experiencing a period of favorable feeding conditions in the Arctic, possibly related due to the combination of expanding ice-free habitat (Moore 2016), increased primary production (Arrigo and Dijken 2015) and increased flow of nutrient-rich waters through the Bering Strait (Woodgate *et al*. 2012). This hypothesis is further supported by the recent (2014/2015 and 2015/2016) increase in abundance of the eastern North Pacific gray whale population (Durban et al. SC/67a)

The trend in median migration dates reported here, indicating that the midpoint of the migration is now occurring about a week later than it did in the mid-1990s, is analogous to the finding of a one week delay in annual mean sighting dates of southbound whales migrating past Granite Canyon, California (Rugh *et al*. 2001). While the impacts of climate change in the Arctic environment are far from being understood, this change in migratory timing of gray whales may reflect a response to shifting habitat parameters on the summer feeding grounds. In the short term, changes in the Arctic environment may represent “boom time” for baleen whales as suggested by Moore (2016).

ACKNOWLEDGEMENTS

Our shore-based surveys of gray whales conducted from the Piedras Blancas Light Station would not be possible without the support and hospitality provided by U.S. Department of Interior, Bureau of Land Management. We are particularly indebted to the support provided by John Bogacki, Jim Boucher and Ryan Cooper. A long list of talented field biologists contributed to this study but the contribution of Richard Rowlett, Susan Chivers and Morgan Lynn stand out as exceptional. The support of NOAA Fisheries and the International Whaling Commission has been a critical component of this research.

ABSTRACT

We conducted shore-based sighting surveys to estimate the number of northbound migrating gray whale calves passing Piedras Blancas, California, for seven consecutive years (1994–2000). In addition, we conducted aerial surveys to determine offshore distribution of the migration in 1994 and 1995, measured day/night migration rates with thermal sensors in 1994–1996, and maintained concurrent replicate watches near the peak of each migration to estimate the proportion of the cow/calf pairs missed by the standard watch team. During good weather, we counted 325, 194, 407, 501, 440, 141, and 96 calves during 1994–2000, respectively. Correcting these counts for periods not on watch and for calves missed, produced final estimates of 945 calves (SE = 68.21) for 1994, 619 calves (SE = 67.19) for 1995, 1,146 calves (SE = 70.67) for 1996, 1,431 calves (SE = 82.02) for 1997, 1,388 calves (SE = 91.84) for 1998, 427 calves (SE = 41.10) for 1999, and 279 calves (SE = 34.79) for 2000. Calf production indices (calf estimate/total population estimate) are 4.2%, 2.7%, 4.8%, 5.8%, 5.5%, 1.7%, and 1.1% for the years 1994–2000, respectively. Fluctuations in calf production over this time period were positively correlated with the length of time that primary feeding habitat was free of seasonal ice during the previous year.

Key words: gray whales, *Eschrichtius robustus,* reproduction, calf production, surveys, arctic ice.

During the spring of each year, gray whale (*Eschrichtius robustus*) cows and calves migrate northward from the nursery lagoons of Baja California, Mexico, to their feeding grounds in the Bering and Chukchi Seas. Along the central California coast and in some areas to the north, this migration passes very close to shore. In the late 1970s and early 1980s, counts of northbound cow/calf pairs were made from sites in Alaska, Oregon, and California to estimate calf production for this stock (Hessing 1981, Herzing and Mate 1984, Poole 1984*a,b*). Hessing (1981) reported that calves represented 4.6% of the total count of gray whales migrating northward through Unimak Pass, Alaska. Herzing and Mate (1984) estimated that calves represented 4.6% of the population based on their 1980 survey of southbound and the northbound whales from Yaquina Head, Oregon. Poole (1984*a,b*) conducted the most intensive of these surveys in 1980 and 1981 from Pt. Piedras Blancas, California. From these surveys, Poole estimated calves passing this site comprised 4.7% to 5.2% of the population.

Since these surveys, the gray whale population has continued to increase at an estimated rate of about 2.5% per year reaching approximately 22,263 whales in 1995/1996 (Buckland and Breiwick, in press; Hobbs *et al.,* in press). During this same period, data collected from specimens taken in the Soviet aboriginal hunt suggested a steep decline in gray whale pregnancy rates (Zimushko and Ivashin 1980; Blokhin 1984, 1989, in press *a,b*). Reilly (1992) noted, however, that potential sampling biases in this hunt should be explored before conclusions were drawn from these data. In addition, benthic sampling in the Chirikov Basin from 1986 to 1988 revealed a 30% drop in biomass and a shift in the size structure of the amphipod community, which researchers suggested could indicate that gray whales were approaching the carrying capacity of this benthic resource (Highsmith and Coyle 1992; Coyle and Highsmith 1994; Stoker, in press).

In light of these studies, the National Marine Fisheries Service (NMFS) included a study of gray whale recruitment as part of the monitoring program associated with the removal of this stock from the List of Endangered and Threatened Wildlife and Plants (Rugh *et al.* 1999). In this paper we report the results of seven consecutive gray whale cow/calf surveys at Pt. Piedras Blancas between 1994 and 2000. Our primary objective was to determine whether the proportion of calves in the population (indexed here as the estimate of the number of calves passing Piedras Blancas divided by the population size estimated from surveys of southbound gray whales conducted by NMFS) had declined since the 1980 and 1981 calf surveys by Poole (1984*b*). We report estimates of the number of calves passing our research site during each survey year, the results of experiments conducted to estimate the proportion of calves missed by observers, and the results of day versus night migration rate experiments. We also explored the relationship between the duration of seasonal ice cover over primary feeding grounds and calf production for this population.

METHODS

Survey Site

We conducted the surveys from Pt. Piedras Blancas, San Luis Obispo County, California (35°40′N, 121°17′W) (Fig. 1a, b). Pt. Piedras Blancas is approximately 160 km south of Monterey and 240 km north of Santa Barbara.

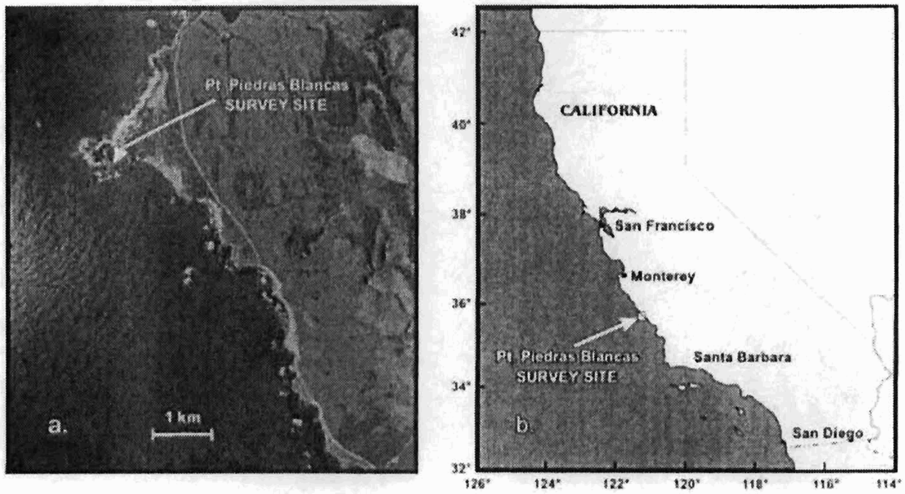

Figure 1. Aerial photograph of survey site at Pt. Piedras Blancas (a) and illustration showing location of site along the California coast (b).

Poole (1984*a,b*) selected this site for his 1980 and 1981 cow/calf surveys and noted it is the only point to intersect a straight-line course from Pt. Buchon to Pt. Sur along 160 km of the central California coast. A protected cove extends to the south and east of Pt. Piedras Blancas through which more than 90% of the cow/calf pairs passed during Poole's surveys.

Shore-based Surveys

We designed the surveys to encompass the entire duration of the northbound cow/calf phase of the migration as reported by Poole (1984*a*). The surveys began in March of each year and extended until late May or early June. Watches were maintained for 12 h/d, 6 d/wk. Two observers divided their effort between inshore and offshore watch areas (Fig. 2a). The offshore observer often assisted the inshore observer in determining the number of cow/calf pairs present and confirming their distance offshore as they rounded the point. Observers stood two, three-hour watches per day (3 h on watch followed by 3 h off watch), rotating from the offshore position to the inshore position after 1.5 h.

The primary searching technique was scans with the naked eye, but handheld binoculars (7×) and tripod-mounted 25× binoculars were used for confirming the presence of a calf and for searching far offshore. The offshore observer used 25× binoculars mounted on an adjustable tripod to scan the distant offshore area for approximately five minutes every half hour. Offshore search effort with the 25× binoculars totaled two hours per day. As pods exited the viewing area, observers measured the distance offshore using the reticle scale in the 25× binoculars if the whales were beyond 400 m, the minimum distance measurable on the reticle scale. We used the formulae

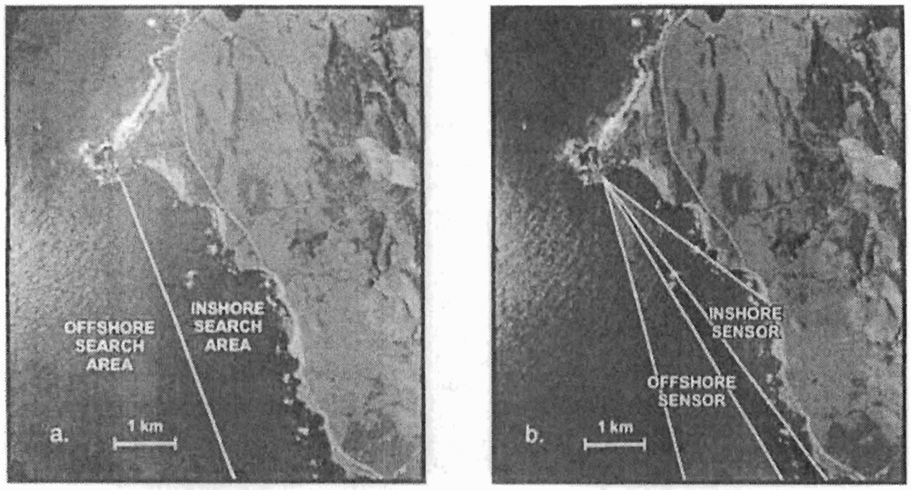

Figure 2. Approximate areas searched by inshore and offshore observers (a) and areas covered by two infrared sensors (b).

developed by Lerczak and Hobbs (1998) to determine offshore distance from reticle measurements. When cow/calf pairs passed too close to the shore to use the reticle scale, observers visually estimated the distance in meters. Observers recorded sea state (Beaufort scale) and visibility at the beginning of each watch and when conditions changed. We used the same visibility codes as Reilly *et al.* (1983), which range from a visibility code of 1 for excellent conditions to a code of 6 for unacceptable conditions. We chose, as did Poole (1984*b*), to exclude effort and sightings from periods when visibility conditions were poor (code 5, visibility <0.8 km).

Gray whale calves were identified by their small size, dark color, and lack of mature barnacle patches. Calves passed the survey site swimming in close association with an adult gray whale. We assumed that the large whale was the mother of the calf and refer to the two animals as a cow/calf pair. Our goal in these surveys was to count calves, but the presence of the cow with each calf greatly increased our probability of detecting the calves. Often the blow of a small calf was not visible to the observers even at a distance of 200 m, while the blows of adult gray whales were generally visible to the unaided eye beyond 4 km. Thus, we refer to cow/calf pairs when dealing with the topics related to detection of the passing calves and then to calves alone in sections concerning estimates of total calf numbers.

The probability of detection for a given cow/calf pair was not known in advance. To estimate the total number of whales that passed, we first needed to estimate these probabilities. For instance, whales that pass far offshore are less likely to be detected than those passing close to the survey team. In addition, no pairs which passed during off-watch hours (*e.g.,* at night or on Sundays) were recorded, and differing rates of passage during off-watch hours could bias estimates based on assumptions of equal rates. Finally, to account for imperfect nearshore detection, we used a replicate watch scheme to estimate nearshore detection probability. Methods for addressing each of these sources of bias in our total calf estimate are discussed below.

Aerial Survey

To estimate the fraction of pairs that were unlikely to be detected because of their distance offshore, we conducted a series of aerial surveys (seven between 27 April and 8 May 1994 and eight between 20 April and 2 May 1995) of the area from Piedras Blancas to a point of land about 35 km to the southeast. Each survey consisted of seven parallel transects spaced 2 km apart with the final transect about 12.3 km offshore. The leg nearest the shore followed the contour of the coast about 30 m outside the surfline. We alternated the starting point of the surveys between southern end and the northern end of the nearshore leg to avoid visibility bias caused by glare on southbound legs. Survey speed was maintained at 185 km/h at an altitude of 305 m.

The surveys were flown in a twin-engine, high-wing Partenavia aircraft. The forward section of this aircraft is made of clear plexiglass, which provided excellent visibility below and ahead of the plane. Large bubble windows were installed in each side of the cabin. Three observers, one in the forward section and one at each bubble window, searched for gray whales along the trackline and out to a distance of about 1 km on each side of the trackline. Distances to whales were determined by measuring vertical angles with hand-held inclinometers. The observer in the nose of the aircraft also operated the data-acquisition system which automatically recorded time and aircraft position for each sighting.

Infrared Sensor Sampling

To determine if our calf estimate required correction for diel variation in migration rate, we collected data during the 1994–1996 surveys with two forward-looking infrared (FLIR) sensors developed by the U.S. Navy (model AN/KAS-1A). These sensors sample in the far infrared region of the spectrum (wavelengths 8–12 μm) and can detect differences in temperature of 0.1°C. Our previous experience with these sensors has indicated that they can detect the blow of a gray whale in a temperate environment up to 8 km away (Perryman *et al.* 1999). The instrument can be selected to operate in either a narrow (1.1° × 2.2°, magnification 9×) or wide (3.4° × 6.8°, magnification 3×) field of view. We sampled using only the wide field of view.

The instruments were mounted on tripods positioned on a knoll (about 20m above sea level) that was adjacent to the visual survey site. From this position, the infrared sensors captured roughly two-thirds of the area monitored by the survey team (Fig. 2b). Weather permitting (no fog or rain, light winds), we operated these sensors for four hours each day and night during the peak of the migration (mid-April to mid-May).

Output from these instruments is standard composite RS-170 video. We recorded this output on 120-min VHS video tapes. Data titlers inserted between the instruments and the video recorders displayed time and date on the video record. We screened the tapes for blows at high speed and then reviewed sections with whales several times at normal speed. We identified cow/calf pairs by the relative sizes and frequencies of the blows and the relative position of the two whales. We used a paired *t*-test to test the null hypothesis of no difference in migration rates between our day (0700–1900) and night (1900–0700) strata. Counts from video tapes were paired for comparison with the most recent tape from the other stratum. Counts were not paired if the interval between day and night samples exceeded 24 h.

Replicate Watch Effort and Detection Probabilities

We conducted independent, concurrent replicate watches during part of each survey to estimate the fraction of calves passing near shore that are undetected by the primary observers (*e.g.,* Rugh *et al.* 1993). An experienced observer stood replicate watches at a site approximately 200 m from the primary observers. A small knoll located between the two locations prevented actions by observers at either location from cueing the other team to the presence of whales. Replicate observers stood watch for 6 h/d but the duration of each watch varied from two to three hours based on environmental conditions and personal preference.

To estimate the detection probabilities, we fit a heterogeneous mark-recapture model (Huggins 1989, Alho 1990, see also Appendix) to the paired standard/replicate watch data. This model is a "paired" logistic regression, and allows detection probability to depend on both environmental covariates (*e.g.,* sighting conditions) and sighting-specific covariates (*e.g.,* whale behavior), *via* a linear predictor and logistic link function. The model assumes independence in detections not only among different cow/calf pairs, but also between watch stations. No communication between watch teams is a necessary condition for between-station independence, but if detection probability varies among cow/calf pairs, it is not sufficient. Specifically, if one or more random factors that affect detection probability act on both watch stations simultaneously (*e.g.,* glare off the water), then detection will be correlated between watches unless these factors are included in the model through appropriate covariates. The correlation between stations can be either positive or negative, depending on the specific dependence on each random factor, but in either case it will create a bias in the estimated detection probabilities. Similarly, if random factors that affect detection probability are correlated among cow/calf pairs (*e.g.,* pod size), then detection will be correlated among cow/calf pairs unless these factors are included in the model, leading to overestimation of precision. Problems with non-independence are well-known in the context of mark-recapture models (*e.g.,* Seber 1982) and are not detectable in the data unless appropriate covariates are considered.

The detection probability covariates that we tested for significance were year (1994–2000), watch station (standard/replicate), pod size (1–4 pairs), glare (present/absent), visibility code (1–4), number of other pairs being tracked (0–7), and migration path (inshore/offshore). We used conditional maximum likelihood (ML) (Huggins 1989, Alho 1990) to fit coefficients for these covariates and asymptotic normal approximations to estimate their covariance matrix. We selected covariates using approximate chi-squared tests for the difference in deviance between nested models, along with residual analysis using partial residual plots and simulated half-normal plots (*e.g.*, Collett 1991). Finally, we used a Taylor series approximation (*i.e.*, the delta method) to estimate the covariance matrix for the fitted detection probabilities themselves. Simulations indicated that the analytic approximations used to estimate precision were sufficiently accurate, particularly because the estimated probabilities were not the largest source of uncertainty in the final abundance estimates.

Conditional on the n cow/calf pairs that were sighted by one or both watch stations, the likelihood in the paired observer model is given by

$$l_c(\beta; y) = \prod_{i=1}^{n} \frac{p_{i,std}{}^{y_{i,std}}(1 - p_{i,std})^{1-y_{i,std}} p_{i,rep}{}^{y_{i,rep}}(1 - p_{i,rep})^{1-y_{i,rep}}}{1 - (1 - p_{i,std})(1 - p_{i,rep})}$$

where

$$p_{i,s} = e^{x_{i,s}'\beta}/(1 + e^{x_{i,s}'\beta})$$

is the unconditional probability of detection at watch station s for the ith sighting, $x_{i,s}$ is a vector of covariates for that station/sighting, β is the vector of coefficients to be estimated, and

$$y_{i,s} = \begin{cases} 1, & \text{if the } i^{\text{th}} \text{ sighting was detected at station } s \\ 0, & \text{otherwise} \end{cases}$$

are binary indicator variables for station-specific detections.

Given estimates of the detection probabilities, we could then estimate the number of whales that passed by undetected during watch periods. The usual method in a mark-recapture model would be to use counts from both watches to estimate the number of undetected animals. However, the replicate watch was only on station during part of the survey period. Therefore, we used a somewhat simpler (see Discussion) estimator which was similar to the "Horvitz-Thompson-like" estimators used by Huggins (1989) and Alho (1990), but used sighting counts only from the standard watch. With this, we estimated the total number of whales passing during each 3-h period that observers from the standard team were on watch:

$$\hat{N}_j = \sum_{i=1}^{n_j} \frac{1}{\hat{p}_{i,std}}$$

$$\hat{\sigma}_j{}^2 \equiv \widehat{\text{var}}\, \hat{N}_j = \sum_{i=1}^{n_j} \frac{1 - \hat{p}_{i,std}}{\hat{p}_{i,std}}\left(1 + \frac{\hat{\sigma}_i{}^2}{\hat{p}_{i,std}{}^2}\right) + \sum_{i=1}^{n_j} \sum_{i'=1}^{n_{j'}} \frac{\hat{\sigma}_{i,i'}{}^2}{\hat{p}_{i,std}\hat{p}_{i',std}}$$

$$\hat{\sigma}_{j,j'}{}^2 \equiv \widehat{\text{cov}}(\hat{N}_j, \hat{N}_{j'}) = \sum_{i=1}^{n_j} \sum_{i'=1}^{n_{j'}} \frac{\hat{\sigma}_{i,i'}{}^2}{\hat{p}_{i,std}\hat{p}_{i',std}} \qquad (1)$$

where j indexes three-hour periods, i indexes sightings within each period, n_j is the number of sightings during three-hour period j, and the quantities

$$\hat{p}_{i,std},\ \hat{\sigma}_i^2, \text{ and } \hat{\sigma}_{i,i'}^2$$

are the conditional ML estimated probabilities and their estimated variances and covariances.

With the assumptions (1) that the number of whales that were completely undetectable because they passed too far offshore was negligible (see Results, Aerial Survey), and (2) that the estimated inverse detection probabilities ($1/\hat{p}_{i,std}$) were unbiased, these estimated three-hourly totals are unbiased. The assumption of no bias in the estimated inverse detection probabilities was based on simulations that indicated that their estimation bias was small with respect to their sampling variance, at least for the range of detection probabilities and sample sizes considered here.

To correct for periods when no observers were on watch, we embedded the above estimators in a finite population model. This model used 3-h periods as the sampling units, and we stratified by week to account for varying passage rates over time. The sample of observed hours was not taken at random: it comprised only daylight hours during acceptable observing conditions. However, with the assumption that whale passage rates did not depend on time of day or on weather (see Results, Infrared Sensor Sampling), the sample can be considered random with respect to the cow/calf pairs.

The actual number of whales passing during each 3-h period was not observed directly, but rather was estimated from the observed counts using the estimated detection probabilities. Thus, we used a finite population model that accounted for measurement errors (Cochran 1977) in the three-hourly totals. Specifically, from above, we assumed that the estimated three-hourly totals were unbiased and had uncertainty due both to random detection and from using estimated (*i.e.,* random) detection probabilities. Further, although individual detections were assumed independent, the estimated three-hourly totals were not independent because the estimated detection probabilities were used across all 3-h periods. With the assumption of no bias in the estimated three-hourly totals, the effect of correlated measurement errors is to inflate the true variance of the estimator of total abundance. Thus, we added appropriate terms to the usual finite population estimator of variance:

$$\hat{N} = \sum_k \frac{T_k}{t_k} \sum_j \hat{N}_j$$

$$\widehat{\text{var}}\ \hat{N} = \sum_k \frac{T_k}{t_k}\left(1 - \frac{t_k}{T_k}\right) s_k^2 + \sum_k T_k \hat{\sigma}_k^2 (1 - \hat{\rho}_k) + \sum_k \sum_{k'} T_k T_{k'} \hat{\sigma}_k \hat{\sigma}_{k'} \hat{\rho}_{k,k'}$$

where k indexes weeks, T_k and t_k are the total number and the observed number of three-hour periods during week k, s_k^2 is the usual sample variance of estimated three-hour counts during week k, and the sums are over all weeks observed. The quantities

$$\hat{\sigma}_k{}^2 = \frac{1}{T_k}\sum_j \hat{\sigma}_j{}^2 \quad \text{and} \quad \hat{\rho}_{k,k'} = \begin{cases} \dfrac{1}{T_k T_{k'}} \displaystyle\sum_j \sum_{j'} \dfrac{\hat{\sigma}_{j,j'}{}^2}{\hat{\sigma}_k \hat{\sigma}_{k'}} & \text{when } k' \neq k \\ \dfrac{1}{T_k(T_k - 1)} \displaystyle\sum_j \sum_{j' \neq j} \dfrac{\hat{\sigma}_{j,j'}{}^2}{\hat{\sigma}_k{}^2} & \text{when } k' = k \end{cases}$$

are stratified versions of quantities defined by Cochran (1977), where j indexes three-hour periods within week, and the sums are over all watch periods in week k.

To develop indices of calf production from our surveys and those conducted by Poole (1984*b*) from the same site, we divided the calf estimate for each year by abundance estimates derived from an unweighted GLM model fit to point estimates from counts of southbound gray whales passing Granite Canyon, California (Buckland and Breiwick, in press). Annual estimates of abundance from this model for the years 1980, 1981, and 1994–2000 were 15,954, 16,360, 22,702, 23,281, 23,875, 24,484, 25,109, 25,750, and 26,407, respectively.[1] A Taylor series expansion (Seber 1982) was used to calculate the variance of the indices.

Ice Conditions in the Northern Bering Sea

In a typical year, ice spreads rapidly southward through the Bering Straits in December, January, and February, driven by prevailing northerly winds. Ice continues to advance across the Bering Sea until late March and early April when melting and interactions with currents at the shelf edge stop its progress, and the ice slowly recedes. The temporal and spatial pattern of seasonal ice cover in the Bering Sea varies on both a seasonal and decadal scale. Several climatic features, including the position and intensity of the Aleutian Low, the sign and scale of the Pacific Decadal Oscillation (PDO), and El Niño-Southern Oscillation events probably all interact to drive the scale and timing of ice events (Cavalieri and Parkinson 1987, Francis and Hare 1994, Trenberth and Hurrell 1995, Maslanik *et al.* 1996, Mantua *et al.* 1997, Parkinson 2000). We selected sea ice as a factor to explore in our analysis of calf production because summer feeding in gray whales is restricted to specific shallow water areas that are ice-free only part of the year (Pike 1962, Moore and DeMaster 1997, Moore *et al.* 2000). Newly pregnant females are the first to return to these feeding grounds and they must store adequate fat to fast through the upcoming winter migration during which they give birth and lactate for a calf. Environmental effects that shorten the feeding season may affect the nutritive condition of these females and subsequently impact recruitment to the population.

We used a technique devised by Wyllie-Echeverria and Wooster (1998) to develop an ice index for comparison with our estimates of calf production. We obtained weekly ice charts for the Bering and Chukchi Seas from the National

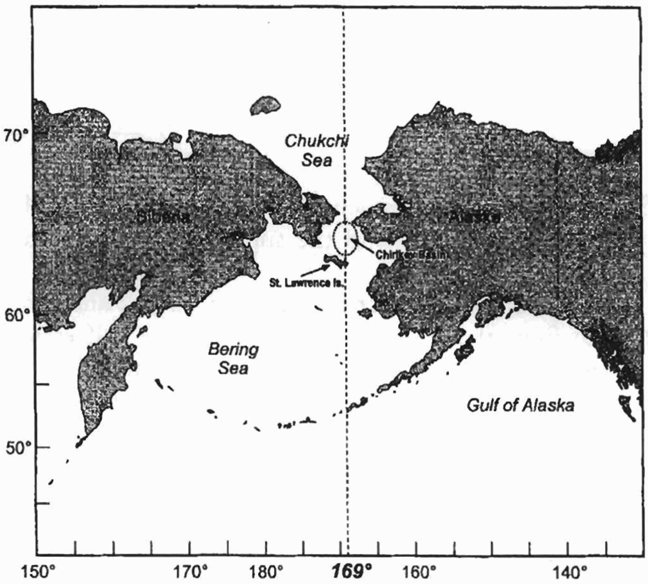

Figure 3. Location of 169°W longitude as it passes through the Bering Sea, across the Chirikov Basin feeding grounds and into the Chukchi Sea.

Snow and Ice Data Center (NSIDC) in Boulder, Colorado, for the years 1993–1999. From each chart, we determined the position of the ice edge along 169°W longitude. This meridian runs through St. Lawrence Island, across the primary gray whale feeding grounds of Chirikov Basin (Nerini 1984, Moore *et al.* 1986, Moore and DeMaster 1997), and then through the Bering Straits into the Chukchi Sea (Fig. 3). For each year, we developed a plot of the weekly locations of the ice edge along the selected meridian and then determined the length of time that a point near the center of the Chirikov feeding grounds (64°00′N, 169°00′W) was free of pack ice. We tested for correlations between the lengths of the feedings season (the ice-free periods) and our estimates of calf production for the following spring seasons. We also tested for such correlations with a one-year lag. If a reduction in feeding time impacts the probability that a pregnant female gray whale will carry a fetus to term, then a reduction in calf production should occur in the season immediately following the ice event. If a reduction in the feeding season impacts recruitment through suppression of ovulation or failure to conceive, there would be a one-year lag between the ice event and an observed reduction in the number of calves.

RESULTS

Raw Survey Data

During the seven years of this study our observers spent over 4,679 h searching from the Piedras Blancas field station and sighted 2,106 gray whale calves (Table 1). Each year we began the survey in mid- to late March and

Table 1. A summary of effort and counts for gray whale cow/calf surveys conducted between 1994 and 2000 from Piedras Blancas, California.

Survey year	Begin date	End date	Hours searched	Total calf count	Median migration date
1994	17 March	4 June	671	325	26 April
1995	20 March	26 May	610	194	20 April
1996	20 March	31 May	694	407	27 April
1997	10 March	28 May	709	501	29 April
1998	23 March	22 May	554	440	18 April
1999	22 March	10 June	737	141	11 May
2000	13 March	2 June	704	96	15 April

continued until sightings of gray whale cows and calves dwindled to insignificant numbers in late May or early June (Fig. 4). Because the timing of the northbound migration proved to be less predictable than the southbound gray whale migration, we adjusted timing and duration of our surveys to adapt to the passage rates of the northbound whales. The median migration dates ranged from 15 April to 11 May, and there was no statistical correlation between median date and total calf count ($r = 0.403$, $P = 0.460$). There was a 5.2-fold difference between our low count of 96 calves in 2000 and the high count of 501 calves in 1997.

Most of the northbound cows and calves (87.4% of pods) passed the survey site at a distance offshore that was too close to measure with the reticulated 25× binoculars (<400 m), so these distances were estimated by the survey team (Fig. 5). The two most distant detections were of two pairs that passed the point just over 1 km offshore, a distance at which gray whales can still be easily detected with the unaided eye.

Cows and calves generally remained close together, swimming side by side, as they approached and passed the survey site. On a few occasions, the calf was seen turning back into the protected cove when its mother rounded the point heading northward. On all these occasions, the mother turned back into the cove and retrieved the calf. Associations between cow/calf pairs and other northbound cows with calves or the occasional adult or juvenile were very ephemeral in nature, and most sightings (86%) were of single pairs. The largest aggregation of cows with calves that we recorded consisted of three pairs.

Aerial Surveys

In 1994 we flew nine complete replicates of the seven track lines extending from Pt. Estero to Pt. Piedras Blancas. Of the 34 cow/calf pairs sighted during the aerial surveys, all except two were found during flights along the most inshore tracking (Fig. 6a). Both of the offshore pairs were swimming toward the shore rather than parallel to the survey track lines. During the 1995 survey, we completed eight replicates of the same seven transects. All of the 41 cow/

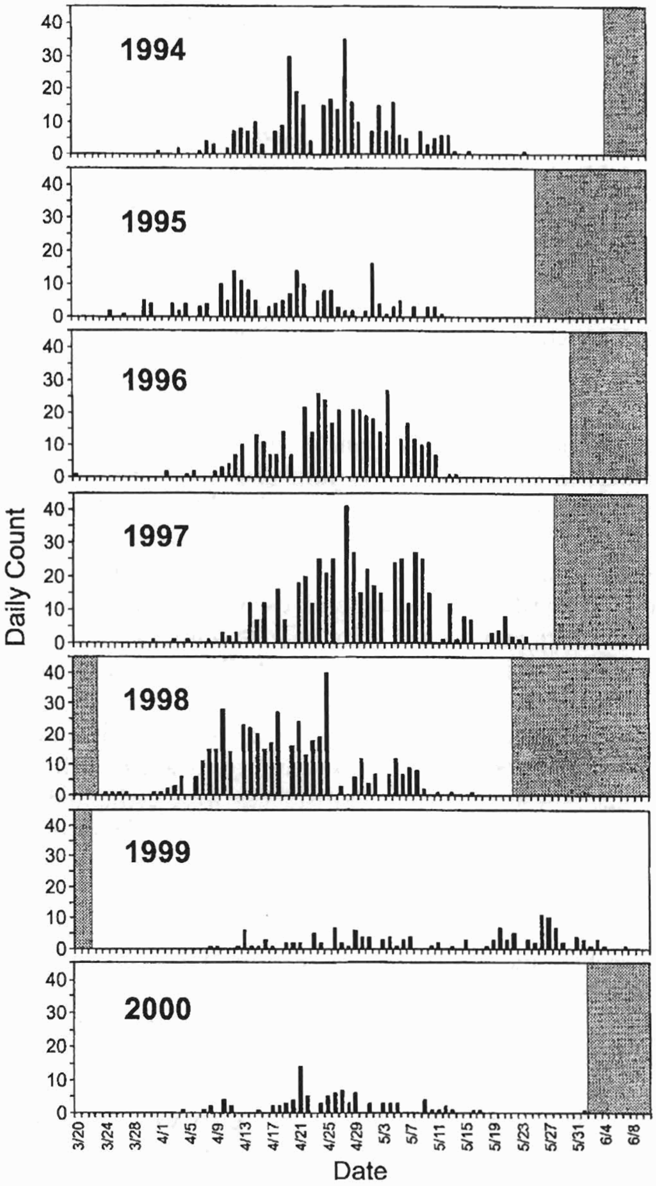

Figure 4. Daily counts of northbound gray whale calves from surveys conducted from Piedras Blancas, California. Shaded areas indicate days before and after survey period for that year.

calf pairs sighted were on the leg closest to shore (Fig. 6b). Our surveys indicated that most cow/calf pairs were found very close to shore and that the few found offshore were heading inshore. These results were consistent with the seven years of survey effort which indicated that cow/calf pairs are occasionally sighted offshore, south of Pt. Piedras Blancas, but that these pairs

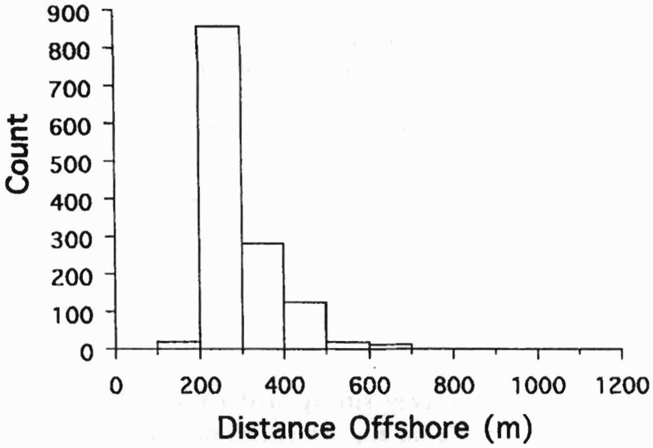

Figure 5. Distribution of offshore distances for gray whale calves passing Piedras Blancas during the surveys. Distances <400 m were estimated and those >400 m were calculated from measurements using 25× binoculars.

consistently pass the point <1 km offshore. Based on these results we did not adjust our estimates for calves passing far offshore.

Infrared Sensor Sampling

We compared day and night migration rates for northbound cow/calf pairs with data collected simultaneously by the two FLIR sensors (paired *t*-test) and found no evidence of diel differences in migration rates (Table 2). To increase the power of this test, we lumped the data from all three years and again tested for differences in counts between the day and night strata. This test also supported the hypothesis of no difference in day-night migration rates for

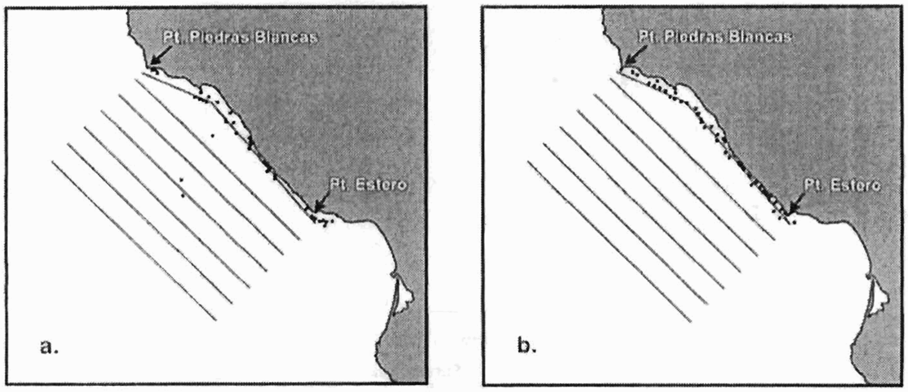

Figure 6. Aerial survey transects and gray whale calf sightings for 1994 (a) and 1995 (b). In 1994, nine surveys were flown and 34 calves were sighted. During eight surveys flown in 1995, 41 calves were sighted.

Table 2. Results of analysis of paired day and night counts of northbound gray whale calves on 2-h video tapes recorded from thermal sensors. Mean differences are absolute values for differences between all pairs of 2-h tapes in that test, and tapes averaged about 2 cow/pairs each.

Survey year	Paired samples	Mean differences	Paired *t*	*P*
1994	26	0.0	0.33	0.74
1995	32	0	0	1
1996	30	0.3	0.57	0.57
All years	88	0.2	0.19	0.85

cow/calf pairs passing the survey site (paired *t*-test, $P = 0.847$, df = 87). Given these results, we made no adjustment to our final calf estimate for diel differences in migration rate.

Replicate Watch

Of the covariates considered (year, watch station, pod size, glare, visibility code, number of other pairs being tracked, and migration path), only the main effects for year, pod size, and glare were significant at the 5% level (Table 3a). The significance of a yearly effect was due to the difference between a relatively large estimated detection probability for 1997 and a relatively small estimated detection probability for 1998 (Fig. 7). The result for 1997 may reflect the fact that the watch teams for that year were the most experienced, whereas the result for 1998 may reflect a learning curve for new observers. Because the object of this analysis was to compare yearly estimates of calf production, we chose to fully stratify by year so that differences in annual estimated numbers of calves would be less likely the result of differences in annual detection

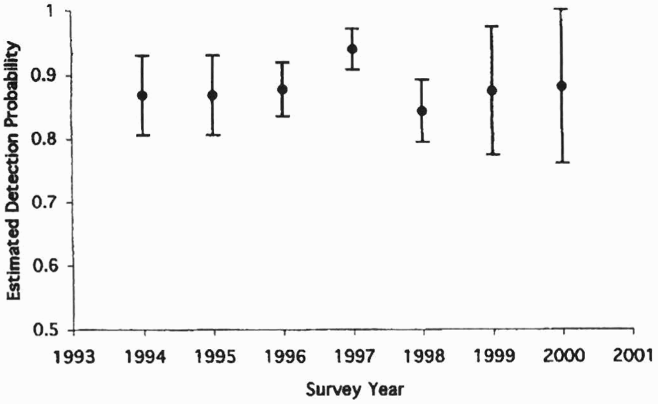

Figure 7. Annual estimates of detection probabilities for northbound gray whale cow/calf pairs. The 2000 estimate is pooled estimate for all previous years. Error bars are for ±1.96 SE.

Table 3a. Significance of adding main effects to the constant model. Change in deviance in each row of table represents the improvement in fit of model where detection probabilities p_{ij} depend on corresponding covariate, over model where the p_{ij} are constant. The P-value is from asymptotic χ^2 approximation to change in deviance.

Base model	Added covariate	Change in deviance	Change in df	P
Intercept only	—	(775.8)	(583)	—
	pod size: 1 *vs.* 2+	4.6	1	0.031
	Glare	3.7	1	0.056
	Year	11.2	5	0.047
	# Other pairs 0–3 *vs.* 4+	1.7	1	0.19
	Vis. code 1–2 *vs.* 3–4	1.7	1	0.19
	Path	0.82	1	0.36
	Watch station	0.29	1	0.59

probabilities. Stratifying fully by year did increase estimated standard errors over a partially stratified model, but it had little effect on estimated precision for the final calf abundance estimates. This was because most of the uncertainty in those final estimates was due to extrapolation to periods when the watch teams were off effort, *i.e.*, night and poor weather conditions.

After including year, the main effects for pod size and glare were no longer significant at the 5% level, although they were nearly so (Table 3b), and no other main effects or interactions were significant. It would have been possible to include terms for pod size and glare in the model, but we chose not to do so. One reason for this choice was that neither covariate could be measured precisely. Specifically, pod associations were often short-lived, and pairs along the same line of sight were sometimes recorded as groupings even though they were not. In addition, glare was defined by time of day, rather than being recorded directly by observers. There are two possible negative consequences of using a simpler model without terms for pod size and glare. First, ignoring covariates can introduce statistical dependence between watch stations and

Table 3b. Significance of adding main effects to year-stratified model. Change in deviance in each row of table represents improvement in fit of model where detection probabilities p_{ij} depend on both corresponding covariate and on year, over model where the p_{ij} depend only on year. The P-value is from the asymptotic χ^2 approximation to the change in deviance.

Base model	Added covariate	Change in deviance	Change in df	P
Intercept + Year	—	(764.6)	(578)	—
	Pod size: 1 *vs.* 2+	3.3	1	0.067
	Glare	2.5	1	0.11
	# Other pairs 0–3 *vs.* 4+	0.34	1	0.56
	Vis. code 1–2 *vs.* 3–4	1.8	1	0.18
	Path	1.2	1	0.28
	Watch station	0.29	1	0.59

Table 4. Estimates of detection probabilities p_{ij} as function of pod size and glare. Year-specific estimates were made, however estimates presented here are averaged over all years for simplicity of presentation. Final estimates used in our analysis depended only on year, and not pod size or glare; see text.

Factor	Level	Estimated average detection probability	Estimated SE
Pod size	1 pair	0.866	0.014
	2 or more pair	0.914	0.014
Glare	present	0.835	0.033
	absent	0.891	0.011

thus lead to biased estimates of detection probability. The effects of pod size and glare (Table 4), though practically significant for individual detections, were of a small enough magnitude that any bias in an estimated detection probability that ignores those factors was not important. This was confirmed by Monte Carlo simulation using a range of possible models, including ones with effects of larger magnitude than those actually estimated for pod size and glare. Second, the estimated detection probabilities come from data collected during the replicate watch period, but are applied to data from the remaining portion of the survey period as well. If covariates that were ignored have values that are, on average, different between the two periods, then the estimated average probabilities from the former period would not be applicable to the latter. There is no reason to expect that this is the case for either pod size or glare.

It is worth noting that partial residual plots for all of the covariates tested other than watch station showed a systematic pattern that, while not statistically significant, was consistent with what would be expected for those factors. For example, residuals plotted against visibility code showed that detection was somewhat less likely for higher codes (poorer visibility). The magnitude of the estimated coefficients for covariates whose main effects were not declared significant was of the same order as those for pod size and glare. In light of the residual plots, their lack of statistical significance may be caused by a difficulty, as with pod size and glare, in determining precise values for these covariates. For example, the path taken by a given cow/calf pair can include what would be considered both inshore and offshore areas. In any case, as with pod size and glare, their effects are of a small enough magnitude that any bias in estimating detection probabilities averaged over those factors would be small. Larger sample sizes (*i.e.,* more replicate watch effort) or a more objective or precise means of measuring those covariates might lead to smaller standard errors and statistically significant effects.

Calf Estimates

Our estimates of the total number of calves passing the survey site are based on counts from the standard watch, which were corrected for imperfect prob-

Table 5. Total calf estimates, estimates of detection probability, and indices of calf production for each survey years.

Survey year	Calf count	Detection probability	Total calf estimate	SE	Abundance estimate	Calf production index	SE
1994	325	0.868	945	68.21	22,710	4.2%	0.003
1995	194	0.868	619	67.19	23,281	2.7%	0.003
1996	407	0.878	1,146	70.67	23,875	4.8%	0.003
1997	501	0.894	1,431	82.02	24,484	5.8%	0.003
1998	440	0.844	1,388	94.84	25,109	5.5%	0.004
1999	141	0.875	427	41.10	25,750	1.7%	0.002
2000	96	0.889	279	34.79	26,407	1.1%	0.001

ability of detection estimated by analysis of the concurrent replicate watch data (Table 5). Although there were obvious and statistically significant (ANOVA, $F = 45.85$, $P < 0.001$, df = 6, 58) differences in total calf estimates between years, no predictable pattern or trend in gray whale reproduction is apparent from these results (Fig. 8).

Calf Production Indices

We divided our annual calf estimates by the corresponding fitted gray whale abundance estimates (Buckland and Breiwick, in press) to produce yearly indices of calf production (Table 5). We compared our indices of calf production with those derived by dividing the calf estimates from Poole (1984*a*) by the modeled abundance estimates for those years (Fig. 9) and again found significant differences between indices for some years (ANOVA, $F = 36.15$, $P < 0.01$, df = 8, 80). Pairwise comparisons (SNK) between yearly indices showed that the 1980 and 1981 indices were not significantly different ($P > 0.05$)

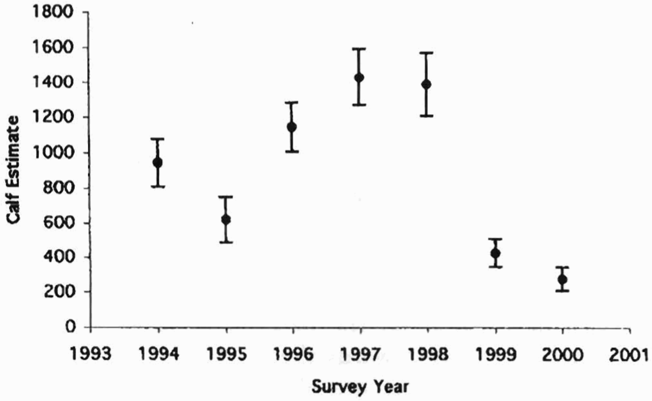

Figure 8. Estimates of the total number of gray whale calves passing Piedras Blancas during each survey year. Error bars are ±1.96 SE.

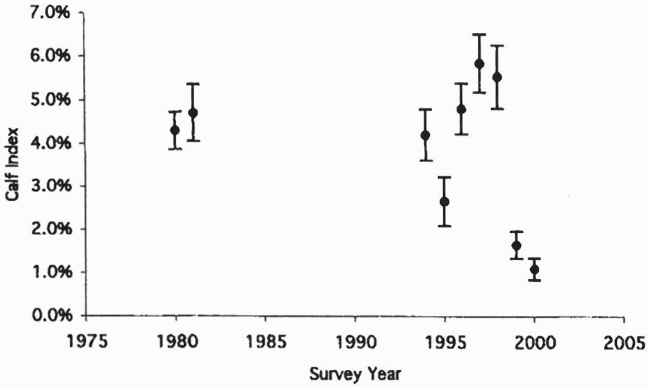

Figure 9. Indices of gray whale calf production derived from counts of northbound calves divided by modeled abundance estimates provided by Jeff Breiwick (AFSC, National Marine Mammal Laboratory). Calf estimates for 1980 and 1981 taken from Poole (1984*a*).

from those of 1994, 1996, and 1998. The clear outliers of the group of indices, 1995, 1999, and 2000, differed significantly from all other annual indices ($P < 0.05$). There was no evidence of a trend or detectable pattern in calf production over the period from 1980 to 2000.

Arctic Ice and Recruitment

The number of days that the selected reference point over the Chirikov Basin was free of seasonal ice varied from a high of 190 d (in 1993 and 1995) to a low of 147 d in 1999. We found a significant positive correlation between the ice (or feeding season) index and our estimates of calf production for the following spring ($r = 0.860$, $P = 0.010$). Thus, shorter ice-free seasons were followed by low estimated calf production, and longer ice-free periods were followed by higher estimated calf production (Fig. 10). When we introduced a one-year lag in our tests, we found no significant correlation between the ice index and calf production ($r = 0.289$, $P = 0.607$).

DISCUSSION

Like Poole (1984*a,b*), we found that the northbound migration of gray whale cows with calves closely followed the coastline in the vicinity of Piedras Blancas, with pairs often swimming just outside the surf line. This phase of the gray whale migration generally extends from late March to late May, with a median date around the last week of April. Cows with calves were most often sighted as single pairs. As the pairs approached the point from the southeast, they swam directly towards the survey site providing an excellent perspective for detecting the presence of a calf alongside the associated cow, even when the whales were still over 4 km from the survey team.

Although the cows with calves passed so close to the survey site that they

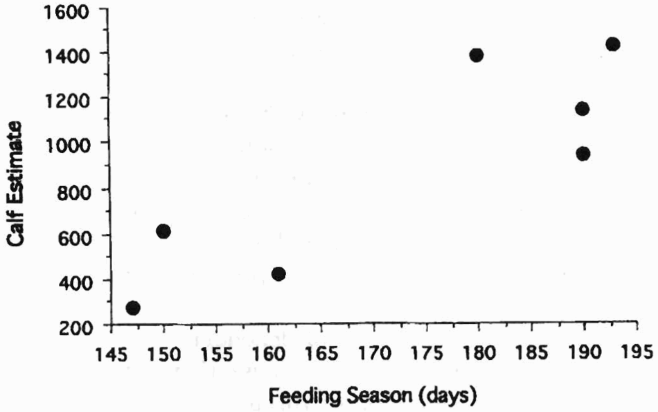

Figure 10. Number of days that gray whale feeding grounds on the Chirikov Basin were free of seasonal ice ("Feeding Season") and number of calves estimated from our surveys in subsequent spring.

could sometimes be heard as well as seen, we attempted to address each of the potential sources of bias raised from the much more difficult shore-based abundance surveys of southbound gray whales conducted from Granite Canyon, California (Reilly 1984). We scheduled the surveys to encompass the entire migration to avoid extrapolating the tails of the migration from whales counted during the core period. We conducted aerial surveys well offshore from the survey site and determined that correcting shorebased counts for whales passing far offshore was unnecessary. We excluded sightings and effort with poor visibility, codes >4, and our analysis of the replicate watch data revealed that the effect of visibility on sighting probabilities within the range of codes 1–4 was negligible. We estimated day and night migration rates from counts of whales detected with thermal sensors and found that the rates were not significantly different. We conducted concurrent replicate-watch effort each year and estimated the probability that gray whale cows and calves passing nearshore would be detected by the standard watch. Finally, as part of a complementary photogrammetric study, we used an aircraft to search for cows with calves among the adults and juveniles that constitute the first phase of the northbound migration and found none (Perryman, unpublished data). Based on these results, we assumed that passage rates measured during on-effort periods were representative of those during off-effort periods and only corrected our estimates for whales that passed nearshore but were missed by the survey team.

It would have been possible to include the replicate watch sighting counts directly in our estimates of three-hourly totals, as well as including them indirectly through the estimated detection probabilities. In fact, because the probability of detection by both watches together $(1 - (1 - p_{i,std})(1 - p_{i,rep}))$ was higher than that for the standard watch alone $(p_{i,std})$, the uncertainty due to random detection would have been somewhat smaller in our estimates of abundance. However, simulations indicated that because detection probability was already high, the decrease in standard error by including replicate sightings was only a few percent, and we did not use this more complicated estimator.

Although our results are inconsistent with the negative trend in pregnancy rates suggested by data from the Russian hunt (Reilly 1992), we found significant fluctuations in calf production for this population (over five-fold between some years). We suggest that years with low calf production were associated with feeding seasons effectively shortened by extensive seasonal ice and that suboptimal nutritive condition in pregnant females was the link in this apparent biophysical connection.

There is a continuum in the degree of dependency animals place on stored fats for reproduction (Thomas 1990). Because they rely almost entirely on stored fats and other tissues for support through the final stages of pregnancy and most of the lactation period, gray whales are an example of one extreme of this relationship. Recognizing the physiologically demanding nature of this life history, Rice and Wolman (1971) suggested that selective pressure for suppression of ovulation at times when a female is incapable of carrying a pregnancy to term might exist. Lockyer (1986) reported a link between prey abundance and subsequent ovulation rates for eastern North Atlantic fin whales (*Balaenoptera physalus*). Because we have observed lower calf production in the spring immediately following ice-shortened feeding seasons (1994, 1998, 1999), we attribute the lower levels of calf production to a failure to carry existing pregnancies to term. This suggests that in this case it was existing pregnancies, rather than ovulations or conceptions, that were impacted.

In addition to the very low calf numbers reported here, unusually large numbers of dead gray whales were found along the North American coast in 1999 and 2000 (Moore *et al.,* in press). Le Boeuf *et al.* (2000) reviewed the strandings data and other unusual aspects of gray whale demographics and behaviors and suggested that gray whales were undernourished when they began their long two-way migration in 1999. We agree that the symptoms observed in this population in 1999 and 2000 are likely related to an overall reduction in nutritive condition of individuals within this population. We suspect that the dramatic nature of these events are the result of a synergistic interaction of lower overall food availability (Highsmith and Coyle 1992, Grebmeier and Dunton 2000) and reduced access to this already depleted resource caused by extensive seasonal ice. It is still unclear, however, whether the observed changes in productivity and mortality indicate that this population has exceeded the carrying capacity of its environment or whether they reflect reactions to shorter term environmental events.

ACKNOWLEDGMENTS

Funding for this study was provided by the NMFS Office of Protected Resources and we are especially appreciative of the support given to us by Tom Eagle. We are greatly indebted to Norman Scott of the Biological Resources Division, U.S. Geological Survey, who kindly allowed us to use the Piedras Blancas Research Station for our study. Richard Rowlett has been the leader of our observation team since the beginning of the study and his professionalism and unique skills are responsible in a large part for the consistent quality of our data set. Monica DeAngelis was a watch-team leader for several surveys and her leadership and attention to detail were critical to our success. We acknowledge Alexandra Von Saunder, LTJG, NOAA; Thomas Martin, LTJG, NOAA; and Todd Pusser for their long hours of valuable watch effort. We also thank Jeff Breiwick from the National Marine Mammal Laboratory, AFSC, who kindly provided abundance estimates for the years of our survey. This manuscript was improved by comments from Robert Brownell, SWFSC, and Richard Neal, SWFSC, and two anonymous reviewers.

APPENDIX

COMPARISON OF METHODS WITH BUCKLAND *ET AL.* (1993)

Much of the work described here was based on methods developed by Buckland *et al.* (1993) to estimate gray whale abundance. However, our statistical analysis differs in three ways.

First, whereas we accounted for unobserved periods using a finite population model, they estimated the number of whales passing during those periods by fitting a smooth function to the time series of estimated daily totals. An advantage of smoothing the time series is that, with appropriate assumptions on the form of the smoothed data, passage rates can be extrapolated before and after the range of days when observers are present. Because observers in this study were present over the entire duration of the northbound migration, such extrapolation was not needed.

Second, we used conditional ML to estimate detection probabilities from paired watch data, by maximizing the likelihood (Equation 1) derived by Huggins (1989) and Alho (1990) directly. In contrast, Buckland *et al.* (1993) developed a conditional ML algorithm that uses iterative maximization of a simpler likelihood (denoted by L, their page 239), in much the same spirit as the E-M algorithm (*e.g.,* Tanner 1996). However, their description inadvertently implies that their algorithm ultimately maximizes the simpler likelihood, when in fact that likelihood is used only as an intermediary. While not obvious, it can be shown that Buckland *et al.*'s iterative logistic regression algorithm does indeed maximize the correct conditional likelihood for the paired observer model (Equation 1). However, as with the E-M algorithm, using the simpler likelihood to derive the usual asymptotic variance estimators from ML theory leads to estimates of standard error that are too large, particularly with detection probabilities less than about 40.

Finally, the variance estimator given by Buckland *et al.* (1993, p. 240) accounts for variation in the estimate of abundance due to random detections of whales but does not account for variation due to using estimated (*i.e.,* random) detection probabilities. This component may or may not be a large portion of the total variance depending on the actual detection probabilities, which determine the magnitude of the first component of variance, and the sample size, which primarily determines the magnitude of the second component of variance. Our variance estimator for the hourly totals included components due to both sources of variance.

Is it 'boom times' for baleen whales in the Pacific Arctic region?

Sue E. Moore

Office of Science and Technology, NOAA/Fisheries, Seattle, WA, USA

SEM, 0000-0002-3104-1740

The marine ecosystem in the Pacific Arctic region has experienced dramatic transformation, most obvious by the loss of sea ice volume (75%), late-summer areal extent (50%) and change in phenology (four to six weeks longer open-water period). This alteration has resulted in an opening of habitat for subarctic species of baleen whales, many of which are recovering in number from severe depletions from commercial whaling in the nineteenth and twentieth centuries. Specifically, humpback, fin and minke whales (*Megaptera novaeangliae*, *Balaenoptera physalus* and *Balaenoptera acutorostrata*) are now regularly reported during summer and autumn in the southern Chukchi Sea. These predators of zooplankton and forage fishes join the seasonally resident grey whale (*Eschrichtius robustus*) and the arctic-endemic bowhead whale (*Balaena mysticetus*) in the expanding open-ocean habitat of the Pacific Arctic. Questions arising include: (i) what changes in whale-prey production and delivery mechanisms have accompanied the loss of sea ice, and (ii) how are these five baleen whale species partitioning the expanding ice-free habitat? While there has been no programme of research specifically focused on these questions, an examination of seasonal occurrence, foraging plasticity and (for bowhead whales) body condition suggests that the current state of Pacific Arctic marine ecosystem may be 'boom times' for baleen whales. These favourable conditions may be moderated, however, by future shifts in ecosystem structure and/or negative impacts to cetaceans related to increased commercial activities in the region.

1. Introduction

A 'new normal' climate is emerging in the Pacific Arctic marine ecosystem [1], coincident with the dramatic loss of sea ice at a rate which accelerated after 2000 [2]. Overall, the region has lost 75% of sea ice by volume and 50% in late-summer surface cover, coincident with the extension of the open-water period by four to six weeks. The marine ecosystem north of the Bering Strait is warmer, fresher and stormier than in the past, with annual inflow of Pacific waters roughly 50% higher now than prior to 2001 [3]. Satellite data suggest that this biophysical transformation supports increased rates of phytoplankton net primary production (NPP) by 42% in the Chukchi Sea and 53.1% in the Beaufort Sea, probably in response to reduced sea ice thickness and extension of the open-water period [4]. However, satellites cannot sample subsurface peaks in NPP, which are common throughout the Arctic Ocean [5]. Thus, a full accounting of changes to regional primary productivity remains elusive.

Whether owing to habitat expansion, increasing whale numbers, or both, subarctic species of baleen (mysticete) whales are now commonly reported in the Chukchi Sea. Specifically, humpback, fin and minke whales were seen between Bering Strait and 69° N latitude during aerial surveys conducted from July through to September 2009–2012, where none were seen during surveys conducted from 1982 to 1991 [6]. These three species appear to have expanded their range in late summer to now join the Arctic-endemic bowhead whale and

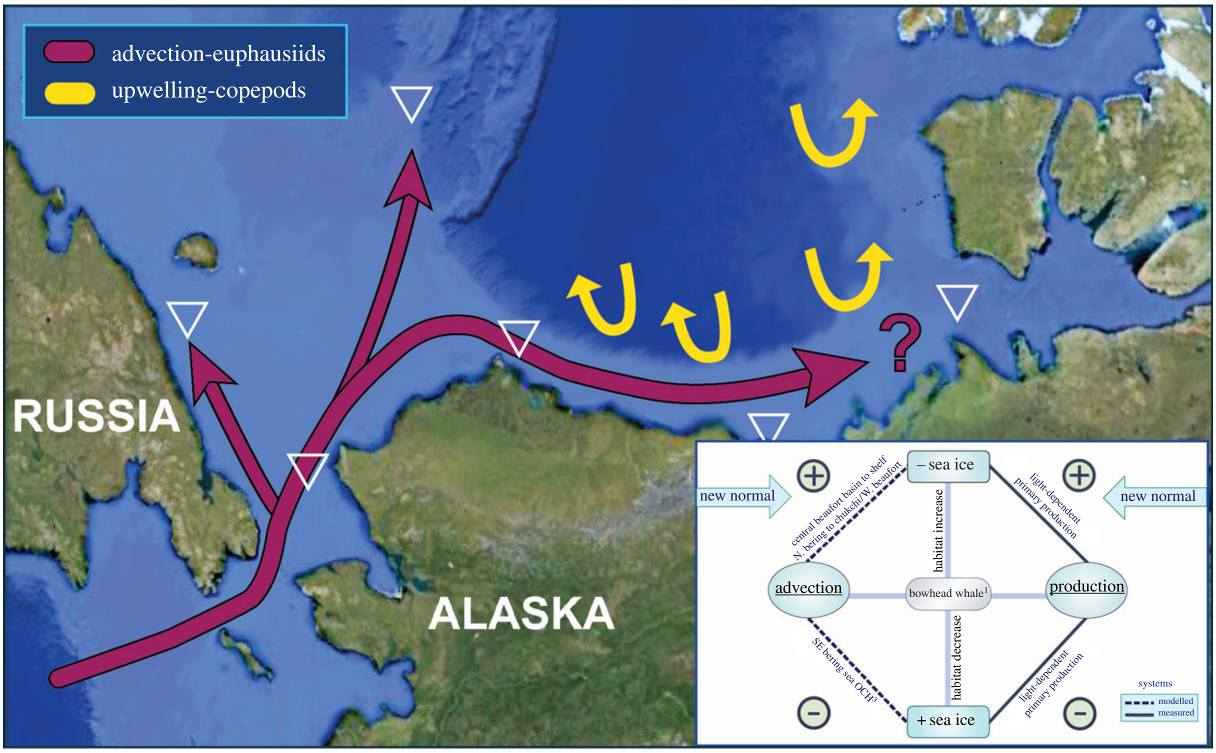

Figure 1. Advection of euphausiids (red) into the Chukchi Sea and upwelling of copepods (yellow) from the basin to the continental shelf in the Beaufort Sea are prey-delivery pathways that are probably enhanced by increased transport through the Bering Strait and wind-forcing combined with the loss of sea ice. Both enhanced production and increased advection common in the 'new normal' Pacific Arctic marine ecosystem deliver food to bowhead whales (inset). This graphic is a composite of revised figures [14,15]; triangles indicate areas where whale-prey associations have been reported [14]. (Online version in colour.)

the seasonally resident grey whale [7] in the rapidly changing marine ecosystem of the Pacific Arctic. Detections of whale calls at an autonomous recorder deployed from 2009 to 2012 revealed that humpback and fin whales remain in southern Chukchi waters through October and in some years into November [3]. Of note, detections of humpback and fin whale calls ceased near the onset of sea ice formation each year, coincident with the onset of bowhead whale call detections. In other words, the subarctic species departed as the Arctic-endemic species arrived, along with seasonal sea ice.

The pan-Arctic reduction in sea ice evident early in the twenty-first century triggered a number of reviews regarding the impact of this loss of habitat on marine mammals [8–10]. Polar bears (*Ursus maritimus*), walruses (*Odobenus rosmarus*) and ice seals appear to be particularly vulnerable because they rely on sea ice as a platform for key life-history functions such as birthing, nursing young, hunting and resting. Conversely, with the loss of sea ice, ocean habitat for cetaceans has expanded both spatially and temporally. This expansion of habitat coincides with the ongoing recovery of most populations of baleen whales from decades of commercial harvest in the nineteenth and twentieth centuries [11,12]. It also facilitates offshore commercial activities, including shipping and oil and gas development, which can have significant negative impacts on cetaceans [13].

In this opinion piece, I summarize observations and offer plausible explanations regarding changes to baleen whale-prey production and delivery coincident with the dramatic loss of sea ice, increased transport through the Bering Strait and amplified upwelling along the Beaufort Sea slope. This synoptic description, coupled with an overview of recent baleen whale seasonal occurrence in the Pacific Arctic, underpins a schematic of habitat partitioning among the five species. The diagram is intended as a first-step in recognizing the current status and role of baleen whales in the changing ecology of the Pacific Arctic.

2. Changes to baleen whale-prey production and delivery

Two well-documented alterations to the Pacific Arctic ecosystem that probably have changed production and delivery of baleen whale-prey in the twenty-first century are the aforementioned loss of sea ice and the increased inflow of Pacific water through the Bering Strait (figure 1). The thinning and extensive seasonal retreat of sea ice has fostered increased NPP, which probably supports higher rates of secondary production, including the mesozooplankton and forage fish prey of baleen whales. This suggested link between sea ice loss and increased prey production is supported by limited observations in the Chukchi Sea [16], where the abundance and biomass of mesozooplankton was higher in reduced-ice years (2007/2008) compared with years with extensive sea ice (1991/1992). The delivery of mesozooplankton prey from the northern Bering to the Chukchi Sea has also probably increased with the more robust northward transport at the Bering Strait since 2001 [3]. Corroborating evidence that prey are advected through the Strait includes the report of grey whales feeding on euphausiids in the southern Chukchi Sea in 2003 [17], and the description of large copepods and euphausiids abundant in the cold, nutrient-rich Bering Sea Anadyr Water advected into the southern and central Chukchi Sea in 2007 [18]. Humpback, fin and minke whales are efficient predators of these mesozooplankton as well as of forage fishes that may follow this plankton stream.

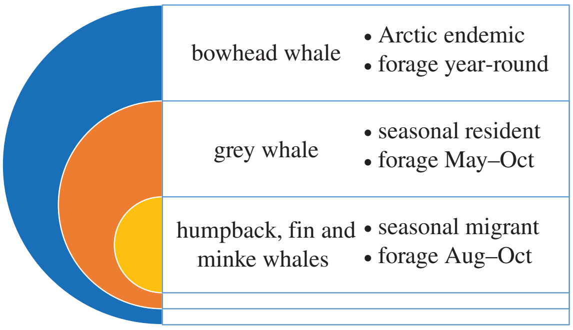

Figure 2. Schematic of habitat partitioning for five species of baleen whales in the Pacific Arctic. Bowhead whales feed on pelagic and epibenthic zooplankton from the northern Bering to Beaufort Sea (blue); grey whales feed on pelagic, epibenthic and benthic prey from the northern Bering through the Chukchi Sea (orange); humpback, fin and minke whales feed on zooplankton and forage fishes primarily in the Bering and southern Chukchi seas (yellow). (Online version in colour.)

The extreme retreat of sea ice combined with upwelling-favourable winds has also probably increased localized abundance of copepods and other mesozooplankton upwelled onto the Beaufort Sea shelf. Notably, the number and strength of upwelling events in the Alaskan Beaufort Sea has increased over the past 25 years [19]. In the western Beaufort, a sudden cessation of upwelling-favourable winds can spring a ‘prey trap’, which concentrates zooplankton for efficient foraging by bowhead whales [20]. Combined, the recent ‘new normal’ conditions in the Pacific Arctic seemingly provide Arctic-endemic bowhead whales with optimal foraging opportunities, both from increased upwelling of copepod prey in the Beaufort Sea and robust advection of copepod and euphausiids prey through the Bering Strait into the Chukchi and western Beaufort Sea (figure 1: inset). A suite of observations, including the seasonal ecology of bowhead whale core-use areas [21] and improved whale body condition coincident with sea ice loss [22], support this assertion.

3. Habitat partitioning among baleen whales in the Pacific Arctic

Habitat partitioning among the five baleen whale species is accomplished largely through temporal separation, underpinned by species-specific migration cycles and dissimilar prey preferences (figure 2). Bowhead whales occupy Bering Sea waters in winter, migrating though the Bering Strait in spring and feeding in the Beaufort and then Chukchi seas from late spring through to autumn [7,21]. Grey whales arrive in the northern Bering Sea in late spring and feed there and in the Chukchi Sea through to autumn [7]. Sightings and acoustic detections of humpback, fin and minke whales over the past decade suggest that they occupy the southern Chukchi Sea roughly from August through to October [3,6].

Foraging capability and prey selection can amplify habitat partitioning among the five species. The long, finely fringed baleen of bowhead whales are specialized for filtering zooplankton, while the coarse and short baleen of grey whales provide the means to filter out benthic prey from sediments sucked up from the seafloor—a capability unique to this species. Humpback, fin and minke whales are lunge feeders, adapted with variable length baleen and throat pleats for gulping both mesozooplankton and forage fishes. It is important to note that all five species can and do consume euphausiids or krill. While the role of krill as a key trophic-link in the Pacific Arctic is poorly understood, its importance as prey for baleen whales is well established in Atlantic Arctic and Antarctic marine ecosystems (e.g. [23,24]).

At present, conditions in the Pacific Arctic appear to be favourable (i.e. ‘boom times’) for all five species of baleen whales. Although the seasonal influx of subarctic species may result in some resource competition with bowhead and grey whales, migration timing and species-specific foraging capabilities will probably curtail inter-specific prey competition. More important is the capability of these species to act as sentinels to alterations in the marine ecosystem [25]. Specifically, baleen whales can provide clues as to the nature, direction and mechanisms of ecosystem shifts, such as where, when and how ‘new’ NPP is cycled. Whether new production is channelled to pelagic or benthic trophic pathways will restructure the ecosystem in ways that will be reflected in the distribution and relative abundance of these large consumers. Baleen whales also act as ecosystem engineers and their recovering numbers may actually buffer the marine ecosystem from destabilizing stresses associated with rapid change [26]. With more baleen whales recycling nutrients vertically and horizontally and, with increasing numbers of bowhead and grey whales re-suspending sediments during epibenthic and benthic foraging, the Pacific Arctic marine ecosystem will probably continue to change in ways now difficult to predict. A much needed circumpolar assessment of Arctic marine ecosystems (e.g. [14]) could be achieved by comparing changes in the Pacific Arctic to those in other regions, especially where sea ice loss has been quantified (e.g. [10]).

Update on the use of a simulation-based approach to evaluate plausible levels of recruitment into the Pacific Coast Feeding Group of gray whales

Lang, A.R., and Martien, K. K.
Protected Resources Division, Southwest Fisheries Science Center, La Jolla, CA 92037

ABSTRACT

Previous genetic comparisons of the Pacific Coast Feeding Group (PCFG) of gray whales with whales feeding north of the Aleutians have shown significant levels of mitochondrial differentiation. The magnitude of the differentiation, along with the relatively high levels of genetic diversity identified within the PCFG, have raised questions about how much immigration into the group could occur before the signal of mtDNA differentiation is erased. Here we use a simulation-based approach to evaluate the range of plausible levels of immigration into the PCFG that could be occurring. The simulations incorporate annual immigration ranging from between 0 and 16 animals per year (once the larger ENP population reaches K), and simulations both with and without a pulse of +20 immigrants over two years are included. Results suggest that under the scenarios tested, current immigration into the PCFG of one migrant per year or less would produce levels of genetic diversity and differentiation that are inconsistent with the empirical data. The simulations were less informative with regard to placing an upper limit on the number of animals per year which could be immigrating into the PCFG, although comparison of F_{ST} and χ^2 (per degree of freedom) values between the simulated and empirical data suggests that immigration higher than 8 animals per year is unlikely. Comparisons between the observed and simulated values for the number of haplotypes, F_{ST}, and χ^2 (per df), which were the most informative measures, suggest that immigration of approximately 4 animals per year is most plausible.

INTRODUCTION

Genetic comparisons of samples collected from gray whales considered to be part of the Pacific Coast Feeding Group (PCFG) with those from animals that feed north of the Aleutians have revealed small but significant levels of mtDNA differentiation but no nuclear differentiation (Lang *et al.* 2011). In addition, a relatively large number of mtDNA haplotypes were identified within the PCFG (n=23 haplotypes, Lang *et al.* 2011), which is estimated to contain ~200 animals (IWC 2011). Analysis of photo-identification data indicates that on average, 10 animals per year were recruited[1] into the PCFG between 2004 and 2008, with larger numbers of recruits identified between 2000 and 2002 (IWC 2011). These recruits could be internal (i.e., calves born to PCFG mothers) or external (animals that previously fed north of the Aleutians and subsequently immigrated into the PCFG). An average of three calves per year were identified in the PCFG between 1998 and 2008 (Calambokidis *et al.* 2010), and it is presumed that at least half of the calves born each year may not have been identified as such (IWC 2011). Based on those assumptions, an estimated four animals per year may have recruited into the PCFG from northern feeding area(s) between 2004 and 2008, and a pulse of higher immigration may have occurred between 1999 and 2002, potentially in response to the increase in gray whale mortality that occurred in 1999 and 2000.

The results of these genetic and photo-id studies of the PCFG have raised questions about how much external recruitment into the PCFG could occur while still maintaining the observed level of mtDNA differentiation between the PCFG and animals feeding north of the Aleutians. The use of a simulation-based approach has the potential to provide information relevant to this question. As part of a previous IWC exercise (the Testing of Spatial Structure Methods, or TOSSM, project), simulated genetic datasets representing different population structure archetypes were created for performance testing of different analytical methods (Martien *et al.* 2009). The demographic parameters underlying the dataset generation model were based on the vital rates of

---

[1] Here a 'recruit' is defined as an individual first photographed in the PCFG seasonal range (within the area spanning 41-52°N and between June 1 and November 30) in a given year and resighted within the seasonal PCFG range in at least one subsequent year.

eastern gray whales (Martien *et al*. 2004, Martien 2006). In discussions with the IWC Stock Definition subcommittee, it was agreed that the TOSSM dataset generation model could be useful in creating simulated datasets that would allow the plausibility of different hypotheses (e.g., different immigration rates into the PCFG) to be evaluated.

METHODS

Rmetasim

Simulated datasets were produced using the *rmetasim* package (version 1.1.05, Strand 2002) as run in the R statistical environment (R 2.14.1). *Rmetasim* performs individual-based population genetic simulations utilizing stage-based matrix population models. The transition probabilities in the matrices are used to randomly assign births, stage transitions, and deaths of individuals over time. Density dependent growth is implemented by the linear interpolation between matrices representing survival and reproduction rates at carrying capacity (K) and at zero population density (ZPD). A pre-birth pulse model is used, such that at the end of each simulation year, the youngest animals in the population are one year old.

Stage-based matrices

As previously mentioned, vital rate estimates for eastern Pacific gray whales (as described in Martien *et al.* 2004, Martien 2006) were used to parameterize stage-based matrices for the TOSSM exercise. Since the construction of these matrices, additional information has become available on the life history of gray whales. This new information was utilized to update the stage-based matrices from TOSSM, and when possible the vital rates used in constructing the new matrices were chosen to be the same as those utilized in the IWC's Implementation Review of gray whales. The following changes were made:

1) Adult survival rate was increased to the median estimate from Punt & Wade 2010 (S_A=0.982)
2) A separate term for calf survival rate (set to S_c=0.732, the median estimate in Punt & Wade 2010) was utilized. In the previous matrices, calf survival was the same as juvenile survival.
3) The median estimate from Punt & Wade 2010 was utilized for the rate of increase at ZPD (λ =1.063)
4) The age of first reproduction (AFR) was increased to 7 years at ZPD based on the Bradford *et al.* 2010 review.
5) A third juvenile stage was added to provide better control of AFR.

In addition, three identical adult stages for each sex were included in the new matrices. In contrast, the matrices used in the TOSSM project included a single adult male stage and separate fertile and lactating stages for adult females. This change was implemented for two reasons. First, it allowed for better control of generation time and greatly reduced the proportion of individuals in the simulations that lived to unrealistic ages under the increased adult survival rate. Secondly, it reduced the number of multiple births by the same female in a given year. In *rmetasim*, the fertility term represents the mean number of calves produced per female based on a Poisson distribution (Strand 2002). This results in some females producing more than one calf per year. Eliminating the separate fertile and lactating stages allowed us to reduce the fertility term (since it was applied to all adult females, not just a subset in the lactating stage), thereby reducing the number of multiple births (Table 1). However, this change also eliminated the minimum two-year calving interval that had been enforced in the TOSSM matrices. As such, under the new matrices some females in the simulation will give birth in consecutive years (Table 2).

Given the number of changes implemented in the new matrices, we ran the simulations using both the updated nine-stage matrices as well as the original five-stage matrices (as described in Martien 2006) utilized in the TOSSM exercise. The vital rates used to construct the original matrices and those utilized in the updated 9-stage matrices are detailed in Table 3. The parameter for juvenile survival rate was not derived from the literature but was calculated from the matrices to produce the desired value of lambda. The

Maximum Sustainable Yield Rate (MSYR) calculated from the 9-stage matrices is ~3.3%, while MSYR for the 5-stage TOSSM matrices is ~3.6%.

These vital rates were used to construct stage-based matrices representing the demography of the population near carrying capacity (K) and near zero population density (ZPD). Transition probabilities were calculated according to Caswell (2001) and the resulting matrices are shown in Table 4.

Population Trajectories

Dataset generation followed the steps outlined in Martien 2006, with the exception that coalescent datasets were generated using FastSimcoal (Excoffier and Foll, 2011) rather than SimCoal 2.1.2 (Laval and Excoffier 2004) to establish the effective size (Ne). In all scenarios, a single population was simulated in *rmetasim* for 4000 years to provide datasets representing the equilibrium population. This time period was shown to be sufficient for reaching equilibrium in a similar exercise for bowhead whales (Archer *et al.* 2010), that have a markedly longer generation time.

The mutation parameter incorporated in the simulations was adjusted to produce genetic diversity levels (as measured by the number of haplotypes and the haplotypic diversity) that are similar to the values observed for the "North" strata in the Lang *et al.* 2011 study. A range of mutation parameters were explored before setting the mutation parameter to 3.8×10^{-3} per generation, which produced measures of genetic diversity that were the most consistent with the observed data.

Carrying capacity (K) for the larger ENP population of gray whales was set to 20,000 animals, similar to the most recent abundance estimate (19,126 animals in 2006/2007; Laake *et al.* 2009). Carrying capacity for the PCFG was set to 200 in accordance with the estimated abundance of 194 animals in 2008 (Annex F, IWC 2011).

For all population trajectories, depletion due to commercial whaling was simulated as having occurred between 1846 and 1930. Attempts were made to utilize the catch history (Annex E, IWC 2011) with a multiplier to produce the desired level of depletion in 1930 (10% of K). However, when this modification was incorporated it resulted in a high number of simulation runs that failed due to the simulated population(s) going extinct. As such, the depletion per year was set to a constant proportion of K, such that the population was depleted by 7.1% of K in each year for the duration of the simulated whaling period. This level of depletion allowed the population to reach the desired level (0.10 of K, or ~2000 animals) by 1930. Examples of the population trajectories produced are shown in Figure 5.

Given that little is known about the origin of the PCFG, two different population histories were simulated. The first scenario ("post-whaling split") assumes that the PCFG split from the larger ENP population following depletion. After reaching equilibrium a single population was projected forward through the 1846-1930 whaling period with depletion occurring as described above. In 1930, 20 animals (10% of K_{PCFG}) were split from the larger population to represent the PCFG. The two populations were then allowed to increase until reaching K. *Rmetasim* employs a "hard ceiling" to restrict population growth to K, such that individuals are killed off randomly after reaching levels >10% higher than K.

The second scenario ("pre-whaling split") assumes that the PCFG split from the larger ENP gray whale population prior to the depletion of gray whales due to commercial whaling. In this scenario, the equilibrium population was split into two feeding groups to represent the northern feeding ground (K_{ENP}=20,000) and the PCFG (K_{PCFG} = 200). The split was presumed to occur at the start of the Little Ice Age (considered here to be at 1540), a period in which it seems plausible that ice conditions would have been favorable for gray whales to begin using more southern feeding grounds. Both populations were projected forward until 1846, when the depletion due to commercial whaling was simulated as described above. After reaching 1930, the simulated depletion ceased and the two populations were allowed to grow until reaching K.

Immigration rates ranging from 0 to 0.0008 were simulated. These migration rates correspond to the immigration of between 0 and 16 animals per year into the PCFG from the larger ENP population once it has reached K (Figure 6). In addition, each population history and migration rate combination was also simulated with a migration "pulse" of 20 individuals over two years. This pulse is reflected in the abundance of the PCFG in 2000 and in 2001. Examples of abundance trajectories for the PCFG under the different immigration scenarios are shown in Figure 7.

Additional simulations were performed in which the value of K_{PCFG} was increased from 200 to between 500 and 5000. These simulations incorporated a post-whaling split of the PCFG from the larger ENP, with the pulse migration of +20 animals over two years but no annual immigration into the PCFG. As in the "post-whaling split" scenarios described above, the split of the PCFG from the larger ENP was modeled such that the number of animals colonizing the PCFG in 1930 was 10% of K.

A final set of simulations were performed that incorporated a more recent split (between 1940 and 1990) of the PCFG from the larger ENP population. The number of animals splitting off to form the PCFG in a given year was derived by taking an average (over ten replicates) of the simulated abundance of the PCFG in each year when the abundance trajectories were modeled under the scenario of a post-whaling split of the PCFG in 1930 with no annual immigration.

A list of scenarios that have been simulated to date is included in Table 7. Of note, the simulations incorporating a pre-whaling split of the PCFG from the larger ENP are in progress and have not yet been completed.

Sampling and Genetic Analyses:

To generate the simulated dataset, the number of simulated animals sampled per year was set to match the number of animals sampled per year and per stratum in the Lang *et al*. (2011) study (Table 8). In the empirical study, some animals were sampled multiple times, and only one sample per individual was retained for the data analysis. For the simulated sampling, the year of sampling for such individuals was assigned as the first year that the animal was sampled. A total of 103 samples were collected from simulated ENP individuals and 71 samples were collected from simulated PCFG individuals.

These sampled individuals were used to generate summary statistics for each group. Genetic diversity was characterized by the number of mtDNA haplotypes, the mtDNA haplotype diversity, and the mtDNA nucleotide diversity. Differentiation between the two simulated groups was measured using F_{ST}, χ^2 (per degree of freedom), and ϕ_{ST}. The summary statistics generated from the simulated datasets were then compared to the observed summary statistics generated for the PCFG and the North strata in Lang *et al.* 2011.

To further evaluate how well the shape of the haplotype frequency distribution for the simulated ENP population matched the shape of the distribution for the North stratum in the empirical data, a χ^2 test was used to compare the two haplotype frequency distributions, and the number of significant tests ($p<0.05$) was calculated. In addition, the frequency of the most common haplotype in each replicate simulation was calculated and compared to the frequency of the most common haplotype in the empirical data for the North stratum. Given that the mtDNA summary statistics produced for the simulated ENP population under all scenarios was similar, these tests were only conducted using the data for the simulated ENP population produced under the model with a post-whaling split with pulse migration but no annual immigration.

In addition to showing the proportion of simulations that had higher and lower values for each statistic than the values generated from the empirical data, we used interpolation to calculate the "crossover point" at which the 50% probability (median) was reached (i.e. the point at which the proportion of simulated runs had values higher than the observed reached 50%). For the number of haplotypes, the crossover point was calculated as the point at which the lines representing the proportion greater than and the proportion less than crossed (as for the other statistics), but because some simulation replicates had values equal to (rather than less than or greater than) the observed value, this point was slightly lower than the 50% probability.

RESULTS

Although the goal is to produce 500 replicates of each scenario, currently only 100 replicates of each scenario are complete and are utilized in the results shown here.

Comparison of simulated and observed data for ENP

Table 9 includes a summary of the number of haplotypes, haplotypic diversity and nucleotide diversity for the simulated ENP population for the model incorporating the 9-stage matrices with a post-whaling split and pulse immigration. Results were similar under all scenarios tested (data not shown). Overall, median values for both the haplotypic diversity and the number of haplotypes were similar among the simulated and empirical datasets. The haplotypic diversity values generated in the simulated data were slightly lower than that in the observed data, with median values for the simulated data ranging from 0.948 to 0.950 (as compared to the observed haplotypic diversity of 0.952) and with 52-64% of replicates under the different immigration scenarios having lower haplotypic diversity than found in the empirical data. In contrast, the median number of haplotypes generated in the simulated datasets (33 to 34 haplotypes) was slightly higher than that found in the observed data (32 haplotypes). Between 62 and 75% of replicates for the different immigration scenarios generated values higher than the number identified in the empirical dataset. Although the nucleotide diversity calculated from the empirical data fell within the 90% range of the simulated values, nucleotide diversity in the simulated data was higher than that found in the observed data.

To evaluate whether the shape of our simulated haplotype distributions matched the shape of the observed distribution, we used a χ^2 test to compare the observed (North stratum) versus the simulated haplotype frequency distributions for the ENP population. The χ^2 test evaluates whether the haplotype distributions representing the empirical and simulated data could have been generated by random sampling of a single population. The χ^2 test is particularly sensitive to the frequencies of the most common haplotypes, as those haplotypes are the most likely to be represented in the random draws that represent immigration events. In our comparison, 12% of tests showed significant ($p<0.05$) differences (Figure 10), suggesting that the shape of the observed and simulated distributions were similar in most cases. We also compared the frequency of the most common haplotype in the empirical data with the frequency of the most common haplotype in the simulations. We found that the frequency of the most common haplotype was higher than that found in the empirical data for 47% of the simulation replicates. This finding is consistent with the expectation that if two samples are drawn from the same distribution, the frequency of most common haplotype would be expected to be greater in one sample than the other 50% of the time.

Comparison of simulated and observed data for the PCFG

Figure 11 shows a graphical representation of the proportion of simulated values for each statistic that are lower (shown in black) or higher (shown in gray) than the observed value generated from the empirical data for one of the scenarios tested (post-whaling split with pulse immigration, nine-stage matrices). Summaries of the number of mtDNA haplotypes (Table 12), mtDNA haplotype diversity (Table 13), mtDNA nucleotide diversity (Table 14), F_{ST} (Table 15), ϕ_{ST} (Table 16), and χ^2/df (Table 17) produced by the simulations under all completed scenarios are shown below.

With regard to comparisons between the observed and simulated data, the statistics based on haplotype frequencies (haplotypic diversity, F_{ST}, and χ^2/df) and haplotype numbers were the most informative. For all four of these statistics, scenarios based on annual immigration of one animal or less per year (at K) produced values that were inconsistent with the empirical data. The comparisons were less informative with regard to the highest level of immigration that could be occurring, although comparison of F_{ST} and χ^2/df values suggested that levels of immigration including > 8 animals/year (along with the pulse immigration) would produce values inconsistent with those produced by the empirical data.

Similar to the pattern seen in comparison of the observed and simulated data for the larger ENP population, the nucleotide diversity identified among the simulated datasets was higher than that seen in the empirical data. In the ϕ_{ST} comparisons, the value generated in the empirical comparison was more consistent with the lower range of values for annual immigration and indicated that more than 8 immigrants per year into the PCFG would produce values of ϕ_{ST} lower than that observed. Caution should be applied when interpreting this pattern, however, given the lower nucleotide diversities identified in the observed data when compared to the simulated datasets.

Table 18 shows the results of simulations evaluating scenarios in which the PCFG splits from the larger ENP population between 1940 and 1990. The results shown suggest that for no annual immigration into the PCFG to be plausible, the PCFG would have had to split from the larger population after 1950.

Table 19 shows the results of simulations evaluating scenarios in which the carrying capacity for the PCFG was set to between 500 and 5000. The results indicate that the carrying capacity for the PCFG would need to be higher than 500 animals for the simulated results to be consistent with the empirical data under a scenario of no annual immigration. Examples of the abundance trajectory of the PCFG for the K values tested are shown in Table 20. For all K values simulated, the abundance of the PCFG was close to carrying capacity by 2010 (Table 21).

DISCUSSION:

Comparison of the simulated and empirical datasets for the larger ENP population suggests that the simulations represent the empirical data reasonably well with regard to the number of haplotypes and their distribution. Although the simulations predict that we would find slightly higher number of haplotypes and a slightly lower haplotypic diversity than is present in the empirical data, the differences are small and the χ^2 test suggests that the two samples would be interpreted as being drawn from the same population in the majority (88%) of cases. The results of these comparisons suggest that similar frequency-based comparisons of the simulated and empirical data representing the PCFG should be informative.

The level of nucleotide diversity in the simulated data representing the larger ENP population is higher than that found in the empirical data, indicating that there are some aspects of the population's history that are not being captured by the simulations. It is likely that the gray whales in the North Pacific have experienced numerous fluctuations in abundance due to changing ice conditions in the past, and historic K may have been substantially larger than we have simulated here (e.g., Alter *et al*. 2007). Our simulations incorporate only a simplified version of the recent history of gray whales, and our results suggest that the statistics relying on nucleotide differences (e.g., nucleotide diversity and ϕ_{ST}) may be more sensitive to violations of our assumptions about past (pre-commercial whaling) population size and equilibrium. As such, the results derived from the comparisons of nucleotide diversity and ϕ_{ST} warrant further investigation and should be interpreted with caution.

The comparison of frequency-based statistics between the simulated and empirical datasets representing the PCFG suggests that annual immigration into the PCFG is likely to be higher than 1 immigrant per year under the scenarios tested. The simulations were less informative with regard to the upper bound on annual immigration that could be occurring. Although the F_{ST} and χ^2/df comparisons indicated that immigration of >8 animals/year would be inconsistent with the empirical data, the proportion of simulations with higher than the observed values for the number of haplotypes and the haplotypic diversity never exceeded 84% and 63%, respectively. For all four statistics, the proportion of simulations with higher (for the number of haplotypes and haplotypic diversity) or lower (for F_{ST} and χ^2/df) values than the observed appears to level off at the higher (8 -10 or more per year) levels of immigration. This pattern is particularly evident in the comparisons utilizing haplotypic diversity, where the proportion of simulations with higher or lower values than the observed levels off at ~50% for immigration of 8 or more animals per year. Haplotypic diversity is calculated based on the sum of squared allele frequencies. Given that relationship, as the number of haplotypes in a population increases, the addition of another haplotype, particularly one found in low frequencies as would be expected to be brought in by an immigrant, has little impact on diversity. As such, this statistic, and to a lesser extent the others, appear to have limited power to differentiate between the higher levels of immigration.

Although these statistics were limited in their ability to distinguish an absolute upper bound on how much immigration could be occurring, the calculation of the number of immigrants per year which corresponds to the “crossing point” provides some information on what the most plausible values of immigration could be (Table 22). The estimated number of migrants ranged from ~2 to 8 for the scenarios with pulse immigration under the updated matrices. For the reasons discussed above, the calculations based on ϕ_{ST} and haplotypic diversity may not provide the best estimates. Comparisons between the observed and simulated values for the number of haplotypes, F_{ST}, and χ^2/df, suggest that immigration of approximately 4 animals per year is most plausible. If the current abundance of the PCFG is approximately 200 animals, this represents immigration of ~ 2% per year. Of note, this estimate does not include the +20 animals which were simulated to immigrate into the PCFG in 2000 and 2001.

Although the simulation results could be sensitive to other parameters incorporated in the models, a limited evaluation of the effects of increased carrying capacity for the PCFG or a more recent founding time was conducted. These simulations suggested that to obtain the empirical results presented in Lang *et al.* 2011 under a scenario of no annual immigration, the abundance of the PCFG would have to be larger (>500 animals) than currently estimated. Gray whales have been observed feeding off of Kodiak Island, Alaska since at least 1999, with ~350-400 individuals counted during a single day in July 2000 (Moore *et al.* 2007). Approximately 20% of the animals photographically identified in this area between 2002 and 2005 are known to be animals that have also been photographed in the Pacific Northwest from northern California to southeast Alaska (Gosho *et al.* 2011). However, the median “crossing point” calculated from these comparisons suggest that values of K between 2000 (based on F_{ST}) and 3000 (based on the number of haplotypes) animals produce values that are most consistent with the empirical data, indicating that additional explanation may be needed.

The simulations exploring more recent founding times suggest that under a scenario with no annual immigration, the PCFG would have to have been founded after 1950, and more plausibly between the mid-1960s to mid-1970s, to produce simulated results that are consistent with the empirical data. Small numbers of gray whales have been sighted within the seasonal range of the PCFG since at least 1926 (Howell & Huey 1930, Gilmore 1960, Pike and MacAskie 1969, additional references in Rice & Wolman 1971), but photo-identification studies did not start until the 1970s, when the repeated return of individuals to the area was first documented (Hatler & Darling 1974, Darling 1984). Our simulations model an instantaneous colonization of the PCFG, such that for the scenarios modeling colonization in 1960 or later at least 60 whales become part of the PCFG in a given year. This aspect of our simulations is clearly an oversimplification. Given both the limited information available on use of the PCFG seasonal range prior to the 1970s and the limitations of our model, it is difficult to evaluate how the simulation results fit in with past records.

The simulations incorporating a pre-whaling split of the PCFG from the larger ENP population are in progress and are expected to be completed by the 2012 SC meeting. Future work will also include integrating the genetic data representing ENP gray whales in LeDuc *et al*. 2002 and Lang 2010 with the data represented in Lang *et al.* 2011 to ensure that the diversity values utilized here are as representative as possible of the larger ENP population. Simulations will also be performed to explore the effect of incorporating lower MSYR rates for the PCFG into the life history matrices underlying the models.

ABSTRACT

Gray whales (*Eschrichtius robustus*) occur along the eastern and western coastlines of the North Pacific as two geographically isolated populations and have traditionally been divided into the eastern (California-Chukchi) and western (Korean-Okhotsk) populations. Recent molecular comparisons confirm, based on differences in haplotypic frequencies, that these populations are genetically separated at the population-level. Both populations were commercially hunted, but only the eastern gray whale has returned to near pre-exploitation numbers. In contrast, the western population remains highly depleted, shows no apparent signs of recovery and its future survival remains uncertain. Research off Sakhalin Island, Russia between 1995 and 1999 has produced important new information on the present day conservation status of western gray whales and provided the basis for the World Conservation Union (IUCN) to list the population as 'Critically Endangered' in 2000. The information presented here, in combination with potential impacts from anthropogenic threats throughout the range of this population, raises strong concerns about the recovery and continued survival of the western gray whale.

KEYWORDS: GRAY WHALE; PACIFIC OCEAN; NORTHERN HEMISPHERE; CONSERVATION; OKHOTSK SEA; EXPLOITATION; POPULATION STATUS

INTRODUCTION

Gray whales (*Eschrichtius robustus*) are known to occur along the eastern and western margins of the North Pacific (Andrews, 1914; Rice and Wolman, 1971); they have been extinct in the North Atlantic for several hundred years (Mead and Mitchell, 1984). Recent genetic studies show that animals from the eastern (California-Chukchi) and the western (Korean-Okhotsk) Pacific should be recognised as geographically and genetically separated at the population level (LeDuc *et al.*, 2002). Although both populations were greatly reduced by commercial whaling, only the eastern gray whale has returned to numbers approaching the suspected pre-exploitation population size (IWC, 1998). In contrast, the western gray whale was thought to be extinct as recently as the early 1970s (Bowen, 1974), but later published reports confirmed that the population was extant (Berzin, 1974; Brownell and Chun, 1977). Today, the western gray whale population remains highly depleted and shows no apparent signs of recovery (e.g. Weller *et al.*, 1999; IWC, 2002b). Information regarding the life history and biology of the western population is sparse (Andrews, 1914; Rice and Wolman, 1971) and only recently has it come under concerted study (e.g. Brownell *et al.*, 1997; Weller *et al.*, 1999).

Historic records and recent data suggest that summer feeding grounds for the western population are in the Okhotsk Sea, but the location(s) of the winter breeding grounds, suspected to be along the coast of southern China, remain unknown (Wang, 1984; Henderson, 1990). Contemporary findings from an ongoing US-Russia mark-recapture photo-identification project between 1995 and 2001 suggest that the total population size is <100 individuals (e.g. Weller *et al.*, 1999; IWC, 2002b). Low-level human-related mortality south of the Okhotsk Sea (Brownell and Kasuya, 1999; Baker *et al.*, 2002), and the onset of large-scale multinational oil and gas development programmes within Okhotsk waters, pose potential new threats to the continued survival of this population.

Serious concern over the status of this population has been expressed by the World Conservation Union (by assigning it 'Critically Endangered' - Hilton-Taylor, 2000) and by the International Whaling Commission (IWC, 2002b).

RANGE AND DISTRIBUTION

Western gray whales occur off Russia, Japan, the Democratic People's Republic of Korea (North Korea), Republic of Korea (South Korea) and People's Republic of China (China). Although historic sighting and whaling records indicate that gray whales occurred in areas north of the presently described Okhotsk Sea feeding ground, the present day population range appears to be largely confined to the region between the west central Okhotsk Sea off the northeastern coast of Sakhalin Island (summer-autumn) and the South China Sea (winter). Individuals remain in shallow, mainly nearshore waters, year-round; except when crossing the La Perouse and Tartarskiy Straits off the southern end of Sakhalin Island or during north-south migrations in the Sea of Japan, and the Yellow and East China Seas. Although few records of gray whales are available south of Hong Kong (Wang, 1984; Zhu, 1998), it is presumed that they maintain a nearshore affinity throughout the southern portion of their range.

Main habitat

Gray whales are known for their long-distance migrations between sub-tropical calving and mating grounds near continental coasts and high-latitude feeding grounds in the Arctic and sub-Arctic (e.g. Rice and Wolman, 1971; Swartz, 1986). As bottom-feeding specialists, gray whales aggregate during summer and autumn in shallow shelf waters and offshore banks where benthic and epibenthic invertebrate communities are concentrated (Nerini, 1984; Oliver *et al.*, 1984; Kim and Oliver, 1989). Traditional nearshore migratory routes connect high-latitude feeding areas with warm-water coastal and inshore wintering grounds. Today, the primary summer-autumn feeding habitat for western

gray whales is located off the northeastern coast of Sakhalin Island (Weller *et al.*, 1999; 2002). The calving and mating grounds for this population are unknown, but records from sightings, strandings and whaling catches from 1933-1996 indicate that at least some western gray whales occur in coastal waters off China in the South China Sea (Wang, 1984; Zhu, 1998).

Distribution

Key areas of distribution include the summer feeding grounds off northeastern Sakhalin Island (~52°50'N 143°20'E). Known portions of the north-south migratory route include regions off the eastern shore of Sakhalin Island in the Okhotsk Sea and along the eastern shores of mainland Russia near Peter the Great Bay and along the Korean peninsula in the Sea of Japan (Andrews, 1914; Brownell and Chun, 1977; Berzin, 1990). It is thought that prior to the 20th century, two groups of gray whales may have migrated to coastal waters off Japan (Omura, 1984). One of these groups was thought to travel along the eastern (Pacific) shore of Honshu during their southbound migration while en route for a supposed calving ground in the Seto Inland Sea (Omura, 1984). The other group was suspected to migrate along the eastern shore of Korea, cross the Korean Strait near Ulsan, and ultimately arrive at southwest Honshu and northwest Kyushu (Omura, 1984). Although gray whales were once hunted by net fishermen off the eastern shore of Honshu (Omura, 1984), present-day sightings of the species off Japan are very rare (Kato and Tokuhiro, 1997).

The winter distribution of this population is unknown. Whaling records indicate that peak gray whale numbers off southern Korea occurred in two seasonal pulses, one during the southward migration between December and January, and the other between March and April during the northward migration (Andrews, 1914; Kato and Kasuya, 2002). Whalers working off Ulsan, South Korea found that a majority of adult females taken between December-January were carrying near-term foetuses and were thought to be within two to three weeks of parturition (Andrews, 1914). Based on these observations, and his own measurement of one 4.76m foetus, Andrews suggested that calves were probably born somewhere off the southern end of the Korean Peninsula, and that this region represented the probable southern terminus of the winter migration (Andrews, 1914).

The idea that western gray whales overwinter off the southern coast of Korea, as suggested by Andrews (1914), was largely speculative (Rice, 1998). Several lines of evidence suggest that Andrews miscalculated the true position of the wintering grounds. Rice and Wolman (1971) reported an average near-term foetus size of 4.62m for eastern gray whales taken off central California between December and January. Thus, the observed foetus size, seasonal timing and latitudinal position (about 34°N) reported for Korea and central California closely corresponded. However, eastern gray whales migrate to breeding areas as far south as 20°-27°N off Baja California (Rice and Wolman, 1971; Swartz, 1986). Although Andrews suspected that western gray whales terminated their southern migration off southern Korea, a location approximately 7°-14° north of the eastern gray whale wintering grounds, historical records indicate that they occur as far south as the Yellow Sea, East China Sea and South China Sea (Henderson, 1972; 1984; 1990; Wang, 1978; 1984; Omura, 1988; Zhu, 1998; Kato and Kasuya, In press). Some evidence is available that western gray whales range at least as far south as 20°N off Hainan Island in southeastern China (Wang, 1984; Zhu, 1998). In addition, several unverified sighting reports led Omura (1974) to suggest that an alternative or additional calving and mating area was in the Seto Inland Sea (34°-35°N) off southern Japan, but little direct evidence is available to support this idea.

EXPLOITATION

Groups of Koryak natives (Kamentsy, Parentsy and Itkantsy) living along the northeastern shores of the Okhotsk Sea hunted whales, although the particular species killed by these aboriginal whalers were not well documented (Krupnik, 1984); the author, however, believed that gray whales were hunted until the early 20th century. Whaling by Japanese hand-harpoon whalers was underway by at least the 16th century and Japanese net-whalers continued to take whales during the 17th-19th centuries (Omura, 1984). European and American whalers operating in the western North Pacific (mainly in the Okhotsk Sea) took gray whales from the late 1840s to perhaps the start of the 20th century (Henderson, 1984; 1990). Russian steam whalers took gray whales in the coastal waters of the Far East at the end of the 19th century (Andrews, 1914; Brownell, unpublished data). Japanese and Korean whalers continued to hunt gray whales until as recently as 1966 (Kasahara, 1950; Mizue, 1951; Brownell and Chun, 1977; Omura, 1984).

The reduction in the western Pacific gray whale population can be attributed largely to modern commercial whaling off Korea and Japan between the 1890s and 1960s. The population has been protected from commercial whaling since 1946, under the International Convention for the Regulation of Whaling. The Soviet Union and Japan joined the International Whaling Commission (IWC) in 1948 and 1951, respectively. The Republic of Korea and China, however, did not join until 1978 and 1980, respectively. Prior to their IWC membership, at least 67 gray whales were killed in the period 1948-1966 off the Republic of Korea (Brownell and Chun, 1977). Although no capture records are available from 1967 to the time that either the Republic of Korea or China joined the IWC, it cannot be assumed that gray whale catches did not occur during this period. Kasahara (1950) summarised whaling operations off northern Korea prior to 1945. Today, the Democratic People's Republic of Korea is not a member of the IWC and nothing is known about whaling in its waters since the end of World War II.

Western gray whales were probably never as numerous as their eastern counterparts. While pre-exploitation numbers for the western population are unknown, it has been speculated that they once may have numbered between 1,500-10,000 individuals (Yablokov and Bogoslovskaya, 1984). Berzin and Vladimirov (1981) estimated that only 1,000-1,500 gray whales remained in the population by 1910, after some commercial exploitation had already occurred. However, details of how these pre-exploitation and 1910 estimates were derived are not provided.

Kato and Kasuya (In press) estimated that some 1,800-2,000 whales (including 44 individuals killed by net whaling in the 1890s) were taken in the period 1891-1966, mostly off Korea and Japan. Peak annual catches of 100-200 whales began as early as 1907, but occurred primarily between 1911 and 1919 (no data were available for 1910) during which time at least 1,034 whales were killed, with a mean annual take of 115 whales. In the period 1920-1929, 289 whales were killed, with a mean annual take of 29 whales. By the 1930s, gray whale captures had greatly declined, with only 48 whales killed between 1930 and 1934 for a mean annual take of 10. No known additional catches occurred until 1942. Based on these catch data, it is apparent that by the early 1930s gray whales were far less abundant off the coasts of Korea and Japan and had likely reached commercial extinction. Continued low-level hunting between the 1940s and 1966, including the 67 whales captured in waters off South Korea, resulted in at least 71 whales killed. Kato and Kasuya (In press) hypothesise that the continued, albeit low-level, whaling pressure during this time is responsible for hindering the recovery of the western population. If the projected population size in 1910 was between 1,000-1,500, as estimated by Berzin and Vladimirov (1981), the removal of at least 1,442 whales recorded in the period 1911-1966 lends support to the above hypothesis offered by Kato and Kasuya (In press).

By the 1930s, the western gray whale was considered by many to be extinct (Mizue, 1951; Bowen, 1974). Nishiwaki and Kasuya (1970), believing the western population to be extinct and unaware of the Korean catches and sightings in the 1960s, suggested that sightings of two gray whales, one in about 1959 and one in 1968 off the coast of Japan, represented strays from the eastern population. However, Brownell and Chun (1977) described the probable existence of the western population based on catch records from the Korean coast during a nearly 20-year period between 1948 and 1966. These catch records, combined with the observation of four gray whales in the western Okhotsk Sea in 1967 (Berzin, 1974) and the sighting of a female gray whale and her calf in Korean waters in May 1968 (Brownell and Chun, 1977) indicated that western gray whales continued to survive in small numbers and that the observations reported by Nishiwaki and Kasuya (1970) were likely to be of western rather than eastern gray whales.

CURRENT POPULATION STATUS

The western gray whale population survives as a small remnant population (Blokhin *et al.*, 1985; Weller *et al.*, 1999). Aerial and ship-based sighting records in the Okhotsk Sea between 1979 and 1989 indicated that gray whales aggregated predominantly along the shallow-water shelf of northeastern Sakhalin Island and were most common offshore of the southern portion of Piltun Lagoon (Blokhin *et al.*, 1985; Berzin *et al.*, 1988; 1990; 1991; Berzin, 1990; Blokhin, 1996). Two non-quantitative population estimates have been reported in the Russian literature (Vladimirov, 1994; Blokhin, 1996). An estimate of 250 by Vladimirov (1994) was derived from cetacean sighting records collected between 1979 and 1992 in the Okhotsk Sea; these records were collected from a variety of observation platforms, during different seasons, and employed mostly non-systematic sampling strategies. Although counts may be inflated by repeated observations of the same individuals, the highest number reported by Vladimirov (1994) during any sampling period was 34 gray whales observed in 1989 off northeastern Sakhalin Island. The author does not explain the origin of the estimate 250. An estimate of 100 by Blokhin (1996) was based on eight shore counts and one helicopter survey conducted between July and August of 1995 along the northeastern Sakhalin Island coast. The highest number of whales counted on any one day during that period was 42 but again, the author did not explain the origin of the estimate of 100. Therefore, both of these estimates must be considered unreliable.

Recent photo-identification studies conducted between 1994 and 1999 on the primary feeding ground off northeastern Sakhalin Island (Weller *et al.*, 1999; 2000; Würsig *et al.*, 1999; 2000) have identified a total of 88 individual whales (Table 1). These photo-identification data indicate high levels of annual return and pronounced seasonal site fidelity for most whales (Table 2). While new individuals continue to be identified annually, the rate at which this is occurring is low. Only 18 previously unidentified whales (excluding calves) were photographed during 91 days of effort between 1998 and 1999. This finding suggests that a majority of the population had been identified in the period 1994-1997 (Weller *et al.*, 2000). Between 1995 and 1999, 11 reproductive females and their

1997	47	2/45 (4.3%)	25	44.4% ($n=20$)
1998	54	8/46 (14.8%)	5	89.1% ($n=41$)
1999	70	3/67 (4.3%)	13	80.6% ($n=54$)

* Insufficient data available to calculate crude birth rate.

15 calves were observed (Weller *et al.*, 2000). Two calves were observed in each of 1995 and 1997, eight in 1998 and three in 1999. Crude birth rates ranged between a low of 4.3% in 1997 and 1999, to a high of 14.8% in 1998. Of the 12 calves identified between 1995-1998, seven (58.3%) have not been resighted on the Sakhalin feeding grounds subsequent to their birth year.

Mature population size[1]

Estimating the number of whales inferred to be capable of reproduction or 'number mature' is problematic for western gray whales because there are limited direct data, and demographic estimates depend on the population growth rate, which is currently unknown. Two approaches are used here to estimate plausible, albeit conservative, numbers mature. The first uses information from Rice and Wolman (1971), who found that 24% of the eastern gray whales in their sample were sexually immature and from this suggested that the total proportion of immature animals in the population was more likely to be 44%-61%. Using the minimum estimate of 88 western gray whales (Weller *et al.*, 1999; 2000) and using the estimated proportion immature from Rice and Wolman (1971), the number of mature whales in the western population ranges between 34 and 49.

However, the eastern gray whale population was growing at the time Rice and Wolman conducted their study and would therefore be expected to consist primarily of immature animals; this would not be the case for a stable population. The second method used here is based on the premise that the proportion mature for a stable population can be estimated using age-specific birth and mortality rates. Rice and Wolman (1971) reported the mean age of sexual maturity for eastern gray whales to be eight years (range = 5-11 years). Reilly (1992) estimated adult survival to be 0.95. Although there are no data for first year survival in gray whales, it is assumed here that survival does not differ strongly from that for humpback whales (*Megaptera novaeangliae*), which is 0.875 (Barlow and Clapham, 1997). For a stable population, therefore, the estimated proportion mature is 63%, which for the estimate of 88 whales in the present case results in 55 mature animals.

In addition to the uncertainty surrounding the estimated values of the population parameters, this estimate assumes that all mature adults are capable of reproduction. If, as suspected, the western population is not growing, then it is plausible that reproduction has been compromised because the population is so small. Data from another small population that has failed to recover provide a pessimistic comparative scenario. Only 70% of North Atlantic right whale (*Eubalaena glacialis*) females known to be mature are reproductively active (IWC, 2001). If it is assumed that all males reproduce but only 70% of the females do, then 85% of the sexually mature animals are capable of reproduction. Thus, of the 55 mature western gray whales estimated using this approach, only 47 would meet the IUCN definition of mature (see below).

Clearly, both these approaches are somewhat crude and are based on assumptions that may not be valid. However, both suggest a mature population size of less than 50 mature individuals, including only 11 known calf-bearing females documented between 1995 and 1999.

Potential threats to the population

Although there is some evidence that an undetermined level of hunting may occur (e.g. Brownell and Kasuya, 1999; Baker *et al.*, 2002), it seems likely that the major threats for this population may stem from indirect mortality (e.g. bycatches and ship strikes) and habitat pollution and degredation.

Gray whales are known to be vulnerable to incidental catches in fisheries (e.g. IWC, 1994) and there are extensive coastal net fisheries off southern China, Korea and Japan (Zhou and Wang, 1994; Kato, 1998; Kim, 2000). The substantial nearshore industrialisation and shipping congestion throughout the migratory corridor(s) of this population also represent potential threats by increasing the likelihood of exposure to chemical pollution and ship strikes. Present and planned large-scale offshore gas and oil development in the South China Sea and in close proximity to the only known feeding ground for western gray whales off northeast Sakhalin Island in the Okhotsk Sea is of particular concern (e.g. see Brownell *et al.*, 1997; Brownell and Yablokov, 2001; IWC, 2002b). Activities related to oil and gas exploration, including high-intensity geophysical seismic surveying, drilling operations, increased ship and air traffic, and oil spills all pose potential threats to gray whales (e.g. Moore and Clarke, 2002). Disturbance from underwater industrial noise may displace whales from critical feeding, migratory and breeding habitat (e.g. Bryant *et al.*, 1984; Richardson *et al.*, 1995; Brownell and Yablokov, 2001). Physical habitat damage from drilling and dredging operations, combined with possible impacts of oil and chemical spills on benthic prey communities, also warrant concern.

A recent concern is the deterioration in physical condition of numerous individuals; during 1999, 2000 and 2001 whales have been observed that appeared to be unusually thin ('skinny') while on the summer feeding grounds (Weller *et al.*, 2000; authors' data). Morphological attributes correlated with this description varied among individuals, but consisted of at least one of the following: (1) an obvious sub-dermal protrusion of the top edge of the scapula from the body with associated thoracic depressions at the anterior and posterior insertion points of the flipper; (2) the presence of depressions near and posterior to the blowholes and head; and (3) a pronounced depression along the neural/dorsal spine of the lumbar and caudal vertebrae resulting in the appearance of a 'bulge' along the lateral flank.

While the causal mechanism(s) for the observed deterioration in physical condition and apparent health status of some whales is unknown, any of the following alone or in combination may be contributing factors: (1) natural or human produced changes in prey availability or habitat quality; (2) physiological changes related to stress; or (3) disease. Regardless of the cause, the loss of even a few whales (especially reproductive females) due to this deterioration in physical condition will greatly hinder population growth and ultimately prevent its recovery. Therefore, it is essential that this situation is carefully monitored and that all anthropogenic activities be reduced to an absolute minimum.

Although a natural occurrence, predation by killer whales (*Orcinus orca*) may also pose an additional threat to the recovery of this population at its currently reduced number. Killer whales are known to kill eastern gray whales, especially calves, off central and northern California (Rice and Wolman, 1971; Baldridge, 1972). Andrews (1914) found killer whale tooth raking on the flukes and flippers of a majority of the gray whales killed off Korea and

---

[1] In terms of evaluating the western gray whale population under 'Criterion D' (population estimated to number less than 50 mature individuals) of the World Conservation Union (IUCN), the definition of 'mature individuals' in this context is defined as 'the number of individuals known, estimated or inferred to be capable of reproduction' – see section on 'International concern and conservation measures'.

documented numerous accounts of killer whales attacking both living and already captured gray whales. Although killer whales are somewhat common off the Sakhalin Island gray whale feeding ground, no aggressive interactions between the two species have been observed (Weller *et al.*, 2000). However, of 69 gray whales photographically identified between 1997 and 1998 on the feeding ground off Sakhalin, over 33% had tooth rakes from killer whales on their flukes, flippers or bodies (authors' data). This finding suggests that killer whales are at least threatening, and perhaps killing, western gray whales somewhere within their range but any associated mortality related to these observations is currently unknown.

Other factors, for which the cause is unknown but which give rise to concern for this population include low calf survival estimates ($<42\%$) between 1995 and 1998; a male bias (59.4% males, 40.6% females; $n=64$) in the [biopsy] sampled population and a more pronounced male bias (77.8% males, 22.2% females; $n=9$) in sampled calves.

INTERNATIONAL CONCERN AND CONSERVATION MEASURES

Largely on the basis of the recent information provided by the joint USA-Russia research programme (1995-2001) initiative and summarised here, the World Conservation Union (IUCN) listed the western gray whale population as 'Critically Endangered' in 2000 (Hilton-Taylor, 2000). In particular, this was due to the criterion that the population is estimated to have less than 50 mature individuals.

Serious concern over the status of the population has also been expressed by the Scientific Committee of the International Whaling Commission (IWC, 2002b). As a result of this, the Commission itself passed a Resolution in 2001 calling for concerted action by range states and others to pursue actions to eliminate anthropogenic mortality and disturbances on this population (IWC, 2002a). The IWC also strongly endorsed a continuation and expansion of the current research programme.

CONCLUSION

It is apparent that long-term research and monitoring efforts of the western gray whale population need to be continued and expanded. The extensive past exploitation of this population, in combination with potential new threats from anthropogenic activities throughout its range, raises questions about the potential recovery and continued survival of the western gray whale. Future measures to protect this population will require international research collaboration between all range state countries and development of effective conservation measures and dedicated cooperation between science, industry and government.

ACKNOWLEDGEMENTS

In the field we were fortunate to work with S. Blokhin, A. Bradford, Y. Ivashchenko, S. Reeve-Rickards, Y. Shvetsov, G. Tsidulko and Y. Zhalinsky. Thanks to P. Clapham, J. Darling, D. DeMaster, T. Kasuya, S. Reilly, S. Swartz, W. Perryman and A. Yablokov for their excellent advice and willingness to serve as scientific advisors. A. Dizon and R. LeDuc conducted genetic analyses of the tissue samples to determine the sex of individuals. R. Reeves and the Editor provided quality advice and comments on earlier drafts of this manuscript. Financial support for studies conducted between 1997-1999 were provided by Sakhalin Energy Investment Company (1997-1999) and Exxon Neftegas Ltd. (1997-1998). This project was conducted as part of the Marine Mammal Project under Area V: Protection of Nature and the Organization of Reserves within the US-Russia Agreement on Cooperation in the Field of Environmental Protection. This represents contribution no.75 of the Marine Mammal Research Program, Texas A&M University.

Sightings of grey whale (Eschrichtius robustus) near southeastern Kamchatka

1. Sevvostrybvod, Petropavlovsk-Kamchatskiy, Russia
2. Kronotskiy Sate Nature Biosphere Reserve, Elizovo, Russia

В последние годы в прибрежных водах Камчатки и Командорских островов участились случаи встреч серых китов (*Eschrichtius robustus*). На полуострове они наблюдаются от мыса Рубикон на севере до мыса Лопатка на юге. Основываясь на данных мониторинга, проводимого в отдельных местах со стационарных постов, можно утверждать, что в настоящее время появление серых китов носит регулярный характер.

О встречах одиночных и небольших групп серых китов в камчатской акватории неоднократно упоминалось многими авторами (Слепцов 1955, Votrogov, Bogoslovskaya 1980), но все встречи были характерны для севера Камчатки до м. Олюторский в приграничных с Чукоткой районах, куда заходят серые киты чукотско – калифорнийской популяции. При авиаучетных работах, выполненных в августе 1983 г. южнее м. Олюторского, встречаемость серых китов резко падает (Богословская 2002) и численность их не превышает 30 голов, причем в Карагинском заливе их насчитывалось всего 6 особей. Сдерживающим фактором продвижения чукотских серых китов на юг вдоль Камчатского побережья, возможно, является активная рыболовная деятельность. Например, от устья р. Ильпырь до устья р. Озерная (560 км) в летний период промысла лосося выставляется более 200 ставных неводов с обслуживающим маломерным флотом и крупнотоннажными приемщиками рыбы и эта обстановка является неблагоприятной для обитания китов.

В 1999-2000 гг. два серых кита отмечались в акватории о. Беринга (Командорские острова) в бухтах Лисинской и Никольской. Причем в бухте Никольской киты периодически наблюдались на протяжении более месяца.

Серые киты, наблюдаемые на самом юге Камчатки и Курильских островах, могут принадлежать к охотско-корейской популяции (Blokhin et al. 1985, Votrogov nad Bogoslovskaya 1986). По личному сообщению М.К. Маминова, при обследовании юго-востока Камчатки он наблюдал одиночных серых китов в акватории этого района еще в 1980-х гг.

В бухте Вестник серые киты отмечаются с 1994 г. Ежегодно от 3 до 6 китов проводят здесь 8-9 месяцев. В бухте Ольги киты встречаются с 1995 г. В настоящее время их численность достигает 10 особей (таблица). В устье р. Кроноцкой в 2000-2001 гг. наблюдались 3 серых кита, но позднее обследование данного района не

During the recent years, in the coastal waters of Kamchatka and Commander Islands gray whales (*Eschrichtius robustus*) have been sighted increasingly frequently. In Kamchatka, they have been sighted from Cape Rubikon in the north to Cape Lopatka in the south. Based on monitoring data, conducted in certain areas from stationary posts, there are grounds to conclude today, that gray whales occur regularly.

The sightings of single whales and small groups in the Kamchatka water area, has been repeatedly mentioned by numerous authors (Слепцов 1955, Votrogov, Bogoslovskaya 1980), but all the sightings were characteristic of northern Kamchatka to Cape Olyutorsky in areas bordering on Chukotka where gray whales of the Chukotka-Californian population enter. In the course of aerial surveys conducted in the August 1983 south of Cape Olyutorsky, the rate of occurrence of gray whales sharply declines (Богословская 2002), their number not exceeding 30 individuals, with only 6 individuals in Karaginsky Bay. A limiting factor for advance of Chukotka gray whales southward along Kamchatka shore may be active fishery. For instance, from the mouth of the Ilpyr River to the mouth of the Ozernaya River (560 km) during the summer season of salmon fishery over 200 trap nets serviced by small tonnage fleets and a large-tonnage fish receiver and this situation is unfavorable for whales.

In 1999-2000, two gray whales were recorded in the water area of Bering Island (Commander Islands) in the bays Lisinskaya and Nikolskaya. In Nikolskaya Bay, whales were repeatedly sighted for over a month.

Gray whales observed in the very south of Kamchatka and the Kurils can belong to the Okhotsk-Korean population (Blokhin et al. 1985, Votrogov nad Bogoslovskaya 1986). According to personal communication by A.K. Maminov who surveyed southeastern Kamchatka, he sighted gray whales in the water area of that region as early as the 1980s.

In Vestnik Bay, gray whales have been sighted since 1994. Each year from 3 to 6 whales spend 8-9 months there. In the Olga Bay, whales have been sighted since 1995. To date, their number reaches 10 individuals (table). In the mouth of the Kronotskaya River in 2000-2001 there were 3 gray whales, but subsequent survey of the region concerned was not conducted. During the проводилось. В конце 1990-х гг. в бухте Калыгирь отмечали 2 китов, из которых 1 был детенышем. В устье р. Налычева до 8 серых китов наблюдаются с 1996 г. Киты придерживаются предустьевых зон крупных и средних рек, где они имеют возможность кормиться на выносах ила на небольших глубинах.

Во второй декаде сентября 2002 г. напротив Халактырского Пляжа (район г. Петропавловска-Камчатского) было встречено 6 серых китов на изобатах 50-70 м. В конце сентября 2002 г. в районе бухты Русской был отмечен мигрирующий на юг одиночный серый кит, за которым было проведено наблюдение в течении 38 минут. Всего отмечено 9 серий фонтанов со средней продолжительностью заныриваний между ними 4 мин. 20 сек. (1:18 - 5:56). За период нахождения у поверхности кит делал в среднем 5-6 всплытий с фонтанами (2-9), средняя продолжительность между фонтанами составила 14,9 сек (11-20). Однажды кит занырнул, выставляя хвостовую лопасть, видимо проверяя место на пригодность кормежки (глубина 88 м). После сближения с судном, которое шло параллельным курсом со скоростью 6-5,2 узла и пересечением курса судна по носу и сокращением дистанции с 1,5 км до 200 м, кит стал вести себя осторожно, остановился, начал затаиваться и слегка выставлял дыхало на поверхность воды, практически не давая фонтаны. После ухода судна, кит стал вести себя обычно и сделал серию из 7 фонтанов. После чего наблюдение было прекращено.

Серые киты, обитающие на юго-востоке Камчатки, облюбовали акваторию Кроноцкого заповедника, Южно-Камчатского заказника и прилегающие к ним воды (таблица), где, согласно Правилам охраны и промысла морских млекопитающих, существует 3-х мильная охранная зона, в которой запрещена всякая хозяйственная деятельность, в том числе и судоходство.

Иногда отмечаются отдельные встречи китов в необычных местах. В августе 2000 г. наблюдался заход некрупного животного в реку Большую на западной Камчатке. Другая встреча одиночного кита отмечена в Авачинской бухте в декабре 2003 г. Взрослый зверь провел половину суток в небольшой полынье и спокойно кормился возле механического цеха судоремонтного завода в черте города Петропавловска-Камчатского и ушел вслед за рабочим буксиром. Общее количество китов в акватории полуострова достигает примерно 20-25 особей.

Таким образом, в последние годы серые киты неизвестного происхождения регулярно встречаются вдоль восточного побережья Камчатки и в акватории Командорских островов, хотя и в небольшом количестве. Можно предположить, что в северной части акватории полуострова и на Командорах обитают киты чукотско-калифорнийской популяции, а в южной части акватории Камчатки наблюдаются киты охотско-корейской популяции. Особый интерес представляют киты, встречающиеся в юго-восточной части Камчатки, которые, возможно, появились здесь из-за влияния нефтеразведки и добычи на шельфе о. Сахалин. Так, в 2000 г. серый кит, встреченный на о. Парамушир, был отмечен ранее на о. Сахалин (Трухин А.М., лич. сообщ.).

late 1990s in Kalagyr 2 whales were sighted, one being a calf. In the mouth of Nalycheva River up to 8 gray whales have been recorded since 1996. Whales stick to the pre-mouth zones of big and middle-sized rivers, where they feed at silt accumulations and at small depths.

During the second ten days of September 2002 against the Khalaktyrsky Beach (the region of Petropavlovsk-Kamchatkskу) 6 gray whales were sighted at isobaths of 50-70 m. In late September, 2002 in the Russkaya Bay regions, a gray whale migrating southward was sighted, which was monitored for 38 minutes. A total of 9 spout series with a mean length of diving duration of 4 minutes 20 seconds (1:18 - 5:56) were recorded. While it stayed near the surface, the whales surfaced 5-6 times with 2-9 spouts, the mean duration of the period between the spouts being 14.9 seconds (11-20). Once the whale dived its tail flukes above the surface: apparently it was testing the site for suitability for feeding (depth 88 m). Upon approaching the ship, which was sailing in a parallel direction at a speed of 6-5.2 knots and crossing the course on the bow side and reduction of the distance from 1.5 km to 200 m, the whale started behaving carefully, would protrude the blowhole onto the surface practically without making spouts. After the ship left, the whale behaved normally producing 7 spouts, whereupon the observation was discontinued.

Gray whales dwelling in southeastern Kamchatka prefer the water area of the Kronotsky Reserve, Southern Kamchatka Sanctuary and adjacent waters (table), where according to the Regulations for Protection and Harvest of Marine Mammals, there is a three-mile protection zone, where any economic activity, including navigation, is banned.

Occasionally, there are some individual sightings of whales in unusual places. In the August 2000, a big animal entered the river Bolshaya in western Kamchatka. Another sighting of a solitary whale was recorded in Avachinsky Bay in the December, 2003. An adult individual spent half a day in a small polynya and was quietly feeding near a mechanical shop in a shipyard within Petropavlovsk-Kamchatsky area and left after a tug. The total number of whales in the Kamchatka water area reaches roughly 20-25 individuals.

Thus, during the recent years gray whales of unknown origin regularly occur along the eastern coast of Kamchatka and in the water area of the Commander Islands although in small number. There are grounds to believe that in the northern part of the water area and in the Commander Islands, there dwell whales of the Chukotka-Californian population, and in the southern part of the water area of Kamchatka, whales of the Okhotsk-Korean population are observed. Of special interest are whales occurring in the southeastern Kamchatka, which, presumably, appeared there due to the effect of oil prospecting and oil extraction on the Sakhalin shelf. In fact in 2000, the gray whale that was sighted off Paramushir Island was previously recorded off Sakhalin (Трухин А.М., pers. com.).

Назрела необходимость полного и целенаправленного мониторинга серых китов у берегов Камчатки, выяснения их статуса, происхождения, сопоставления полученных по единой методике данных с материалами из других регионов.

Выражаем искреннюю благодарность Корневу С.И., Владимирову А.В., Маминову М.К. Трухину А.М., Белецкому И.С. за помощь в сборе информации.

A need has arisen for complete and goal-oriented monitoring of gray whales off Kamchatka, revelation of their status, origin, comparison according to a single method of data available and materials from other regions.

We are sincerely grateful to S.I. Kornev, A.V. Vladimirov, M.K. Maminov, A.M. Trukhin, and I.S. Beletsky for assistance in collecting information.

ECOLOGY

The Peculiarities of Foraging Migrations of the Korean–Okhotsk Gray Whale (*Eschrichtius robustus*) Population in Russian Waters of the Far Eastern Seas[1]

Received September 15, 2009

Abstract—Photographic identification of the Korean–Okhotsk gray whale *Eschrichtius robustus* population has been conducted since 2002 by researchers of the Institute of Marine Biology at the Far East Branch of the Russian Academy of Sciences (IMB FEB RAS), with financial support provided by Exon Neftegas, Ltd. and Sakhalin Energy Investment Co., in order to study the migration features and biology of this species. In 2008, photo-ID studies were carried out in two areas, off the northeastern coast of Sakhalin Island and off the southeastern coast of Kamchatka. As a result of the studies, 122 whales known from the Sakhalin gray whale catalogue were photographed. Of them, 97 individuals were registered off Sakhalin, 24, off Kamchatka, and one whale was observed at both sites. In addition, 25 more gray whales that had not been sighted off Sakhalin Island before were found off the coast of Kamchatka. Based on these photographic materials, the whales physical and skin conditions were also analyzed. Cases of sightings of gray whales in areas that are remote from their traditional summer and fall feeding grounds in the Far Eastern seas of Russia are discussed.

Key words: gray whale, photo-ID, distribution, Sakhalin, Piltun, Kamchatka, oil-gas projects.

DOI: 10.1134/S1063074010020069

Studies of the relatively small in number and endangered Korean–Okhotsk (or western) gray whale (*Eschrichtius robustus*) population have been conducted off northeastern Sakhalin Island, Russia since 2002 [4, 6, 10]. The work is performed as a part of the monitoring program financed within the oil and gas projects Sakhalin-1 (operated by Exon Neftegas, Ltd.) and Sakhalin-2 (operated by Sakhalin Energy Investment Co.). Observations generally covered the two traditional feeding areas visited by gray whales in the summer and fall: (1) Piltun area (52°40′–53°30′ N), which stretches along the shore opposite to Piltun Bay, where the whales forage mostly at depths of less than 20 m, and (2) the Offshore area located about 30–40 km off Chaivo Bay (51°50′–52°25′ N), with depths of 35–60 m [2, 12, 22]. Recently, gray whales were also observed off the southeastern coast of the Kamchatka Peninsula [1]. Gray whale sightings took place in the waters of Nalychev Bay with depths of around 30 m in 2004; the animals were also observed in Vestnik Bay at depths of about 15–24 m and in waters of Olga Bay at depths of 5–17 m in 2006–2007 [5, 19].

Observations of the gray whale distribution off Sakhalin Island and the Kamchatka Peninsula shows that the current migration pattern of this species along the Asian coastline needs farther investigation. For this reason, the necessity arose to analyze the peculiarities of the interrelations between Korean–Okhotsk and California–Chukchi (or eastern) gray whale populations with the use of additional data obtained through up-to-date techniques. International practice has shown that many questions about the spatial distribution and biology of marine mammals, particularly cetaceans, can be successfully answered by means of photographic identification [8, 13]. Use of this method for the study of the Korean–Okhotsk population of the Gray Whale (*E. robustus*) made it possible to compose the Sakhalin gray whale catalogue [15, 18], which is updated annually. In this paper, we present the results of our efforts on photoidentification of *E. robustus* individuals sighted offshore Sakhalin Island and the Kamchatka Peninsula in 2008.

MATERIAL AND METHODS

The primary data for the gray whale photo-IDs were collected in two areas off Sakhalin Island during expeditions on the R/V *Akademik Oparin* from June 25 to July 23 and from August 24 to October 10, 2008 (Fig. 1). Between these two periods, while the vessel operated under another program off the West Kamchatka shore and along the Kuril Islands, regular day-

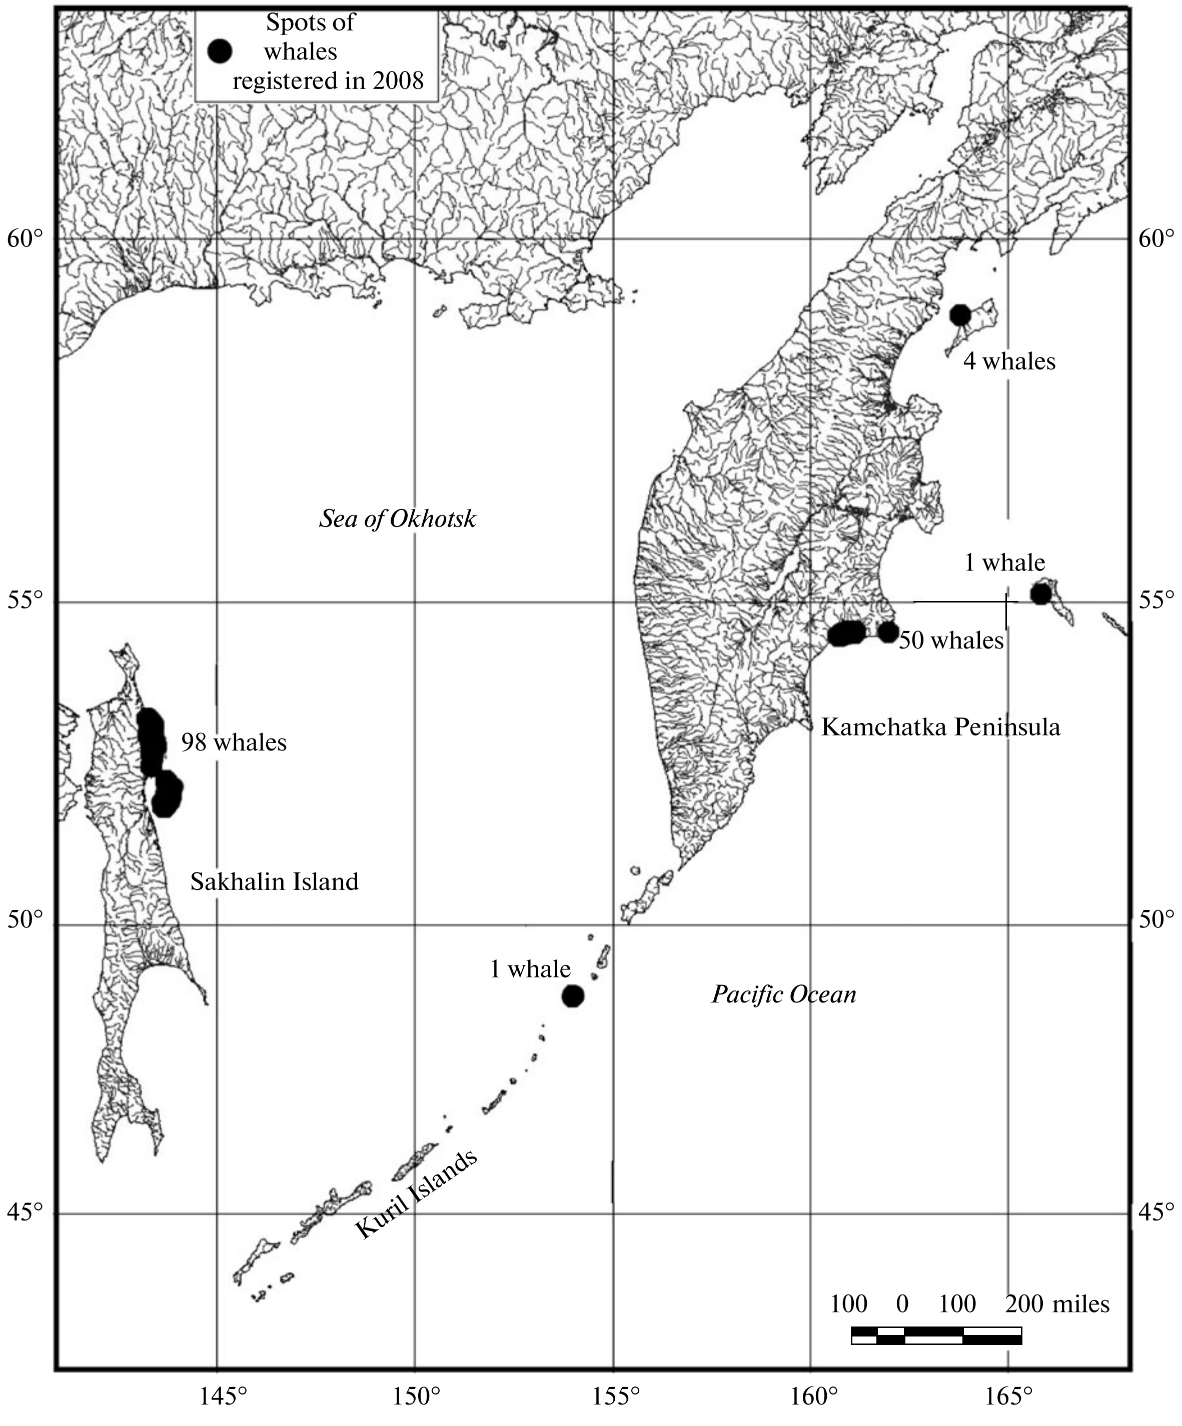

Fig. 1. Distribution of gray whales known from the Sakhalin and Kamchatkan catalogues in waters of Russian Far East in June–October 2008.

time observations of marine animal distributions were also conducted on board.

The material was obtained through the well-coordinated operations of an observer in the pilot house and a research team in a Zodiac boat. When the observer sighted a whale or a group of whales, he informed the team in the Zodiac about the location and distance to the animals, their number, and the behavior. At a distance of around 100 m from a whale, researchers began photo and video recording (with a Nikon D2X digital camera equipped with a telephoto lens Nikkor 80–400 mm and a Sony HDR-HC7 digital video camera). At the time of these operations, the position of the boat (and the whale) was fixed with a

Note: * Whales in brackets have temporary ID Nos. This ID is assigned to an animal that does not have good photographs of its right side in the catalogue.

GPS receiver, and other characteristics of the environment, such as the depth, sea state, presence of other marine mammals or watercraft, the whales mud plumes, etc., were recorded.

The same type of information was collected during the studies in Olga Bay off the Kamchatka Peninsula shore (Fig. 1). Whales were photographed through a Canon 40D digital camera with a 75–300 mm telephoto lens.

Individual gray whales were identified by distinctive marks on their sides and flukes. For this, we used standard photo ID methods, which are described in Special Issue No. 12 of the International Whaling Commission [9]. Left to right side matches were recognized confidently provided all the following criteria were satisfied: (1) the whale was photographed as a solitary individual; (2) two photographic series of both sides of the whale with the same fluke were obtained during one sighting; (3) as a final check, the height, spacing and ratio of the distinctive knuckles in the ridge on the caudal peduncle were considered [7]. A whales body pigmentation was the primary feature used in identifying individuals, and scars and barnacle patches were considered as supplementary signs.

Upon being included into the Sakhalin catalogue, whales recorded off Sakhalin were assigned an ID number starting with KOGWno., and those observed in Kamchatkan waters received the code KamGW with an ID number in the Kamchatka catalogue. If known gray whales were sighted in both regions, then they were assigned dual numbers, for instance, KOGWno. = KamGWno., and included in both catalogues. Special attention was paid to finding whales with various abnormalities in physical condition of their bodies, obvious sloughing, or an anomalous skin condition.

Data obtained in previous years of studies [3, 11, 15, 17] and data from direct counts of gray whales [20] were also used when discussing the results of the photo-ID conducted in 2008.

RESULTS AND DISCUSSION

Number of Identified Gray Whales

The Sakhalin gray whale catalogue created in 2002 and updated annually now numbers 165 identified individuals (Table 1). Among the whales listed in the catalogue, some individuals have been regularly registered off Sakhalin Island for the past 6 years, other ones have not been seen for a long time, and a third group were found for the first time. In 2008, 97 gray whales from the Sakhalin catalogue were sighted on the shelf off Sakhalin Island, 24 individuals from the same catalogue were photographed in Olga Bay, Kamchatka Peninsula, and one whale was seen both off Sakhalin and Kamchatka. Thus, in 2008, we observed 122 whales known by the Sakhalin catalogue (Fig. 2).

Currently the Kamchatka catalogue, which was composed in 2004, numbers 78 gray whales; 39 of them are also included in the Sakhalin catalogue, which means they were sighted off Sakhalin previously. In 2008, among 50 gray whales registered off southeast Kamchatka, 25 individuals had never been observed previously off Sakhalin Island and therefore were not entered in the Sakhalin catalogue. It is now unclear if these whales belong to the Korean–Okhotsk

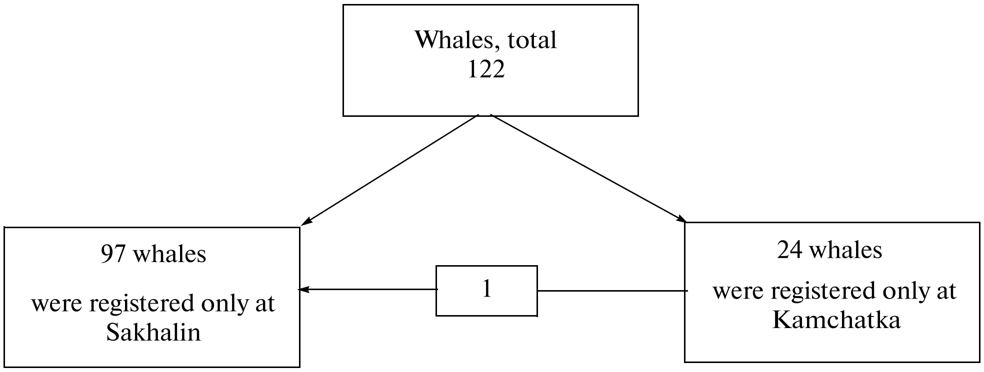

Fig. 2. The number of Gray whales that were registered, (i.e. photoidentified) in Sakhalin and in Olga Bay, Kamchatka, in 2008.

(western) or California–Chukchi (eastern) population.

In 2008, the total number of gray whales identified offshore Sakhalin Island was 98, which was fewer than in 2007 (125 individuals). This can be probably explained by the duration of the studies and the number of whale sightings. Thus, photo-ID studies offshore Sakhalin in 2008 lasted for 29 days and those in 2007 lasted for 62 days. Consequently, the number of registrations of animals in 2007 was about 2.5 times larger.

Gray Whale Movements between Feeding Areas

The data available show that gray whales not only perform seasonal migrations from their wintering sites to the areas where they forage in summer and fall, but also make significant spatial relocations in order to use resources of one or several feeding areas [3, 22]. The spatial relocations of this kind can be divided into intra-annual and inter-annual ones.

Intra-annual relocations of whales between feeding areas can be of various scales. An example of relatively small-scale relocations is whale movements between feeding areas off the northeastern Sakhalin coast. In 2008, of all the 98 whales identified in Sakhalin waters, 36 were sighted only in the Piltun feeding area, another 36, only in the Offshore feeding area, and 25 more whales were registered in both sites (Table 2). This fact indicates that some of whales use both feeding areas in the same season. Furthermore, one whale among those sighted in the Piltun and Offshore feeding areas was also found north of the Piltun area, in the nearshore waters not far from the town of Okha. Cases of intra-annual relocations like these were also recorded previously; in 2007, 38 whales were registered both in the Piltun and the Offshore feeding areas.

Table 2. Grey whale relocations between feeding areas on the northeastern shelf of Sakhalin Isl. in 2002–2008

Year	Number of whales identified in various areas						
	Piltun	Offshore	Piltun and Offshore	Chaivo	Chaivo/Piltun and Chaivo/Offshore	northern areas	Chaivo/Piltun/Offshore
2002	13(12)*	35(34)	1	–	–	–	–
2003	51(47)	35(31)	4	–	–	–	–
2004	95(89)	7(1)	6	–	–	–	–
2005	114(109)	7(2)	5	–	–	5(1)	–
2006	105(67)	33(14)	16	28(7)	19(1)	–	2
2007	93(48)	70(25)	38	20(0)	13(0)	–	7
2008	61(36)	61(36)	25	1(1)	–	1	–

Note: * Whales in brackets were registered only in the areas above.

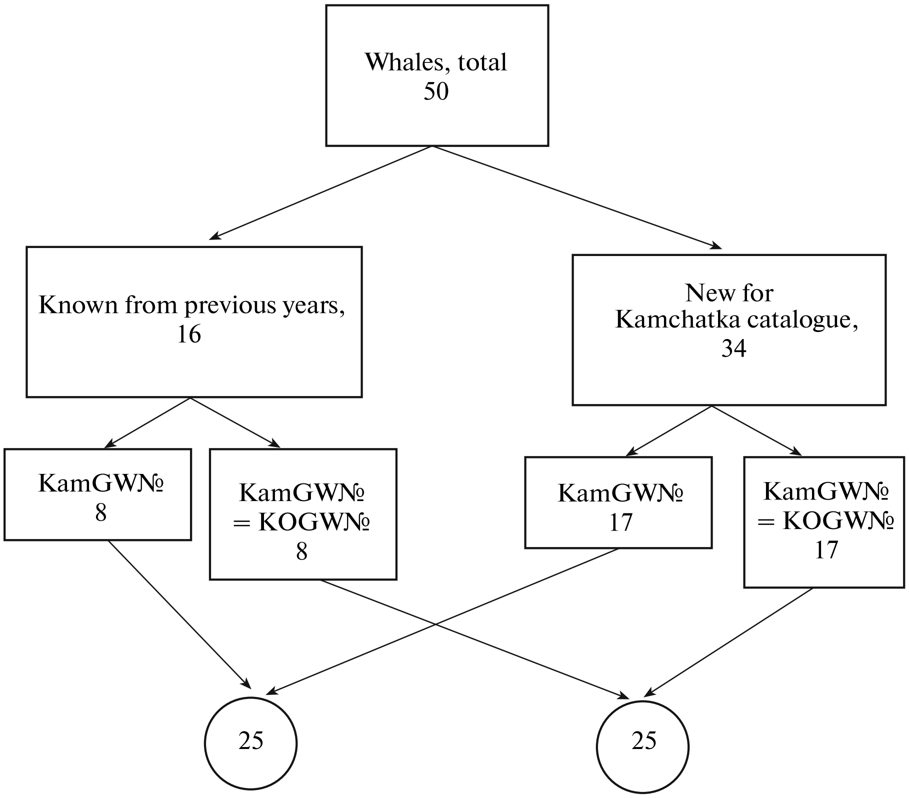

Fig. 3. Gray whales from the Sakhalin catalogue that were registered off the northeastern coast of Sakhalin Isl. (KOGWno.) and in Olga Bay, southeastern coast of the Kamchatka Peninsula, (KamGWno.) in 2008.

It was also established that whales may forage both in Sakhalin waters and off Kamchatka during the same season, which means they make large-scale intra-annual relocations. Two whales in 2006 and one whale in 2008 were first identified off Kamchatka, and later in the season they were found again in the Offshore feeding area off Sakhalin. In 2007, 13 whales sighted off Kamchatka were then observed in Sakhalin waters.

Inter-annual relocations are whale movements between feeding areas over consecutive years. Thus, some of the whales that were seen in 2008 only in the Piltun feeding area were recorded in the Offshore feeding area in previous years. Half of the whales registered in Olga Bay, Kamchatka Peninsula, in 2008 previously had been recorded off Sakhalin (Fig. 3). Those ten whales recorded off the Sakhalin shore in 2008 were also sighted off Kamchatka in 2007. In 2007, 20 of 37 whales identified on the southeastern shelf of Kamchatka had been sighted off Sakhalin in previous years. Similarly, 5 whales of the 13 sighted off Kamchatka in 2006 were also observed off Sakhalin Island both in previous and subsequent years.

It should be mentioned that, besides the previously known areas of whale aggregations that form off the northeastern coast of Sakhalin Island and off the Kamchatka Peninsula in the summer and fall, other areas in far eastern seas exist where representatives of the western gray whale population have been repeatedly observed. After the pictures of three whales photographed in Kekurny Bay on July 13, 2006 and Babushkin Bay on July 28, 2006 in the Northern Sea of Okhotsk, were analyzed the animals were included in the new catalogue under the ID code NOGW [19]. In 2007, one of these whales was sighted both in the Piltun feeding area and in Olga Bay and therefore assigned the ID number KOGW159/KamGW034/NOGW003 in the Sakhalin and Kamchatkan catalogues. Furthermore, one whale that was registered in Olga Bay, Kamchatka Peninsula, in 2007 was then photographed in Zakatny Bay off Shiashkotan Island, Kuril Ridge, in 2008. Later in 2008, this whale was sighted again in Olga Bay (Fig. 1). On June 6, 2008, one whale photographed near Medny Island, Commander Islands, had been encountered in Olga Bay, Kamchatka, in 2007, and then was sighted again in Olga Bay in August 2008. Four gray whales observed off Karaginsky Island, Northeast Kamchatka, on July 8, 2008, previously had not been sighted anywhere else (Fig 1). It is difficult to judge if the new locations of gray whale sightings given above are potential feeding areas for these animals, because data are scarce and no reliable evidence of their foraging there has been obtained. But we may suppose that these are cases of spatial relocations that gray whales make in search of sites with enough food resources.

Data on the movements of young whales are of great interest. A total of eight whales first recorded as calves off Sakhalin in 2007 were photographed in Olga Bay, Kamchatka Peninsula, in the following year. A whale identified as a suckling calf in the Piltun feeding area in 2004 was never seen there subsequently but was regularly registered off Kamchatka in 2006, 2007, and 2008. Similarly, two calves that were identified first in the Piltun area in 2003 were observed only off Kamchatka during the 3 years noted above. One whale that was identified as a calf off Sakhalin in 2005 was repeatedly sighted there in 2006 and 2007 and then photographed off Kamchatka in 2007 and 2008.

Mother–Calf Pairs

Unlike other categories of whales, mother-calf pairs were registered only in the Piltun feeding area until 2008. They were observed most frequently in shallow waters near the Piltun Bay opening, in the sites of higher concentrations of benthic organisms, where mothers teach their offspring to forage from July through mid September. In 2008, three cow–calf pairs and two independent young whales, possibly calves, were photographed in the Piltun feeding area.

In 2008, for the first time in the entire period of studies one cow–calf pair was recorded in Olga Bay, Kamchatka Peninsula. Previously, this mother was recorded offshore Sakhalin in 2002–2006 and in Olga Bay, Kamchatka, in 2007. In 2003, the female brought her calf to Sakhalin. The low occurrence of mother–calf pairs in Kamchatkan waters can be more probably explained by the smaller scale and shorter duration of gray whale observations, as compared to those conducted off Sakhalin.

The Physical Conditions of Whales

As we showed earlier in materials collected in 2005–2007, characteristics of the bodys physical condition (BPC) in the underfed and sometimes very emaciated whales that arrive to feed offshore Sakhalin Island in the spring greatly improve during summer [16].

In 2008, the BPC in 20 whales (including three nursing cows) photographed offshore Sakhalin in the beginning of the season was lower than the normal level. For the summer and fall season, the body condition of eight whales improved to the normal level. However the rest of the animals either did not restore their normal BPC or were not observed in the late season. Furthermore, five of the six nursing cows that had subnormal body conditions in 2007 were again photographed in 2008 when all five had regained their optimum physical state. As in previous years, the body condition of all the calves recorded in 2008 fitted the optimum.

The high-quality photographs also allowed evaluations of skin condition. In 2008, no whales were recorded with skin sloughing, as had been the case previously [21]. However, two individuals had noticeable white patches of an unknown nature on their skin; the same had been earlier observed in western grey whales [14].

CONCLUSIONS

Based on the results presented here, it can be concluded that adult individuals of the studied population of gray whales perform intra- and interannual relocations between the Piltun, Offshore, and Kamchatkan areas. One of the probable explanations of a behavior like this is changes in food abundance, although comprehensive monitoring studies of the composition and resources of benthos and nektobenthos in the newly discovered areas of whale sightings are needed to substantiate this statement.

Half of the gray whales listed in the Kamchatka catalogue (39 of 78 individuals) probably belong to the western population, while the affiliation of the other half remains unclear. The same can be said about the whales identified off the southeastern shore of Kamchatka in 2008; half of them (25 of 50) had been earlier included in the Sakhalin catalogue, and the population status of the remaining ones is undetermined. These results allow us to make two suppositions: (1) a substantial proportion of gray whales of unknown origination belong to the western population but they have not been sighted near Sakhalin Island to date; or (2) these gray whales belong to the eastern population. In the former case, it is necessary to ascertain why individuals of the western population have not been registered near Sakhalin Island. With the latter supposition, we can assume that gray whales of the eastern and western populations are not sufficiently isolated from one another geographically, and an overlap of their ranges exists in feeding areas.

The recent gray whale sightings in the Northern Sea of Okhotsk, off Shiashkotan Island, Kuril Ridge, and off Medny Island, Aleutian Ridge, indicate that these animals can be encountered in places other than off northeast Sakhalin Island or southeast Kamchatka. However, up to this time, encounters like these have remained sporadic and it is still poorly known why and how frequently these sites are visited by gray whales.

To better understand the degree to which western grey whales have fidelity to certain feeding areas, to reveal peculiarities in the movements made by animals between the feeding areas, to establish the frequency of their visits, and to find the causes of these movements, we need additional data that would cover the entire variety of gray whale habitats and the routes of their seasonal migrations.

ACKNOWLEDGMENTS

We thank offshore observers A.G. Afanasyev-Grigoriyev, M.S. Kornienko, V.B. Stekhov (IMB FEB RAS) for providing the information on whales distribution, to Yu. Bychkov (LGL, Canada) and K.A. Drozdov (Pacific Bioorganic Chemistry Institute, FEB RAS) for supporting the database. We are also grateful to Judy E. Muir, Christine Tombach Wright (LGL, Canada), Sandra R. Werner (Exon Neftegaz, Ltd.) for their assistance in writing this paper and to the crew of the R/V *Akademik Oparin*. Financial support of this study was provided by Exon Neftegas, Ltd. and Sakhalin Energy Investment Co.

Abstract

Animals belonging to the small, endangered population of western gray whales (*Echrichtius robustus*) are observed today primarily during the summer open-water season in feeding areas off the north-eastern coast of Sakhalin Island, Russia. The migration route(s) and wintering area(s) used by this population are largely unknown. Gray whales once had a fairly extensive distribution in the Sea of Okhotsk but little detailed information has been published on when and where they occurred. Open-boat, ship-based whalers from the United States and a few other countries conducted an intensive hunt for bowhead whales (*Balaena mysticetus*) and North Pacific right whales (*Eubalaena japonica*) in the Sea of Okhotsk from the 1840s to 1870s. According to entries in voyage logbooks, the American whalers regularly encountered (and sometimes hunted) gray whales in the far north-eastern corner of the Okhotsk Sea (Shelikhov Bay, Gizhiginskaya Bay and Penzhinskaya Gulf) between early May–late August. They also observed gray whales in summer along the northern coast of the sea (especially Tauskaya Bay), around the Shantar Islands, in Sakhalin Bay, off Cape Elizabeth at the northern tip of Sakhalin Island and along the west coast of the Kamchatka peninsula. No evidence was found in the logbooks studied of gray whales (and indeed of whaling effort) off north-eastern Sakhalin Island where most observations of gray whales occur in the present day.

Introduction

Recent and current interest in gray whales (*Eschrichtius robustus*) from the western Pacific (Korean-Okhotsk) population has centred on that population's endangered status and the ongoing threats to its survival and recovery. Specifically, there is concern about (a) the small number of whales in the population; (b) environmental degradation and disturbance from oil and gas development on the north-eastern Sakhalin Island shelf, the main area where the population is presently known to congregate in summer to feed; and (c) mortality of gray whales in Japanese waters, mainly in set nets.

The history of this population has been reviewed by Mizue (1951), Nishiwaki and Kasuya (1970), Brownell and Chun (1977), Omura (1988), Weller et al. (1999, 2002) and Kato and Kasuya (2002). In addition to those reviews, Henderson (1972, 1984, 1990) made reference to ship-based whaling on the western population during the 19th century, primarily by American and French whalers. In our recent studies of whaling history in the North Pacific, we have examined a sample of American voyage logbooks that contain substantial unpublished data on western gray whales. The present paper uses those data to describe where and when western gray whales were observed by ship-based whalers during the 19th century.

The data confirm that in the past gray whales used various parts of the Okhotsk Sea, likely as feeding grounds and as routes to and from such grounds. Given the rapid proliferation of offshore oil and gas operations around the perimeter of the Okhotsk Sea as well as on the entire Sakhalin Shelf, understanding the historical (and thus both current and potential) summer range is essential.

Background

Offshore or ship-based whaling for gray whales along the Asian coast from southern China to Japan and in the Sea of Okhotsk has been less well documented than shore-based whaling there. Among the reasons for this difference is the death in June 1999 of David Henderson, who authored classic studies of the American pre-modern, ship-based fishery for *eastern* Pacific gray whales (1972, 1984) and was working on a similarly exhaustive study of the Okhotsk fishery for *western* Pacific gray whales (e.g. see Henderson 1984, p. 176, note 14; Kugler 1984, p. 157, note 6). Henderson (1972) provided only limited information on western gray whales although on his Map I, he offered an intriguing sketch of their distribution (Fig. 1). Henderson's 1984 book chapter (pp. 176-177) indicates that gray whales were not hunted by the American whalers in the Sea of Okhotsk until sometime in the 1840s and that catches of 6-7 whales per ship were being made by the 1850s. He judged that the total kill of gray whales in the Okhotsk Sea by the American fleet was probably similar to that in the Bering Sea and Arctic Ocean, i.e. a few hundreds (his estimate of total kill in the latter areas between 1845-1874, adjusted for hunting loss, was 539; Henderson 1984, p. 169). Some American whaling for gray whales continued in the Sea of Okhotsk until at least the mid-1880s (Henderson 1984, p. 177), by which time most of the remaining Arctic fleet was committed to the 'hazardous, though profitable, whaling in the Arctic [i.e. Bering, Chukchi and Beaufort seas]' (Clark 1887, p. 19). The Sea of Okhotsk was also a frequent destination of French whalers from the mid 1840s until perhaps the mid 1860s (Du Pasquier 1982, pp. 183, 192, 245-249; Kugler 1984, p. 152) and they probably took at least some gray whales although we have not found any direct evidence for this (Du Pasquier 1986, p. 274). At least three Russian whaleships (all originating from Finland) also visited the Okhotsk Sea in the 1850s (Clark 1887, pp. 206-207).

The Okhotsk Sea fishery for balaenids was most intensive from 1847-1867, with nearly 1,400 vessel-seasons, 90% of them from the United States and the rest from France, Bremen, Russia, and the Hawaiian Islands, and occasionally Great Britain, Norway, and Chile (Kugler 1984, p. 153). As an example of the intensity of this fishery, one ship's logbook reported that 65 other whaling vessels were in sight on 27 August 1854 in Shantar Bay (*Good Return*). In that same month, Lindholm (1863) counted 82 ships in the bay and on one day 363 whaleboats were in sight from his ship (*Storfursten Constantin*). Bowhead whales (*Balaena mysticetus*) and North Pacific right whales (*Eubalaena japonica*) were the principal targets and, according to Henderson's preliminary analyses (as reported by Kugler, *op cit.)*, more than 15,000 bowheads and

2,400 right whales were killed and processed by the Okhotsk whalers in those first 20 years. The fishery continued until the 1890s.

Henderson's only publication containing data on western Pacific gray whales (apart from the few references to Okhotsk whaling in his 1972 book and his 1984 book chapter) was a short article on American whaling in southern China in the 1860s (Henderson 1990). There he recounted two voyages to the 'Chinese gray whale ground' in the winter of 1868-69 – by the New Bedford ships *Cornelius Howland* and *Onward*. Although they failed to strike any, the crews of these vessels sighted gray whales near the Chinese mainland coast at c. 25-26ºN off the island of 'Hatan Ho Tan' (Haitan, Pingtan Dao, or Tao on modern maps, according to Henderson), in the middle of Taiwan (Formosa) Strait, and off the northern coast of Taiwan.

Materials and Methods

In addition to a search of the literature, we sampled whaling voyage logbooks from the Kendall Whaling Museum and Old Dartmouth Historical Society collections, both available at the New Bedford Whaling Museum library in New Bedford, Massachusetts. Okhotsk Sea logbooks were identified using library finding aids, *Whaling Logbooks and Journals* (Sherman et al. 1986), and *The History of the American Whale Fishery* (Starbuck 1878), as well as through references in logbooks to other vessels sighted or 'spoken' on the grounds. Data from the logbooks, including date, position, details concerning whale observations, and other vessels spoken, were entered into an Access database and plotted using ArcMap.

Frequently, the exact location could not be determined from the logbook and therefore it was necessary to estimate positions by interpolation and reference to landmarks. A particular problem encountered while working with this material was that place names used by the American whalers did not always correspond to the Russian names. For that reason, we compiled a gazetteer in the course of our logbook reading as a research tool. Sketch maps prepared by the whalers themselves were useful in that regard (Fig. 2). A composite map of the region was developed from a variety of sources (Fig. 3). When places are mentioned throughout the text of this paper, alternative names have been indicated in brackets.

The American whalemen used several different terms to refer to gray whales, including ripsacks (rip sacks), musseldiggers (mussel diggers), devil fish, scrags, scamperdowns, California grays, graybacks and California whales.[1] They called bowheads polar whales, steepletops, bowheads (bow heads) or often just whales (in most but not all instances, the species can be inferred from the context). Blue whales (*Balaenoptera musculus*) were consistently called sulphur bottoms (or sulfur bottoms). Right whales, humpback whales (*Megaptera novaeangliae*) and 'finback' whales (probably mainly fin whales, *B.*

---

[1] Henderson (1972, pp. 34-35; 1984, pp. 163-164) included mud digger, digger and hard head in the list of names used for the gray whale by American whalemen, but we did not encounter these terms in our limited sampling of logbooks.

physalus, though this name also may have been applied to sei whales, *B. borealis*) were referred to as such.

Results

Our sample of logbooks included 21 multiyear voyages that visited the Okhotsk Sea one or more times, for a total of 43 ‘vessel-seasons’ in the Okhotsk. The ships were in the region for more than 5000 days, and daily positions have been determined or estimated for most of those days (Fig. 4). The sampled voyages spanned the period from 1847-1885 though the majority of them took place in the 1850s and 1860s. Logbooks of 14 voyages, including 24 vessel-seasons in the Okhotsk, contained references to sightings of gray whales. There was a total of 152 daily entries with observations of gray whales, including sightings, chases, strikes and captures (Fig. 5).

Occurrence

Citing early Russian literature, Yablokov and Bogoslovskaya (1984) described gray whales (and humpback whales) as having been “very common and even abundant in the coastal waters of the northern part of the Okhotsk Sea and off the western shores of the Kamchatka Peninsula.” They surmised (as did Tomilin 1957, p. 314) that gray whales migrated into the Okhotsk Sea from the Sea of Japan via both Tatar Strait (Tatarskiy Proliv) and La Perouse Strait. Indeed, American logbook data imply that gray whales at least occurred in or near La Perouse Strait in mid-June (e.g. some were sighted and chased there by *Cicero*, 16 June 1859, c. 46ºN, 142ºE). Vladimirov (2004) questioned the feasibility of gray whales entering (or leaving) the Okhotsk Sea via Tatar Strait ‘due to the small depths of the Amur Firth (2-3 m) … which must be a natural obstacle for migrating animals’. In contrast, Rice and Wolman (1971, p. 20), citing Mizue (1951), suggested that all gray whales passed through Tatar Strait ‘as none was ever seen in La Perouse Strait’.[2]

Many voyages to the Okhotsk Sea originated in Hawaii and therefore the ships entered via the northern Kuriles (usually in the vicinity of Paramushir Island) and then worked northwards along the western shore of Kamchatka. According to Henderson (1972, p. 87, citing reports from *Fortune*, 6-8 June 1855, *Mary and Susan*, 19-30 August 1848 and *Montezuma*, 30 May and 29 September 1860), gray whales were observed mainly along the northern coast of the Sea of Okhotsk, and this is consistent with Yablokov and Bogoslovskaya (1984).

Gray whales were observed consistently by the American whalers in the southeastern portion of Shelikhov Bay (Zaliv Shelikhova) and in Penzhinskaya Gulf (Penzhinskaya

---

[2] From Mizue (1951, p. 79): “… it is reported by Mr. Tago that they reach Hokkaido or the western coast of Sakhalin in May or June and then through the Mamiya [Tatar] Channel go to the northern part of the sea of Okhotsk, where they seem to spend their summer. On their southwards migration they seem to take the same course as they come up north. It is not probable that grey whales pass through the Soya [La Perouse] Channel to the farther north, for fin and hump-back whales are captured there from the landstation in Hokkaido but not grey whales.”

Guba) from early May (earliest record 6 May 1885; *Mary and Helen II*) to the end of August (approximately 43 observations in our sample; Fig. 5). They were seen in Gizhiginskaya Bay (North-east Gulf) between mid-May and late August (approx. 46 observations, including a report of ‘thousands of devilfish but no bowheads’ in the logbook of the *Benjamin Cummings* on 3 June 1869) and in the vicinity of Magadan along the north-central coast of the Sea of Okhotsk (i.e. in Tauskaya Gulf/Guba, generally called Tausk or Taousk Bay) from at least early June to early July and from mid-August to mid or late September (approx. 19 observations). Gray whales were seen occasionally just east of Okhotsk City in the north-western Sea of Okhotsk (*Lancaster*, 12 September 1860; *Oliver Crocker*, 29 August 1861). There is little evidence that they still occur in any of those northern areas (Maminov and Blokhin 2004) although it is unclear how much search effort has been expended there at the appropriate times.

Only a handful of references to gray whales in the vicinity of the Shantar Islands were found in the logbooks: ‘a few rip sacks’ northeast of Big Shantar Island on 5 June 1860 (*Oliver Crocker*), ‘muscle diggers’ somewhere in the Shantars on 7 September 1855 (*Nassau*) and ‘Devilfish or Ripsack whales’ in Taylor’s Bay, off Ulbansky Bay, on 13 August 1885 (*Mary and Helen II*). Another sighting was recorded about midway between Ayan and the Shantar Islands on 14 June 1860 (*Lancaster*). Tomilin (1957, p. 314) cited Russian observations in Akademii and Ulbanskii bays. Also, in recent years a few observations have been reported in September in Tugurskiy and Ulbanskiy bays (Maminov and Blokhin 2004).

The American whalers observed gray whales, sometimes in sizeable concentrations (e,g., 20-30 seen in a day, references to “plenty” being seen), in Sakhalin Bay (Sakhalinskiy Zaliv) and off Cape Elizabeth (Mys Yelizavety) at the northern tip of Sakhalin Island (*Mary and Susan*, various entries between 18 August – 9 September 1848). A sighting of two gray whales in summer 2005 in Severnyy Bay (just south-west of Cape Elizabeth) (Tyurneva et al. 2006) demonstrates the continued use of that area by the extant population. Also, gray whales were seen in southern Sakhalin Bay in August 2000 (Maminov and Blokhin 2004).

Finally, American whalers sighted gray whales at least occasionally near the northern (Cape Huntsville, 58º05'N, 157º06'W; *Europa*, 17 May 1869), central (vicinity of Moroshechnoye, 55º51'N, 155º52'E; *Mary and Susan*, 13 July 1849) and southern coasts of western Kamchatka (51°16'N, 155º23'W; *Europa*, 14 September 1868). Although Blokhin (1996) reported that gray whales had not been seen along the western coast of Kamchatka in many years, one was reported in August 2000 at the mouth of the Bolshaya River (Vertyankin et al. 2004). In that regard, the logbook of *Mary and Helen II* refers to arrival at the Bolshaya mouth on 12 September 1885, the vessel having departed the Shantar Islands on 23 August bearing east “for ‘Bolshaya River’ for Right Whales”. The 13 September logbook entry states: “I am bound back to the west end of the Sea north of the Shantar Islands for I am convinced there are no whales to be seen about this locality or where I have been expecting to find ‘Ripsack Whales’ off the mouth of the ‘Bolshaya River’.” Having found neither right nor gray whales off Kamchatka, the *Mary and Helen*

II relocated to Tauskaya Bay, with the top of the logbook page for 19-20 September declaring, “In ‘Tausk Bay’ among the ‘Ripsack Whales’.”

In recent years sightings of gray whales have become regular in Olga Bay (between Cape Seniavin and Cape Kozlov) and Vestnik Bay (just north of Cape Lopatke, c. 51º35'N) on the south-eastern coast of Kamchatka (Vertyankin et al. 2004) and at least some of the individuals seen there have been photographically matched to individuals observed off north-eastern Sakhalin (Yakovlev et al. 2007).

We found no evidence beyond that presented by Henderson (1990) that American whalers observed or took gray whales in Chinese waters where sightings and a few strandings and kills were reported in the 20th century (Wang 1984; 1993, 1999; Zhu 1998; Blokhin and Blokhin 2006). However, our logbook sample included little coverage of whaling in those waters.

Removals

Our reading of logbooks thus far has not revealed any major inconsistencies with Henderson’s (1984) findings as summarised above. Gray whales clearly were secondary targets and they were pursued mainly at times when the preferred bowheads and right whales were unavailable. For example, in 1859 the ship *Oliver Crocker* arrived in Tauskaya Bay at the end of May, with its first sighting of ‘mussel diggers’ reported on 3 June. Within a few days the boats were engaged in the pursuit of bowheads in the bay. Three were bomb-lanced and/or harpooned, but lost, between 6-10 June. By 15 June the run of bowheads had ended, and after a few more days the hunt for gray whales began. Between 19-30 June the *Crocker*’s boats were lowered daily and no fewer than nine gray whales were taken and processed. In addition at least two were lost when the harpoon drew or the line was cut. Two of the processed whales had sunk initially and, in both instances, were only recovered two days later. Three other ships were spoken in the bay during the second half of June – *L.C. Richmond*, *Robert Morrison* and *Cambria* – but it is unclear whether any of them took gray whales (the *Richmond* was seen taking a bowhead on 13 June; the *Cambria* reportedly had taken three bowheads that season as of 30 June). On 1 July the *Crocker* sailed towards the Shantar Islands where bowheads were plentiful and hunting for them resumed on 11 July. There is no further mention of gray whales that year in the *Crocker* logbook. Also, in the next two years, even though the *Crocker* followed a broadly similar itinerary, there is nothing in the logbook to suggest another episode of intensive gray whaling. Two were taken in North-east Gulf on 3 August 1861, the only day during the 1861 season when the logbook indicates the boats were lowered for ‘ripsacks’.

The ship *Europa* arrived in Gizhiginskaya Bay (North-east Gulf) early in the 1868 season, with its first bowhead sighting on 19 May. From then until 28 June, when the first bowhead was taken, only one more bowhead was seen by the crew (on 7 June), whereas gray whales (and ‘finbacks’) were seen often and the boats were lowered on at least three occasions with the explicit intention of hunting gray whales (none was taken by the *Europa* until 20 June). The logbook records that on 5 June 1868: “Lowered for Ripsacks for the purpose of trying our new whaling guns, tried four shots and the irons would not enter the blubber.” In 1869 the *Europa* followed the same itinerary but had more success finding and taking bowheads, and there was only one brief lull (11-12 June) when attempts were made to take both gray whales and a ‘finback’. Later that season (26 July), the *Europa* ‘picked up’ and processed a dead gray whale found floating in Penzhinskaya Gulf between Ship Rock and Big Grampus Island and the log refers frequently to ‘ripsacks’ being observed (e.g. 17 August near Ship Rock, ‘…not seeing anything but Ripsacks’) but with only one more desultory attempt made to hunt them (27 August).

In 1885 the *Mary and Helen II* reached the north-eastern part of the Okhotsk Sea by the end of April and gray whales were sighted on 6 May and again on 20 May, by which time no bowheads had yet been seen. In fact, only one brief sighting of a bowhead was made before mid-June. Even though gray whales were seen many more times, the boats were not lowered to chase them (except on 21 June and 11 July ‘by mistake’) until the brief and intense episode in Tauskaya Bay in mid-September mentioned above.

Before the present study is considered complete, we expect to produce a quantitative estimate of the American catch of western gray whales, adjusted appropriately to account for hunting loss. For the present, we note the following catch information: 9 (plus 2 struck/lost) by *Oliver Crocker* in 1859 and 2 in 1861 (see above); 1 by *Florida* (15 bbl) (Williams 1964, pp. 185) and 1 by *South Boston* in 1861 (Williams 1964, p. 186); 4 by *California* in 1863 (Henderson 1972, p. 87); 1 each by *Endeavour*, *Rainbow* and *Europa* in 1867 (*Europa* 1867); 1 by *Europa* (salvaged) in 1869; and 4 by *Mary and Helen II* in 1885.

The estimated total landed catch of western gray whales by modern whaling and Japanese net whaling between 1890-1966 was 1,800-2,000 (Kato and Kasuya 2002). No other catches are known to have taken place during that time or since 1966 although some unreported catches may have been made by catcher boats from the People’s Republic of China or the Republic of Korea, neither of which belonged to the International Whaling Commission until 1980 and 1978, respectively. It is also possible that some catches were made by whalers from the Democratic People’s Republic of Korea or from Taiwan.

Discussion

Occurrence

Mizue (1951) analysed catch dates and positions for 545 gray whales in the ‘East Sea Area’ of Korea. The catches all occurred between November and May with a strong peak in December (63%) and January (22%). The infrequency of catches in other months from September through March apparently was not related to effort because, as Mizue (p. 76) points out, the same area was an important whaling ground for fin whales and ‘many catcher-boats work during the season, from September to March next year’ and so the whalers ‘would have certainly caught grey whales if they had seen them in the months of October, November, February and March’.

The speculation by Mizue (1951) that gray whales migrated northwards from Korea through the Mamiya Channel (Tatar Strait) in May or June and thence to summering grounds in the northern Sea of Okhotsk is not inconsistent with some of the American whalers' observations. It is unclear, however, whether Mizue was correct in his belief (shared by Andrews 1916, p. 210) that gray whales calved and mated in Korean waters. There is no reason to doubt that at least some of the whales migrated to as far south as 25ºN along the Chinese mainland and moved though Taiwan (Formosa) Strait (Henderson 1990). Also, it is important to consider that Mizue's reasoning that gray whale females with large foetuses taken in mid-December off Korea were 'immediately before birth' and that 'delivery is made among the islands at the southern extremity of the Korean Peninsula' was without the benefit of Rice's (1983) analysis showing a 'prenatal diapause' in eastern Pacific gray whales such that foetal growth 'virtually ceases' during the final month of pregnancy and birth occurs between early January and mid-February (median 27 January). It is therefore plausible that the strong peak in occurrence of female gray whales in Korean waters from early December to early January (Mizue 1951, his Table 5) represents primarily a movement of migrating animals towards a destination farther south for parturition.

Based on the American whalers' observations summarised in this paper, gray whales were consistently observed in specific portions of the Sea of Okhotsk during the middle decades of the 19th century. Although most of the observations reported in the logbooks occurred on grounds where bowhead whales were the primary targets, some observations were also made on right whale grounds (e.g. on the Okhotsk side of Paramushir Island/Mys Lopatka, 51º16'N, 155º23'W, 14 September 1868, *Europa* 1867-1868). No sightings were reported on the north-eastern Sakhalin Shelf where western gray whales are observed most often today. However, none of the logbooks read for this study contained evidence that the American whalers visited that area (Fig. 4). The ship positions of whaling voyages into the Okhotsk Sea between 1844-1852 indicate some effort off the far northern, east-central and southern shores of Sakhalin but almost none along the north-eastern coast on or near the present-day feeding areas (Josephson et al. 2008). Lindholm (1863), a whaleman with much experience in the southern part of the Okhotsk Sea (particularly around the Shantar Islands), reported that gray whales were 'found in large numbers close to Cape Elizabeth [northern end of Sakhalin Island] and in the northern section of the sea during the summer'.

It is important to emphasize that the spatial and seasonal coverage of the Sea of Okhotsk represented by the logbooks was dictated primarily if not solely by the whalers' interest in catching bowhead whales and right whales though it was also influenced by the logistical constraints of sailing conditions, ice coverage and day length. It is fair to question whether the relative concentration of sightings of gray whales in the far north-eastern reaches of the sea (Gizhiginskaya Bay and Penzhinskaya Gulf ; Fig. 5) reflects relative density or is instead the result of a strong bias in search effort. It was not possible to address this issue rigorously given the biased nature of the effort data (the whalers went where they hoped to find bowhead whales and right whales) and the uncertainty about how consistently observations of non-target or secondary-target species like the gray whale were reported in the logbooks.

Removals

As indicated earlier, Henderson (1984) suggested that commercial ship-based whalers in the Sea of Okhotsk took about as many gray whales between the 1840s-1880s as were taken over roughly the same period in the Bering Sea and Arctic Ocean. Our findings are consistent with Henderson's suggestion. It is clear from the logbooks we read that gray whales were of little interest to the whalemen during the early years of the Okhotsk fishery when bowheads and right whales were available in good numbers. In the 1840s and early 1850s, few masters bothered to lower the boats when gray whales were observed on or en route to the bowhead or right whale grounds. This seems to have begun changing by the mid 1850s when logbooks record gray whales being chased more often (e.g. *Gov. Troup*, 9 July 1854 near the Jamskiye Rocks [Yamske Islands]; *Cicero*, 16 June 1859 in La Perouse Strait).

Within a given voyage, particularly from the 1860s onwards, it was not unusual for the crew to pursue *eastern* gray whales in the Mexican lagoons or alongshore Baja California and California in the winter, and *western* gray whales in the Sea of Okhotsk in the summer. Kugler (1984, p. 153-4) referred to these as 'loop voyages', with the southern and northern components separated by visits to Hawaii and perhaps the Sea of Japan in the spring. Charles M. Scammon, for example, on the San Francisco ship *William C. Nye* during his last year as a whaling captain, sailed to the Okhotsk Sea for bowhead whaling in summer 1862 and then to Magdalena Bay for gray whaling in the following winter (Henderson 1972, pp. 86, 271).

The gray whale's reputation as a 'devilfish' is borne out by occasional statements in the logbooks. For example, when boats from the ship *Europa* (1866-1867) attacked a 'ripsack' in North-east Gulf on 19 August 1867, the bow boat 'got stove' after making the first strike, and then the other boats made the kill.

Conclusions

In the sample of logbooks examined, there was no evidence that American 19th century whalers visited the north-eastern coast of Sakhalin Island where gray whales have been studied intensively over the past decade. However, gray whales were observed regularly in certain other parts of the Sea of Okhotsk where the ship-based whalers hunted bowhead whales during the summer. They observed and hunted gray whales relatively often in the north-eastern corner of the sea, especially in Gizhiginskaya Bay (North-east Gulf) and Penzhinskaya Gulf. Gray whales were present in Gizhiginskaya Bay as early as mid-May when (or at least very soon after) the whalers arrived and gray whales continued to be observed there through the end of August. Good numbers also were observed in early June and as late as the third week of September in Tauskaya Bay Magadan coast) and in late summer (mid-August to mid-September) in Sakhalin Bay off the north-western coast of Sakhalin Island.

The historical distribution of gray whales in the Sea of Okhotsk appears to have been much more extensive than it is at present although increased search effort at appropriate times in areas of historical occurrence is needed confirm their absence from such areas. Although not definitive, the information on western gray whales obtained from American 19th century whaling logbooks is of potential value in the following ways:

- To inform the timing and spatial coverage of modern survey effort.
- To support, in principle if not also in planning as to time and location, a satellite tagging and tracking programme to learn more about the movements of western gray whales.
- To contribute to an accurate reconstruction of catch history for input to population models.
- To provide a basis for formulating hypotheses regarding stock structure.

Acknowledgements

Most of the work reported here was funded by the Lenfest Oceans Program of the Pew Charitable Trust through Stanford University and we thank Steve Palumbi for his pivotal role in securing the grant. Library staff at the New Bedford Whaling Museum (specifically Laura Pereira and Mike Dyer) provided much assistance by helping us identify and gain access to relevant materials. Also, Judy Lund kindly shared her extensive knowledge of whaling history and checked several references for us.

FOREWORD.

The present paper is the first of a series of monographs which are in course of preparation upon the large Cetaceans of the Pacific Ocean. The collection of specimens and field studies upon this group began in 1908 upon the coasts of Vancouver Island and southeastern Alaska and has since been carried on along the shores of Japan and Korea.

It was originally intended to embody all the results of these investigations in a single volume but continued field work and many interruptions have so delayed the assembling of the vast amount of data secured that it has seemed advisable to bring out the material upon each genus or species as fast as it is prepared for publication.

ACKNOWLEDGMENTS.

It gives me the greatest pleasure to acknowledge the generosity and assistance of the President and Directors of the Toyo Hogei Kabushiki Kaisha (Oriental Whaling Co., Ltd.) of Osaka, Japan. Not only did these gentlemen freely extend the courtesies of their ships and stations but presented to the Museum the skeletons of the whale which forms the subject of the present paper. At all times the officers and employees of the Toyo Hogei Kaisha assisted me in every way possible, and it was entirely through their efforts that field studies and the collection of specimens was made possible.

To the untiring efforts of my friend Mr. D. Ogiwara, formerly an officer of the whaling company, much of the success of my two expeditions to Japan is due. Mr. Ogiwara, who is deeply interested in the advancement of science, not only rendered great practical assistance but always stood ready to give me the benefit of his sound advice and intimate knowledge of Japanese business methods.

Mr. T. Shibuya, Manager of the Shimonoseki branch of the Toyo Hogei Kaisha, was of the greatest assistance in many ways, especially in securing the two skeletons of *Rhachianectes* which were shipped to America.

Mr. Kondo, the station master at Ulsan, Korea, and Mr. T. Matsumoto, his assistant, deserve the greatest thanks not only for contributing materially to my study but also for making my stay in their home most enjoyable as well as profitable.

Thanks are also due to Messrs. Oto, Iku Kita, E. J. Kitson and S. Reed for assistance in various ways.

Captain H. G. Melsom of the S.S. 'Main' was my constant companion at Ulsan. Not only did he entertain me frequently upon his ship but contributed much information from his vast store of knowledge and long experience with Gray Whales. Captain Melsom was the first whaleman to learn to take "Devilfish" in Korean waters and it was he who laid the foundation for the winter fishery which has been so successfully prosecuted there by the Japanese for the last fifteen years. Captains Johnson and Hurum also entertained me frequently and gave me much valuable information.

Sincere thanks are due to Mr. Chas. L. Bernheimer of New York City for generous financial assistance during the field work upon which this paper is based.

During the years 1880–1882, Dr. J. A. Allen began work upon an extensive monograph of the Cetacea. A vast amount of material was examined and numerous plates were prepared by the well known artist, Mr. J. H. Blake. Because of ill health, however, this work was later abandoned and has remained in manuscript to the present day with the exception of the portion relative to *Eubalœna glacialis*, which was published in 1908.[1] Dr. Allen has very kindly offered me the use of this material and so far as possible it will be combined with the results of my own research. For the present paper the only available portion was that of the "general history" from the years 1868 to 1879. It is also a pleasure to acknowledge Dr. Allen's invaluable assistance and advice in preparing this paper for the press.

Dr. F. W. True has not only read portions of the manuscript but has devoted considerable time to an examination with me of the fossil genera of baleen whales in relation to *Rhachianectes*, and I was thus afforded the benefit of his thorough knowledge of this difficult material. For his never-failing kindness I wish to express my sincere appreciation. My thanks are also due to Dr. W. K. Gregory for much advice and many valuable suggestions.

My mother, Mrs. C. E. Andrews, kindly prepared the table of percentage measurements and assisted me in other ways, and to her my sincerest thanks are extended.

The photographs of the skull and skeleton were made by Mr. Julius Kirschner, the Museum photographer.

INTRODUCTION.

Knowledge of the habits and external anatomy of the California Gray Whale has rested almost exclusively upon the observations of Captain C. M. Scammon made nearly forty years ago. Shortly after the publication of his book 'The Marine Mammalia,' in 1874, the Gray Whale fishery began to decline and for several years was conducted only in a desultory manner by a number of Portuguese upon the shores of Lower California. During the past twenty years the species had been lost to science and many naturalists believed it to be extinct.

While studying Cetaceans upon the coast of Japan in 1910, the writer learned from the Japanese whaling company of the existence of an animal known as the *Koku kujira* or "Devil-fish," which formed the basis of their winter fishery upon the southeastern shore of Korea.

The descriptions indicated that the *Koku kujira* would prove to be none other than the lost California Gray Whale and I determined to investigate it at the earliest opportunity. Consequently, during the winter of 1911–12, I returned to the Orient and spent the months of January and February at the station of the Toyo Hogei Kaisha at Ulsan, a small village on the southeastern coast of Korea, forty miles north of Fusan.

During this time fifty or more Gray Whales were taken and it was possible to make a careful study of the habits and external characters of the species. Skeletons of two adult individuals were also secured, one of which was sent to the American Museum of Natural History in New York City and the other to the U. S. National Museum at Washington, D. C.

These are the first skeletons of this species to be preserved in any American Museum and are, moreover, the only *complete* specimens in the world.

The British Museum of Natural History, South Kensington, England, contains a skeleton and a second is to be found in the Imperial Museum of Tokyo, Japan. There is also one skull of the Gray Whale from California in the United States National Museum.

The study of this animal has been especially interesting since it was almost an untouched field. The fact that the most diligent search of the literature of the subject discloses only 23 titles, and that the great majority of these papers are either short notices or compilations, indicates how little this whale, which is among the most remarkable of all large Cetaceans, has been studied.

General History.

"The California Gray whale was first introduced into scientific literature by Professor Cope in 1868 [1] under the name *Agaphelus glaucus*. For our first knowledge of its characters, however, we are indebted to Dr. W. H. Dall whose manuscript notes, outline figures and specimens of baleen transmitted by him to the Museum of the Essex Institute (now the Museum of the Peabody Academy of Science), Salem, Mass., formed the basis of Professor Cope's description. Dr. Dall's notes and figures were based upon an examination of two specimens, and though very incompletely indicating the characters of the species, were sufficient to show it to be one not previously described.

"Shortly afterward the external characters were quite fully given by Captain Scammon together with a detailed account of the habits, habitat and products, and of the California coast whaling of which it formed the chief basis. Captain Scammon's account was accompanied by two rough figures of the animal. At the same time the species was made the basis of a new genus (*Rhachianectes*) by Prof. Cope.[2] Captain Scammon's account was substantially republished in 1871 in the 'Overland Monthly' magazine,[3] and in 1874 was incorporated into his 'Marine Mammals' [4] with, however, much additional matter and new and creditable illustrations. In 1871 Pechuel-Losch gave a short account and figure of the animal in his 'Wale und Walfang' [5] but added nothing of importance to its history as given by Scammon in 1869. In 1870 Professor Van Beneden thus refers to the genus *Rhachianectes:* 'Si ce genre ne repose pas sur une balénoptère mutilée, c'est-à-dire qui a perdu sa nagoire dorsale, c'est une des plus belles découvertes qui aient été faites depuis bien longtemps en Cétotologie." [6]

"In view of Scammon's history of the species, the doubt here expressed has a strange aspect, but happily he later had abundant opportunity of satisfying himself that his doubt was groundless and it was also his good fortune to publish in 1877 the first description and figure [7] of the skull of the 'California Gray' from photographs, transmitted by Dr. O. Finsch." [8]

In 1879, Professor Cope examined at San Francisco, a "schooner-load of bones" of this species brought from Scammon's Lagoon, Lower California, to be ground up and sold as fertilizer and says: "Having examined a large number of the bones I can complete the characters of the genus *Rhachianectes*,[9] which have been but imperfectly known. The cervical vertebræ are all

[8] J. A. Allen, manuscript notes.

[9] Professor Cope's original reference to the genus, embraced in four lines, is as follows: "This genus is now first characterized. Its only known species I originally united with Agaphelus Cope, but the form of the scapula is so different that it must be distinguished. While that of Agaphelus is identical with that of Balænoptera, it is in the present genus quite like that of Balæna." — Proc. Acad. Nat. Sci. Phila., 1869, p. 15.

distinct, and the second and third at least enclose a vertebral canal. A first rib (the only one not broken up) has two heads; two other short ribs, perhaps first and second, are united distally into a broad sheet of bone. It is uncertain how far the union of these ribs is constant. The scapula has both coracoid and acromion. The orbital process of the frontal is of medium width, somewhat as in some species of *Megaptera*." [1]

A. W. Malm [2] described in 1883 fragments of the skeleton of *Rhachianectes* secured by the 'Vega' Expedition and figured parts of the skulls of several individuals.

In 1886 Charles H. Townsend published in the 'Bulletin of the United States Fish Commission' a brief report upon the condition of the Gray Whale fishery at that time along the coast of California and remarks: "Of the eleven whaling stations mentioned by Scammon as established along the coast ten or twelve years ago, only five remain. . . ." In commenting upon the numbers of the Gray Whale, he says: "At the San Simeon station in December, 1885, I could see whales blowing almost every hour during the day. From the elevated 'look-out,' or observation station, on shore an extensive stretch of ocean could be examined with the telescope. During my stay, and for a short time afterward, covering a period of fully a month, Mr. Clark counted forty whales passing southward. Many of these were too far off shore to be pursued by the three boats that were daily cruising outside during the season, and a few may have been other species than gray whales, but counting the forty whales actually seen in December and doubling that number to include those that passed at night during the same period, we have eighty whales per month easily accounted for. Doubling this number again to include those which pass within sight of the lookout station in January (for the 'down season' lasts two months), we have one hundred and sixty whales as the number that may readily be seen at the present time from one point alone during the 'down season.' What proportion this number bears to the number passing off shore would be hard to say, but it is certainly less than half, since the whales near the coast are mostly females seeking bays and lagoons in which to bring forth their young, which would leave the males and young whales unaccounted for.

"These safe and obviously low estimates, and the above table showing the actual catch during the past three seasons, afford a very fair showing for a species so scarce in 1880 that only one individual could be captured, and indicate a tendency towards its re-establishment while unmolested in its breeding resorts." [3]

In the 'American Naturalist' for 1888, John Dean Caton [4] gave a popular compiled account of the Gray Whale and its habits, and twelve years later F. E. Beddard [5] very briefly described a skeleton of this species in the British Museum.

The last contribution to our knowledge of this interesting animal was made by Dr. F. W. True [6] in 1904. Dr. True summarized the existing facts relative to the external and internal anatomy of *Rhachianectes glaucus* with enlightening critical comments and also presented detail measurements and photographs of the Monterey skull in the National Museum.

LIFE HISTORY.

Migration.— The Gray Whales begin to appear at Ulsan, southeast Korea, about the end of November on their southward migration. Single pregnant females come first and a little later both males and females are seen but the latter considerably outnumber the former. About January 1, schools of from ten to fifteen males, with perhaps one or two females, appear, the female always leading. From the 7th to the 25th of January, when the migration is completed, only males are present, the females all having passed.

In November and December, when the females are taken, almost every individual will be found to be carrying young nearly ready for birth. As these would necessarily be delivered within two or three weeks after passing Ulsan, the birth must occur in the bays among the numerous small islands at the extreme southern end of the peninsula. Indeed Captain H. G. Melsom, who has hunted Gray Whales for fifteen years along the Korea coast, has often observed them in this vicinity, but because of the abundance of other and more valuable species, they are not killed at this time by the Japanese. When travelling southward the whales are always hurrying straight ahead as though anxious to arrive at the breeding grounds and are never accompanied by small calves; upon the northward migration, however, young have been seen following their parents.

The "Devilfish" again arrives at Ulsan, travelling north, about the middle of March and by the 15th of May they have all passed by. Although the greater portion of the herd goes straight northward, Captain Melsom reports that during the end of April and first week of May he has observed many Gray Whales in Broughton Bay, Korea; these animals seemed to be feeding and had apparently broken the migration by a sojourn in the bay.

A comparison of these observations upon the Korea whales and those made by Scammon on the California coast is interesting. It shows that the breeding grounds of the two herds are in very nearly the same latitude and that their migration dates correspond closely. In regard to this Scammon writes: "The California Gray whale is found only in north latitudes, and its migrations have never been known to extend lower than 20° north. It frequents the coast of California from November to May. During these months the cows enter the lagoons on the lower coast to bring forth their young, while the males remain outside along the seashore. The time of gestation is about one year. Occasionally a male is seen in the lagoons with the cows at the last of the season, and soon after both male and female, with their young, will be seen working their way northward, following the shore so near that they often pass through the kelp near the beach. It is seldom they are seen far out at sea. This habit of resorting to shoal bays is one in which they differ strikingly from other whales. In summer they congregate in the Arctic Ocean and Okhotsk Sea. It has been said that this species of whale has been found on the coast of China and about the shores of the island of Formosa, but the report needs confirmation.[1]

"In October and November the California Grays appear off the coast of Oregon and Upper California, on their way back to their tropical haunts, making a quick, low spout at long intervals; showing themselves but very little until they reach the smooth lagoons of the lower coast, where, if not disturbed, they gather in large numbers, passing and repassing into and out of the estuaries,

---

[1] From personal observation and the statements of the whalers, I doubt if the Gray Whales migrate far south of the peninsula of Korea. During my own travels along the China and Formosa coasts, I have neither seen nor heard of Gray Whales. R. C. A.

or slowly raising their colossal forms midway above the surface, falling over on their sides as if by accident, and dashing the water into foam and spray about them. At times, in calm weather, they are seen lying on the water quite motionless, keeping one position for an hour or more. At such times the sea-gulls and cormorants frequently alight upon the huge beasts. The first season in Scammon's Lagoon, coast of Lower California, the boats were lowered several times for them, we thinking that the animals when in that position were dead or sleeping, but before the boats arrived within even shooting distance they were on the move again" (*l. c.*, pp. 22–24).

As yet it is impossible to state whether or not the Korea and California herds mingle in the north during the summer. Information gathered from the whalers tends to show that a large part of the former herd summers in the Okhotsk Sea and the latter in Bering Sea and further north. Individuals of the two herds may mingle and interbreed during their sojourn in the north, but it is probable that whales which have been born near either the Korea or California coasts will find mates among the members of their own herd during the southward migration and return annually to their birth place. It is quite conceivable that the case of the Gray Whale may be analogous to that of the Fur Seal where it has been shown conclusively that members of the American and Japanese herds do not mingle in the north although separated by comparatively few miles of water at certain times of the year.

Period of gestation and rate of growth.— Because of its regular annual migrations the period of gestation of this species can be more nearly determined than in the case of most other large whales, and appears to be about one year. Mating probably takes place in the south during December or early January, and the calf is ready for delivery the following year.

As stated above (see 'Migration'), the females which appear at Ulsan, Korea, travelling southward are nearly all bearing calves almost ready for birth. Upon the return journey the females are accompanied by young calves, and Capt. H. G. Melsom writes that he killed on March 13 and 14, 1912, at Chan Chien Dogo (near Broughton Bay), Korea, upon their northward migration, two females bearing fœtuses 7 and 10 inches long, respectively. These fœtuses were probably not more than 2½ months old, which would indicate that the mating had taken place late in the previous December and that the calves would be delivered the following December or January when the whales returned to the south. A female 1300 cm. (42′ 8″) in length taken at Ulsan, Korea, on January 8, 1912, contained a fœtus 476 cm. (15′ 7½″) long, and ready for birth; it would certainly not have been carried more than a week or ten days longer.

Whether or not the females again mate immediately after giving birth to their young it is impossible to state, but from Scammon's observations, quoted below, I believe it to be unlikely and that calves are born but once in two years.

Scammon says that the period of gestation is about one year, and remarks: "This statement is maintained upon the following observations: We have known of five embryos being taken from females between the latitudes of 31° and 37° north, on the California coast, when the animals were returning from their warm winter haunts to their cool summer resorts, and in every instance they were exceedingly fat, which is quite opposite to the cows which have produced and nutured a calf while in the lagoons; hence we conclude that the animals propagate only once in two years" (*l. c.*, p. 23, note).

Mr. C. H. Townsend, writing in 1886 of the San Simeon (Cal.) station, says: "Unlike Monterey, this station depends almost entirely for its business upon the gray whales, which pass southward with great regularity from December until February. The 'up season,' lasting until

April, is also profitable at San Simeon, but the catch there consists chiefly of males, the females keeping farther off shore when passing northward with their young. During the last ten years Captain Clark has seen but one female accompanied by young in the vicinity of his station. At San Simeon, and all the whaling establishments situated south of it, females exceed the other sex in numbers during the 'down run' and most of them contain well-developed young. At this place and at San Luis Obispo, the nearest neighboring station, I saw four young whales lying on the beach, which had been taken from females killed in the vicinity during that season (December, 1885). Their average length was about 12 feet; the largest, which I sketched, being 17 feet long, and from an adult nearly 40 feet in length. They were probably within two weeks of the time of birth when the parent animals were killed" (*l. c.*, pp. 347–348).

From the above data it may be safely affirmed that the length at birth of the majority of Gray Whales is between 12 and 17 feet. When the females go north in March on the Korea coast, the calves which have been born near the end of the previous December accompany them, and by the time they reach Ulsan are about twenty-five feet in length, This makes a growth of nine or ten feet during a little less than three months. This may seem extraordinary, but it is quite in accord with what apparently takes place in all baleen whales. Without doubt the rate of growth for the calf is very rapid during the first few months after birth and until sexual maturity is reached.

Thirty-two feet is the minimum length for Gray Whales taken at Ulsan, and individuals of this size must certainly have been born during the previous winter. Thus, accepting 14 feet as the average length at birth, we get a growth of 18 feet during a little less than one year.

How long the young nurse is problematical but it must be considerably less than one year because, so far as I am aware, nursing calves or females have not been taken at Ulsan on the southward migration, and some would certainly have been brought in if the suckling period was not over before the animals reached that point upon the coast.

Spouting and diving.— The height and form of the spout varies with conditions. Normally the vapor rises vertically ten or eleven feet in a thick column having the width at the summit about twice that at the base (Plate XXIV, Fig. 7). It may, however, reach a height of fifteen feet if the whale is large and has been submerged for a considerable period. The spout is single in the majority of cases, but Captain Melsom asserts positively that at times it is divided like that of a Right Whale. As in all Cetaceans the initial spout after a period of submergence is generally the highest and fullest.

The number of respirations between the dives is fairly regular. When the whale has been below for several minutes upon rising to the surface it will usually blow two or three times before again going down.

When cruising along the shore the animal generally remains submerged seven or eight minutes and blows three times when it reappears. Captain Melsom assures me that when a large female is taking a straight course it will remain below four or five minutes and rise to make three spouts very regularly; at other times a single whale will remain down ten minutes and a school between fifteen or twenty minutes, depending upon circumstances.

When travelling straight ahead and unmolested the Devilfish swim under water for a distance of 300 or 400 fathoms quite regularly and rise to spout three times.

Under normal conditions the animals 'sound' much as do Humpbacks. As soon as the spout has been delivered, the body begins to revolve and as the dive progresses the flukes are lifted out of the water and drawn slowly under. The flukes are not invariably shown, however, even when sounding; some animals will almost always 'fluke out' and others, not at all. Under no circumstances do the Gray Whales arch the back as strongly as do the Humpbacks nor do the animals raise themselves so far out of the water.

During the 'surface' or 'intermediate' dives only a small part of the back is shown, the motion is forward and downward, and the flukes are never exposed.

Speed.— The Gray Whales are slow swimmers and cannot exceed seven or eight knots per hour even when badly frightened and doing their best to get away. Ordinarily when 'travelling,' and unmolested, they make about three or four knots, and when cruising along the shore perhaps two or three knots per hour.

The Gray Whale is essentially a shore-loving species and on its annual migration always prefers to swim along close to the beach. At times the whales will go in so close to the shore that they are actually rolling in the surf and seem to enjoy being pounded by the breakers. Scammon has observed the same habit in the California animals and says: "About the shoals at the mouth of one of the lagoons, in 1860, we saw large numbers of the monsters. It was at the low stage of the tide, and the shoal places were plainly marked by the constantly foaming breakers. To our surprise we saw many of the whales going through the surf where the depth of water was barely sufficient to float them. We could discern in many places, by the white sand that came to the surface, that they must be near or touching the bottom. One in particular, lay for half an hour in the breakers, playing, as seals often do in a heavy surf; turning from side to side with half extended fins, and moved apparently by the heavy ground-swell which was breaking; at times making a playful spring with its bending flukes, throwing its body clear of the water, coming down with a heavy splash, then making two or three spouts, and again settling under water; perhaps the next moment its head would appear, and with the heavy swell the animal would roll over in a listless manner, to all appearance enjoying the sport intensely. We passed close to this sportive animal, and had only thirteen feet of water" (*l. c.*, p. 24).

Frequently when being hunted the Korea whales would escape by swimming into water so shallow that the ships could not follow them and remaining there until the men had given up the chase.

Food.— Although the stomachs of a great number of Gray Whales were examined carefully I could never discover what constitutes their food. In every case the stomach was more or less filled with dark green water in which the only solid materials were bits of kelp, a little sea weed, and small masses of a light green gelatinous material. The stomachs of two individuals contained a number of small water-worn pebbles and several masses, six to eight inches long, of what appeared to be finely shredded raw meat still connected by its fibers; this was certainly not fish. It is probable that the kelp and sea weed had been taken in with other material, as in the case of the pebbles. The excrement of all the whales had about the consistency of thick cream and was dark green like the water in the stomach.

All the gunners asserted that when the Gray Whales appear at Ulsan on their migrations they are invariably travelling straight ahead and apparently not stopping to feed. This information, combined with the fact that little except water could be found in the stomachs, lends strong support to the theory that upon their annual migrations the Devilfish feed but very little, if at all. If feeding is indulged in, it would seem extraordinary that no specimens have been brought to the station having food, or its remains, in their stomachs. The presence of fæces in the intestines may be due to the fact that these organs had not entirely emptied themselves since the last period of feeding in the north. The green color of the water in the stomach and of the excrement is probably due to bileary secretions.

It is possible that while upon their migrations the whales eat quantities of the jelly fish which are so frequently seen near the kelp fields just off shore. These animals, consisting largely of water, would be very quickly acted upon by the digestive fluids and the lack of solid material in the stomach be thus explained. Captain Melsom has seen Gray Whales in the Okhotsk Sea during the summer which were not travelling but were swimming slowly about.

It is interesting to note that neither Scammon nor Townsend could get any definite information as to the food of the Gray Whales of the California coast. Scammon remarks: "To our personal knowledge, but little or no food has been found in the animal's stomach. We have examined several taken in the lagoons, and in them we found what the whalers called 'sedge' or 'sea-moss' (a sort of sea-cabbage), which at certain seasons darkens the water in extensive patches both in and about the mouths of the estuaries. Whether this was taken into the stomach as food some naturalists doubt, giving as a reason that the whale, passing through the water mixed with this vegetable matter, on opening its mouth would of necessity receive more or less of it, which would be swallowed, there being no other way in which it could be disposed of. The quantity found in any one individual would not exceed a barrelful.

"From the testimony of several whaling-men whom we regard as interested and careful observers, together with our own investigations, we are convinced that mussels have been found in the maws of the California Grays; but as yet, from our own observations, we have not been able to establish the fact of what their principal sustenance consists" (*l. c.*, pp. 24, 25, note).

Townsend says in regard to the food: "The opinion of the men with whom I talked is that it does not feed to any great extent outside of its arctic habitat. It is certainly much thinner on the northward than on the southward run, a male that would yield 30 or more barrels of oil in the down season yielding less than 25 two months later. Whalers admit their ignorance of what constitutes the food of this animal, and can find nothing in its stomach during the breeding season" (*l. c.*, p. 349).

Affection.— The male Devilfish at all times shows strong affection for the female and Captain Melsom tells me that during the migration, when a school of males led by one or two females is found, if one of the latter is wounded, often the former will refuse to leave until she is dead. One day when hunting a pair he wounded the cow and the bull would not leave, keeping close alongside and pushing his head over her body. Later he struck the male with a harpoon but did not get fast and even then it returned and was finally killed. Captain Melsom assures me, however, that if the male is killed the female will seldom remain.

Scammon has recorded instances of the female's love for her young and it was because of her vigorous defense when attacked on the breeding grounds that the name "Devilfish" was gained. The whalemen in Korea, however, where the hunting is done from small ships by the Norwegian method, do not regard the animals as especially dangerous. They seldom lance one from the 'pram,' as is frequently done with Finbacks because the Gray Whales seem to be very sensitive to pain, and as soon as the iron penetrates the body the animal will raise itself in the water, throwing its head from side to side and sometimes lashing about with its flukes and fins.

Attacks by Killers (*Orca orca*).— The Gray Whales seem to be objects of continual persecution by the Killers; much more so than any of the other large whales. Among the first eight or nine Devilfish which I examined at Ulsan, three attracted my attention at once because the entire anterior part of the tongue had been torn away. Teeth marks plainly showed in the remaining portion and upon consulting the gunner, Captain Hans Hurum, who had killed them, he told me that it had been done by Killers at the time he shot the whales. Seven Gray Whales were in the school, and shortly after he began to hunt them fifteen Killers appeared. The whales became terrified at once and he had no difficulty in killing three of the seven. When the Orcas gathered about, the whales turned belly up and lay motionless, with fins outspread, apparently paralyzed by fright. A Killer would put its snout against the closed lips of the Devilfish and endeavor to force the mouth open and its own head inside. This extraordinary method of attack was corroborated by Capt. Johnson who had been hunting the same school of Gray Whales, and, moreover, by all the whalemen at the station who had witnessed it upon many other occasions.

Out of the thirty-five Gray Whales which I examined especially, seven had the tongues eaten to a greater or less extent and one had several large semicircular bites in the left lower lip. The Killers do not confine their attention entirely to the tongue for almost every whale which was brought in had the tips and posterior edges of the fins and flukes more or less torn; in several specimens fresh teeth marks were plainly visible where the fin had been 'shredded' as the whale drew it out of the Orca's mouth.

Although none of the Gray Whales exhibited teeth marks on other parts of the body undoubtedly some of them are killed by the Orcas. A female Killer which was brought to the station had several pieces of flesh in its stomach besides a strip of whalebone three inches long; I could not positively identify the latter but believe it to have been from a small Devilfish. A male Killer was taken at the same time by Captain Hurum who told me that in the animal's death flurry it had thrown up two great chunks of flesh.

Captain Melsom brought a Gray Whale to the station one day and I was interested to find the tongue almost gone. He said he had passed a school of Killers in the morning and later, after steaming about fifteen miles, had killed the Devilfish. A short time afterward, a long distance away, he saw the fins of a school of Killers which were coming at full speed straight for the ship. They circled about the vessel and one of them forced open the mouth of the dead whale to get at the tongue. When Captain Melsom fired at the Killer with his Krag rifle the animal lashed out with its flukes, smashing the ship's rail, and disappeared.

As soon as Orcas appear if the Gray Whales are not paralyzed by fright they head for shore and slide in as close as possible to the beach where sometimes the Killers will not follow them. The Devilfish will actually go into such shallow water as to roll in the wash and even try to hide behind rocks. The Orcas are not afraid of the ships and will not leave the whales they are chasing when the vessels arrive, thus giving much assistance to the human hunters.

Captain Johnson, of the 'Rex Maru,' brought to the station at Ulsan a Gray Whale which had been shot in the breast between the fins. He had first seen Killers circling about the whale which was lying at the surface, belly up, with the fins outspread, being absolutely paralyzed by fright. The vessel steamed up at half speed and Johnson shot at once, the iron striking the whale in the breast.

Such is the fear of the Gray Whale that when, as frequently happens, porpoises are playing about a single animal, it will sometimes become terrified, thinking that the Killers have appeared.

I have never personally witnessed it but the gunners tell me that a pod of Gray Whales can be stampeded much as can a herd of cattle. If three or four ships are near each other when a school of Devilfish are found, they draw together, each vessel going at full speed and making as much noise as possible. The whales at once sound, but as soon as they rise to spout the ships steam at them again. The Devilfish go down once more but do not stay under long, ascending at shorter intervals until finally they are ploughing along at the surface. The animals are 'scared up' as the gunners say, and become terrified to such a degree that everything is forgotten except the desire to get away. It is not always possible to stampede a herd, and often the whales will disappear at the first sound, not rising again until a long distance away. If Killers are about at the time a herd of Gray Whales are being hunted it is very easy for the ships to stampede them.

Even if the Devilfish do exhibit considerable stupidity when danger from Killers threatens, at other times they are the cleverest and most tricky of all large whales. One day the S. S. 'Main,' Captain Melsom, was hunting a Gray Whale in a perfectly smooth sea. The whale had been down for fifteen minutes when suddenly a slight sound was heard near the ship and a thin cloud of vapor was seen floating upward from a patch of ripples which might have been made by a duck leaving the surface. The whale had exposed only the blowholes, spouted, refilled the lungs and again sunk, doing it almost noiselessly. The gunners assert that this is quite a usual occurrence when a single Gray Whale is being hunted.

Diseases.— Most whales are subject to diseases of various kinds and the Devilfish is no exception. One specimen was brought to the station at Ulsan, with all the flesh on the left side of the head badly decomposed and in some places entirely gone, leaving the bone exposed; what remained hung in a soft, green, evil-smelling mass. The whale had evidently suffered considerably from the disease for it was very thin and the blubber dry.

A second specimen had a large swelling on the ventral ridge of the peduncle, which upon being opened, proved to be a large capsular tumor about one foot in depth and of a like diameter.

The skin upon the snout of a third individual was drawn into small circular patches leaving large sections of the blubber exposed.

SIZE.

The available material relating to the size of *Rhachianectes glaucus* consists of the following: From Korea, records of one hundred and twenty-two specimens taken by the whaling company during 1909–10, and of twenty-three measured by myself in 1912; from California, the measurements given by Scammon and Dall of two specimens taken in Monterey Bay, and the record by Pechuel of one from the Bay of San Simeon.

My own measurements of the total length were taken from the notch of the flukes to the tip of the snout, either along the side of the belly as the animal lay in the water or as each section was drawn upon the cutting wharf. Every whale was also measured by a representative of the company, and as the total length was secured by the Japanese in a way similar to mine it may be assumed that all the Korean specimens are directly comparable.

In the following tables measurements of both males and females are arranged according to size.

Table I. Measurements of 53 females.

Like all baleen whales, the female *Rhachianectes* is larger than the male. The maximum size of the 123 specimens measured by the whaling company was 1371 cm. (45′); this length was reached by four females. The maximum for males was 1310 cm. (43′). A female 1317 cm. (43′ 3″) long and two males each 1250 cm. (41″ ½′) were the largest of the 23 specimens which I measured in 1912. Dall has recorded an unsexed individual 1554 cm. (51′) and a male 1462 cm. (48′) in length. If these measurements are correct Dall's specimens must have been of unusual size for the whalers in Korea assured me that examples longer than 1371 cm. were extremely rare. Measurements of his 1462 cm. whale show such a remarkable disagreement with all other specimens that there must have been some error in either taking or recording the dimensions. My friend Capt. H. G. Melsom, who has spent nearly fifteen years hunting Gray Whales in Korea, tells me that he killed two female whales 49 and 47 feet long, respectively; these are the largest specimens he has ever known killed.

The average length for all females measured by the whaling company and by myself agrees closely and is respectively 1254 cm. (41′ 2″) and 1259 cm. (41′ 4″); for all males it is 1188 cm. (39′) and 1172 cm. (38′ 6″). There can be little doubt that specimens larger than 1371 cm. (45′) are exceedingly rare.

It is difficult to arrive at a satisfactory conclusion as to the length at which *Rhachianectes glaucus* becomes sexually mature, for at present there are few data relative to this subject. Townsend took a fœtus 518 cm. (17′) long from a female, "about forty feet long," and the only pregnant female which I examined was a specimen 1300 cm. (42′ 8″) in length. The condition of the skeleton proved this animal to be fully adult.

The measurements of length are arranged in tabular form in the following table (Table III).

Table III. Summary of Measurements.

Locality	Average for all specimens of both sexes		Average for all females		Average for all males		Maximum for females	Maximum for males	Minimum for females	Minimum for males
	No. of Whales	Length	No. of Whales	Length	No. of Whales	Length	Length	Length	Length	Length
Korea, measured by R. C. A.	23	cm. 1184 ft. 38′9½″	3	cm. 1259 ft. 41′4″	20	cm. 1172 ft. 38′6″	cm. 1317 ft. 43′3″	cm. 1250 ft. 41′1″	cm. 1160 ft. 38′1″	cm. 980 ft. 32′2″

PROPORTIONS.

In the following tables detail measurements of Korea and California representatives of *Rhachianectes glaucus* will be found. It was possible to take a fairly complete series of measurements of some of the Korea specimens while of others only a few could be secured but all have been presented with the hope that they may be of aid to future students of this species.

In the second table certain of the most reliable measurements have been selected, and their ratios to the total length given, to ascertain the degree of individual variation and to facilitate comparison.

It will be seen upon examination of the table of ratios that there is a greater or less variation in almost all the proportions. The question at once arises as to whether or not this can be due wholly to individual differences or in part to inaccuracy of measurement. The lengths of all specimens were secured while the animals were lying in the water or else were the totals of the different sections as the whales were being "cut in." The length was never taken over the back but usually along the side or breast, and in most cases I believe it to be accurate. In Nos. 2, 9, and 11 there is a possibility of doubt, but none of the ratios of these specimens show unusual variation.

All the measurements, except the total length and the distance from the tip of the snout to the axilla, were secured without difficulty after the sections of the whale had been drawn upon the wharf.

I have included in the table, measurements of the fully grown fœtus No. 1*a*, for as these were taken at leisure with the greatest care there is no doubt as to their accuracy and they furnish a valuable standard for comparison with the adult individuals.

[1] Nos. 1 and 1a had the ear *above* the eye.

It will be seen from the table that the greatest variation appears in the distance from the notch of the flukes to the dorsal "hump" amounting to 11%; this will be discussed later.

The variation of 5.3% in the width of the flukes from tip to tip may in great measure be accounted for by the fact that the tips of the flukes were very frequently injured. The same can be said of the measurement of the pectoral from the tip to the head of the humerus, but in a less degree, for usually one of the flippers, at least, was uninjured and the correct length could thus be secured.

The measurements of the California examples neither conform to each other nor to those from Korea. In Scammon's specimen the distance from the tip of the snout to the blowholes is 14.2% of the total length. This is much less than in any of the Korea whales and, moreover, gives a difference of 3.6% between the measurements from the tip of the snout to the eye and to the blowhole. This can hardly be correct. The same discrepancy is apparent in Dall's figures, but to a greater degree. The ratio to the total length of the tip of the snout to the eye is greater than in any of the Korea specimens, and that from the tip of the snout to the blowholes is much less, the difference between the two being 11.6%. One, or both, of these measurements is certainly incorrect.

Pechuel's figures give the distance from the snout to the blowhole as 25% of the total length, while the greatest in the Korea specimens is 19.5%. It is impossible to account for this discrepancy.

Scammon's measurements from the snout to the axilla, of the flukes from tip to tip, and of the depth of the peduncle just anterior to the flukes, are all at such variance with the Korea specimens that they must either be incorrect or have been taken in quite a different manner from my own. The same is true of Dall's measurements of the flukes from tip to tip and of the length of the fin. These data in reference to the California specimens are, therefore, of little value either for comparison with the Korea examples or with each other.

Table V.—Proportional Measurements of Korea and California specimens.

Color.

Plates XIX and XX.

None of the published descriptions of the color of *Rhachianectes glaucus* which I have been able to find occupy more than three or four lines, or give other than the vaguest impression of the animal's appearance. Scammon says: "The California Gray is unlike other species of baleen whales in color, being of a mottled gray, very light in some individuals, while others, both male and female, are nearly black" (*l. c.*, p. 20). Scammon's figure (*l. c.*, plate ii, fig. 1) shows a rather slender whale, gray, and irregularly marked with white on the entire upper half of the body from the head to the flukes; the lower half is represented as almost plain.

This type of coloration is just the reverse of what was observed in Korea specimens. It is true that several examples were seen which had the back more or less heavily marked, but in every case where this occurred the lower half of the body was so thickly covered with white and gray patches that there was a great preponderance of the light color. Unless the California specimens are very different from those of Korea, which is highly improbable, Scammon's figure is incorrect. This view is strengthened when the drawing of *Balænoptera sulfurea* (*l. c.*, plate xiii) is examined for it is quite unlike a Pacific Sulphurbottom in coloration. Scammon's first figure of *Rhachianectes*, published in 1869,[2] although very crude, gives in the side view a really better suggestion of the color of the animal than does the plate in his 'Marine Mammalia.' In his first figure the markings are shown evenly distributed over the entire body from the head to the flukes and not confined to the dorsal surface as in the later drawing.

In Cope's article on the Gray Whale (1868), Mr. W. H. Dall's description of two specimens seen by him at Monterey, Cal., is quoted, as follows: "Color above and below, black, with a gray bloom like a plum. This distinguishes this species from the known Balænæ of the Pacific, which are more or less white on the belly and fin" (*l. c.*, p. 226).

Pechuel's figure of *Rhachianectes* is diagrammatic and there is little attempt at coloration.

---

[1] This does not include fœtus No. 1a.

PLATE XIX.

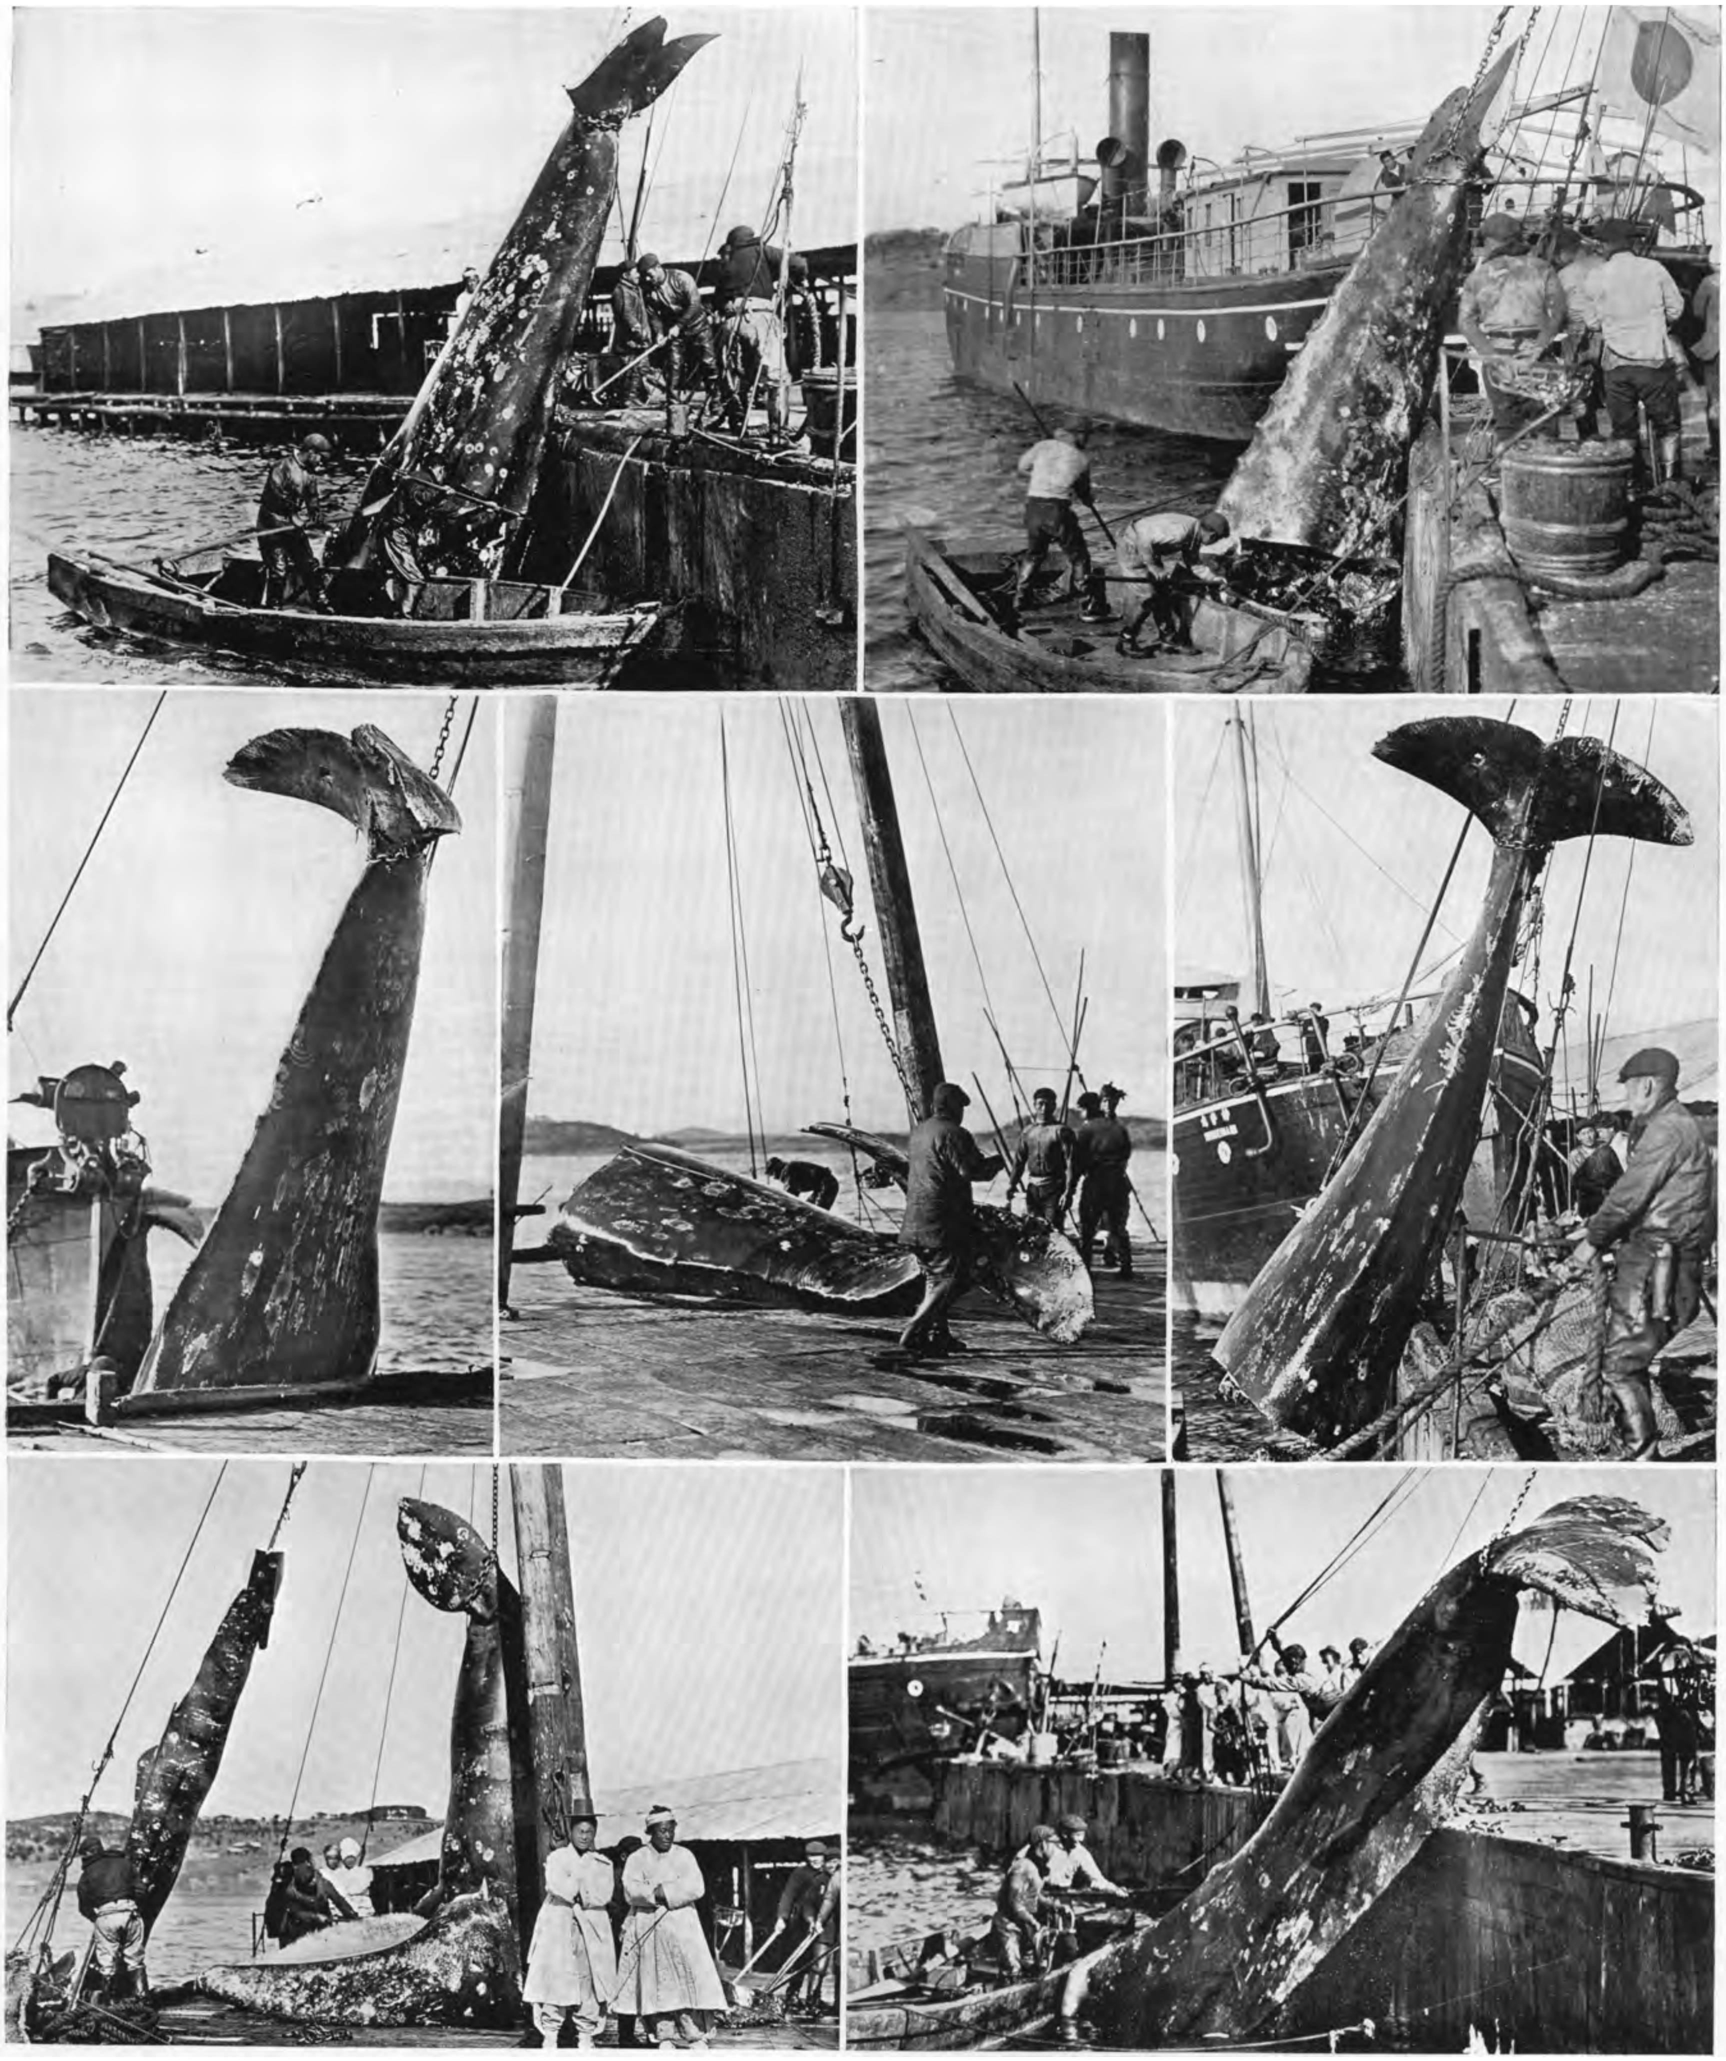
Rhachianectes glaucus.

Fig. 1. Lateral view of peduncle showing white markings, mostly cirriped scars.
Fig. 2. Lateral view of peduncle showing normal gray and white markings and total absence of cirriped scars.
Fig. 3. Head, pectoral fin and section of back blubber.
Fig. 4. Direct lateral view of peduncle showing dorsal crenulations.
Fig. 5. Dorsal view of peduncle showing normal gray markings and flukes.
Fig. 6. Peduncle lying upon the wharf.
Fig. 7. Posterior portion of body showing inferior outline.



Rhachianectes glaucus.

He says in regard to this: "Abweichend von allen anderen Walen ist seine Farbe ein melirtes grau, Manche sind ganz fleckig, selten sieht man gleichmässig dunkel gefärbte."[1]

The following description of Korea examples is, therefore, the only detailed account of the color of the Gray Whale that has thus far been published.

There seems to be quite as much individual color variation in *R. glaucus* as in other baleen whales, some examples being abnormally dark with but few gray markings while others are very light, the entire body being so thickly covered with blotches of white and gray that there is a preponderance of the light color. It is obvious, therefore, that no description which will apply to all individuals can be given, but between the light and dark extremes there was a certain type of coloration possessed by a majority of the examples which came under my observation. This may be described as follows: The head, throat, back, and the dorsal and ventral ridges of the peduncle are black, or very dark slate, and are usually unmarked. On the dorsal and lateral surfaces of the distal half of the rostrum there is considerable white and light gray in flecks and small spots; this is frequently true of the chin, lower lips, and both mandibular rami. On the under side of the rostrum just exterior to the bases of the baleen rows, there is a band of flesh pink, or white, about three inches wide. The amount of white on the rostrum and lips varies greatly with individuals but it is seldom entirely absent. The throat and sides to the pectorals are usually unmarked. From the fins to a point opposite the anus, on the sides, breast and belly, are many roughly elliptical and circular markings with irregular edges. These markings have gray centers shading to very light gray, or white, on the edges and are broken by small round, or oval, black spots (Plate XX, Fig. 6). They follow the long axis of the body and generally closely approximate each other.

On the sides of the peduncle the gray markings become scattered and are generally smaller and darker. The whole body from the head to the flukes has many white or light gray circular scars of varying sizes, apparently left by parasitic cirripeds; on some individuals these almost obscure all other markings.

The pectoral fins are dark slate like the body. Above, on the posterior half, there are a few scattered white circles and spots. Below, the white circles are more numerous and on the distal half are two more or less broken bands of white, or very light gray, about 8 cm. wide and 45 cm. long between the 2nd and 3rd and 3rd and 4th fingers; the band between the 2nd and 3rd fingers is usually the longer. The posterior edge of the fin is very frequently white.

The flukes are black or dark slate like the body, a few white circles and spots being scattered over both surfaces, generally more on the lower. Frequently the posterior edges and tips are white.

In connection with the preceding description it is interesting to refer to the color of fœtus No. 1*a*, described below. This specimen was almost ready for birth and gives an excellent idea of the disposition of the markings on the Gray Whale before the body has been scarred by parasites and by contact with rocks. The general color must become much darker after birth than it is during fœtal life.

Color Variations.— There are striking variations from the type of coloration described above. Three specimens out of the twenty-one on which color notes were taken were exceptionally light colored. One (No. 8, male) had the entire rostrum, lips and mandibular rami dotted and specked

---

[1] Pechuel-Loesche, Wale and Walfang. Ausland, Vol. 44, 1871, p. 1186.

with gray and white. The sides of the breast and throat, from the fins forward, were streaked longitudinally with long gray lines, and the center of the throat thickly splashed with white. The back was heavily marked with oblong blotches of white. The only portion of the whale unmarked was the dorsal and ventral ridges of the peduncle.

A second whale (No. 11, male) had almost no white on the lips, rostrum or throat, but the sides of the body and peduncle, from the fins to the flukes, were so thickly washed, circled and blotched with gray and white that there was much more light than dark color.

No. 19, female, had the lower lips and distal portion of the mandible finely dotted and flecked with gray and white. The sides, belly, and the entire peduncle were so thickly covered with small light gray patches, that there was more light than dark color. The ground color of this whale was dark gray and not slate, or black, as usual.

No. 3 was a dark whale and No. 5 exceptionally so. The body was black and had only a few small and rather indistinct gray markings on the sides, back and lower half of the peduncle.

No. 6, female, was black. On the left side of the throat were a few long stripes of white, which seemed to be scars. The remainder of the throat, breast and belly was unmarked save for a single large, irregular, light-gray patch on the belly; the entire peduncle was plain except for a little white along the dorsal ridge. No. 14, male, was much like No. 6; No. 17, male, although a very dark individual, had the rostrum, lips and mandibular rami mixed white and gray, and the sides of the peduncle, body and back streaked with long, narrow gray lines.

There seems to be a tendency among the whalers to believe that all individuals which show a preponderance of light color are of the greatest age. Averages and comparisons of the lengths of the very dark, very light, and normal examples of *R. glaucus* shows but little difference between them and gives no basis for believing that the animals become lighter with increasing years. Only three of the whales which I examined were females, one of these being exceptionally dark and the other somewhat lighter than normal. The males presented both light and dark extremes and every variety of intermediate coloration. I believe, therefore, that the color differences have nothing whatever to do with sex or age, or that they are other than purely individual.

For reference the field descriptions of twenty-one individuals examined at Ulsan, Korea, are given below:

Field color descriptions of 23 Korea specimens.

No. 1. Female. Length, 1300 cm. General color dark slate. Much white on the distal half of the rostrum, snout and upper lips just above the bases of the baleen rows. Many fine, grayish lines on the back, and numbers of irregular white streaks over the entire body; the latter appeared to be scars from old wounds. Inferior half of peduncle from genitalia to flukes thickly marked with irregular elliptical patches of light gray.

Pectoral fins dark slate above, having both margins and tips whitish, the light color extending far up on the superior surface of the fin.

Flukes above dark slate with many white dashes and circles, the latter undoubtedly caused by parasitic cirripeds.

No. 1*a*. Fœtus. Male. Length, 476 cm. General color gray. The entire head and throat to the posterior insertion of the pectoral fins is light gray. A line of small, dark gray spots and dashes extends from the eye to a point a short distance above the pectoral. On the throat are a few small patches of very light gray, almost flesh white, and several large irregular markings of dark gray.

PLATE XX.

PLATE XX.

RHACH~~I~~ANECTES GLAUCUS.

Fig. 1. Direct lateral view of head showing few parasite scars.

Fig. 2. Three-quarters posterior view of head showing many parasite scars.

Fig. 3. Dorsal view of head and blowholes; note the barnacles *Cryptolepas rhachianecti* embedded in the skin, and the masses of *Cyamus scammoni*.

Fig. 4. Front view of head.

Fig. 5. Direct lateral view of head and mandible of fœtus No. 1*a*.

Fig. 6. Section of peduncle showing normal gray and white markings.

4

RHACHIANECTES GLAUCUS.

On the sides a slight ridge is formed by the ends of the vertebral transverse processes below which the lateral and ventral surfaces of the body, forward almost to the pectoral fins, bear many irregular oblong and elliptical patches of very light gray; the markings are longitudinal, follow the long axis of the body and are so thick that there is more of the light than of the dark color. The back, above the line of the transverse processes, is light gray thinly marked with irregular, dark gray oval and oblong patches. On the right side, just posterior to the tip of the pectoral laid back, is a circular, pure white spot about 4 centimeters in diameter and a second smaller one above the posterior insertion of the fin.

The pectorals are plain dark gray on both surfaces but have light posterior and anterior edges.

The flukes are plain light gray above with dark anterior and posterior margins. Below, the ground color is light gray but coarse, broken whitish lines run transversely across each fluke from the anterior edge and curve inward toward the notch; this gives more white than dark color to the inferior surface.

No. 2. Male. Length, 1160 cm. Many fine white spots and flecks on snout, symphysis of mandible, and on both rami, but the remainder of the head is plain dark gray. Posterior to the genitalia both sides of the body have many large irregular patches of light gray about thirty cm. long by twelve cm. wide, and numerous blotches, circles and spots of white. There is a large patch of light gray about 150 cm. long by 45 cm. wide on the right side of the back and a large white spot just posterior to the tip of the pectoral fin laid back. The mid-dorsal region has either very few gray markings or none at all. The lower half of the peduncle is covered with rather fine dashes and circles of white.

The pectoral fins are alike on both surfaces. On the distal two-thirds between the second and third and the third and fourth digits there are two broad parallel bands of white. The remainder of the fin is so dotted, barred and circled with white that there is more white than dark.

Both surfaces of the flukes are dark slate thickly covered with irregular bands, spots and dashes of white. The left lobe has the inferior surface of the distal end almost entirely white.

No. 3. Male. Length, 1240 cm. A dark individual. The general color is dark slate, almost black. On the dorsal and lateral surface of the rostrum there is considerable light gray, but except for numerous cirriped scars, especially on the sides of the peduncle, the body has comparatively few light markings.

On both surfaces of the pectoral fins there is a broad longitudinal band of white between the fingers, and a few circles and spots of white on other parts of the flipper. The posterior edges are also white.

No. 4. Male. Length, 1170 cm. General color of body dark slate. The entire rostrum is clear light gray, shading into darker on the head, but does not show much white; neither is there white on the lips or mandibular rami. The dorsal region of the peduncle and body forward to the pectoral fins is unmarked dark slate but the sides have many small spots, dashes, and circular scars of white.

The pectoral fins are dark slate above and have a whitish longitudinal band between the fingers; also a few large cirriped scars. The anterior edge of the fin is dark slate and the posterior edge white.

No. 5. Male. Length, 1143 cm. A very dark individual. Head, back, sides and upper half of peduncle, black. Lower half of peduncle has a few small, light gray markings and on the back and sides near the pectorals are several rather indistinct, gray patches; scattered over the body are a few large, white circular scars. Mucous membrane in the roof of the mouth light pink as are the lips just above the bases of the baleen rows.

The pectoral fins are black, above, except for two or three large white circles. Below, there is one large oblong patch of white between the fingers.

Both surfaces of the flukes are plain, unmarked black.

No. 6. Female. Length, 1317 cm. A very dark whale. Throat, breast and belly plain black except for a few long white stripes (apparently scars) just above the furrows and a large, irregular, light gray patch on the belly. The back and sides are black, almost unmarked, and on the peduncle *there are no gray patches* and only a few cirriped scars; along the dorsal ridge is a little white.

The superior surface of the pectoral fins is black with a few white circles; inferiorly both flippers are marbled and circled with white.

No. 7. Male. Length, 1202 cm. The entire distal third of the rostrum and the dorsal ridge to the blowholes is greatly roughened, or "cornified," thickly infested with parasitic *Cyamus*. There is no white on the rostrum.

The superior surface of each pectoral fin has but little white. On the inferior surface two broad bands of white run between the fingers to the tip of the fin and there is a large white patch near the base.

No. 8. Male. Length, 1240 cm. The lightest colored specimen which has been brought to the station. The dorsal ridge of the rostrum is almost entirely white having but few gray specks; the left side of the rostrum is like the dorsal surface but the right side is covered with fine gray and white flecks and dots giving a "pepper and salt" effect (apparently many small barnacles had fastened here). From chin to pectorals the sides of the throat and breast are streaked with long, longitudinal gray lines about five mm. wide and the center of the throat is thickly splashed with white. The rami of the mandible and the lower lips are mixed white and gray ("pepper and salt"). The entire back is thickly marked with small white circles and dots and the sides of the body, posterior to the fins, and of the peduncle are covered with blotches of white, fairly regular in size and about 25 cm. long by 10 wide; the edges of the blotches are irregular. The mid-dorsal and mid-ventral regions of the peduncle are plain black except for a circular patch of white about 30 cm. in diameter.

On the inferior surface the pectorals have two broad longitudinal bands between the digits, that nearest the posterior edge being the longest; there are also many smaller patches and scars on the lower surface. Above, the pectorals have much less white, only one band being present.

The flukes are black, above, thinly circled with white but below have much white.

No. 9. Female. Length, 1160 cm. Sides of body and of the peduncle blotched with light gray; the markings are heavier on the body. Ventral region almost plain.

No. 10. Male. Length, 1050 cm. A dark individual. Throat and lips plain dark slate with practically no lighter color. On the sides backward to a point opposite the anus are a good many large, gray, oval and oblong markings having irregular margins; the sides are also thickly studded with barnacles. The dorsal and ventral regions of the peduncle are plain but there are a few white circles and spots on the sides. The dorsal "hump" has patches of light gray, almost white, on either side and a large white spot on the right side; just anterior to the penis is a gray blotch.

Above, the pectoral is black with only one white spot.

The flukes are black on both surfaces save for a few white circles; the distal half of the posterior edge is all white.

No. 11. Male. Length, 1075 cm. A light individual. There is almost no white on the rostrum, lips, or throat. Sides of body and of peduncle so thickly washed, circled and marked with gray and white that there is much more light than dark color present.

No. 13. Male. Length, 1250 cm. Sides of body from the fins to a point opposite the anus, have many large gray and white markings and an extensive area of clear light gray. The peduncle has few gray markings on the sides but many white barnacle scars (many barnacles are still in position).

On the inferior surface, both fins are black but have a number of white spots joining to form a band about 60 cm. long between the second and third fingers. There are a good many other white spots and circles along the posterior edge, the remainder of the fin being unmarked. The superior surface is almost like the inferior but shows somewhat less white.

No. 14. Male. Length, 1160 cm. An exceptionally dark whale. The head is black showing practically no white or gray markings and but few parasites. On the chin and throat and on the breast between the fins there are many white flecks and circles but the remainder of the breast and belly is plain. On the left side from the fin to a point opposite the penis is an area of clear light gray about 60 cm. wide; on the right side its place is taken by a number of rather dark gray, roughly oblong, markings. The peduncle is almost entirely black but has a few gray patches on the inferior half.

No. 15. Male. Length, 1085 cm. The head shows a little white on the dorsal surface of the rostrum and on the sides a good many white barnacle scars. The sides of the body from the pectoral fins to a point opposite the anus have numerous light gray patches with white edges which almost join each other; these also cover the belly but do not extend on to the back. The superior half of the peduncle is plain black and the remainder thinly covered with rather small gray markings.

No. 16. Male. Length, 1180 cm. A light individual. The head, lips, throat and back are black except for a few gray patches just posterior to the blowholes and a white spot on the lips. The sides of the body from the fins to a point opposite the anus are covered with rather small gray patches which become larger and more numerous on the lateral surfaces of the peduncle. (These patches are gray in the center shading to white on the edges and broken by small black spots or dashes). The dorsal and ventral regions of the peduncle are unmarked.

The pectoral fins are black, above, circled with white. The inferior surface has fewer circles but is washed with white in several places. The flukes are black below with a few white circles. (In coloration the tail resembles that of *Megaptera*).

No. 17. Male. Length, 980 cm. A dark whale. The sides of the rostrum, lips and mandibular rami are mixed gray and white ("pepper and salt"). The back, sides of body and peduncle are marked with long gray lines which resemble scratches but seem to be normal.

The flukes are very light colored on the inferior surface and have whitish lines running transversely across each lobe and curving inward toward the notch.

No. 18. Male. Length 1190 cm. The dorsal and lateral surfaces of the rostrum are very light gray; the entire mandible is dark but shades into very light gray about 60 cm. from the symphysis. The sides of the body from the pectoral fins to a point opposite the anus has many, rather dark gray markings a few of which are present on the proximal half of the peduncle; the remainder of the peduncle is very dark slate. The back is unmarked save for a few small barnacle scars.

No. 19. Male. Length, 1180 cm. A very light whale. The ground color of the body is dark gray and not the usual slate, or black. Distal half of mandible gray and white mixed. The sides of the body, belly and entire peduncle are thickly covered with small gray patches, irregular in shape, but having their longitudinal axes following the axis of the body. The gray markings are about 15 cm. long by 8 cm. wide and coalesce so that there is more of the light gray and white than the darker ground color.

No. 20. Male. Length, 1215 cm. Ground color dark gray. Sides of rostrum and head to the eyes very light gray; just above the bases of the baleen rows is the usual narrow pinkish band. Sides of body to the fins have many gray markings, and the back, belly and, in fact, the entire body is thickly covered with white cirriped scars. The dorsal and ventral regions of the peduncle are unmarked, but the sides have a number of gray patches which become smaller posteriorly and cease about 120 cm. from the flukes.

The pectorals are dark on the superior surfaces with only a few white flecks. There is a considerable quantity of white flecks, spots and circles scattered over the inferior surfaces and the posterior edges are white.

The flukes are dark above and below showing but few white circles and spots.

No. 23. Male. Length, 1235 cm. A light individual. The head, lips and jaws are mostly light gray with flecks of white. There is much light gray on the sides of the body in small patches, bars, dashes and flecks. The sides of the peduncle show some light gray markings and the ventral surface a few irregular white lines resembling scratches.

EXTERNAL ANATOMY.

Plates XX–XXIV.

Outline of Body.— The rostrum is strongly convex, the highest point being just anterior to the blowholes. Directly behind the spiracles there is a shallow concavity about sixty cm. long, and from that point to the "hump" the dorsal outline is regularly convex. From the hump the upper ridge of the peduncle slants very gradually downward to the flukes. The throat is rather flat but opposite a point midway between the eye and the anterior insertion of the fin, the breast and belly swell outward in a gradual curve to the anus broken only by a slight bulge at the penis. At the anus there is an abrupt dip and from that point to the flukes the ventral outline of the peduncle is slightly convex; the greatest convexity is just anterior to a point midway between the anus and flukes. The body is deepest opposite the tip of the pectoral fin laid back.

The outline of the body in Scammon's figure of *Rhachianectes* needs some correction. From the blowholes to the end of the peduncle crenulations the back is straight when it should be convex and there is little indication of a hump. The breast and belly are hardly full enough, the prominent dip just posterior to the anus is not shown, and the ventral outline of the peduncle should be slightly convex.

Head.— The head of *Rhachianectes* is distinctly characteristic and differs strongly from that of all other baleen whales. Its shape, in some respects, is intermediate between that of the

RHACHIANECTES GLAUCUS.

Balæninæ and the Balænopterinæ. It is not so large proportionately, and the rostrum is neither as narrow nor as curved as in the former, but is much narrower and deeper than in the latter.

The rostrum is convex dorsally, narrow and very deep, especially so just anterior to the blowholes. On either side of the rostrum just anterior to, and below, the spiracles is a prominent swelling about forty-five cm. wide which runs forward, narrows, and gradually becomes lost. Immediately below this swelling is a shallow depression extending for the entire antero-posterior length of the rostrum.

The head is deep vertically and in whale No. 3, male, 1240 cm. in length, the distance from the eye to the summit of the head over the curve of the side was 94 cm.

The blowholes are situated in a slight depression just behind the highest point of the rostrum, the anterior ends being slightly higher than are the posterior. They appear as two slightly curved slits, the convexities inward, having a long and rather shallow furrow between them. In whale No. 1, 1300 cm. in length, the blowholes were 25 cm. long, the anterior ends being 7 cm. apart and the posterior ends 23 cm.

In Cope's description from Dr. W. H. Dall's note there is the following statement: ". . . . the blowholes are entirely concealed by four dermal plicæ, which accounts for the small misty spout peculiar to the species" (*l. c.*, 1868, p. 226). I am at a loss to know what is meant by the "four dermal plicæ," as the blowholes of all the specimens which I examined were open and did not differ greatly from those of other baleen whales.

The region immediately about the spiracles was usually thickly infested with parasitic *Cyamus scammoni*.

Eye.— The eye forms a rather prominent swelling above, and a little behind, the corner of the mouth and is surrounded by two furrows the anterior and posterior ends of which almost meet. In some cases the ends of the furrows actually join thus forming a complete circle about the eye but in the majority of individuals the ends stand a short distance apart. The upper lid is considerably fuller and more prominent than is the lower. On whale No. 21, male, 1225 cm. in length, the furrows about the eye were each 18 cm. long, and the eye opening itself 5 cm. from the anterior to the posterior commissure.

The eyeball from an adult male 1158 cm. in length had a circumference of 205 mm. after it had been trimmed of adhering fat. The iris was 26 mm. long and 17 mm. in vertical diameter. The pupil was 10 mm. long and 6 mm. in diameter, oval, with the superior edge somewhat flattened.

The iris was a clear, dark brown band 6 mm. wide, the outer edge of which shaded into a narrow whitish ring. Encircling the iris was a band of light gray, 4 mm. in width, which shaded off gradually into very dark gray.

Auricular orifice.— The ear opening varies in size, as in all large whales, but is usually about 18 mm. in longitudinal diameter and directed upward at an angle of nearly 30 degrees. The meatus is a little larger than a good sized pencil.

The position of the ear is somewhat variable. In whale No. 1, female, 1300 cm. in length, the ear was 56 cm. behind the eye and 20 cm. *above* it. In fœtus No. 1*a*, male, from the same whale, the ear was 24 cm. behind the eye and 1 cm. above it. In none of the other twenty-three specimens on which notes were taken was the ear above the eye, it usually being from 2 to 5 cm. below it.

Scammon remarks in this connection: "The ear, which appears externally like a mere slit in the skin two and one half inches in length, is about eighteen inches behind the eye, and a little above it" (*l. c.*, p. 20). In the table of measurements the distance from the eye to the ear of eleven specimens will be found.

Tongue.— The tongue of *Rhachianectes* is narrow, thick and solid, resembling that of a Right Whale much more strongly than it does the soft, shapeless tongue of *Megaptera* or any *Balænoptera.* The dorsal surface is regularly convex except at the distal end where it becomes concave, and the tip is upturned and deeply cleft. There is a narrow flattened strip on the top which runs from the proximal to the distal end. A cross-section of the tongue would be a semicircle with a slight dorsal compression. The color is usually flesh-pink becoming bluish gray at the tip.

Whale No. 17, male, 980 cm. in length, had a tongue 145 cm. long, 78 cm. wide over the curve and 50 cm. thick in the center. The tongue of No. 18, male, 1190 cm. in length, was 170 cm. long and 110 cm. wide over the curve.

Baleen.— The baleen plates of *Rhachianectes* differ from those of all other whales in being very thick and heavy, in the almost complete absence of transverse ridges, in having the outer edges thick and rounded instead of thin and sharp, and in the coarseness of the bristles. The baleen rows are not joined anteriorly by a narrow strip of small bristle-like plates as are those of the Balænopterinæ, in this respect resembling the Balæninæ.

The basal half of each plate is regularly concave, but in the distal half the concavity gradually disappears and the plate becomes flat. The color of the laminæ is yellowish white, or light yellow.

There are decidedly fewer baleen laminæ in each row than in any other large whale, the number varying from 138 to 174 on each side, the distance between the plates at the bases is from 5 to 10 mm. Following is a record of the number of baleen plates, *on one side only*, of different individuals, counting in every case the first and last lamina which was more than 50 mm. long and 5 mm. wide; the plates were all counted while *in situ:* 174, 168, 164, 162, 160, 158, 154, 148, 138.

The anterior ends of the baleen rows of whale No. 21, male, 1225 cm. in length were 35 cm. from the tip of the snout and 15 cm. apart; the posterior ends at the bases were 14 cm. apart and at the widest point the tips of the two rows diverged 65 cm.

The mucous membrane in the roof of the mouth between the bases of the baleen rows is white or flesh-pink.

The bristles of the proximal half of each plate are about 13 cm. in length but gradually elongate reaching a length of 25 cm. near the tips; they are round, very coarse and contrast strongly with the finer bristles of all other baleen whales. When seen *in situ* the bristles give the effect of a mat of thick, coarse fibers.

The baleen bristles are either entirely yellowish white like the plates themselves, or those of the posterior section may be gray, or dark gray, and the anterior portion yellowish white. The color of the bristles of twelve individuals was recorded showing that seven had some portion gray and five entirely yellowish white. Following is a list of the specimens in which the color of the bristles was noted:

The descriptions given above of the baleen and bristles were written at the whaling station in Korea with fresh specimens at hand. I find upon examination of the set of baleen which was shipped to the Museum that both the bristles and laminæ are now very much darker than when fresh. This is due both to the drying of the plates and from soiling with dirt and grease. The bristles are now a strong brown and the plates yellowish-brown. I believe that in the great majority of cases any light colored baleen while being shipped from the field to a museum will be more or less soiled in transit and consequently the only reliable descriptions of such material are those that have been taken from fresh specimens.

Dall says that *Rhachianectes* has 145 laminæ of baleen on each side and that it is "light yellow," while Scammon describes it as "light brown or nearly white." Van Beneden speaks of the baleen in the Vienna Museum as being pale like that of *Balænoptera acuto-rostrata*. The baleen in the U. S. National Museum from San Luis Obispo, Cal., is stated by Dr. True to be yellowish-white except at one end of the series where for a distance of about eight inches the blades and bristles are dull chocolate-brown. He says: "The largest plates measure 18 in. in length without the bristles, and 6 in. at the base. The longest bristles measure 9½ in., and were perhaps originally a little longer" (*l. c.*, p. 290).

Throat furrows.— On either side of the median gular line *Rhachianectes glaucus* has two or more deep furrows. Their anterior ends closely approach each other and stand parallel for a short distance but gradually spread apart posteriorly. The furrows begin about 165 cm. from the tip of the mandible and end opposite a point half way between the eye and ear; the posterior ends are generally almost three times as far apart as are the anterior. Whale No. 24, male, 1225 cm. in length, had furrows 170 cm. long, the anterior ends being 20 cm. apart and the posterior ends 50 cm.; the anterior ends were 75 cm. from the tip of the lower jaw.

Although two furrows seem to be the usual number for *R. glaucus*, three are not infrequently present, and one individual which I examined possessed *four*. Whale No. 3, male, had three grooves, the left being 150 cm. long and the right 116 cm.; between their anterior ends was a shorter furrow 100 cm. in length. No. 4, male, also had three furrows, the two outer being 165 cm. long and the median 130 cm. The two outer furrows of No. 14, male, were 120 cm. in length and the one between them 154 cm. long; this was the only individual in which the median furrow was the longest of the three. In No. 16, male, the median furrow was 62 cm. in length while the two outer measured 150 cm.

No. 20, male, had *four* distinct furrows; the median and two outer ones were of about the same length and between the middle and left near the *posterior* end was a fourth short groove. Out of the twenty-one specimens in which the number of gular furrows were recorded fifteen had two, and six three, or more. Several whales were brought in which were not measured or described and among them were four or five individuals showing three throat furrows. The grooves are almost 5 cm. in depth and have rounded edges.

The gular furrows of *Rhachianectes* seem to be a specialization in the direction of the throat and breast grooves of the Balænopterinæ. Since in *Rhachianectes* they are presumably present to increase the throat capacity they throw light upon the origin of the folds in the Balænopterinæ and tend to substantiate Prof. Kükenthal's theory that their purpose is to allow the short-headed members of this subfamily to take into the mouth a greater quantity of water containing their food.

The grooves of the Balænopterinæ in their early development were probably few in number and confined to the gular region, as in the case of *Rhachianectes.* As specialization of the entire body continued the furrows increased in number and in length extending backward upon the abdomen to give the greater thoracic expansion made necessary by the extraordinary development of the lungs.

It is well known that the sternum in all baleen whales is reduced to a vestige, and that the proximal ends of the ribs articulate loosely with the vertebral column, the distal ends of all but the first pair being free. Thus the frame-work of the thoracic cavity is capable of great lateral movement. In conjunction with the skeletal changes the lungs become greatly enlarged and adapted to retain the air during a considerable period of submergence. The increased power of lung expansion called for external as well as internal modification of the breast and the furrows which had already developed upon the throat became more numerous and prolonged posteriorly. The greatest number of furrows and their most frequent branching is between the pectoral fins, as might be expected.

In the existing Balænopterinæ, when the lungs are filled with air the whole thorax expands laterally and with it the flexible skin between the folds. Thus the furrows, besides their original function of increasing the throat capacity during the feeding operation, are also of use during respiration. *Rhachianectes* being a shallow water whale and a relatively primitive form, has not as yet developed the furrows upon the breast and abdomen.

In the case of the Balæninæ extensive specialization of the entire head has taken place and it has become of such a proportionately great size that there has been no necessity for increasing the throat capacity by the development of furrows; like the head, the entire thorax has become enormously enlarged by the great thickening of the body and has thus accommodated itself to the processes of respiration.

The Odontoceti, because of the nature of their food and the manner of securing it, are not under the necessity of increasing their throat capacity by the development of furrows.[1] In this group, moreover, which are not as extensively specialized as are the baleen whales, the sternum is long and the "thoracic box" is relatively immobile.

Pectoral limb.— The pectoral fins of *Rhachianectes* are distinctly individual being intermediate in shape between those of the Balæninæ and the Balænopterinæ. They are much broader and thicker proportionately and not so pointed as the fins of the latter subfamily, but are more lanceolate, and not as heavy, as thick or as broad as the pectorals of the Balæninæ.

---

[1] This is not literally true since the Ziphioides have two throat furrows.

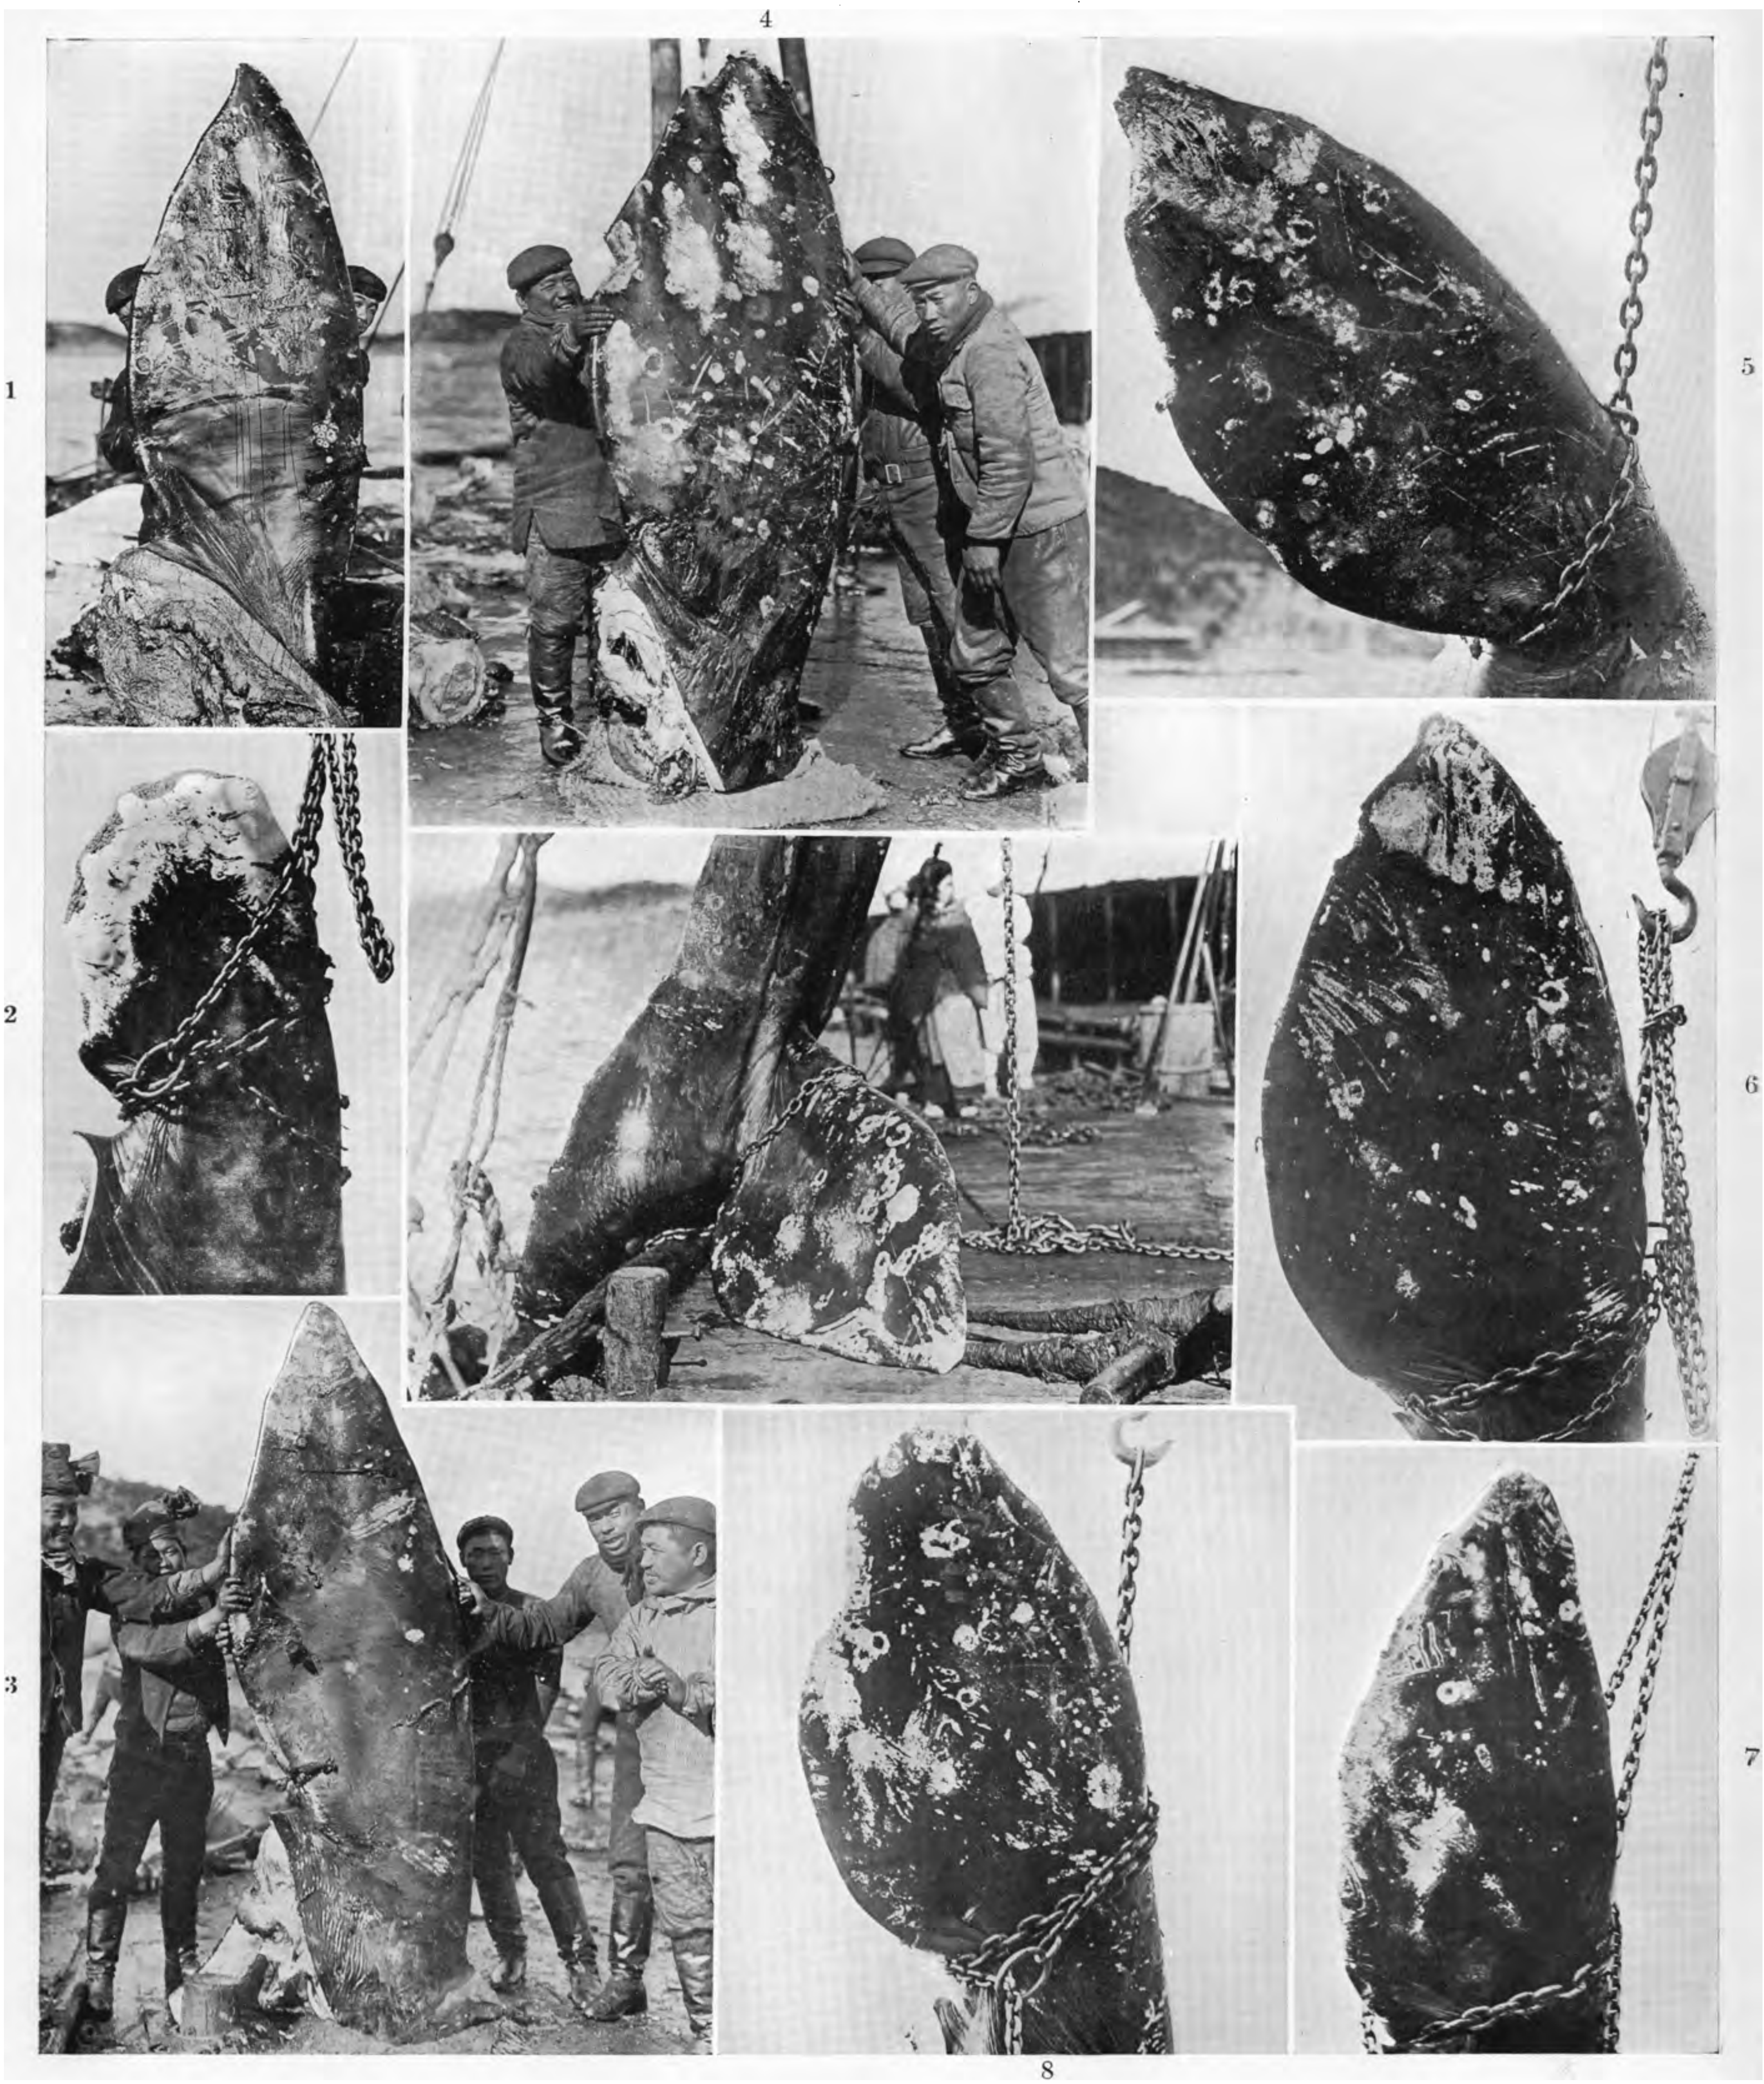
Fig. 8. “ “ “ “ “ “



Rhachianectes glaucus.

If photos of the pectoral of *Rhachianectes* are compared with those of a Right Whale or of any *Balænoptera* it will be seen at a glance that its shape is intermediate between the two types.

The flipper of *Rhachianectes* is broadly lanceolate. The posterior edge is about 3 cm. thick and strongly convex except just behind the rather blunt tip where a shallow concavity is formed; the anterior edge is regularly convex. The greatest breadth of the fin is at a point almost midway between the tip and the axilla, and the four digits are so prominently outlined that each may be traced for almost its full length before the fin has been stripped of blubber. There is considerable variation in the breadth of the pectoral among different individuals due to a greater or less convexity of the posterior border. Out of the twenty-three specimens on which notes were taken all but two had at least one of the flippers more or less injured on the posterior edges or tips. This, I believe, was mainly the work of Killers (*Orca orca*) which apparently keep the Gray Whales in a continual state of terror when upon their annual migrations. It may also be due, in some degree, to contact with rocks, as this species is generally to be found close in shore and frequently rolls about in the surf in very shallow water. Wherever the edges or tips of the fins were injured they were invariably thickly covered with parasitic crustaceans, *Cyamus scammoni*, and frequently the hard barnacle *Cryptolepas rhachianecti* was embedded on both surfaces.

Scammon's figure is hardly an accurate representation of the flipper of *Rhachianectes glaucus*. The outer edge is too straight, the tip is too blunt, and the fin is not broad enough.

In color, the pectorals are dark slate like the body. Above, on the posterior half, are a few scattered white circles, spots and flecks; below, the white circles and spots are more numerous and there are two, more or less broken, bands of white, or very light gray, about 8 cm. wide and 45 cm. long between the 2nd and 3rd, and 3rd and 4th fingers; the band between the 2nd and 3rd digits is usually the longer. The posterior edge of the fin is generally white.

There is much variation in the amount of white on the pectorals. Some individuals had the two bands between the fingers present on both surfaces and the entire fin thickly covered with spots, circles, dashes and flecks of white. Others had the distal third of the flipper washed with light gray, or white, while in still other cases white was practically absent on both surfaces. In almost all cases, however, there was more of the light markings on the lower surface than on the upper. A large proportion of the white circles and spots seemed to be scars left by parasitic cirripeds and were exactly similar to those on the flippers of *Megaptera*.

Flukes.— The flukes of *Rhachianectes glaucus* are quite unlike those of any other large whale. In shape they resemble most closely those of *Physeter macrocephalus* but both the anterior and posterior edges are more convex than in the latter species and the notch is more open and shallower. They are strikingly different from the slender, graceful flukes of *Balænoptera* and equally so from *Balæna* and *Eubalæna*. The resemblances to *Megaptera* are only superficial.

When either lobe of the flukes of *Rhachianectes glaucus* is viewed singly it is strongly suggestive of the pectoral fin in shape. The anterior margin is slightly convex becoming more so near the distal end. The posterior edge for the proximal two-thirds is strongly convex, but the distal third just behind the tip is slightly concave. Since the tips of the flukes in all adult specimens are more or less injured the concavity generally does not show and the posterior edge is evenly convex from the notch to the tip. The posterior edge, instead of being extremely thin as in *Balænoptera*, is almost three cm. in thickness and is broken by shallow, rounded emarginations. These crenulations must be normal as they were present in a fœtus (No. 1*a*) which was almost ready for birth, and in nearly all the adult specimens. They are analogous to the emarginations on the flukes of the *Megaptera* but are neither so numerous nor so deep and give a wavy effect rather than the scalloped appearance seen in the Humpback.

The entire posterior edge is frequently infested with *Cyamus*, which fasten themselves upon the slightest abrasion, and the posterior outline is often entirely changed by the attacks of these parasites or by other injuries. The notch is deep and usually open but varies considerably in this respect.

The flukes are black above and below like the body. A few circles, flecks and dashes of white are scattered over both surfaces, the lower usually being most heavily marked. As with the pectorals, the amount of white is extremely variable. The white circles and spots in many cases are the scars left by barnacles; two or three individuals had flukes exactly resembling those of a Humpback in color.

The flukes of a fœtus (No. 1*a*) on the inferior surface had wide, dark gray anterior and posterior borders and very light gray central portions. Many broken whitish lines curving inward toward the notch ran transversely across each lobe starting on the anterior edge. In a general way this was suggestive of the inferior surface of the flukes of *Balænoptera musculus*. One adult individual (No. 17) had flukes marked in exactly the same manner but as it was quite unlike all other specimens examined this must be considered to be an unusual type of coloration.

Dorsal crenulations of peduncle.— On the dorsal ridge of the peduncle, beginning about 100 cm. from the insertion of the flukes, is a series of low, rounded crenulations which end a short distance beyond a point opposite the anus in an evenly rounded bunch, or "hump," about 50 cm. long and 7 or 8 cm. high. The crenulations are about 30 cm. apart, those nearest the flukes being the least developed and those just posterior to the "hump" the most prominent. Their number and size are open to considerable variation, one individual having only 6 rather indistinct tubercles while another had 14, even the most posterior of the row being well developed; 9 or 10 is the usual number as shown by the following table:

Number of crenulations.

Capture Number	Sex	
5	♂	9
6	♀	6
8	♂	10
10	♂	10
11	♂	8
13	♂	10
14	♂	10
15	♂	7
20	♂	14
22	♂	9
23	♂	9

These crenulations are very similar to those on the dorsal ridge of the peduncle of the Humpback but are somewhat more prominent. They were noted by Dall, Scammon and Townsend. Dall says: "On the vertebral line, for fourteen feet from the caudal flukes, is a series of 18 ridges, like the teeth of a saw, which are altogether dermal in their character" (*l. c.*, 1868, p. 226). Out of some 30 individuals which I examined only one possessed as many as 14, the next highest being 10; it would appear, therefore, that 18 is rather an unusual number.

Scammon's statement that it "has a succession of ridges, crosswise along the back, from

Rhachianectes glaucus.

opposite the vent to the flukes" is misleading for the ridges are certainly never transverse; although he figures them in their proper position he does not show the hump at the anterior end of the series.

Townsend speaks of the crenate ridge as being present in a fœtus but says he did not observe it in the adult. He may have seen a specimen in which it was so slightly developed as to have escaped his notice for it is probably never entirely absent.

In a fœtus 476 cm. long which I examined it was fully developed and 12 crenulations could be distinguished. Townsend's figure shows the crenate ridge as an elevated phlange which gives a somewhat erroneous idea of its true character for the dorsal ridge of the peduncle is not itself extended.

It seems somewhat remarkable that the presence of the hump or bunch, which ends the series of crenulations anteriorly, has not been previously mentioned, for in nearly all the individuals examined it was prominent and attracted my attention at once. By referring to the table of proportional measurements it will be seen that the relative position of the hump is decidedly variable, there being a difference of 11% between the highest and lowest ratios to the total distance from the notch of the flukes to the hump. Its average position relative to the length of the animal is the same as in the *Megaptera*, and by but little modification a dorsal fin similar to that of a Humpback could be derived from it. The fact that Humpbacks have the dorsal ridge of the peduncle distinctly crenulated from the flukes to the hump, in a way similar to that of the Gray Whales, is exceedingly interesting. There is a greater individual variation in the relative position of the dorsal fin in the *Megaptera* than in the *Balænoptera;* it is situated much further forward in the former genus than in the latter, and it has almost every possible shape between a prominent, falcate fin and a low rounded bunch.

Before the pectoral and caudal fins of the Humpback had reached their present high state of specialization it is very probable that the dorsal may have been much less prominent and that, as in the Gray Whales, it formed the terminal bunch at the anterior edge of the peduncle crenulations. As the specialization of the animal continued the dorsal hump increased in size, its shape became modified, and the crenulations in the remainder of the series grew less prominent.

It is possible, therefore, that we may see *Rhachianectes* developing a dorsal fin in a parallel way to the *Megaptera* and that, if specialization is continued, it may become as prominent as in the case of the Humpback and its relative position be more constant.

Hairs.— Both the fœtal and adult *Rhachianectes* possess longer hairs, and they are more widely and more uniformly spread over the entire head, than in any other baleen whale. The hairs were scattered in six irregular rows over the whole rostrum of fœtus No. 1*a*, and a line of 16 on the dorsal ridge extended from the blowholes to the snout. The most posterior hair was on the left side of the head opposite the posterior end of the blowholes.

On each rami of the mandible there were 21 hairs in three irregular rows, the most posterior being a little anterior to a point opposite the corner of the mouth. At the mandibular symphysis three irregular vertical rows, which closely approximated each other, contained 40 hairs. The areas most thickly covered with hirsute remains were the tips of the snout and mandible. Each hair was white, about 20 mm. long, and situated in a small pit surrounded by a dark ring.

On the head and lower jaw of the adult *Rhachianectes* the number and arrangement of the hairs is essentially the same as on the fœtus described above. The hairs are generally longer in the adult than in the fœtus, sometimes reaching a length of 40 mm.; on whale No. 18, male, in several places on the mandibular rami two hairs were found in a single follicle.

A careful examination was made of all parts of the body, both in the fœtus and adult, but in no place other than the head and jaws were there evidences of hair.

Blubber.— The blubber is very thick and fat, and varies in color from red to flesh-pink. Because of this, as noted by Dr. True, the Japanese recognize two kinds of Gray Whale, the "aosaki" (red blubber) and the "shirosaki" (white blubber). Although specimens with blubber strongly red, almost white, and of every intermediate shade, were taken during my stay at Ulsan, I could detect no differences, other than those purely individual, between them.

The blubber varies in thickness with individuals, and on different parts of the body, usually being from 20 cm. at the thinnest to 35 or 40 cm. at the thickest part.

The Japanese consider the meat and blubber to be of poorer quality for eating than those of any other baleen whale. In the winter, during the months of December and January when the price is at its highest, the blubber sells for about 4 sen (2 cents) per pound and the red meat 10 sen (5 cents).

In regard to the blubber Scammon says: "The coating of fat, or blubber, which possesses great solidity and is exceedingly sinewy and tough, varies from six to ten inches in thickness, and is of a reddish cast" (*l. c.*, p. 21).

Parasites.— The entire body of *Rhachianectes* is more or less thickly infested with the parasitic amphipod crustacean *Cyamus scammoni* Dall, and the hard barnacle *Cryptolepas rhachianecti* Dall. The barnacles embed themselves deeply on all parts of the body as well as on the flukes and pectoral fins.

The *Cyamus* are almost invariably to be found about the blowholes, the genital and anal openings, and on the tips and posterior edges of the flukes and flippers. Wherever a cluster of *Cryptolepas* have become embedded, *Cyamus scammoni* will also fasten and frequently cover a wide area having the barnacles as a nucleus; an injury or abrasion of the skin at once becomes the resting place of numbers of parasites. The snout of *Rhachianectes* for a distance of sixty or seventy cm. from the tip is usually cornified in a way similar to the "bonnet" of the Right Whale, and is produced, as in that species, by the action of the parasitic *Cyamus*. In some individuals the entire dorsal ridge of the rostrum from the snout nearly to the blowholes becomes cornified.

When a *Cryptolepas* detaches itself a circular grayish pit remains, which in time becomes white as the wound heals; these scars are exactly like those left by the barnacle *Coronula diadema* upon the *Megaptera*. No barnacles other than *Cryptolepas rhachianecti* were observed upon the Gray Whales, and it seems probable that none other infest this species.

A careful examination of the *Cyamus* taken from Korea specimens demonstrates that they are certainly identifiable with Dall's *Cyamus scammoni* described from the California examples of *Rhachianectes glaucus*. In any case it is doubtful if such highly specialized parasitic forms would show strong changes even if isolated for a long period and thus they furnish little information on the question as to whether or not the Gray Whales of the east and west sides of the Pacific actually mingle in the north.

Osteology.

The skeleton of *Rhachianectes*, other than the skull, has never been completely described, consequently a rather detailed account of its principal characters will be given in the following pages; also comparisons with other genera will be instituted whenever individual peculiarities can be emphasized thereby.

The length of the skeleton of the American Museum specimen, measured in a straight line, is 1107 cm. (36′ 4″). It was taken from a very old male (No. 20), 1250 cm. (41′ ½″) long, on January 19, 1912, at Ulsan, Korea.

The vertebral epiphyses are all firmly ankylosed, in most cases the lines of union being lost, and there are other evidences of extreme age.

SKULL.

Plates XXV–XXVII.

In general form the skull of *Rhachianectes* is directly intermediate between the skulls of *Eubalæna* and *Balænoptera,* and somewhat resembles *Neobalæna.* The dorsal outline is much curved and especially high from the nares posteriorly, thereby giving to the occipital plane a comparatively slight obliquity, scarcely greater than in *Eubalæna.* The skull, as seen in profile, is thus quite unlike that of a Fin Whale, not only the whole dorsal outline being more convex but the rostral portion more arched. The interorbital region is thus deep and quite constricted.

The rostrum is narrow and elongate and the lateral outline tapers regularly toward the tip. The premaxillæ in the distal portion are very deep and have almost vertical sides, as in *Eubalæna,* but become somewhat flattened where they spread apart for the narial opening. Proximally they end a considerable distance from the vertex of the skull *leaving a wide area of the frontals exposed,* a primitive condition. The proximal portions of the premaxillæ enclosing the nasals appear as broad strips, superiorly placed, and articulate with the frontals by a deep interdigitating suture.

The maxillæ instead of being almost horizontal as in the Balænopterinæ are sharply oblique. Their inner (superior) edges slope abruptly downward in the distal half of the rostrum but in the proximal half are almost parallel with the skull axis. Each maxilla sends a narrow projection backward toward the vertex of the cranium, ending beside the premaxillæ. The lateral extentions of the maxillæ are remarkable in the fact that each one *overlaps the anterior edge of the orbital process of the frontal,* and bears posteriorly a strong tubercle which, with the anterior end of the orbit, partially encloses a large oblique foramen.

The nasals are very broad and long, joining in the median line to form a prominent crest; they occupy half the space between the nares and the summit of the occipital bone.

Compared with *Balænoptera* and *Megaptera* the orbital processes of the frontals are narrower, shorter and consequently less massive, but are much wider and less elongate than in *Eubalæna.* Viewed from below they have the trumpet-shaped form so characteristic of the fossil genus *Plesiocetus.* The posterior edges of the orbital processes of the frontals from the skull-vertex to the orbits present irregular margins; a primitive character.

The squamosal is comparatively small and has a straight outer edge quite unlike the concave squamosals of either *Balænoptera, Megaptera* or *Eubalæna;* in this respect the squamosal of *Rhachianectes* resembles that of fossil genera. The "temporal ridge," formed by the anterior margins of the temporal fossa, is well marked, thus showing an interesting primitive condition.

The supraoccipital presents three deep concavities, and on the superior portion two prominent and peculiar rugosities. These are undoubtedly homologous with the similar processes just under the lambdoid crest on the supraoccipital of dogs and other mammals, where the *rectus capitis posterior major* and *minor* muscles, which assist in raising the snout, are attached.

Their development, and the presence of similar rugosities below upon the basi-sphenoid and basi-occipital bones, are probably correlated with the fact that the cervical vertebræ are all free, and the neck is somewhat less abbreviated than in other large cetaceans thus allowing greater movement of the head.

The most interesting characters of the inferior surface of the skull are the comparatively short posterior extension of the vomer and pterygoid bones, the heavy pterygoids and, as mentioned above, the strongly down-turned edges of the basioccipital and basi-sphenoid which are exceedingly thick and massive.

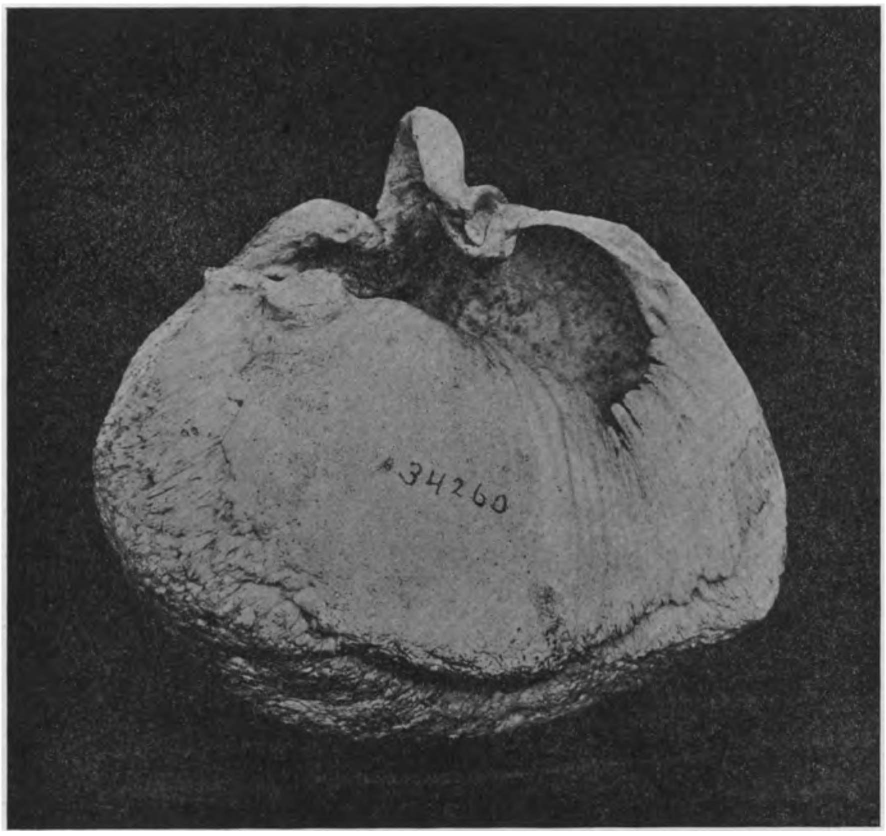

Fig. 1. Inner view of tympanic bulla of *Rhachianectes glaucus.*

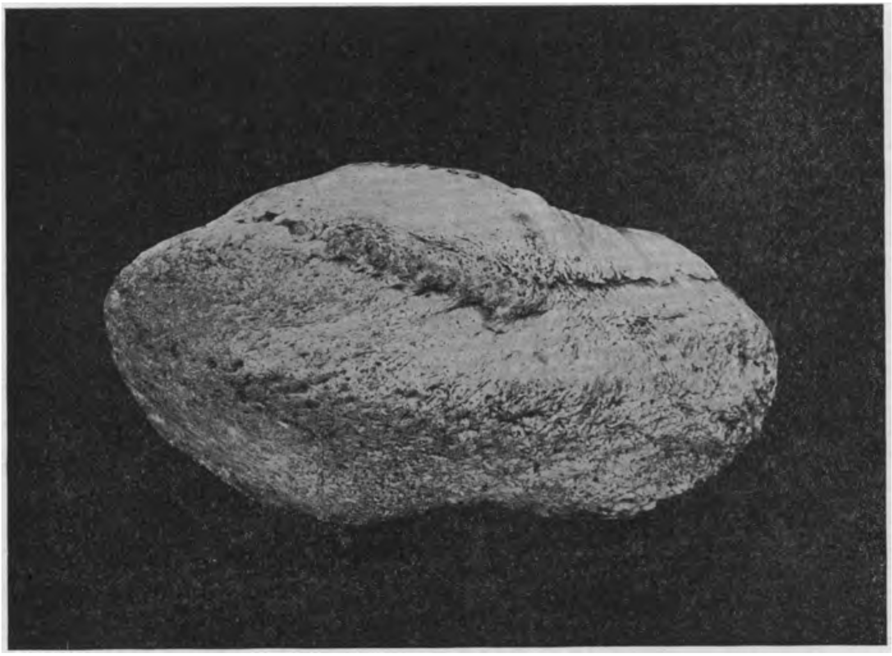

Fig. 2. Inferior view of tympanic bulla of *Rhachianectes glaucus.*

True remarks in regard to the peculiarities of the skull of *Rhachianectes:* "Most striking are the rugosities of the occipital, the large size of the nasals, the shortness of the nasal portion of the intermaxillæ, and their great depth anteriorly, the overlapping of the orbital processes of the frontal by the proximal portion of the maxilla, and the strong tubercle on the posterior margin of the former. All these characters are seen equally as well developed in the skulls figured by Malm as in the Monterey specimen.

"These and many other characters stamp it as a very distinct form, approaching closely neither *Balœna* nor *Balœnoptera*" (*l. c.*, p. 291). Dall, Van Beneden, Malm and Beddard have also more or less completely described the skull of *Rhachianectes.*

The mandibular rami are without coronoid processes these being represented only by flattened tubercles. Each

ramus is moderately bowed and the superior outline from the coronoid rudiment to the distal end is regularly convex; the inferior outline is a succession of slight convexities and concavities as shown by the figures. On the inner side of the superior edge for the distal three fourths of the ramus is a well-marked alveolar sinus which becomes very deep near the tip. Both rami show the effects of a former injury.

The mandible of *Rhachianectes* strongly resembles that of the Balæninæ, and shows little concavity on the inner side proximally; it is surprising to find a specialized mandible of this type when the many other primitive characters of the skull are considered.

The tympanic bullæ of *Rhachianectes* are small and remarkable because of their strong lateral compression and slightly grooved internal border (that is, the border nearest the median line of the skull). They are totally unlike those of *Eubalæna* in size and general shape and differ from *Balænoptera* in being much less elongate, wider, and more compressed as well as in other points. In size and general outline they somewhat resemble *Megaptera* but instead of being almost globular, as in the latter genus, are greatly flattened. By their compressed form and concave internal border they strongly suggest the tympanic bones of certain fossil genera.

Hyoid Bones.— The hyoid bones differ from those of all other baleen whales with which I am familiar.

The basihyal and two thyrohyals are ankylosed into a long, extremely massive and rugose bone. The central portion (basihyal) is dorso-ventrally compressed and has two short, anterior, conical projections (ceratohyals), but each thyrohyal rapidly thickens, becoming cylindrical in the distal two-thirds and curved slightly backward. The shape of this portion of the hyoidean apparatus is distinctly individual but resembles that of *Eubalæna* much more than any *Balænoptera.*

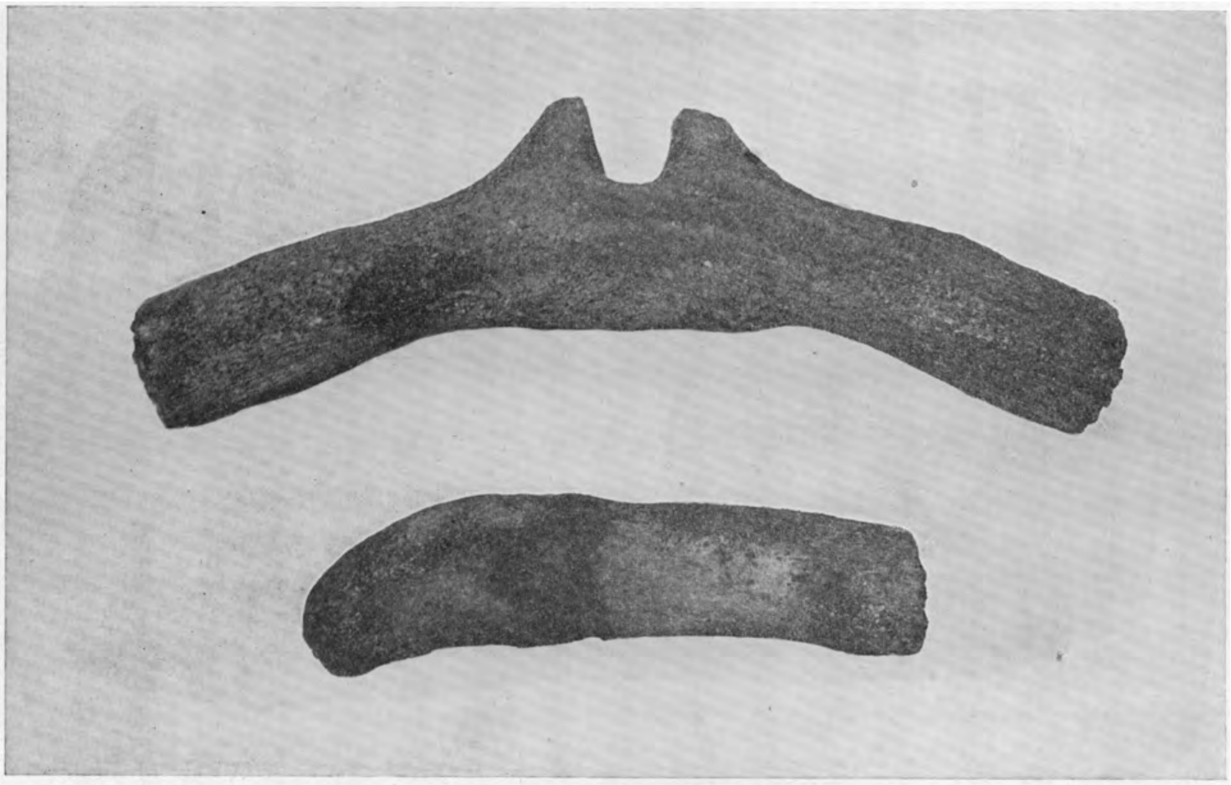

Fig. 4. Hyoid bones of *Rhachianectes glaucus.*

The stylohyals, on the other hand, are decidedly more like those of the latter genus than the former. Each is a massive, rugose bone, slightly curved upward and forward. The anterior edge for its greater part is sharp and the posterior margin rounded so that a cross section of the stylohyal would be an ovoid ellipse. These bones are nearly half again as long and twice wider than are the roughly cylindrical stylohyals of an adult 54 ft. female *Eubalæna glacialis* in this Museum.

VERTEBRÆ.

The vertebræ of *Rhachianectes*, through the combination of characters, differ widely from those of the other known genera of baleen whales, the general resemblance being rather more toward *Megaptera* than *Balænoptera* or *Eubalæna.*

The extremely rugose surfaces of practically all of the bones of the skeleton is interesting. I know of no other large Cetacean, except *Physeter macrocephalus,* in which this condition is so pronounced. Fifty-six vertebræ seems to be the normal number for *Rhachianectes glaucus,* the formulæ of three skeletons being as follows:

C	D	L	Ca.		Total		
7	14	12	23	=	56	Am. Mus. Nat. Hist.	(R. C. A.)
7	14[1]	12	23	=	56	U. S. Nat. Mus.	(R. C. A.)
7	14	14	21	=	56	British Mus.	(Beddard)

The differences in these formulæ will be discussed later.

Cervical vertebræ.— The cervical vertebræ are all free and show no tendency toward ankylosis.

The atlas differs strongly from that of both *Eubalæna* and *Balænoptera* but bears a considerable resemblance to *Megaptera.* Its most distinctive characters are the massive neural arch, the short transverse processes, and the small size of the condylar facets relative to the height of the vertebræ.

The neural arch is high and exceedingly thick and massive, having an irregular rugose superior surface and an indistinct spine; it is perforated by a transverse arterial foramen. The short bunch-like transverse processes are set obliquely to the vertical plane of the axis, have irregular rounded ends, and are directed slightly upward. They resemble the transverse processes of the *Megaptera* but are shorter and not so wide.

The centrum of the atlas at the bottom slopes strongly upward, and at the sides inward, so that the posterior face is considerably smaller than the anterior. The opening between the condylar facets in conjunction with the neural canal is much shallower than is usual with the atlas of other baleen whales; this character is not so pronounced in the National Museum specimen, the opening being roughly V-shaped, the point directed downward.

On the posterior surface, the internal-superior corners of the facets for articulation with the axis are produced inward appearing as two irregular tubercles when seen from the anterior face of the axis through the space between the condylar facets.

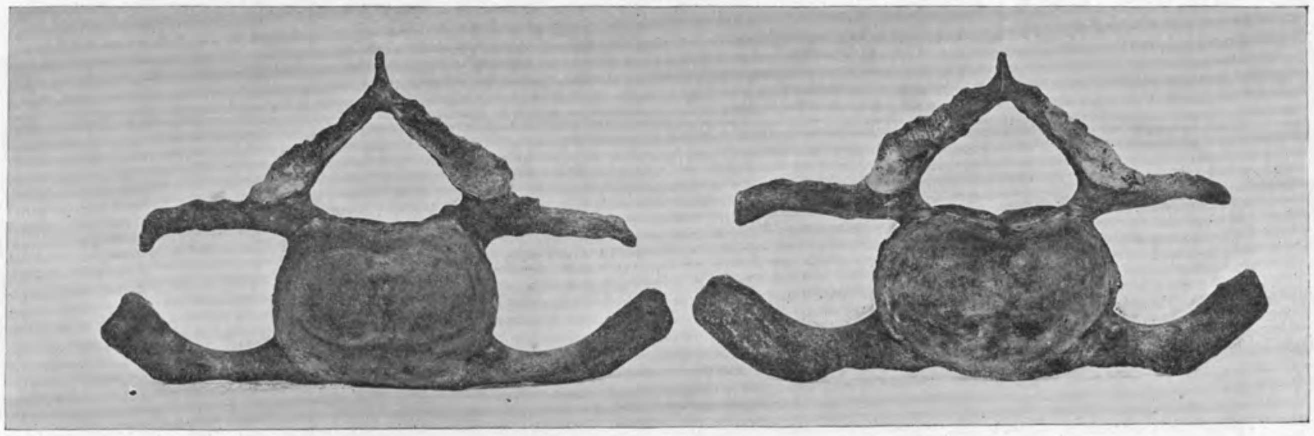
The axis resembles, in general, that of a *Balænoptera.* The neural arch is very thick and massive, has a rugose, truncated summit and an indistinct spine. Each of the posteriorly directed, wing-like transverse processes is perforated somewhat above the center by a rather small oval foramen; the processes are thick and have irregular, rugose surfaces. The articular facets for the atlas are small and between them is a rather prominent odontoid process.

---

[1] Although but thirteen pairs of ribs are present in the U. S. National Museum specimen, the distal ends of the transverse processes of the twenty-first vertebra show distinct articular facets and indicate that the last pair of ribs has been lost.

5

6



7

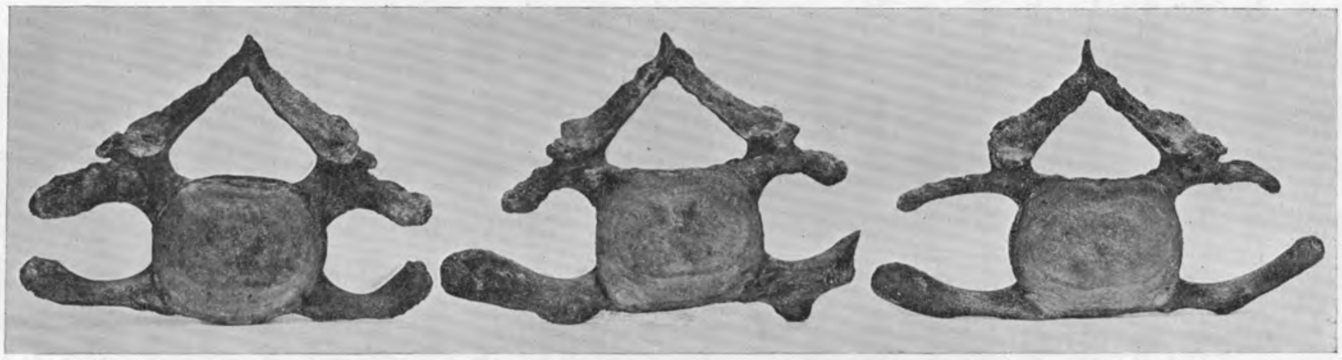


Fig. 5. Atlas and axis of *Rhachianectes glaucus.*
Fig. 6. Third and fourth cervical vertebræ of *Rhachianectes glaucus* (right to left).
Fig. 7. Fifth, sixth and seventh cervical vertebræ of *Rhachianectes glaucus* (right to left).

The third cervical vertebra has a circular body, somewhat compressed dorsally, and on either side two well developed transverse processes. The lower process is thick and roughly cylindrical for half its length, projecting somewhat downward but bends up and back in the distal half where it becomes compressed and blade-like. The upper process is straight, except at the distal end, and directed backward; the distal ends of the two processes stand widely apart (on the right side 50 mm.).

Both the upper and lower transverse processes of the fourth vertebra are similar to those of the third in length and direction, but the lower process is less massive and expanded distally.

On the fifth cervical the lower process is compressed throughout, especially so at the distal end where it is thin and expanded; instead of being directed slightly backward, as are those immediately preceding, it projects straight out and turns upward in the distal portion. The superior process is shorter than that of the fourth vertebra and curved slightly backward and downward.

The inferior transverse process of the sixth cervical is more massive than that of either the fifth or fourth, projects upward and forward and bears on the posterior side, proximally, a prominent flattened tubercle. The superior process of this vertebra is the shortest in the cervical series and projects strongly downward.

The seventh cervical has a lower transverse process which, although it is shorter than that of the sixth, is 135 mm. in length, roughly cylindrical and slightly expanded distally. The lower transverse processes of the seventh cervical of the U. S. Nat. Mus. specimen appear on the right side merely as a rounded tubercle and upon the left as a short process 64 mm. in length; neither seem to have been broken or otherwise injured.

The upper process is thick, compressed and considerably longer than that of the sixth vertebra; both are directed downward.

The anterior zygapophyses of the third vertebra are well developed, becoming larger on each succeeding cervical and appearing on the seventh as tubercles 43 mm. in length.

The spines of all the cervicals increase in height and thickness from the third to the seventh.

The laminæ of the neural arches of the third, fourth, and fifth vertebræ are wide at the bases, narrowing rapidly and uniting at the apices in erect and prominent spines. The arches of all the cervical vertebræ are high and triangular, considerably resembling those of *Megaptera.*

The cervical vertebræ of *Rhachianectes,* considered as a whole, are unique in the *combination* of the following characters:

1. An atlas of peculiar shape.
2. An axis having wing-like transverse processes.
3. Triangular neural arches and long inferior transverse processes in all cervical vertebræ posterior to the axis.[1]

Dorsal vertebræ.—The most distinctive character of the dorsal vertebræ is the zygapophyses, which are extraordinarily thick and massive with heavily rugose surfaces. They appear on the proximal ends of the transverse processes of the fifth dorsal as well developed tubercles rapidly enlarging on the succeeding vertebræ into prominent projections having massive globular ends.

The transverse processes are heavy throughout the series and have expanded, concave distal ends except in the case of the first and last dorsals; the ends of the transverse processes of the tenth thoracic vertebra are the widest of the series.

The neural spines of the first six dorsals are directed forward, those of the seventh, eighth, and ninth are vertical, and the remainder directed backward.[2] The spines increase steadily in antero-posterior width from the first to the twelfth dorsal, which bears the widest spine in the entire vertebral column.

---

[1] As noted above, this was not entirely true of the U. S. Nat. Mus. specimen in which the lower transverse processes of the seventh cervical were small.

[2] The spines of the first four dorsal vertebræ of the U. S. Nat. Mus. specimen are directed backward, the fifth, sixth and seventh upward and the remainder backward.

The centrum of the first thoracic is circular except for a slight dorsal flattening; the dorsal compression of the centra becomes more pronounced in the posterior members of the series.

Lumbar vertebræ.— The lumbar vertebræ present certain individual peculiarities in the spines and zygapophyses, by means of which they may be distinguished from those of other whales. The spines of the entire lumbar series are directed strongly backward, that of the ninth being the most oblique of the vertebral column; the backward direction of the spines in the posterior vertebræ of the series is much greater than in *Megaptera* and somewhat more than in *Balænoptera*. All of the spines are regularly convex distally and that of the seventh lumbar is the longest.

The zygapophyses are prominent and show, in a modified form, the expanded distal ends so characteristic of the dorsal vertebræ. Those of the anterior half of the lumbar series are directed outward so that they overhang the anterior faces of the centra more strongly than is usual. The spines and zygapophyses differ in numerous minor ways from those of other genera.

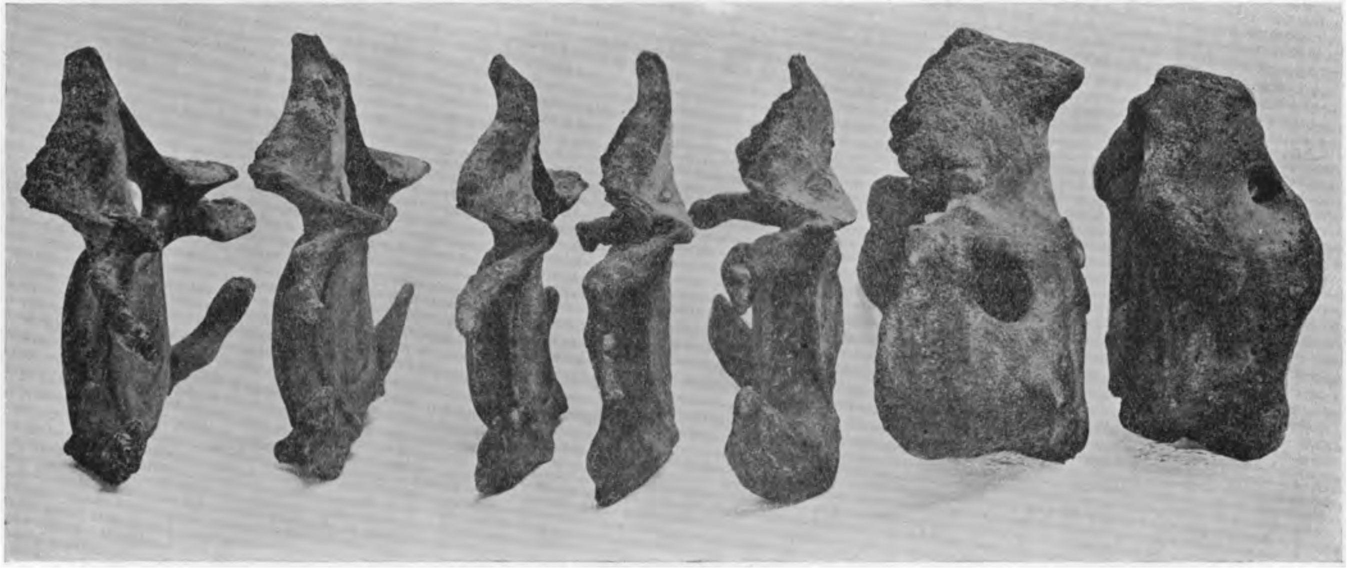

Fig. 8. Cervical vertebræ of *Rhachianectes glaucus*.

The transverse processes of the first four units of the lumbar series are curved somewhat upward, the fifth, sixth and seventh are horizontal, and those of the remaining vertebræ directed more or less downward. The transverse processes of the sixth lumbar are the longest.

Caudal vertebræ.— The caudal vertebræ do not agree closely with those of other baleen whales. In the size, shape, and direction of the transverse processes, spines and zygapophyses, and in the appearance and disappearance of the foramina and processes, many differences are apparent.

The spines decrease gradually in height from the first to the eleventh caudal where they become lost. The zygapophyses of the anterior caudal vertebræ in their expanded, globular distal ends resemble those of the dorsal series, and disappear with the neural spines upon the eleventh vertebra. The spines and zygapophyses show a decidedly greater resemblance to *Megaptera* than to *Balænoptera*.

The transverse process of the first caudal is the widest in the entire vertebral column and is directed strongly downward. The transverse process of the fourth, fifth and sixth caudals arise from the posterior part of the centra and project outward and forward, their inner edges almost meeting the expanded outer margins of the anterior faces of the centra; in this way a partially

9

10

11

Fig. 9. Dorsal vertebræ of *Rhachianectes glaucus.*
Fig. 10. Lumbar " " "
Fig. 11. Caudal " " "

enclosed foramen is formed. On the right side of the sixth caudal this foramen is completely encircled [1] and the transverse process near the center is also perforated by a second vertical canal.

The antero-posterior diameter of the centrum of the first caudal is the greatest of the entire vertebral column and the anterior face is almost a perfect circle. Although the inferior median carina of the thirty-third vertebra is distinctly bifurcated posteriorly, the thirty-fourth is definitely indicated as the first caudal by the presence of the first pair of chevrons which have become firmly ankylosed to its centrum.

Beddard states that he counted in the British Museum specimen 14 lumbar vertebræ and 21 caudals, whereas both the American Museum and U. S. Nat. Mus. skeletons have 12 lumbars and 23 caudals. Since the total number of vertebræ, and also those of the dorsal series, are alike in the three specimens, I believe they will be found to possess a similar number of lumbar and caudal units. Unless the skeletons have been examined with the chevrons *in situ*, or there happens to be an ankylosis as in the case of our specimen, it is difficult to make an absolutely correct determination of the lumbar and caudal units. Although the inferior median carina is usually first distinctly bifurcated upon the first caudal, the division may sometimes occur upon the last lumbar and cannot, therefore, be taken as an infallible guide.

In the following table data as to the appearance and disappearance of the several processes and foramina in *Rhachianectes glaucus* is given. For convenience of reference similar data of other genera are placed in apposition.

CHEVRONS.

The American Museum skeleton has twelve chevrons and the National Museum ten; apparently two have been lost in the latter case and twelve would seem to be the normal number.

The first chevron in the American Museum series is firmly ankylosed to the centrum of the first caudal vertebra. It is 75 mm. in length, 118 mm. wide and free distally. The second chevron is 180 mm. long and 91 mm. wide, the laminæ uniting distally to form a long hæmal spine. The third chevron is the longest of the series, having a maximum length of 240 mm. and a width of 120 mm.

From the third backward, the chevrons increase rapidly in width and gradually decrease in length, the fifth being the widest of the series; its maximum width is 212 mm. The last two members of the series have their distal ends free.

RIBS.

The ribs of *Rhachianectes* are exceedingly interesting. The most important feature of their morphology is to be seen in the proximal ends of the third, fourth, fifth, sixth, and seventh, *on each of which a large tubercle, neck and head are developed.* The prominent tubercle, and the deep concavity between it and the head in all of these ribs gives them a shape very similar to those of the toothed whales and quite unlike any Mystacoceti.

In *Balænoptera* the second and third ribs usually have prominent tubercles and long necks while in the remainder of the series the necks and heads become atrophied, or lost. In *Rhachianectes* the necks and heads do not disappear until the *eighth rib* and up to this point are well developed and prominent. Thus the anterior half of the rib series is articulated to the vertebral column much more firmly than in other baleen whales, and presumably the thorax is capable of less lateral movement.

The proximal end of the first rib is thin and rounded but has a small, outwarding projecting tubercle (the head) near the lower edge. On the second rib this tubercle (the head) is more thoroughly developed, and on the third has become extended into a long neck and an expanded head which project outward at a right angle to the remainder of the rib. The tubercle is very prominent and has a large flattened articular fossa. On the fourth rib the neck is slightly shorter than that of the third and the angle it forms with the shaft is a little wider; its tubercle, however, is considerably larger than that of the third.

Fig. 13. Chevrons of *Rhachianectes glaucus*.

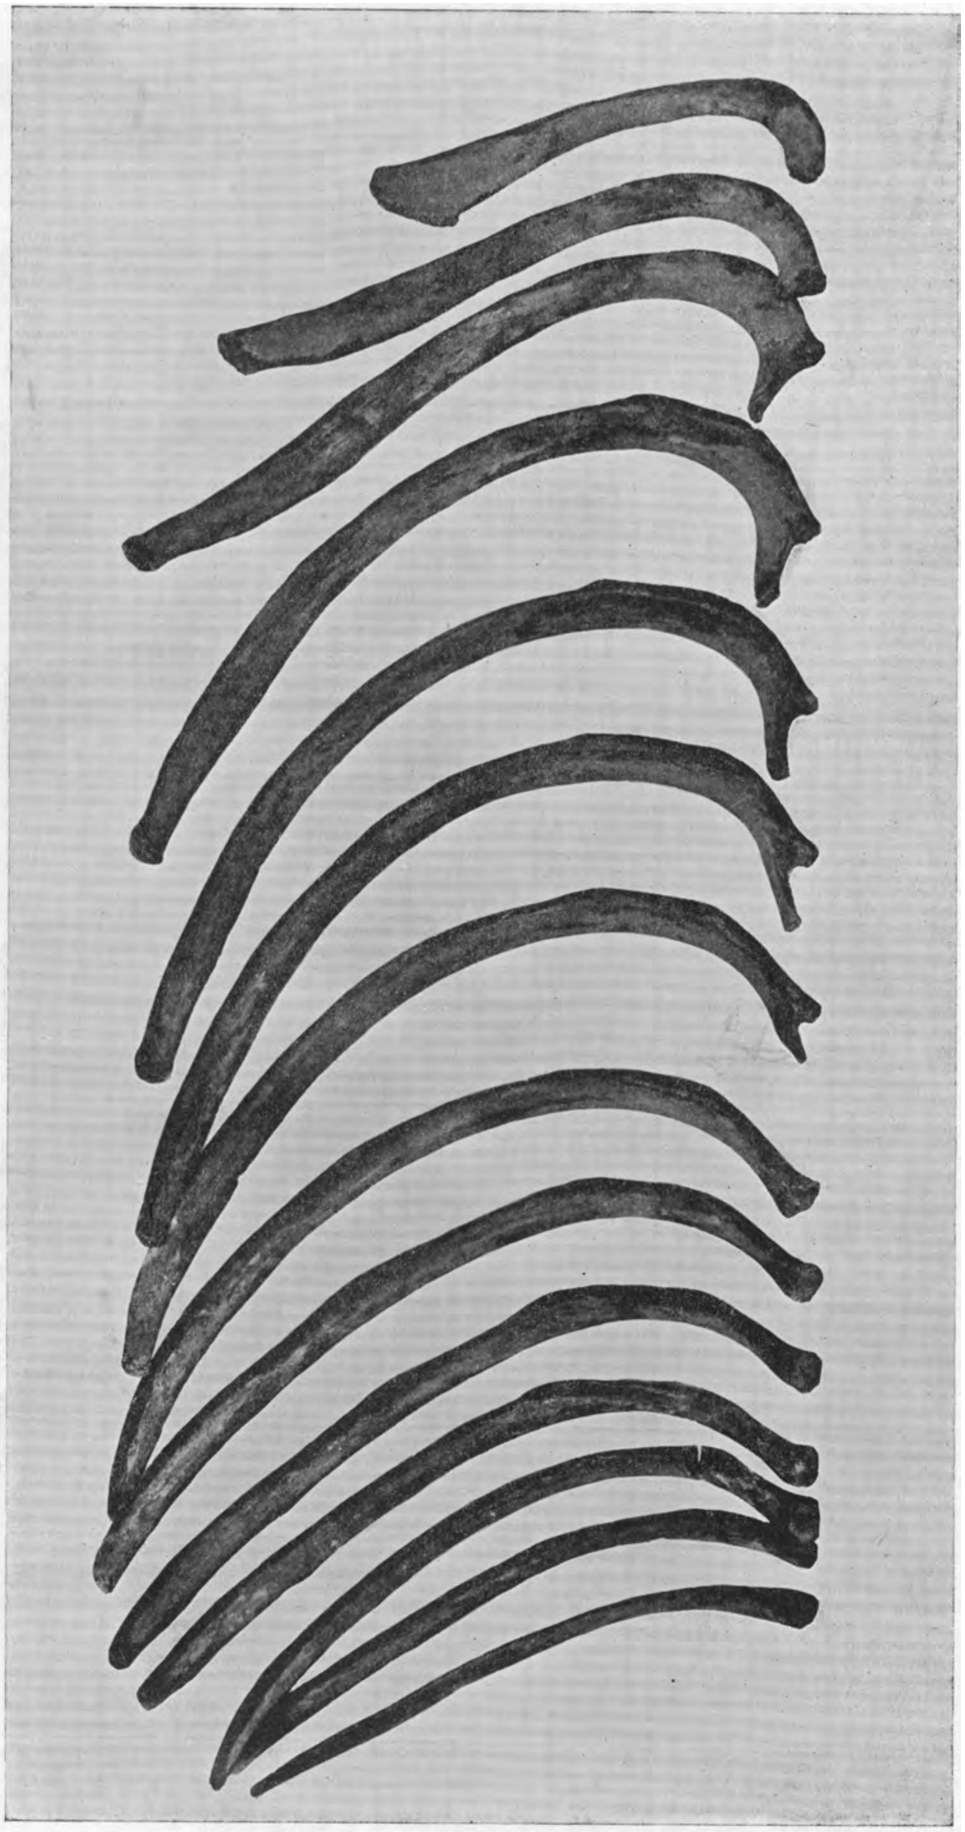

Fig. 14. Ribs of *Rhachianectes glaucus*.

The neck of the fifth rib is shorter and forms a wider angle with the shaft than does the fourth, but its tubercle is larger and more prominent and the concavity of the neck between it and the capitulum is deeper.

The neck of the sixth rib is similar to the fifth in length, size of tubercle and the angle with the shaft. That of the seventh is a little shorter than the sixth, the angle is somewhat wider and the tubercle a little larger.

Upon the eighth rib the neck and head disappear and are represented only by a small projection; the tubercle of the rib is greatly enlarged, however, and is separated from the process representing the neck by a well-marked concavity, which is present to a less extent upon all the succeeding ribs except the last two pairs.

The ribs are all long and massive, considerably exceeding in measurements those of the 40-foot *Megaptera* and the 50-foot *Balænoptera physalus* recorded by Struthers.[1]

The first is of uniform width in its proximal half but rapidly expands in the distal portion where it becomes the widest of the series; the fifth is the longest.

The ribs of the U. S. National Museum specimen differ in the important particulars that upon the first the portion representing the neck and head is considerably more produced than in the American Museum skeleton and that *the second rib bears a fully developed neck and head;* the distance from the tubercle to the end of the head of this rib is 225 mm.

Measurements of the ribs and of the capitular processes of the first eight pairs are given in the appended table:

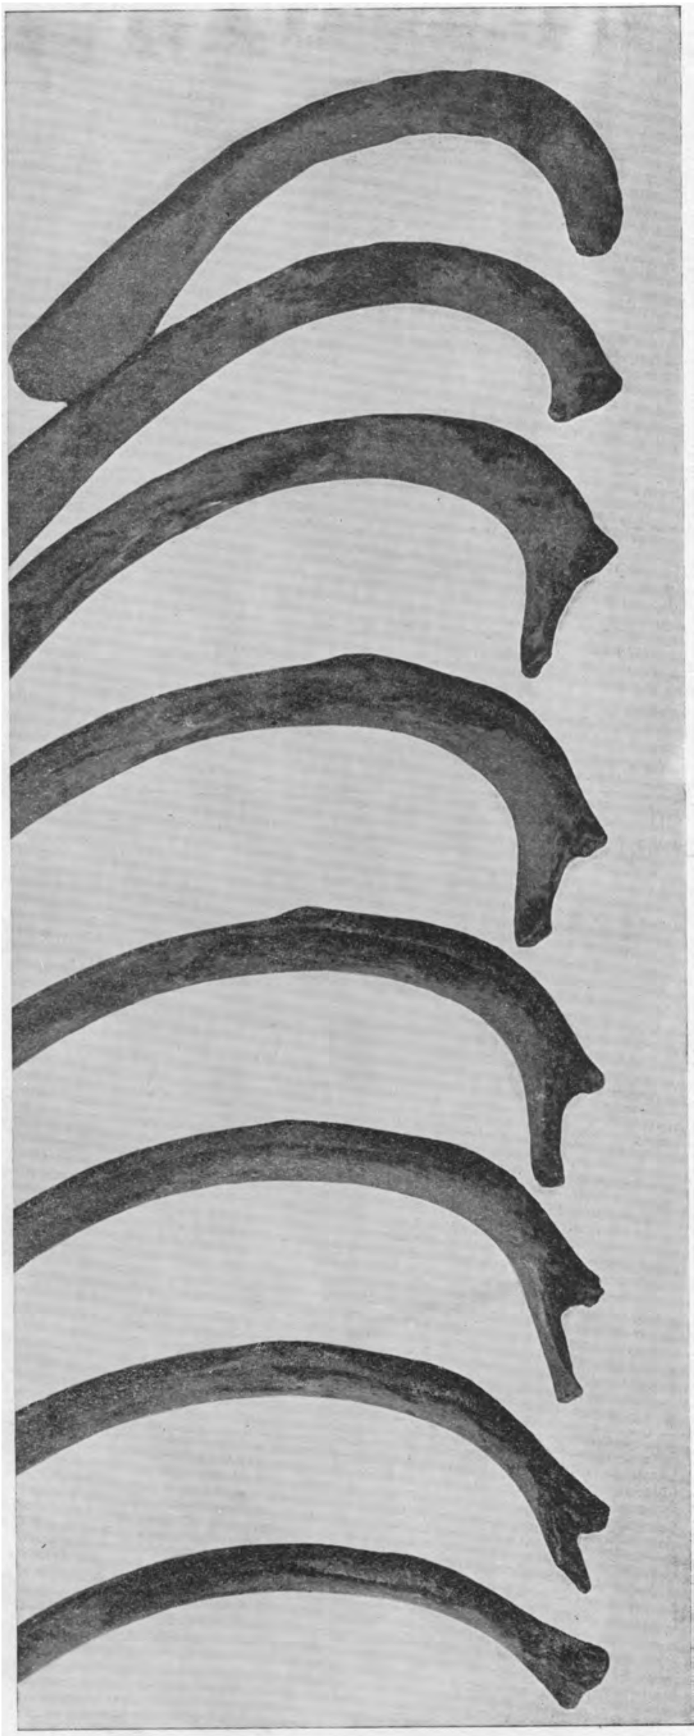

Fig. 15. Proximal portions of first eight ribs of *Rhachianectes glaucus.*

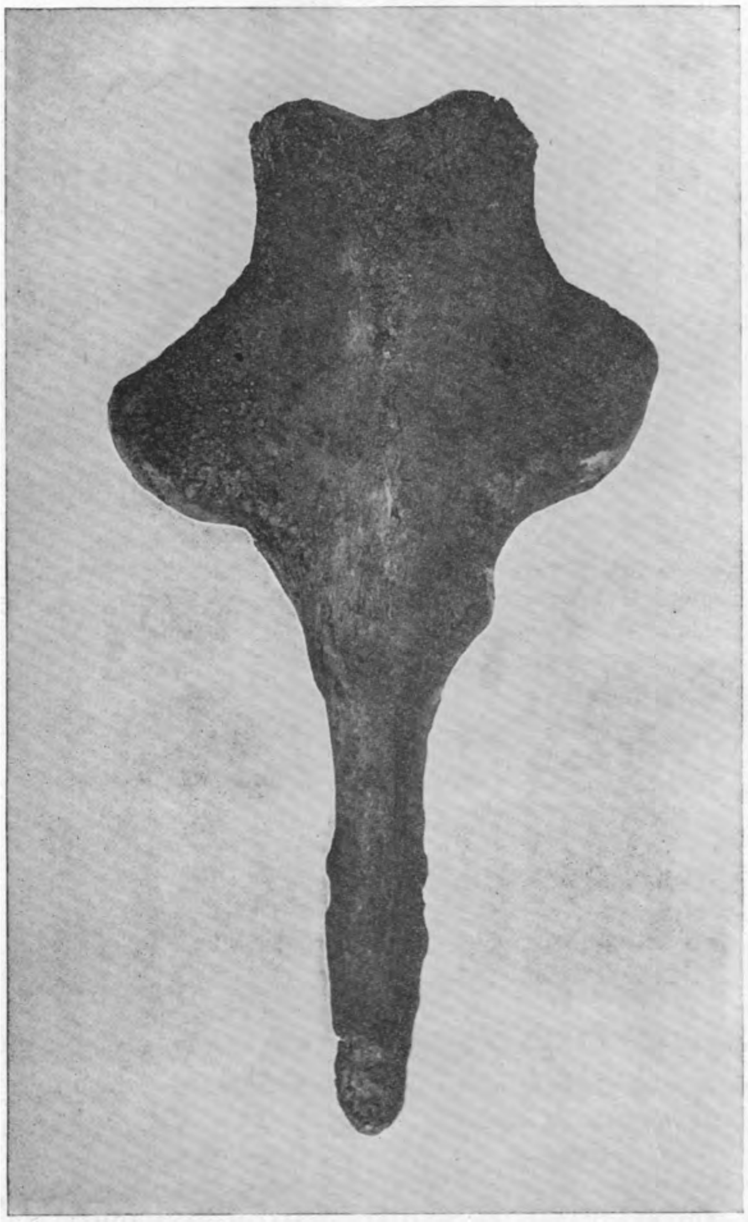

Fig. 16. Sternum of *Rhachianectes glaucus;* Am. Mus. skeleton.

Sternum.

The sternum belonging to the skeleton of *Rhachianectes* in the American Museum has the form of a Latin cross and closely resembles the corresponding bone of *Balænoptera acuto-rostrata.* The lateral arms of the cross are short and irregularly rounded and the summit of the superior portion is abruptly truncated and has a shallow concavity. The inferior prolongation of the sternum is irregularly cylindrical terminating in a blunt point, and is remarkable for its length. The entire sternum, but especially the anterior surface, is rugose and covered with small osseous tubercles which apparently are not due to exostosis but have been developed for tendon attachments.

The sternum of the United States National Museum specimen shows an extraordinary difference in shape from that described above and demonstrates the enormous individual variation to which such almost rudimentary bones are subject. The sternum is concave on the superior surface, has two rounded, wing-like lateral processes and terminates inferiorly in a short irregular spine.

---

Measurements of sternum.

	American Museum mm.	U. S. Nat. Museum mm.
Greatest height (vertical)	460	223
" breadth (across arms)	260	242
Length of lower process	276	165

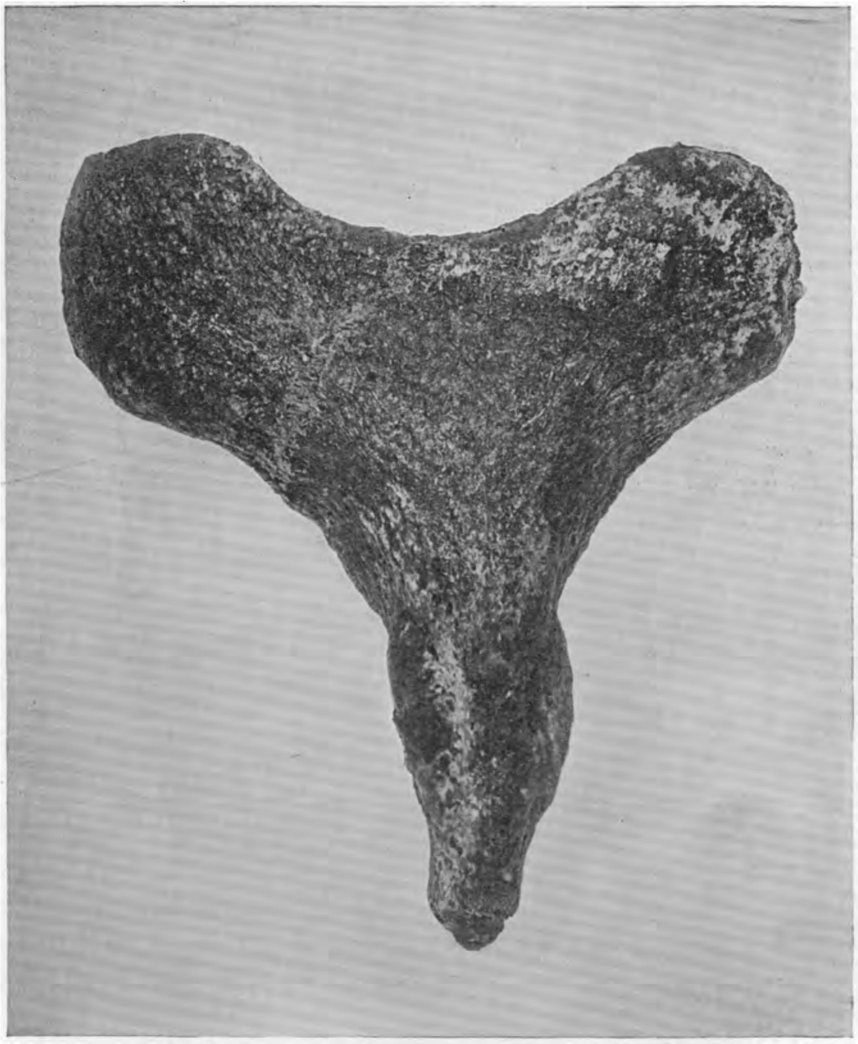

Fig. 17. Sternum of *Rhachianectes glaucus;* U. S. Nat. Mus. skeleton.

Pectoral Limb.

Scapula.— The scapula of *Rhachianectes* is distinctive being intermediate between the wide, low blade of *Balænoptera* and the high, narrower and more symmetrically fan-shaped scapula of *Eubalæna*. In the great height proportional to its width it approaches the latter genus while in the well developed coracoid and large acromion it resembles the former.

The superior margin is quite evenly convex, becoming slightly flattened posteriorly. The glenoid border is almost straight except for a short concavity where it rises from the glenoid fossa and neither it nor the coracoid border overhangs as strongly as in the scapulæ of *Balænoptera*.

The acromion is exceedingly wide throughout, expanded and irregularly rounded distally, and slightly curved.

The coracoid is thick and massive, turned sharply inward and directed somewhat upward from the margin of the glenoid fossa.

The external face of the scapula is quite strongly concave as in *Eubalæna*. It is much thicker and more massive than in *Balænoptera* but not as thick as that of a Right Whale.

Measurements of the scapula are given in Table IX.

Humerus. — The humerus is nearly straight, the superior edge is but slightly concave and the external tuberosity is prominent. In all of these characters the humerus differs from that of *Balæna, Eubalæna* and *Megaptera* and strongly resembles the fossil genus *Plesiocetus;* while in *Balænoptera* the head is almost directly upon the summit of the bone, the concavity of the sides gives the humerus quite a different appearance from that of *Rhachianectes.*

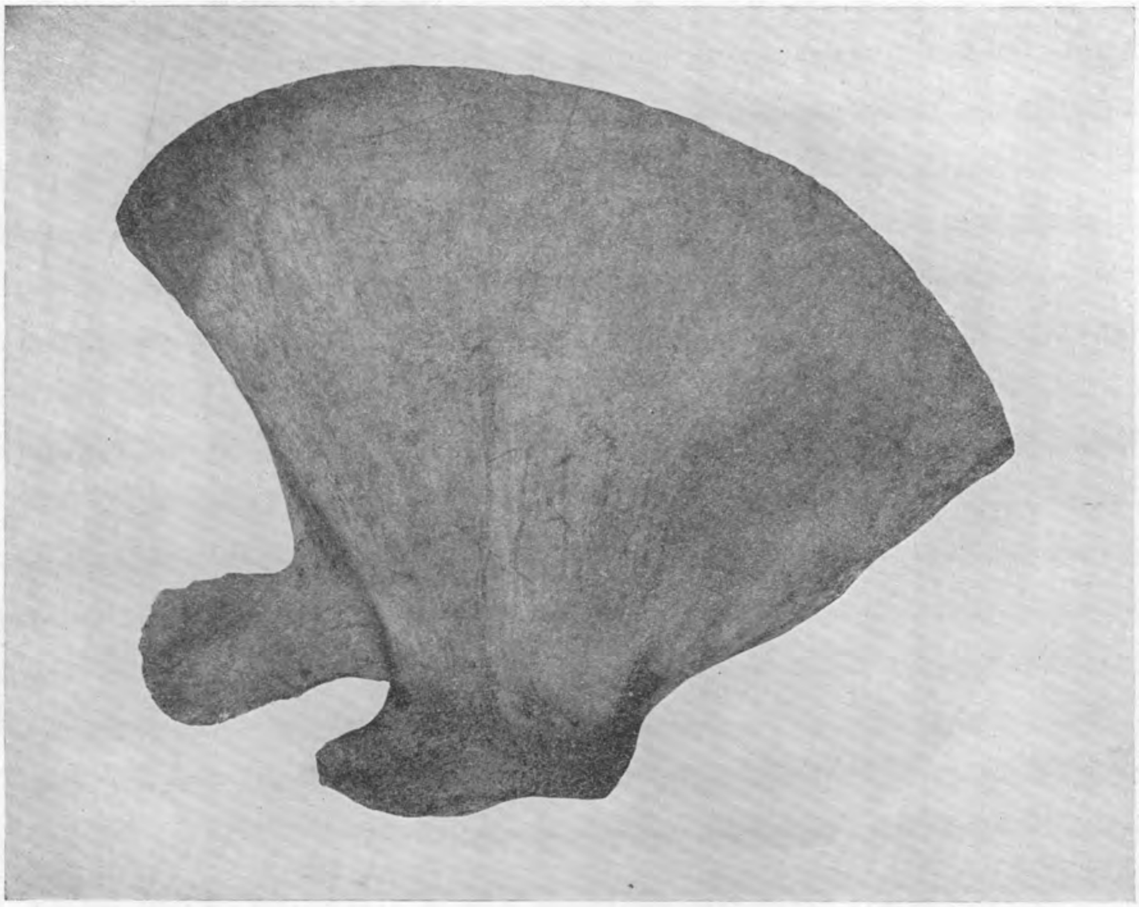

Fig. 18. Inner view of right scapula of *Rhachianectes glaucus;* Am. Mus. skeleton.

Radius.— The radius is remarkable for its width. The exterior edge for its proximal half is slightly convex and in the distal portion a little concave. The interior edge presents a shallow concavity due to the broadening of the bone at the carpal end. For the proximal half the radius is of almost uniform width but in the distal half rapidly expands.

Ulna.— The ulna has a nearly straight inner edge but a strongly concave outer margin due to the rapid broadening of the bone in the distal half. The olecranon process is prominent and projects upward.

The radius and ulna differ markedly from those of *Balæna*, *Eubalæna* and *Megaptera* but in general resemble *Balænoptera*. The broad radius is somewhat similar to that of *B. musculus* but the straight ulna is quite unlike the bone in that species. The radius and ulna of *B. physalus* and *B. borealis* are more slender, more curved and less expanded distally than in *Rhachianectes glaucus*.

Manus.— *Rhachianectes* has four digits in the manus. The phalangeal formulæ of the flippers of the U. S. National Museum specimen (which are more nearly perfect than are those of the American Museum skeleton) are as follows:

Fig. 19. Inner view of right scapula of *Rhachianectes glaucus,* photographed at Ulsan, Korea.

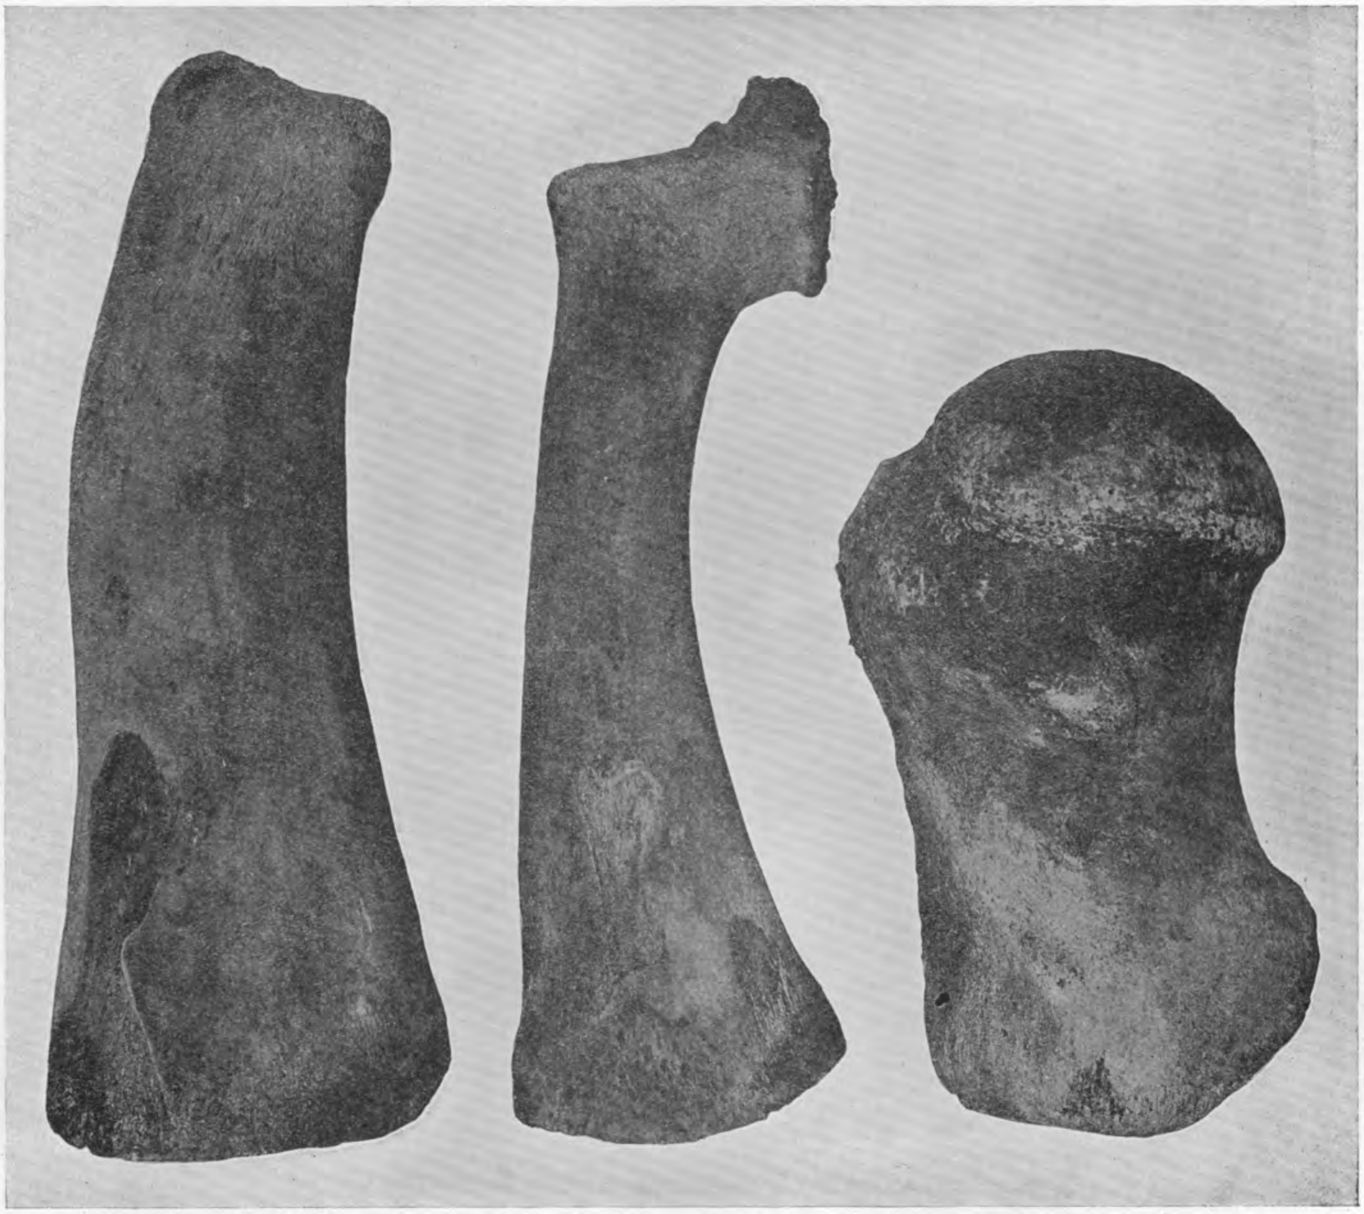

Fig. 20. Humerus, radius and ulna of *Rhachianectes glaucus;* Am. Mus. skeleton.

	II	III	IV	V
Right:	3	3	4	1
Left:	3	4	4	1

The terminal phalanx of the third digit of the left pectoral is a shell of bone and seems to be a normal phalanx which has been injured. This has all the appearance of bony tissue and not of hardened cartilage but it is not present in the right manus. Presumably the tips of both flippers were injured and the correct formulæ for the phalanges is that of the left. The terminal phalanx of the fourth digit of the right manus is also a bony shell but in the corresponding finger of the left hand it has a normal shape and size.

Pelvic Rudiments.

The pelvic elements of *Rhachianectes* are exceedingly interesting, the most remarkable features in comparison with other whales being their great size, the less reduction of the pubis and ischium, and the presence of a large foramen.

Those of the American Museum skeleton are two long, slightly curved bones of exactly the same length. The ilium is exceedingly massive, laterally compressed, and has a long dorsal and ventral ridge; a cross-section would be a wide ellipse. The ischium has the same length as the ilium but it is not as massive, is more compressed, and is deeply excavated at the distal end.

The pubis appears as a prominent, roughly cone-shaped tubercle, turned sharply downward and standing at right angles to the remainder of the bone instead of projecting directly outward as in other baleen whales.

Along the inner base of the pubis is a deep longitudinal concavity in the bottom of which, and slightly posterior to the pubis, is a large curved foramen which perforates the bone transversely, emerging on the dorsal surface almost opposite the point of entrance.

Although both the American and U. S. National Museum specimens from which the pelvic elements were secured were males, there is considerable variation in the size and shape of the bones in the two individuals. Those of the U. S. National Museum skeleton are shorter, due to a reduction of the iliac portion, wider through the pubis, slenderer throughout and more

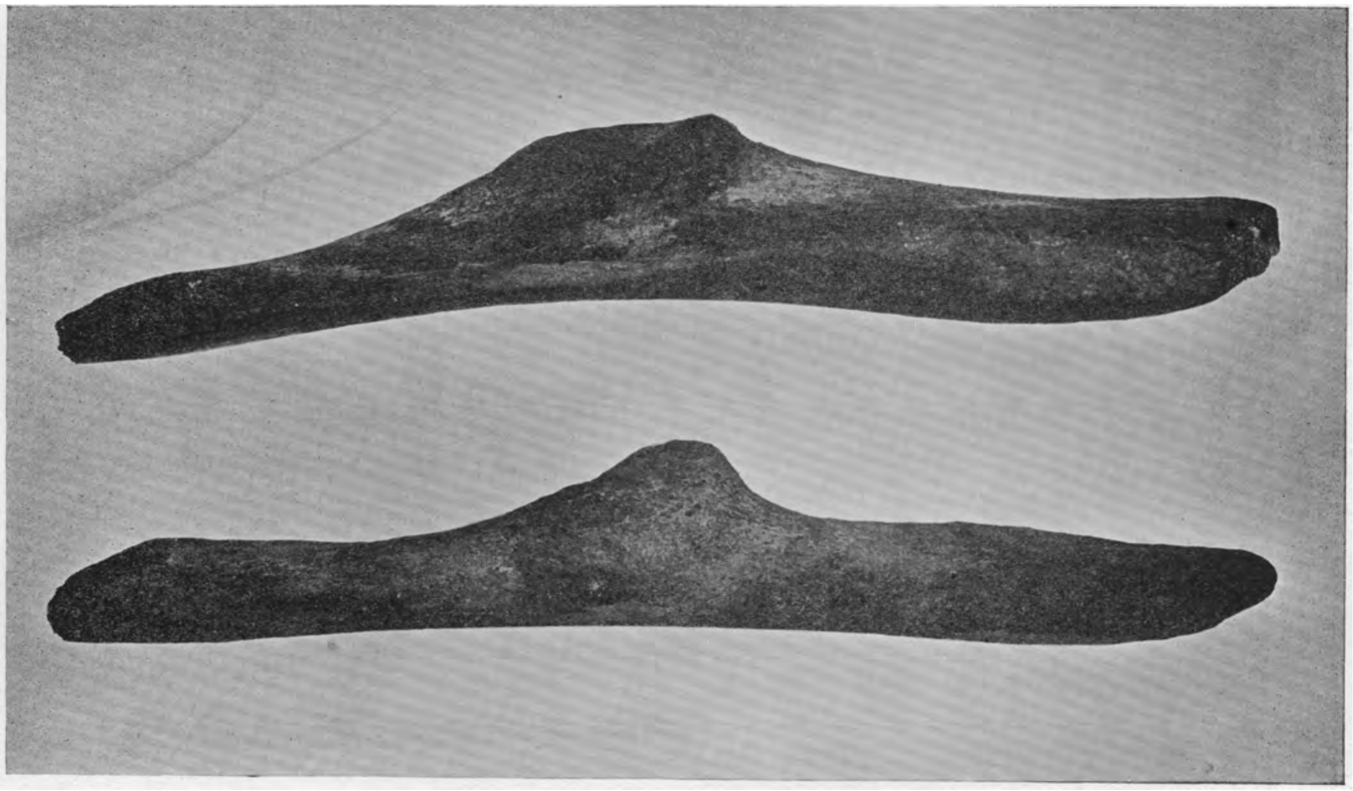

Fig. 21. Pelvic elements of *Rhachianectes glaucus;* Am. Mus. skeleton.

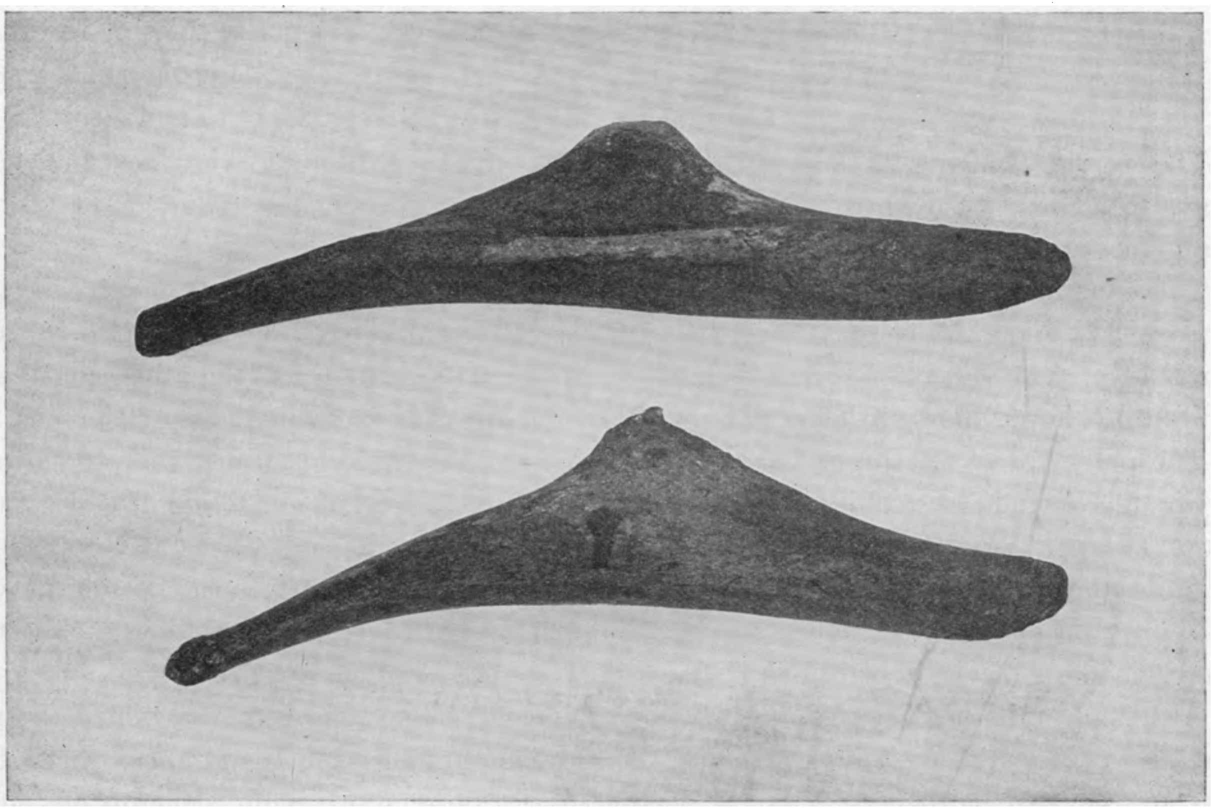

Fig. 22. Pelvic elements of *Rhachianectes glaucus;* U. S. Nat. Mus. skeleton.

curved. In both the ilium is considerably shorter than the ischium, the pubis is not turned as sharply downward as in the American Museum specimen, and the transverse foramen is larger; also there is no excavation of the distal end of the ischium.

The presence of a foramen perforating the pelvic rudiment has been recorded by Struthers in the case of *Balæna mysticetus* but it is rare in other Cetaceans.

It is to be regretted that it was not possible to make a careful examination of the flesh containing the pelvic elements to determine the condition of the femoral rudiments. I believe that *Rhachianectes* will be found to possess a femur larger than that of any other baleen whale when this subject has been more carefully investigated.

CONCLUSIONS.

Specific relationship of California and Korea specimens of Rhachianectes.

Descriptions and measurements of the external anatomy and post-cranial skeleton of California examples of *Rhachianectes* are so general and inaccurate that they furnish few reliable data for use in deciding the specific relationship of the specimens from opposite sides of the Pacific. A discussion of this question, therefore, must rest almost entirely upon the basis of skull characters.

A careful comparison with our Korea specimen of the figures, descriptions and measurements of the American skulls presented by True and Malm shows a remarkably close agreement in all essential points. Examination of the table of measurements shows the only difference worthy of note to be in the proportionately shorter rostrum of the California skull and its less squamosal breadth. Judging from the figures the former difference seems to be due to the fact that the slender prolongations which the maxillæ send backward toward the vertex of the skull are somewhat broken, thus reducing the rostral length. The proportional squamosal breadth of the California skull is somewhat less than in the one from Korea, but since the orbital widths are almost exactly the same, this cannot be considered as of great importance.

There is, so far as I can discover, not the slightest ground for believing the Gray Whales of the east and west Pacific to represent other than a single species. Whether or not the animals mingle in the north during their summer migration has been discussed in the section of this paper relating to habits and need not be again taken up here.

Systematic Position.

Review of former classifications.

1871.— J. E. Gray places *Rhachianectes* in the family Agaphelidæ.

1874.— Gill makes Agaphelidæ of Gray a subfamily under Balænopteridæ and divides that family into the three subfamilies Agaphelinæ, Balænopterinæ and Megapterinæ.

1891.— Flower and Lydekker combine all genera under the family Balænidæ without subfamily divisions.

1897–1904.— Trouessart gives two subfamilies, Balænopterinæ and Balæninæ, under the family Balænidæ and includes *Rhachianectes* in the former.

1900–1902.— Beddard considers *Rhachianectes* as an aberrant genus of the family Balænopteridæ.

1901–04–05.— Elliot recognizes two subfamilies of the Balænidæ and in the Balæninæ includes *Balæna*, *Rhachianectes* and *Megaptera*.

1904.— Max Weber recognizes three families, Rhachianectidæ, Balænidæ and Balænopteridæ.

1910.— Osborn, under the family Balænidæ, recognizes the three subfamilies Rhachianectinæ, Balæninæ and Balænopterinæ.

It will be seen from this brief review of the various classifications of the genus *Rhachianectes* that there has been little agreement as to its systematic position. This is partly due to the fact that up to the present time only the skull has been studied, the post-cranial skeleton never having been described. The results of my work upon this remarkable animal, presented in the preceding pages, lead me to believe that it cannot be included in either of the subfamilies of the Balænidæ and must take rank as a separate family. For this designation Weber's Rhachianectidæ is available and a definition of the family and genus may be formulated as follows:

Family *Rhachianectidæ.*— Skull with a broad strip of the frontals exposed upon the vertex. Maxillæ overlapping the anterior edges of the orbital processes of the frontals. Nasals very long and broad. Mandible without a coronoid process. Cervical vertebræ free. Manus consisting of four digits. Ribs of the anterior half of the series provided with tubercles, necks and heads. Furrows few and short.

Genus *Rhachianectes.*— Head less than one-fourth the length of the body. Baleen laminæ few, short, and thick. No dorsal fin. Pectoral limbs of medium width. Furrows only upon the throat. Rostrum of skull narrow and moderately arched. Premaxillæ sending broad, overlapping projections toward vertex of skull. Prominent rugosities upon the supraoccipital and basioccipital bones of the skull. Tympanic bullæ compressed and somewhat concave on internal border. Scapula having both acromion and coracoid processes.

Primitive Characters of Rhachianectes.

The external and internal anatomy of *Rhachianectes glaucus* presents certain characters which seem to demonstrate that this animal is more primitive than any other existing baleen whale. These may be summarized as follows:

1. Long hairs scattered over the entire head and mandible and not confined to certain regions as in other whales.

2. Baleen plates very short, thick, fewer in number and more widely spaced than in other whales.

3. Skull:

a. Exposure of a wide strip of the frontals upon the vertex of the skull.

b. Long nasal bones.

c. Comparatively small squamosals having straight outer edges. This is noticeably different from the concave squamosals of existing baleen whales and is a character of fossil genera.

d. Proximal ends of the premaxillæ very broad, superiorly placed, and articulate with the frontals by a deep, interdigitating suture.

e. Orbital processes of the frontals anteriorly overlapped by the edges of the maxillæ, posteriorly with irregular margins, and trumpet-shaped; all well marked characters of certain fossil baleen whales.

f. A well emphasized temporal ridge.

g. Prominent rugosities upon the supraoccipital, pterygoids, and basioccipital bones of the skull.

h. Compressed tympanic bullæ having concave internal borders.

4. Cervical vertebræ entirely free and showing no evidences of ankylosis between any members of the series.

5. Atlas and axis possessing massive, rugose neural arches; axis with comparatively small foramina through the wing-like transverse processes.

6. Ribs possessing tubercles, necks and heads as far back as the eighth, and in these portions resembling an Odontocete.

7. A long and straight humerus of the *Plesiocetus* type.

8. Very large pelvic elements, the presence of a large foramen in them and the comparatively slight reduction of the pubis and ischium.

RELATIONSHIP OF RHACHIANECTES.

Rhachianectes glaucus is apparently not closely related to any of the existing baleen whales but in some respects it stands intermediate between the Balæninæ and Balænopterinæ being nearer the latter. In many skull characters it approaches closely the Pliocene whales of the genus *Plesiocetus* which is allied to the existing Balænopterinæ; in fact, were it not for its specialized mandible it must certainly be considered as nearly related to them. The fossil whales of the *Pleisiocetus* group possessed mandibles having the proximal portion of each ramus, internally, widely concave and leading into a large dental canal; in short, much as in the mandibles of the existing toothed whales. *Rhachianectes*, however, although resembling *Plesiocetus* in many important skull characters, possesses a specialized mandible similar to that of the Right Whales; that is the proximal portion, internally, is not concave and the dental canal is small. This type of mandible prevents the phylogenist from taking *Rhachianectes* off from the *Plesiocetus* group, unless he wishes to consider that while persisting until the present day with comparatively little modification of its primitive skull characters, it has undergone considerable specialization of the mandible alone. This is a perfectly possible supposition, which I am inclined to believe is true, since *Rhachianectes* shows such marked affinities to *Plesiocetus* and is so strongly separated from the other known genera of fossil and recent whales. It is, upon the whole, one of the most remarkable of existing Cetaceans and might be called a "living fossil."

RHACHIANECTES GLAUCUS.

Grey Whales in the East Sea Area of Korea

BY

KAZUHIRO MIZUE

Introduction

Rhachianebtes goaucus is classified into a Suborder Mystacoceti but it is quite a different species from Balaenidae or Balaenopterynae. Apart from them, it forms a family Rhachianectes by itself. Due to its resemblance to the fossil whales of the Pleisiocetus group in the shape of the skull it is often called a "living fossil".

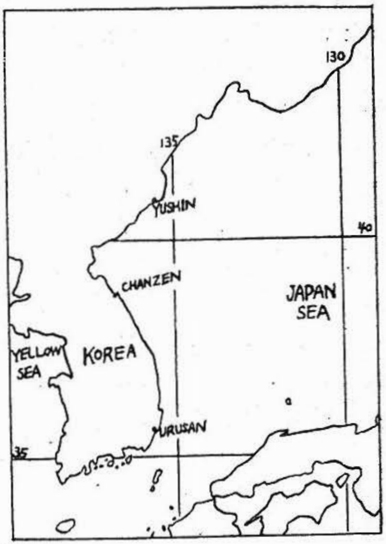

Fig. 1.

Whales of this species were captured so abundantly off the coast of California once that they are still called Californian grey whales. But the catch there began to decrease rapidly towards the middle of the 19th century. It is reported, however, they are on the increase in the recent years. Besides California, a considerable catch of grey whales was made in the East sea area of Korea, but their stock has completely been exhausted at present. Roy C. Andrews made a detailed study of grey whales at Urusan, the landstation in the East sea area of Korea during the season 1909-1910, which will be found in the Memoirs of the American Museum of Natural History-V. We shall here make some study of the same subject statistically based on the data after 1910.

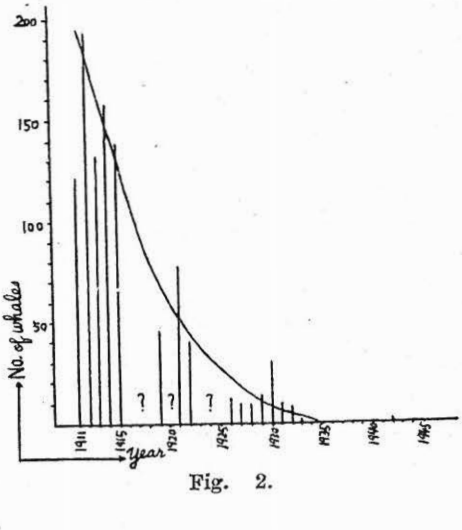

Fig. 2.

Number of the Catch

Fig. 2 shows a number curve of the catches of grey whales in our adjacent waters according to the years. It is based on the data from 1910 up to the present. In spite of the lack of the data of some years, the curve gives a clear idea of the rapid decrease of the catch. It is not before 1903 that Norwegian Whaling was adopted in the East sea area of Korea for the first time, and in thirty years, almost the last grey whale was hunted up there. The fact will indicate that the stock of grey whales in our adjacent waters was but a small one existing, as it were, independently, having no intercourse with the stocks of other waters.

At the middle of the 19th century when grey whales along the coast of California were feared to have gone to exhaustion, in the East sea area of Korea the stock was still kept intact, which began to decrease after 1903; during the fifteen years from 1934 up to the present not a single grey whale was captured there. Meanwhile, along the Californian coast, it is reported, grey whales are on the increase. It apparently proves the fact that there is no intercourse between the two stocks of grey whales on the east and the west sides of the Pacific.

No catch of Grey Whales has been made off the eastern coast of Korea since 1933. Of the thirty years' whaling history there, the records of the seven years, —1911, 1914, 1919, 1921, 1922, 1926, and 1932— are completely preserved in the monthly reports of the various whaling companies forwarded to the Japanese Whaling Society. Based on the data we shall here make some reports of the grey whales in this place.

Table 1.

Sea-area.	%	Whaling season
Kurile-Islands	0.2	August
Hokkaido-Okhotsk	0.2	May
Hokkaido-Pacific	0.2	July
Sanriku	0.7	October
Kinan	0.0	
Bonin-Islands	0.0	
Goto-Tsushima	4.2	December
West of Korea	0.4	May
East of Korea	94.2	November-May
Japan-Sea	0.0	
Formosa-Ryukyu	0.0	

Sea-Area is divided by location of the land-station

In Table 1 are shown percentages of the yearly catches in the seven years according to the sea areas; the division of the sea areas is based on the sites of the landstations. The whaling ground of gray whales in the Goto-Tsushima sea area actually belong to the east sea area of Korea. So 98% of the catch of grey whales are made off the eastern coast of Korea. Grey whales in our adjacent waters are different from other baleen whales in point of the distribution; they have seldom been captured in the ground belonging to the Pacific. Besiees the East sea area of Korea, three were caught at Ayukawa of the Sanriku sea area and one off Nemuro, Hokkaido in 1914, two in the northern part of the Yellow Sea in 1922, one off Sakhalin in 1826 and one off Otomae, the North Kurile Islands in 1942. The number is so small compared with that of the catch made in the East sea area of Korea that they may be regarded as exceptional. However, these eight grey whales were all caught in the waters north of 38°N.

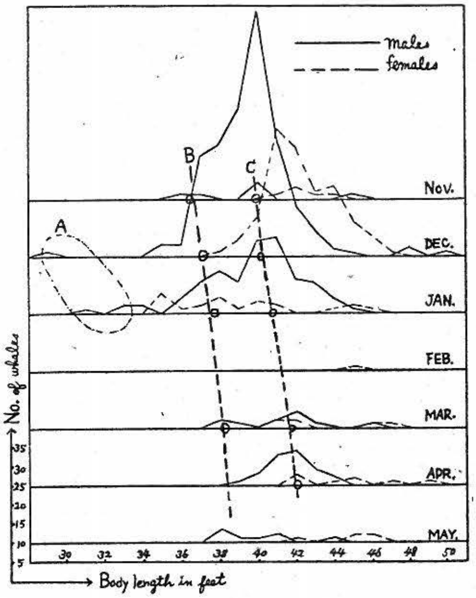

Fig. 3

In spite of the yearly decrease of the number, body-length frequency curves of the grey whales according to the years follow the same pattern every year rising into peaks in almost the similar months. Fig. 3 shows body-length frequency curves of the whale catch according to the months. Here monthly variations in number are noticable, and in the case of male grey whales, the peaks in the curves apparently move from the left to the right according to the months, showing the process of their growth. (As for the females, due to the scantiness of the number, the phenomenon is hardly discernible) A-group in Fig. 3 is composed of one-year-old male animals, B-and C-groups of two-years-old and three-years-old ones respectively. According to R. C. Andrews the period of delivery of grey whales lasts from the end of December to the beginning of January next year, and their body-length at birth is 14 feet, which gains no less than 18 feet during the first year after the birth. Seeing the growth speed of grey whales, like any other species, is extremely high in the first year, it is quite assumable that the young whale born during the previous winter, is some 30 feet long when it appears in the Korean waters the next season. The body-length of grey whales at birth, as it is calculated from my data is 15 to 16 feet.

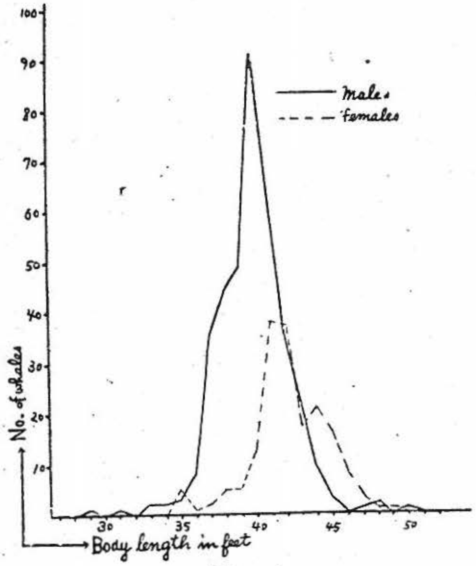

Fig. 4

Fig. 4 presents body length frequency curves of the whale catch according to the sexes. In the case of male grey whales the curve rises into a peak at 40 feet while in females a peak forms at 41 to 42 feet and again at 44 feet. According to Figs. 3 and 4 female grey whales, like any other species of baleen whales, are larger in size than males.

Table 2

	November			December			January			February			March			April			May			Total		
	♂	♀	to.	♂	♀	to.	♂	♀	to.	♂	♀	to.	♂	♀	to.	♂	♀	to.	♂	♀	to.	♂	♀	to.

In Table 2 are shown average body lengths and sex ratios of the whole catch according to the months. There is two feet's variation between the body lengths of the two sexes, and the maximun body length of the males is 50 feet and that of the females 49 feet, while the minimum body length is 29 feet for the males and 35 feet for the females. In Table 3 you will find these particulars of the body length of grey whales compared with the measuring values calculated by other writers in the past.

Table 3

	Average for all Specimens of both sex		Average for all females		Average for all males		Max. of female	Max. of males	Min. of females	Min. of males

Table 4

Month	%
November	2.4
December	63.1
January	21.8
February	0.8
March	3.1
April	6.8
May	2.4

Table 4 presents the percentages of the monthly catches shown in Table 2. According to it the catch of December forms the highest percentage of 63.1 and then comes the 21.8% of January. The catches of the other months cannot be compared with those of the above two months. When we divide the catches of both December and November into decades, it will be found that there is a small variation between the whaling seasons of the two sexes and that the best season for both males and females is from the middle of December towards the end, and the next best is either the beginning of January or that of December.

Total	0	12	57	130	158	88	30	2	0

Localities of the Catch

As has already been made clear by tables and figures, grey whales are quite regular in their appearance in the east sea area of Korea. According to Table 5, males begin to arrive there at the end of November, increase in number till they reach the greatest number at the end of December, which declines towards the middle of January. After that, male grey whales are no longer seen in this sea area. As for females, they begin to appear at the end of November, reach the greatest number at the middle of December towards the end and decrease in number till they leave the place for the north at the middle of January. Thus grey whales stay for only two months in this sea area; the place is also a good whaling ground for Fin Whales and many catcher-boats work during the season,—from September to March next year. They would have certainly caught grey whales if they had seen them in the months of October, November, February and March. The localities of the catch of grey whales, compared with those of fin whales, are quite near the coast. Their chief grounds are found within 10 sea-knots from the shore.

Grey whales come to the east sea area of Korea for the purpose of delivery as was already pointed out by R. C. Andrews. Female animals captured before the middle of December, are, with almost no exception, with big foetuses immediately before birth. It is quite assumable that delivery is made among the islands at the southern extremity of the Korean Peninsula. Pregnant whales hasten to the place of delivery by themselves, and a little later, herds of grey whales appear in this sea area. In the case of sperm ahales, many females led by one strong male, from so-called "Harem". The contrary is true of grey whales; in their case, the leader is a female and many males follow her. The fact will be made clear by a survey of the sex ratio of the catch. Mr. Andrews writes in his book, "One or two females lead ten to fifteen males." By this he must have meant the pairing migration, for the waters at the southern extremity of the Korean Peninsula present a place of pairing for grey whale as well.

After delivery, female animals accompanied by cubs and apart from the herd, go up north on their nursing migration.

According to Cap. H. G. Melson, the two female Grey Whales captured off Chanzen (39° N.) at the middle of March, 1912 are found with foetuses of seven and ten inches respectively,—both are two months and half after fecundation,

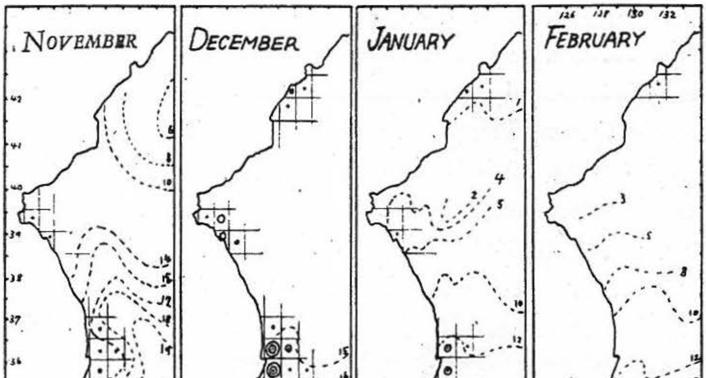

Fig. 5

From this and other data the pairing season of grey whales is assumed to be at the beginning of January. According to Mr. Scammon, the five female whales with small foetuses captured along the coast of California (31°-37° N) in up-season, had thick blubber contrary to the animals nursing cubs. It is not supposable that female grey whales copulate while nursing. So their delivery may happen, in the most favorable condition, every other year.

Grey whales in down-season do not seem to hunt for food, for the animals captured then have no food in their stomach but green colored gastic juice. In up-season, after delivery or pairing, they begin to search for food. Grey whales caught off Yushin, North Korea in up-season-from March to May, are sure to be found with Crustacea in their stomach. According to Mr. Tago, Nephrops thomsonii, small sized Crustacea, was found in the stomach contents of the two grey whales caught in the nothern waters of the Yellow-Sea in May, 1922.

Fig. 5 shows the localities of catch according to the months based on the data of the seven years. At the end of November a small number of grey whales appear both off Urusan and Chanzen. In December, catches are made in three places, the best ground being off Urusan. The animals start on their northwards migration in January and the catch off Urusan decreases. It is interesting to notice that no grey whale is caught in the month of February, except one at Yushin in the north. The fact may indicate that grey whales go up north through the distant offing during that month. In March catches begin to be made in the northern part of this sea area. Either in April or May the catch there forms a comparatively large percentage of the whole catch. These grey whales captured in the northern part, are assumably stray or belated animals from the main herd. Generally spreaking, grey whales on their southwards migration get up speed, but slacken it when they go up north.

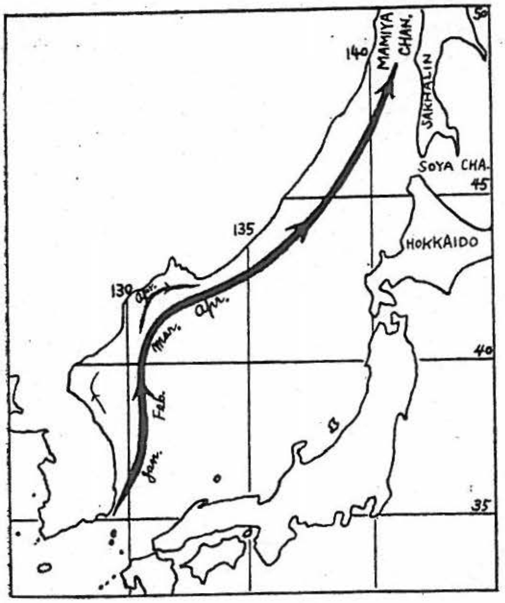

Fig. 6

The general routes of the migration of grey whales off the eastern coast of Korea, based on the various data at our disposal, is shown in Figs. 6 and 7.

From the above two figures, we

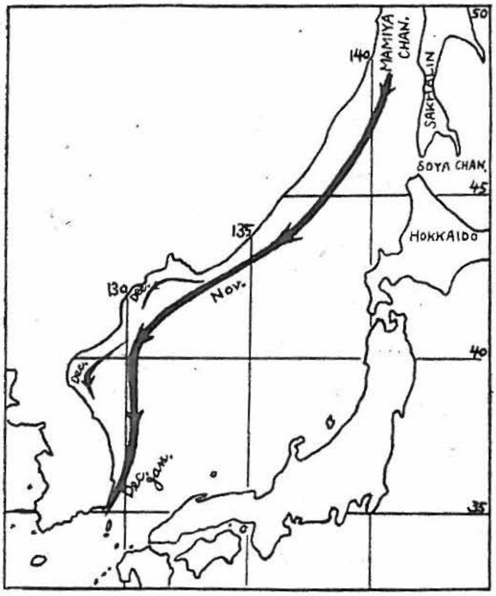

Fig. 7

can assume the movement of grey whales in the east sea area of Korea. As for there where about after then, it is reported by Mr. Tago that they reach Hokkaido or the western coast of Sakhalin in May or June and then through the Mamiya Channal go to the northern part of the sea of Okhotsk, where they seem to spend their summer. On their southwards migration they seem to take the same course as they come up north. It is not probable that grey whales pass through the Soya Channal to the farther north, for fin and hump-back whales are captured there from the landstation in Hokkaido but not grey whales. Nor is it assumable that they go between the Kurile Islands to the North Pacific and further to the Bering Sea, for the North Kurile Islands have many landstations from where both male sperm whales and fin whales were caught abundantly but no grey whale has ever been captured since 1919. (Though one was captured off Otomae, a landstation of the North Kurile Islands, in August, 1942, it ought to be regarded as exceptional.)

According to Mr. Scammon (1874), grey whales in the American side of the Pacific go down as far as 20° N. but in the Asian side they go no farther than 34° N. Nor will they go to the water whose temperature rises higher than 20°C. The right temperature of water for both delivery and pairing of grey whales is assumed to be 15°—20°C. In Fig. 5 the dotted lines show the distribution of the annual mean temperature of the surface water in the East sea area of Korea.

History of Gray Whales in Japan

Hideo Omura

Introduction

The occurrence of gray whales in the coastal waters of Japan prior to the turn of the century was described by Omura (1974). He referred to a population occurring in the south of Wakayama and Kochi prefectures and very briefly to the presence of another population occurring off the north coast of Yamaguchi prefecture, in the Sea of Japan, and off the west coast of Kyushu, in the East China Sea. Catches were made from both populations in the days of net whaling (1675–1890).

The Wakayama/Kochi population is thought to have followed a migration route along the east coast of Japan (Nishiwaki and Kasuya, 1970; Omura, 1974). The Yamaguchi/Kyushu population is thought to have been a portion of the Korean stock. This stock migrated down the east coast of Korea in winter. The majority turned west along the south coast of Korea (Andrews, 1914) but a fraction is assumed to have continued southward until they reached the north coast of Yamaguchi prefecture (near Kayoi, a present Nagato city) and then to have turned along the west coast of Kyushu.

Subfossil mandibles excavated some years ago from the city of Ichikawa were recently identified as belonging to a gray whale. This further supports the contention that this species occurred in coastal waters of Japan.

Brief History of Old Whaling in Japan

Whaling off Japan appears to have a very long history. A poem describing the catching of whales by a small boat is dated prior to the tenth century. Nothing is known, however, about the method and gear used or about the species of whales taken.

In the years of Genki (1570–1573), whaling in Mikawa and Qwari districts (now Aichi prefecture) facing Ise Bay was conducted by villagers who formed teams of 7–8 vessels and used hand harpoons (Otsuki, 1808; Fukumoto, 1960; Hashiura, 1969; Nagasaki, 1981). It can be assumed this whaling began as bay whaling and its center was Morosaki (see Fig. 7). Nothing is known about the species of whales taken, but there is a possibility that gray whales were the target. In the Edo era (1603–1867), gray whales en route to the Seto Inland Sea were thought to enter Ise Bay, passing sufficiently close to shore to become accessible to fishermen.

In years of the Bunroku (1592–1595), a skilled harpooner from Morosaki named Sukebei Mase came to Misaki (now in Kanagawa prefecture) and began whaling (Hashiura, 1969). The species of whales taken are not known, but a considerable number of whales was taken and local fishermen were stimulated to begin whaling with the same technique. It was reported this period did not last more than 20 years, because of a scarcity of whales.

There are grounds to believe that the harpoon method of whaling was transferred to Katsuyama, the village opposite Misaki across Tokyo Bay in Chiba prefecture. According to Yoshihara (1976a), new whaling started there in the years of the Keicho (1596–1603). This was the origin of the small cetacean whaling now in operation in Chiba prefecture, which takes mainly Baird's beaked whales (*Berardius bairdii*) and some other small toothed whales but no gray whales. Hand harpoons, and after 1907 small harpoon guns, were used for killing whales. Nets were not used at all in this fishery, contrary to the practice in other whaling sites in western Japan. The whaling grounds were later shifted to the east coast of Chiba prefecture.

Hand-harpoon whaling originated in Morosaki and spread to the south along the coast of Ise and Kumano districts (present Mie and Wakayama prefecture). In the eleventh year of Keicho (1606), Yorimoto, head of the then powerful Wada clan, established five whaling groups at Taiji, Kumano. He took command of the operation in the Taiji area, consulting with two fishermen, Denji from Morosaki and Jiemon from Sakai near Osaka (Hashiura, 1969). It is thought Denji, possibly a harpooner, assisted Yorimoto with the technical aspects and that Jiemon handled the commercial aspects of whaling. In 1618 a skillful harpooner named Yoheiji, from Onoura, near Morosaki, was employed at Taiji and given the name of Hazashi (chief harpooner), showing superior status to that of any other whaling crew.

In 1675, Yoriharu Wada, a grandson of Yorimoto later renamed Kakuemon Taiji, invented a new method of whaling using nets. Whales trapped and entangled by many folds of nets were easily harpooned. Straw nets were used at first, but they were too weak and were replaced in following years by hemp.

The use of nets was a revolutionary event in the history of whaling in Japan, allowing takes of humpback whales, other balaenopterid whales, and right whales, none of which could have been taken by hand harpoon previously. This method, however, required more fishing boats, more manpower, and a coordinated cooperative operation. At Taiji, five whaling groups were reorganized into one and Yoriharu Wada took the command.

The basic organization of the net-whaling fleet consisted of the following groups:

1. Seko-bune or beater boats (for driving and killing whales), one group of about 15–20 boats, 13 m long and 2.3 m wide, with eight oars. The crew of each boat consisted of 15 men, namely 1 captain, 13 sailors, and 1 apprentice.
2. Ami-bune or netting boats, one group of 6 boats, 13 m long and 3.5 m wide, with eight oars and a crew of 10 men.
3. Mosso-bune or tug boats, a group of 4 boats, nearly the same as beater boats but with a broader beam, and a crew of 1 captain and 12 sailors.

From a hillside hut commanding a wide view, watchmen scanned the sea surface for whale blows. When a whale was sighted within range, the watchmen sent signals with flags or rockets informing the boat crews of the species, position, and swimming direction of the whale. The boats described above waited in scattered positions and moved into action in an orderly fashion when the commander gave the order.

The beater boats surrounded the whale from a distance and drove it toward the netting boats which moved into proper position to set their nets. Nets were sometimes set two or three deep to prevent the whale's escape and to reduce its struggle. The netted whale was harpooned from the beater boats. When the whale was sufficiently weakened by a number of harpoons, a sailor jumped into the water and climbed onto the head of the whale with his knife to make a hole on the septum of the blowholes through which a rope was passed. Another hole was made in a similar way near the dorsal hump. In both cases the sailor stayed on the slippery surface of the whale body by grasping the handle of a struck harpoon. These harpoons also prevented the nets from slipping off.

The invention of net whaling was a major event in the economy of Japanese fishing villages. Whaling supported many hundreds of people, including workers processing the whale carcass, making nets, or engaged in other related activities, as well as sailors at sea.

Net whaling was soon introduced at Koza, a town close to Taiji, and at other places in Kumano district (part of the present Mie and Wakayama prefectures). In 1683 this method was transferred to Tosa (in the present Kochi prefecture), where the two whaling groups of Ukitsu and Tsuro were already in operation. In the following year a whaling boss named Gidayu Fukazawa from Omura, west Kyushu, came to Taiji and learned this method from Yoriharu (Hashiura, 1969). When Fukazawa returned to Kyushu, net whaling soon spread over the west coast of Kyushu and the north coast of Yamaguchi prefecture.

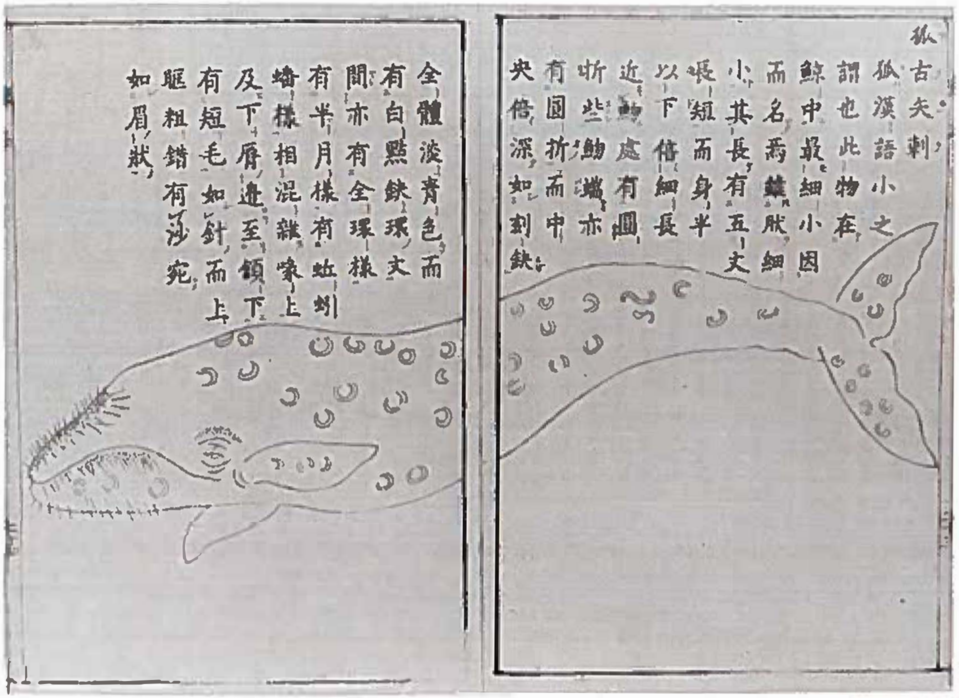
Descriptions of Gray Whales in Old Literature

Old Japanese whaling flourished in the Edo or Tokugawa era (1603–1867). Several books and picture scrolls of whales and whaling published during this period are useful because they contain such information on the whales migrating to Japanese waters as their species composition, migratory pattern, and catch statistics.

"Geishi" (the Treatise of the Whale), written in 1758 and printed in 1760 by Jiemon Kandoriya, the castellany of Wakayama, is the earliest printed monograph of the cetacea of Japan. It contains a drawing and brief description of the gray whale (Fig. 1), named Kokujira from *ko* meaning small and *kujira* meaning whale. The gray whale was so called because it was thought to be the smallest species among whales. There is evidence to suggest that at that time the minke whale was not identified as an independent species of baleen whale.

Kokujira had no dorsal fin but was illustrated as having several knobs in the posterior portion of the back. On both upper and lower jaws there were many hairs that spread over the entire head. This agrees with the description by Andrews (1914) who states "they (hairs) are more widely and more uniformly spread over the entire head, than in any other baleen whales."

The body color of Kokujira is described as pale blue, and there are many circular or



孤

古失刺孤漢語小之謂也此物在鯨中最細小因而名焉[illegible]狀細小其長有五丈喉短而身半以下倍細長近[illegible]處有圓[illegible]些[illegible]亦有圓折而中央倍深如刺鈌

Fig. 1. *Kokujira in Geishi, 1760 (from Hawley, 1958)*

various stages of semicircular markings on the body surface. These are thought to be scars left by detached barnacles (*Cryptolepas* sp.). These barnacles embed themselves deeply in all parts of the body as well as the flukes and pectoral fins. When a barnacle detaches, it creates a circular grayish wound which in time becomes white as it heals (Andrews, 1914).

Another drawing of Kokujira (Fig. 2) appears in a scroll appended to "A History of Whaling at Taijiura, Kumano," by the Committee for the Compilation of the History of Whaling at Taijiura (Hashiura, 1969). It is assumed this scroll was made during the early years of Kambun (1661–1673), 100 years before "Geishi" was printed. These two drawings are quite similar, except for the shape of markings on the surface which is shown as pale blue in color. In both there are needle-like white hairs approximately 6 cm long. In the second (Fig. 2), barnacles and lice are shown attached to the body. The positions of blowholes, eye, ear hole, mouth, flippers, navel, genital aperture, anus, and tail flukes are all correctly indicated by arrows.

Kiyonori Otsuki (1773–1850), a famous scholar in the Tokugawa era, left an undated manuscript on whales and whaling entitled "Geishiko (A Draft of a History of the Whale)." It was written perhaps in 1808, but remained unpublished until 1925 when it was printed in a series of various collections in Sendai. In March, 1951 this book was reprinted by the Japan Whaling Association. It is by far the most systematic survey of whales and whaling written in the Tokugawa period (Hawley, 1958).

The author of the "Geishiko" refers to various books on whales and whaling which

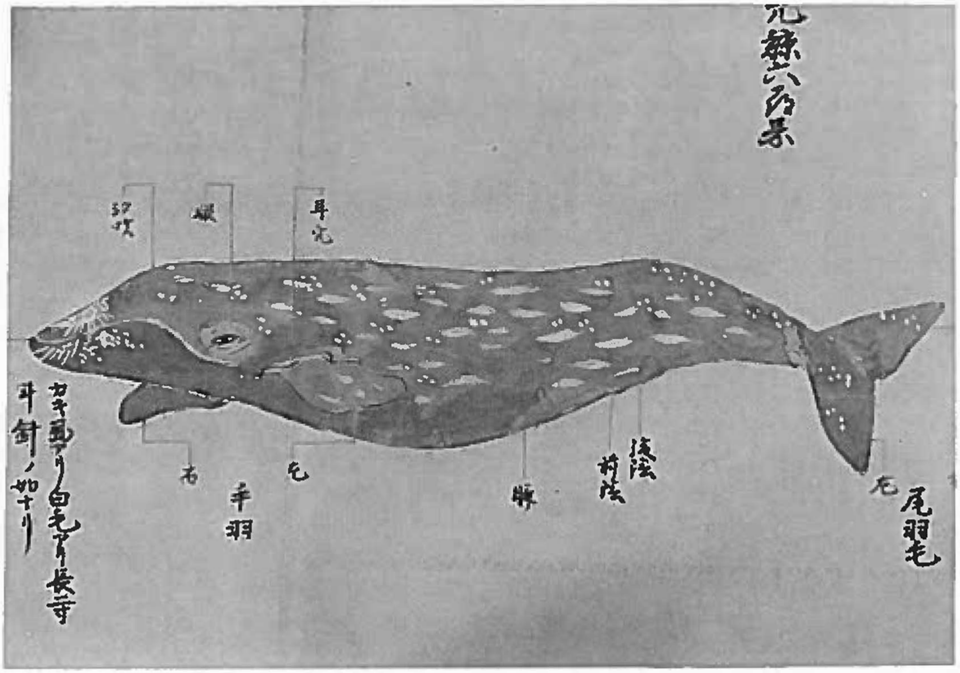

Fig. 2. *Kokujira drawn in 1661–73 (from Hashiura, 1969).*

were then available to him. Kokujira was also called Chikokujira, *chiko* also meaning small. The baleen plates of Chikokujira were described as being white. Two kinds of Kokujira were reported, one called *Aosagi* and the other *Share*. Aosagi was preferred to Share because its oil was white. However, interpretation of this old description became somewhat confused in later years. Andrews (1914) states

> The blubber is thick and fat, and varies in color from red to flesh pink. Because of this the Japanese recognized two kinds of gray whale, the 'Aosaki' (red blubber) and the 'Shirasaki' (white blubber). Although specimens with blubber strongly red, almost white, and of every intermediate shade, were taken during my stay at Ulsan, I could detect no difference, other than those purely individual, between them.

In Andrews' description, *Aosaki* is the same as Aosagi. There is only a slight difference in pronounciation of the two words, and Aosagi means blue heron.

I have been unable to find the names of *Shirasaki* or *Shirasagi* in any of the old books on whales and whaling. The only two kinds of Kokujira named are "Aosagi" and "Share." And, contrary to the above description, the color of blubber in Aosagi is said to be white. Hattori (1887–1888) thought that Share were young animals and Aosagi full-grown adults. This may be the correct interpretation. The individual differences in color of the blubber may be due to the different foods they took, as suggested by Andrews (1914). There is a description (Anonymous, 1890) in which the bigger whales which come from the west are called Aosagi (at Kawajiri). If this statement is correct, Aosagi referred to whales that were migrating from the calving ground to feeding grounds.

Biological Evidence of Occurrences

SUBFOSSIL EVIDENCE

In 1966, both mandibles, some vertebrae, and ribs of a whale were excavated from a depth of 4 m in a sand stratum in Ichikawa city, a neighboring city of Tokyo, during construction of the Ichikawa Telegram and Telephone Office. This stratum contained fossil shells, which were radiocarbon dated to 6000 years BP, or the time of the Jomon Sea Regression. The whale was erroneously identified as the sei whale, *Balaenoptera borealis*. The skeleton was then mounted with an artificial skull, vertebrae, and ribs, and exhibited in the main hall of the Ichikawa Municipal Museum.

In March, 1982 I visited the museum, with Dr. T. Kasuya of the Ocean Research Institute, University of Tokyo, and Mr. H. Kato of the Whales Research Institute and positively identified the specimen to be a gray whale. In gray whales the "lower jaws are massive, wide, and without coronoid processes: their inner surface somewhat concave at the proximal part" (Tomilin, 1967). There was no difficulty with the identification, because these features are very prominent even at a glance (Fig. 3).

Both mandibles of the Ichikawa whale have been broken anteriorly. The straight-line length of the right bone from broken tip to posterior end is 2.22 m. The height is 35

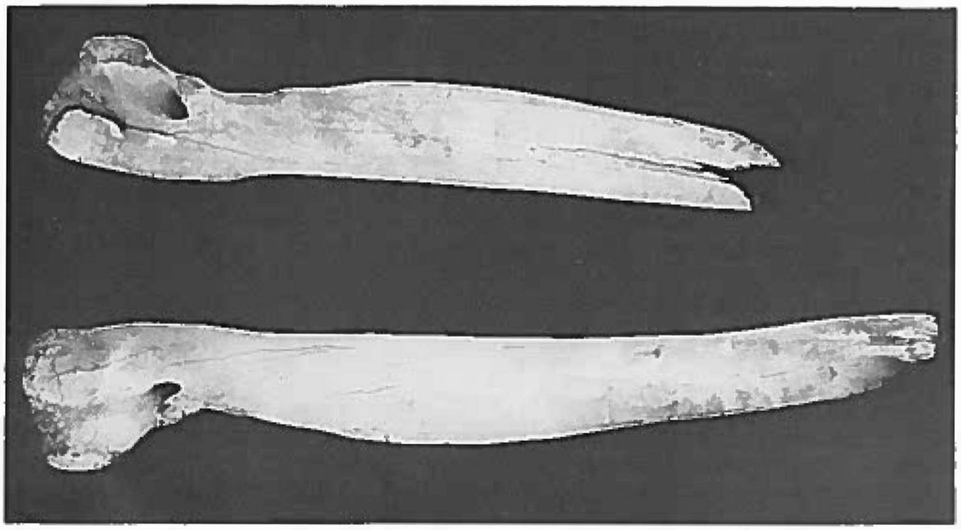

Fig. 3. *Mandibles of the Ichikawa whale (courtesy of the Ichikawa Municipal Museum).*

cm at the articulation, 21.5 cm at the lowest part just in front of articulation, and 29.7 cm at the top of the remaining part. Total length of this mandible is estimated to have been about 2.5 m and the body length of the whale approximately 12 m.

Ichikawa city is situated at the innermost part of the Tokyo Bay. The positive identification of this specimen is direct evidence that gray whales once occurred in the eastern coastal waters of Japan.

RECENT HISTORICAL EVIDENCE

In 1864 two gray whales were taken in the Seto Inland Sea, at Kawanoe, Ehime prefecture, the first on February 20 and the second on February 26. These whales were reported first by Shindo (1968) and then by Omura (1974). It is not necessary to describe them here in detail, but I wish to mention briefly their relationships to Aosagi and Share. Drawings of these whales are kept at the Kawanoe City Library (Figs. 4 and 5).

The first whale is smaller than the second and possibly would have been referred to as Share, although nothing was noted on the drawing (Fig. 4); the second whale (Fig. 5) was labeled as Aosagi. The body surface of the first whale was slightly infested with barnacles. The second whale bears heavy white markings of barnacle infestation, suggesting it was older than the first. A left scapula, possibly from the second whale, has been preserved at Hachiman shrine in the city, presented as Ema in memory of the whaling event (Fig. 6). The scapula of *Rhachianectes* (*Eschrichtius*) is distinctive in being intermediate between the wide, low scapula of *Balaenoptera* and the high, narrower, and more symmetrically fan-shaped scapula of *Eubalaena* (Andrews, 1914). Measurements of

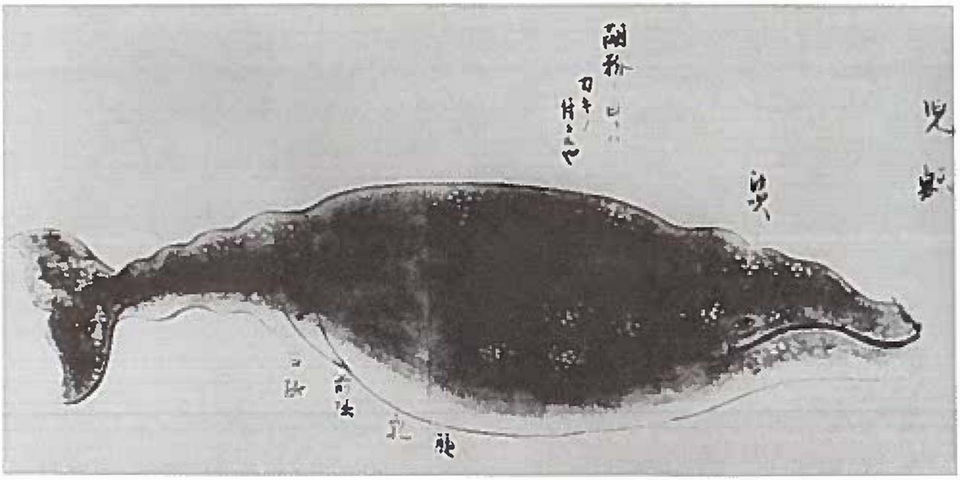

Fig. 4. *Kawanoe whale—first whale (from Omura, 1974).*

the at Hachiman shrine scapula were given by Omura (1974). Greatest breadth and greatest height are 99 and 74 cm, respectively, and the ratio of breadth to height is 1.34.

Omura (1974) thought the nearby waters of Iwaijima in the Seto Inland Sea was a calving ground of the gray whales, which occurred on the south coast of Japan. According to Saito (1977), Engelbert Kaempher, a German traveler and physician, sighted small whales in the waters near Mitajiri on April 30, 1691, while he was returning from a visit to the Shogun's capital of Edo (Tokyo). Mitajiri is close to Iwaijima and not far from Shimonoseki, the western entrance to the Inland Sea. Kaempher referred to these

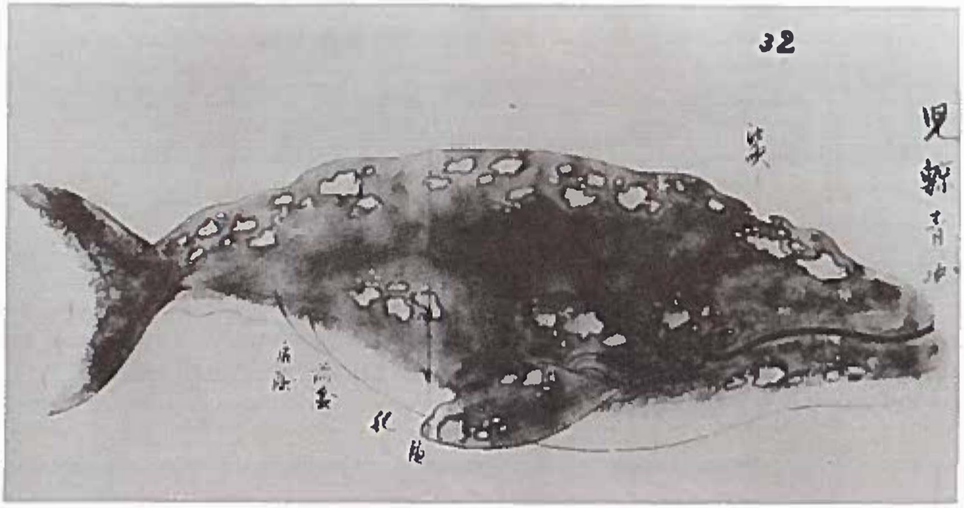

Fig. 5. *Kawanoe whale—second whale (from Omura, 1974).*

Fig. 6. *Left scapula of the Kawanoe whale (from Omura, 1974).*

whales as "Nordcaper," which means right whale, a species not reported from the Inland Sea; he further describes them as small whales. It is possible the whales he sighted were in fact gray whales. Gray whales and right whales have often been confused, even by gunners of modern whale catcher boats.

Nishiwaki and Kasuya (1970) report the accidental catch of a young female gray whale in 1968 at Shingu, Wakayama prefecture (the skeleton of this whale is maintained at Taiji Whale Museum). They also reported the sighting, by a skillful gunner of long experience, of a gray whale in nearby waters around 1959.

Catches of Gray Whales

Net whaling flourished nearly 200 years in the Edo era (1603–1867), during which time gray, right, humpback, and other species of whales were taken. The gray whales were usually taken without nets, because of their relatively smaller size (Taiji, 1937).

Practically no catch statistics exist for Wakayama and Mie prefectures. At Taiji, whaling continued after the Meiji Revolution (1868) until a tragedy occurred in 1878. In that year more than 100 people were killed by a heavy storm while they pursued a right whale accompanied by a calf. This incident was practically the end of old whaling at Taiji.

There remain at Taiji some fragmentary records of the catch. For example, from December 24, 1799 to January 15, 1800, a total of 9 whales was taken, including 1 right, 6 humpback, and 2 gray whales. However, because most of the records were lost by fire or during several floods, it is not clear whether this was an exceptionally good season. This seems to have been a good catch, but further comparison of catch records is not possible.

Whaling on the coast of the Sea of Japan, at Ine, Kyoto prefecture, had been conducted since very ancient times, probably as early as Tenmon (1532–1554). The methods were somewhat different from those used in other places. The village of Ine is located on a small inlet, called Inewan, into which whales occasionally swam. When this happened the fishermen of Ine blocked the entrance of the inlet with nets and then caught the whale using hand harpoons and nets. Catch records of the Ine whaling operation during a period from 1656 to 1913 are available by species (Yoshihara, 1976b). During this time a total of 357 whales, including 167 humpback, 149 "fin" (including minke), and 41 right whales, was taken. No gray whales were taken, evidence that gray whales did not occur on the east side of the Sea of Japan at that time.

Whaling was conducted, however, in several villages on the north coast of Yamaguchi prefecture, including Kayoi in the east and Kawajiri in the west (Tokumi, 1957; Tada, 1978). At Kayoi, at present Nagato city, there is a temple named Koganji where notes are preserved which contain the Buddhist names of each whale taken and from which catches of species have been summarized (Kimura, 1956). Japanese people were given special names from a Buddhist priest when they died, and in this respect the whales were treated somewhat like human beings. The first volume of the Koganji notes is missing, but from remaining volumes catch figures are available for about 50 years, from 1802 to 1850. During this period a total of 308 whales, including 116 fin, 105 humpback, 59 right, and 28 gray whales, was taken. The average catch per year was 6.3 animals; gray whales comprised 9% of the catch.

For Kawajiri, catch statistics arranged by species and by 10-year increments are available from 1699, when whaling was started, until 1888 (Anonymous, 1890). Yearly figures for the 8 years from 1894 to 1901 were given by Tada (1978) (Table I). For a period of 50 years, from 1769 to 1818, only the total number of catches was reported, but catches by species can be compared for the periods 1699 to 1768 and 1819 to 1888. Catches of gray whales increased from 12% in the former period to 16% in the latter. Both figures are greater than proportions of gray whales in catches at Kayoi. Catches of right and humpback whales decreased as those of "fin" whales (again possibly including minke whales) increased, possibly due to decrease of the former two species. Tada (1978) states that no right whales were taken after 1884. Catch statistics at Kawajiri in the later years are given by Tada (1978) for a period from 1894 to 1901. The decline of gray whale catches and the increase of "fin" whale catches during this period are remarkable. Whaling at Kawajiri was virtually terminated in 1902.

In addition to Kayoi and Kawajiri, whaling was conducted at several villages including Mishima (Tada, 1968), a small island about 45 km northwest of Hagi city. Whaling in these villages began around 1680 and lasted until near the end of the nineteenth century. Unfortunately, details of the catches are not available.

On the west coast of Kyushu, whaling was conducted at various places. Otsuki (1808), for example, listed 68 localities. This does not mean, however, that 68 whaling groups existed in Kyushu; rather, it represents the total number of places where whales,

[a] Tada (1978).

especially right whales, were taken. These numbers were reduced to only 3 a few years before the turn of the century, due to heavy reduction in numbers of right whales migrating there (Takahashi, 1899).

Whaling in Kyushu also started as a small enterprise using hand harpoons. After the invention of net whaling, this method spread over the west coast of Kyushu, and whaling flourished there more than in any other place (Anonymous, 1980). Whaling in Kyushu was operated by several groups, such as the Nakao group of Yobuko and Ogawajima (Saga prefecture), the Toi group of Iki Island (Nagasaki prefecture), and the Masutomi group of Hirado and Ikitsuki (Nagasaki prefecture). Among them the Masutomi group was the largest. From 1725, the year when the group was formed by Matazaemon Masutomi, to 1874, a total of 21,790 whales was taken (Yoshihara, 1977), a yearly average of 150 whales for all locations combined. The group operated at several locations in Kyushu, and sometimes at Mishima and Kayoi (both in Yamaguchi prefecture) as well. It was said this whaling group employed 3,000 people and about 200 fishing vessels when in operation.

Whaling at Ogawajima survived long after the introduction of modern whaling (Anonymous, 1980). A hut called Yamami, or lookout, was built on the top of a hill. When the watchmen sighted a whale he telephoned to a modern catcher waiting in the port of Yobuko. The catcher then pursued and killed the whale and returned it to the village, where it was processed by the villagers using traditional methods. This type of whaling lasted until 1948.

It is possible that gray whales were also taken in the waters west of Kyushu, but there are no catch statistics by species. Catch figures of whales at Iki Island in the 16 years from 1845 to 1860 are shown in Table II. Whaling from Iki Island was conducted by two whaling groups, Masutomi and Kuramitsu, operating at Katsumoto one season and

Maeme the next. The catches of whales at Iki decreased after 1849, probably because of the decrease of right whales.

In Tosa (present Kochi prefecture) whaling with hand harpoons dates from the years of Kanei (1624–1643) (Izukawa, 1943), and net whaling from 1683 when it was introduced from Taiji. Two groups of whalers, Ukitsu and Tsuro, operated on the coast of Tosa, splitting their activities between an east and a west whaling ground. There are two peninsulas in Kochi, the Muroto Peninsula in the east and the Ashizuri Peninsula in the west. The east whaling grounds were on the east side (in winter), and west side (in spring) of the Muroto Peninsula. The west ground was on the east side of the Ashizuri Peninsula in both winter and spring.

Each year the Ukitsu whaling group operated in one ground and the Tsuro whaling group on the other, and the two alternated grounds each year. Both groups left good catch records by year, from which general trends of the whaling in Kochi can be detected (Table III).

Table IIIA shows the total catches of whales by the Tsuro group in the years 1693–1712, inclusive. The average catch per year was 20.6 whales, but no species breakdown was available. For the 35 years from 1800 to 1835 (Table IIIB), the Ukitsu group took 959 whales, or 27.4 whales per year. Humpback whales comprise more than one-half of the total catch. In the years 1849 and thereafter (Tables IIIC, D, and E), right whales decreased considerably, while catches of Bryde's, blue, and fin or balaenopterid whales increased. Catches of gray whales appear to have been rather stable.

[e]Shibusawa (1939).

Discussion and Conclusions

Except for a few stragglers, gray whales do not occur in the coastal waters of Japan at present. Prior to the turn of the century, however, they were found in two regions, one on the Pacific side of Japan, from Tokyo Bay to Kochi prefecture, and the other on the west side of Japan off Kyushu, including the north coast of Yamaguchi prefecture. This conclusion is supported by subfossil mandibles excavated from Ichikawa city, old books on whales and whaling, and catch statistics of old whaling operations in the Edo era (1603–1867). The whales in these two regions may represent different populations of gray whales. The latter (the Kyushu group) is clearly a portion of the Korean stock. Distribution of the two populations in the waters off Japan and Korea is shown in Fig. 7. The two populations may have intermingled in the Seto Inland Sea. If so, then both populations belong to the Korean stock.

In summer, the Korean stock of gray whales occupies, or at least formerly occupied, the northern Okhotsk Sea (Rice and Wolman, 1971). It is not clear whether or not the gray whale population occurring off the south coast of Japan also spends the summer in Okhotsk Sea mingling with the Korean stock. Bowen (1974) states that the young female gray whale accidentally taken in 1968 at Shingu (Nishiwaki and Kasuya, 1970) resembled members of the California stock in morphological features and should be regarded as a stray from the Bering Sea. There still exists the possibility, however, that the two populations occurring in the coastal waters of Japan intermingle with each other in the Seto Inland Sea.

The annual catch of gray whales in Kochi prefecture in the days of net whaling was rather small (Table III). The largest catch was 11 in 1877 by the Ukitsu group; the yearly

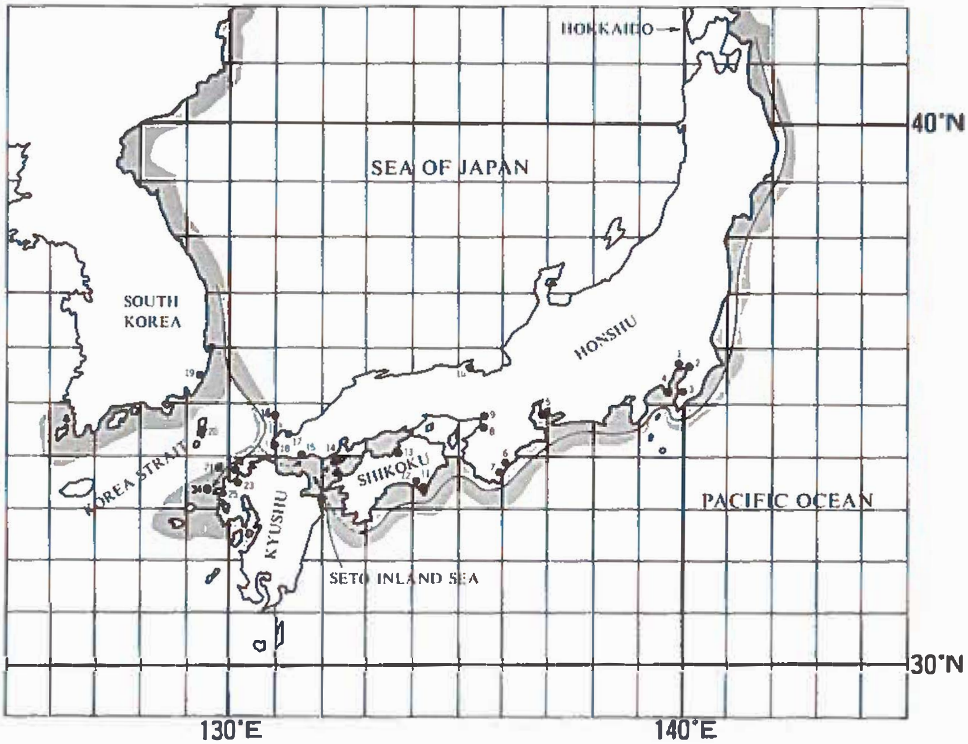

Fig. 7. *Map showing the distribution of gray whales in the coastal waters of Japan and Korea. Place names appearing in the text are indicated by numerals as follows: (1) Tokyo, (2) Ichikawa, (3) Katsuyama, (4) Misaki, (5) Morosaki, (6) Taiji, (7) Koza, (8) Sakai, (9) Osaka, (10) Ine, (11) Tsuro, (12) Ukitsu, (13) Kawanoe, (14) Iwaijima, (15) Mitajiri, (16) Mishima, (17) Kayoi, (18) Kawajiri, (19) Ulsan, (20) Tsushima, (21) Iki, (22) Ogawajima, (23) Yobuko, (24) Ikitsuki, (25) Hirado. Solid arrow, migration routes and area of distribution of Gray whales; broken arrow, movements uncertain.*

average was 2.9–5.9, and there were no remarkable differences between the two whaling groups or among different years. The total yearly catch of gray whales by the two groups in Kochi prefecture is estimated to have been around 10 whales. This suggests gray whales occupied a less important position than right and humpback whales.

Catch figures of gray whales in Wakayama and Mie prefectures are not known. Presumably gray whales were taken in numbers such as in the Kochi prefecture. If one assumes that equal numbers were taken in each of these prefectures, then the total catch of gray whales from the population would have been 30 per year. The catch of gray whales from this population appears to have been rather stable (Table III), suggesting that the catch rate from this population was not high.

The catch of gray whales at Kawajiri, Yamaguchi prefecture during the period of 1699–1768 totaled 110 whales, or an average of 1.6 whales per year (Table I). In the third period, 1819–1888, the corresponding figures are 170 total and 2.4 whales per year, indicating an average increase in take of 0.8 whales per year. These catches are very low compared with the corresponding figures in Kochi prefecture. For the period 1894–1901, the average catch per year was 0.9, less than in previous years. Kimura (1956) also shows a reduction in gray whale catch at Kayoi after 1831.

It is not known how many gray whales were caught on the west coast of Kyushu. It is assumed, however, these catches were far more dependent on availability of right, humpback, and fin whales, as in Kawajiri and Kayoi, and that gray whales were caught only secondarily to the whaling there. It is assumed as many as 20–30 gray whales were taken per year but the catch of gray whales decreased towards the end of net whaling around 1900 and these stocks were finally extirpated.

This reduction does not necessarily mean a reduction of the Korean stock. Mizue (1951) reports heavy catches of gray whales at Ulsan, Korea after 1910. Therefore, the decrease of gray whales migrating to the coast of Yamaguchi and to the west coast of Kyushu may have resulted in a change in migration route.

Modern-type whaling in Japan commenced in 1898, when the first catcher Hokamaru, built of wood, caught three whales (Akashi, 1910). After that year, whaling operated first on the east coast of Korea, the west coast of Kyushu, and the south coast of Japan, and then shifted to the northeast coasts of Japan and Hokkaido. As pointed out by Mizue (1951), only a few gray whales were taken during modern whaling, except in Korea and Tsushima. Omura (1974) speculated the gray whale population on the Pacific side of Japan was driven from its calving ground in the Seto Inland Sea sometime prior to this century by the increase in boat traffic and industrial development on the coast. It now appears this matter is more complicated and that additional material is needed to support firm conclusions.

Summary

Prior to the turn of the century, two populations of gray whales migrated to the coastal waters of Japan, one to the southern coast of Hokkaido and Honshu and the other to the west coast of Kyushu via the north coast of Yamaguchi prefecture. The former migrated along the east coast of Japan from the north and entered the Seto Inland Sea, the supposed calving ground for this population. The latter, considered to be a portion of the Korean stock, migrated along the east coast of Korea and then to southwest Honshu and northwest Kyushu. Intermingling of the two populations in the Seto Inland Sea cannot be denied.

The annual catch of gray whales in the days of net whaling (1675–1890) was approximately 30 whales from the former population and 20–30 from the latter. Virtually no gray whales, however, have been observed in the waters around Japan since about 1898 when modern-type whaling was introduced.

The southern coast population was probably driven from the Inland Sea sometime prior to this century due to increased industrial development and boat traffic on the coast. The matter is complicated, however, and additional material is needed before final conclusions can be drawn.

Acknowledgments

I wish to acknowledge the help of Dr. Fukuzo Nagasaki of the Japan Whaling Association and Dr. Toshio Kasuya of the Ocean Research Institute, University of Tokyo and thank them for their constructive criticisms on the draft of this manuscript.

灰鲸在中国近海的分布*

THOMAS JEFFERSON

王丕烈

（辽宁省海洋水产研究所）

灰鲸（*Eschrichtius gibbosus* Erxleben 1777）现仅存于北太平洋，曾因各捕鲸国滥捕而几近绝灭，是最早受到保护的鲸种之一。东太平洋群体，经数十年的保护，资源量已恢复到一万头左右。但沿亚洲侧洄游的西太平洋群体，资源仍未有恢复迹象，尚亟待保护。对中国近海的灰鲸只有过少量报道。本文根据作者在海上的实际观察和对南、北方重点渔区的数次调查，就灰鲸在中国近海的分布及洄游探讨如下。

一、骨　　骼

原大连展览馆曾收藏1具灰鲸骨骼（♂），系1949年在辽宁黄海岸的搁浅鲸，可惜骨骼已被丢失。浙江省博物馆的1具灰鲸骨骼（♀）系1933年收藏的，种名长期被误植，1977年经作者订正，并调查了当时运输和解剖鲸体的过程，推断该标本可能采自浙江近海。另1具骨骼保存在广东省广州市文化公园水产馆，1954年采自雷州半岛徐闻县的外罗港，经作者鉴定为灰鲸。这3具骨骼证明灰鲸在我国南、北方近海都有分布。3具标本的体长都在12米以上，均为成体。

从表1中看出，浙江省博物馆和广州的标本颅宽皆为颅长的42.3%；朝鲜东海岸所获标本体长12.50米，颅宽为颅长的43.2%（Andrews, 1914），相比差别不太大。从头骨照片看，Nishiwaki 和 kasuya 描述的日本标本的鼻骨前端边缘成凸形，浙江省博物馆标本的鼻骨（图1）同朝鲜标本近似，两块鼻骨的前缘均稍成凹形，广州标本的鼻骨损缺。从侧面看，朝鲜和日本标本的上枕骨向后的坡度都很大，同广州标本大体一样；但浙江省博物馆标本的上枕骨形态，由顶部开始向后微斜，继而骤然下垂，使头骨后部形成陡壁（图3），这些不同可能是属于个体上的差异。

浙江博物馆标本的椎式为$C_7+D_{13}+L_{13}+Ca_{23}=56$。大连1949年的标本和广州标本的胸椎数均为13。而大连1960年的标本的胸椎数为14（王丕烈，1978）。Andrews（1914）记述的朝鲜标本，Nishiwaki & Kasuya（1970）记述的日本标本的椎式皆为$C_7+D_{14}+L_{12}+Ca_{23}=56$。说明胸椎和腰椎数有个体差异。通常记述灰鲸的7块颈椎完全分离（西胁，1965，1970；Томилин 1957，1962），但作者检查浙江博物馆和广州标本的第2和第3颈椎的椎弓及较小的棘突愈合在一起，仅椎体分离（图1）。浙江博物

馆标本骨骼全长11.48米，最后1个尾椎缺失。颈椎为脊柱全长5.5%，胸椎为21.3%，腰椎为32.4%，尾椎为40.8%。

二、分布、洄游

北太平洋的灰鲸分东、西2个群体。西太平洋群体，也称朝鲜群体。夏季在鄂霍次克海栖息索饵、冬季已知它们在朝鲜南部水域产仔。(Andrews, 1914; Mizue, 1951)。日本的濑户内海过去曾是灰鲸的一个生育场所。（Omura, 1914; Shindo, 1975）。东太平洋群体的个别灰鲸可能来到西太平洋群体的所在水域内（Nishiwaki and Kasuya, 1970)。

西太平洋灰鲸群体过去主要渔场在朝鲜东海岸，西海岸的猎捕量只占0.4%(Mizue, 1951）。说明游到中国海区的数量甚少。有的学者曾认为该群体可能灭绝（Mizue, 1951, Bowen, 1974)。但南朝鲜1967—1975年还继续捕获到（Brownell and Chun, 1977），证明该群体尚未灭绝。

在黄海由日本捕获的灰鲸，1917、1918和1922年各2头，1929年1头（笠原昊，1950），其中1922年的2头获自黄海北部。而后黄海北部曾多次发现，1949年9月中旬在辽宁省金县黄海岸的二道城子海边搁浅1头，1958年6月27日在山东烟台近海发现2头，1960年4月30日在辽宁省长海县的大长山岛后海发现1头，同年7月末在渤海海峡的隍城岛附近发现1头（王丕烈，1976，1978），此后十余年来未再发现。直至1977年6月长海县王家岛的渔民在该岛近海又发现1头；1979年1月长海县大长山岛的渔民在该岛后海再发现1头，该鲸在此处滞留10余天才离去。这些记录说明，经朝鲜东海岸洄游的灰鲸，有少量成年鲸沿朝鲜西海岸北上至黄海北部，尤以辽宁省的大长山岛后海发现次数较多。因此，灰鲸进入我国海洋岛渔场和烟威渔场并非偶然现象，为其向南洄游的延续。

浙江省博物馆的1具鲸骨，可为灰鲸游入我国东海近岸的凭证。

福建省及广东省在建国以前没有发现或捕获灰鲸的记载。台湾省缺少确切记录(杨鸿嘉，1964）。经作者数次深入重点渔区调查，确认广东省惠阳地区大亚湾内1954年春季搁浅1头；雷州半岛的徐闻县外罗港1949年曾搁浅1头，1953年春季发现4头，1954年春季发现1头，此后在该水域未再发现。另据徐闻县外罗港有经验的渔民介绍，1960年曾在海南岛东岸的铜鼓渔场（19°—20°N）发现过灰鲸。在五十年代初期广东沿海发现的记录远比北部黄海多，且又是在接近20°N线海域内发现的较多。 Fin whale

五十年代初期在我国近海发现较多的灰鲸，同当时东、黄海长须鲸资源得到恢复有类似原因，即由于长期停止捕鲸，各种鲸都得到生息的时机，而几将灭绝的灰鲸也有所增加。

浙江省博物馆1933年得的灰鲸标本，怀有将分娩的胎儿。广州市水产馆保存1灰鲸幼体的剥制标本，系1954年春季采自惠阳地区大亚湾。1953年春季在徐闻县外罗港发现的灰鲸，有2对母仔鲸伴游。据此分析，广东省海域也是灰鲸的生育区。

在《广东新语》（屈大钧，1680）中曾记述：“海䲡长者亘百里，背常负子，蛋人辄以长绳系铊飞刺之，候海䲡子斃，拽出沙潭，取其脂货，至万钱”。此处海䲡系指大型鲸类。在粤东地区的平海大嘴岛，渔民相传约百年前曾在近岸捕鲸。联系五十年代初

测广东近岸发现的灰鲸，根据其习性极近沿岸，并栖游于岩礁地带，原始方法即能捕获。因此估计过去在该地区发现的主要为灰鲸，在灰鲸种群的兴旺时期游来广东沿海的数量是较多的。

Scammon（1874）认为沿美洲侧洄游的灰鲸分布南限到达20°N。Mizue（1951）记载沿亚洲侧洄游的灰鲸，以往捕获水域南达34°N。但就 Shindo（1970，1975）对日本濑户内海灰鲸的研究，及Nishiwaki 和 Kasuya（1970）对日本太平洋岸获灰鲸的报道，西太平洋群体的分布水域向南达到了 32°N。根据作者的调查，过去在中国海区可能偶有个别灰鲸超越20°N线，向南达到海南岛的东部沿海（图２）。

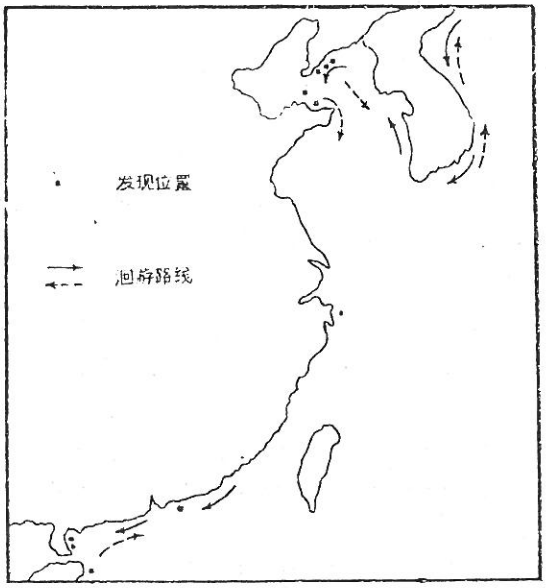

图２ 中国近海灰鲸洄游分布示意图

关于灰鲸在中国南部近海的洄游路线，尚缺乏完整资料。虽然由鄂霍次克海南下的灰鲸，以往有些沿日本太平洋侧沿岸洄游，且认为日本濑户内海曾是个生育场所，但进入二十世纪，濑户内海的灰鲸已绝迹，在太平洋侧的日本九洲南岸以及琉球群岛水域未见记录，我国台湾省也无确切记录。故我国广东沿岸所发现的灰鲸来自日本太平洋侧的可能性甚少。因此，广东沿岸的灰鲸同我国北方海区的有联系，即有少量的灰鲸沿东海中国海岸继续南下，到达广东省沿岸水域进行生育。

灰鲸的洄游规律性及其极近沿岸浅水域栖息的习性，使它易被捕杀。我国沿海在七十年代虽仍偶有发现，但西太平洋群体至今远未得到恢复，需要继续加强保护，为之创造生息的条件。我国颁布的《水产资源繁殖保护条例》，已将灰鲸列为保护对象。1980年我国已成为国际捕鲸公约签字国之一，今后我国也无意进行商业性捕鲸。因此呼吁西北太平洋沿岸国家为保护灰鲸继续做出贡献。

外文摘要 (Abstract)

DISTRIBUTION OF THE GRAY WHALE(*ESCHRICHTIUS GIBBOSUS*) OFF THE COAST OF CHINA

WANG　Peilie

(*Research Institute of Marine Fisheries, Liaoning Province*)

Three skeletons of the gray whales have been obtained off Liaoning, Zhejiang and Guangdong Province in the Yellow Sea, the East China Sea and the South China Sea respectively. It is believed that some individuals of the western Pacific stock migrated through the waters off the east coast of China, and entered the calving grounds in the coastal waters of Guangdong Province in former times, these calving grounds are possibly in the Daya Bay and Wailuo Harbour. Occasionally, a few individuals probably reached as far south as 20°N in the adjacent waters of the east coast of Hainan Island.

ABSTRACT

Photographs of 217 identified gray whales obtained from the Sakhalin Island, Russia feeding grounds were compared with 6,546 photo-identified individuals from the Baja California Peninsula, Mexico breeding lagoons to identify matches between these two populations. A total of 13 matches of individuals were found, including six males, five females and two of unknown sex. Twelve whales had sightings prior to and after to their respective sighting in Mexico. Twelve whales were observed in Laguna San Ignacio and one in Laguna Ojo de Liebre. Ten of the 13 whales were photographed in Mexico only in one year and the other 3 in two years. Twelve whales were sighted in Sakhalin in the summer of 2011. Eleven whales were sighted in consecutive seasons, eight of them in three consecutive seasons (summer-winter-summer), three in two seasons (summer-winter), and four in two seasons (winter-summer). Three whales were sighted the same day in Laguna San Ignacio suggesting that these animals were traveling in association with each other. Four females with calves were sighted in the winter in Mexican waters and in the next summer off Sakhalin, three of them without calves suggesting that these females had either separated from their calves or that their calves did not survive. The time between the last sighting in one season and the first one in the next season was $\bar{x}=195.4$ days (n=11, 141-255) during the summer-winter migration, and $\bar{x}=150.9$ days (n=12, 131-213) during the winter-summer migration. The matches made between whales sighted off Sakhalin and the Mexican Pacific are the first results of the multinational collaboration "PACIFIC WIDE STUDY ON POPULATION STRUCTURE AND MOVEMENT PATTERNS OF NORTH PACIFIC GRAY WHALES" initiated under the coordination and support of the International Whaling Commission last year.

INTRODUCTION

Recent results of genetic and photographic identification comparisons between western and eastern North Pacific gray whales (see IWC, 2011) suggest a mixing of these populations during the winter reproductive season, and illustrate the great conservation and management importance of a more comprehensive examination of gray whale movement patterns and population structure in the North Pacific. The Scientific Committee recommended that a collaborative Pacific-wide study be developed under the auspices of the IWC, recognising that *inter alia* this will contribute to the Committee-endorsed Conservation Plan for western North Pacific gray whales and incorporate previous recommendations made by the Committee. Such a study will involve collaborative analysis and sharing of existing data as well as the collection of new data. This report summarizes the results of the "(Phase 1) photo-identification project". The purpose of this project was to undertake a comparison of two western gray whale catalogues from Sakhalin Island, Russia with the Mexican gray whale catalogue.

METHODS

The comparison was done based on two catalogues of photo-identified gray whales from Sakhalin Island and one catalogue of gray whales from Laguna San Ignacio and Laguna Ojo the Liebre on the west coast of the Baja California Peninsula, México.

The Sakhalin catalogues

The first step was to compare the two catalogues available at that moment:

1) The Russia-US catalogue (2012).

Burudin, A. M., Weller, D., Sychenko, O., and Bradford, A. 2012. *"WESTERN GRAY WHALES OFF SAKHALIN ISLAND, RUSSIA: A CATALOG OF PHOTO-IDENTIFIED INDIVIDUALS".*
205 individuals. Period 1994-2011

2) The IBM catalogue.

Tyurneva, Y. O. y Yakovlev, Y. M. 2010. "THE WESTERN PACIFIC GRAY WHALES OF SAKHALIN ISLAND 2002-2008, LEARING ABOUT A POPULATION OF WHALES THROUGH PHOTOGRAPHS".
165 individuals. Period: 2002-2008

As result of these comparisons 217 photo- identified gray whales from Sakhalin were used in the comparison with the Mexican catalogue. All are represented by the right-side dorsal flank and 215 are associated with the left-side dorsal flank

The Mexican catalogue

This catalogue includes 6,546 gray whales. 5366 photo-identified in Laguna San Ignacio between 1993 and 2011, and 1180 in Laguna Ojo de Liebre (Scammon´s Lagoon) between 2001 and 2003. Of the 6,546 whales in the catalogue 5,890 are represented by a right-side of the dorsal flank image and 1,837 were associated with a left-side dorsal flank image (Table 1).

Table 1. Number of photo-identified gray whales in the Mexican catalogue.
Laguna Ojo de Liebre = LOL, Laguna San Ignacio = LSI.

year	Total photo-id whales	Right and left sides	Only right side	Only left side	Lagoon
2001	398	0	398	0	LOL
2002	462	0	462	0	LOL
2003	320	0	320	0	LOL
1996	157	0	155	2	LSI
1997	310	0	310	0	LSI
1998	392	0	392	0	LSI
1999	253	0	253	0	LSI
2000	448	0	448	0	LSI
2003	247	0	247	0	LSI
2005	438	18	420	0	LSI
2006	249	22	226	1	LSI
2007	495	150	217	128	LSI
2008	358	114	137	107	LSI
2009	662	286	238	138	LSI
2010	750	250	319	181	LSI
2011	607	341	167	99	LSI
Total	**6546**	**1181**	**4709**	**656**	

RESULTS.

The Sakhalin to Mexico catalog comparison resulted in a total of 13 confirmed matches of individuals, including six males, five females and two of unknown sex. Twelve whales had sightings prior and after to their respective sighting in Mexico. Twelve whales were observed in Laguna San Ignacio and one (#3) in Laguna Ojo de Liebre. Ten of the 13 whales were photographed in Mexico only in one year and the other 3 in two years. Twelve whales were sighted in Sakhalin in the summer of 2011(Table 2).

Twelve whales were sighted in consecutive seasons, eight of them in three consecutive seasons (summer-winter-summer), three in two seasons (summer-winter), and four in two seasons (winter-summer). Whale #2, male, was sighted in summer-winter (2006-2007), and summer-winter-summer (2009-2010); similarly whale #9, female, was sighted in summer-winter-summer (2006-2007), and in the winter-summer (2011) (Table 3).

The whales #5, #6 and #12 were sighted the same day, February 24 2006, and whale # 20 was sighted two days later in Laguna San Ignacio. The whales #5 and #12 were in the same group and #6 in a different group, suggesting that these animals were traveling in association with each other (Table 3).

Four females with calves were sighted in the winter in Mexican waters and in the next summer off Sakhalin, three of them without calves (Table 3), suggesting that these females had either separated from their calves (e.g. weaned) or that their calves did not survive (e.g., due to predation).

The time between the last sighting in one season and the first one in the next season was $\bar{x}=195.4$ days (n=11, 141-255) during the summer-winter migration, and $\bar{x}=150.9$ days (n=12, 131-213) during the winter-summer migration. The shorter time was of the whale #13, of unknown sex, with 131 days followed by the whale #4, a male, with 139 days, and the whales #8 and #11, mothers with calves, with 144 and 143 days respectively (Table 3).

Table 2. Sighting summary information for 13 gray whales matched between Sakhalin and Mexico. * = With calf.

DISCUSSION

The 13 individuals sighted in Mexican waters represent about 10% of the western gray whale population based on the population assessment of an estimate of 130 individuals (90% Bayesian CI = 120-142) (Cooke *et al.* 2008). If we combine these matches with the six matches found off the coast of Vancouver Island reported by Weller et al. (2011), presumably during their migration from the breeding lagoons along the Mexican coast, and the two genetic matches noted by Lang et al (2011) with whales sampled in southern California, a total of 21 whales identified as part of the western gray whale population have migrated, at least in some years, to the eastern North Pacific during the winter breeding season.

The presence of three of these whales the same day in Laguna San Ignacio, two in the same group, indicate that these whales may travel in association or in groups, as Weller *et al* (2011) observed based on six matches off Vancouver Island, British Columbia, Canada. This also suggests that these whales may stay together in groups while on the breeding grounds.

The sex of the whales (six males, five females and two of unknown sex) indicates that both sexes, in approximately equal numbers, migrate to Mexican waters during the winter breeding season.

The sighting of females without their calve on the Russian feeding grounds suggests a high mortality of the calves, based on the small sample of four mothers with calf sighted in Laguna San Ignacio and the next summer off Sakhalin (i.e., only a 25% survivorship). The long distance of their migratory destination compared to the Bering and Chukchi Seas could be an important factor in the survivorship of the calves. Alternatively, these females may have separated from their calves as the normal weaning process when the calves were of sufficient age to begin foraging for themselves.

The number of days between the last photograph of the season and the first one of the next season represents the maximum migration time and depends on the presence of the whale, the chance to find and photograph it, and the field work seasons of the different research teams. The shorter times observed 131-143 days could be close to the real migration times of these whales.

The matches made between whales sighted off Sakhalin and the Mexican Pacific are the first results of the multinational collaboration “PACIFIC WIDE STUDY ON POPULATION STRUCTURE AND MOVEMENT PATTERNS OF NORTH PACIFIC GRAY WHALES” initiated under the coordination and support of the International Whaling Commission last year. Additional comparisons and analyses of photographs from the Western and Eastern gray whales are ongoing and will include photographs from the IBM Kamchatka catalogue, and from Laguna San Ignacio and Bahia Magdalena winter aggregation and breeding areas, obtained during the winter 2012.

Acknowledgements

We wish to thank our field researchers and colleagues that assisted with the documentation of the gray whales in Laguna San Ignacio and Laguna Ojo de Liebre. We also thank The Ocean Foundation, and the World Wildlife Fund-Mexico for their support of the field work and analysis of our results. This research was conducted as part of the Laguna San Ignacio Ecosystem Science Program (LSIESP) under special scientific research permits No.SGPA/DGVS/11560/10 and SGPA/DGVS/00640/12from the Subsecretaría de Gestión Para La Protección Ambiental, Dirección General de Vida Silvestre, de Mexico.
